                                   0, 0);  
  
        setColor(a.getInt(R.styleable.ColorMixer_initialColor,  
                          0xFFA4C639));  
        a.recycle();  
    }  
}
```

```
}  
}
```

There are three steps for getting attribute values:

- Get a `TypedArray` conversion of the `AttributeSet` by calling `obtainStyledAttributes()` on our `Context`, supplying it the `AttributeSet` and the ID of our styleable resource (in this case, `R.styleable.ColorMixer`, since we set the name of the declare-styleable element to be `ColorMixer`)
- Use the `TypedArray` to access specific attributes of interest, by calling an appropriate getter (e.g., `getInt()`) with the ID of the specific attribute to fetch (`R.styleable.ColorMixer_initialColor`)
- Recycle the `TypedArray` when done, via a call to `recycle()`, to make the object available to Android for use with other widgets via an object pool (versus creating new instances every time)

Note that the name of any given attribute, from the standpoint of `TypedArray`, is the name of the styleable resource (`R.styleable.ColorMixer`) concatenated with an underscore and the name of the attribute itself (`_initialColor`).

In `ColorMixer`, we get the attribute and pass it to `setColor()`. Since `getInt()` on `AttributeSet` takes a default value, we supply some stock color that will be used if the developer declined to supply an `initialColor` attribute.

Also note that our `ColorMixer` constructor inflates the widget's layout. In particular, it supplies `true` as the third parameter to `inflate()`, meaning that the contents of the layout should be added as children to the `ColorMixer` itself. When the layout is inflated, the `<merge>` element is ignored, and the `<merge>` element's children are added as children to the `ColorMixer`.

Saving the State

Similar to activities, a custom `View` overrides `onSaveInstanceState()` and `onRestoreInstanceState()` to persist data as needed, such as to handle a screen orientation change. The biggest difference is that rather than receive a `Bundle` as a parameter, `onSaveInstanceState()` must return a `Parcelable` with its state... including whatever state comes from the parent `View`.

The simplest way to do that is to return a `Bundle`, in which we have filled in our state (the chosen color) and the parent class' state (whatever that may be).

So, for example, here are implementations of `onSaveInstanceState()` and `onRestoreInstanceState()` from `ColorMixer`:

```
@Override
public Parcelable onSaveInstanceState() {
    Bundle state=new Bundle();

    state.putParcelable(SUPERSTATE, super.onSaveInstanceState());
    state.putInt(COLOR, getColor());

    return(state);
}

@Override
public void onRestoreInstanceState(Parcelable ss) {
    Bundle state=(Bundle)ss;

    super.onRestoreInstanceState(state.getParcelable(SUPERSTATE));

    setColor(state.getInt(COLOR));
}
```

The Rest of the Functionality

`ColorMixer` defines a callback interface, named `OnColorChangeListener`:

```
public interface OnColorChangeListener {
    public void onColorChange(int argb);
}
```

`ColorMixer` also provides getters and setters for an `OnColorChangeListener` object:

```
public OnColorChangeListener getOnColorChangeListener() {
    return(listener);
}

public void setOnColorChangeListener(OnColorChangeListener listener) {
    this.listener=listener;
}
```

The rest of the logic is mostly tied up in the `SeekBar` handler, which will adjust the swatch based on the new color and invoke the `OnColorChangeListener` object, if there is one:

```
private SeekBar.OnSeekBarChangeListener onMix=new
SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar, int progress,
                                boolean fromUser) {
        int color=getColor();
```

```
swatch.setBackgroundColor(color);

if (listener!=null) {
    listener.onColorChange(color);
}
}

public void onStartTrackingTouch(SeekBar seekBar) {
    // unused
}

public void onStopTrackingTouch(SeekBar seekBar) {
    // unused
}
};
```

Seeing It In Use

The project contains a sample activity, ColorMixerDemo, that shows the use of the ColorMixer widget.

The layout for that activity, shown below, can be found in `res/layout/main.xml` of the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:mixer="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical"
>
    <TextView android:id="@+id/color"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
    />
    <com.commonware.android.colormixer.ColorMixer
        android:id="@+id/mixer"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        mixer:initialColor="#FFA4C639"
    />
</LinearLayout>
```

Notice that the root `LinearLayout` element defines two namespaces, the standard `android` namespace, and a separate one named `mixer`. The `mixer` namespace is given a URL of `http://schemas.android.com/apk/res-auto`, which indicates to the Android build system to match up `mixer` attributes with their respective widgets that are supplied via Android library projects.

Our ColorMixer widget is in the layout, with a fully-qualified class name (com.commonsware.android.colormixer.ColorMixer), since ColorMixer is not in the android.widget package. Notice that we can treat our custom widget like any other, giving it a width and height and so on.

The one attribute of our ColorMixer widget that is unusual is mixer:initialColor. initialColor, you may recall, was the name of the attribute we declared in res/values/attrs.xml and retrieve in Java code, to represent the color to start with. The mixer namespace is needed to identify where Android should be pulling the rules for what sort of values an initialColor attribute can hold. Since our <attr> element indicated that the format of initialColor was color, Android will expect to see a color value here, rather than a string or dimension.

The ColorMixerDemo activity is not very elaborate:

```
package com.commonsware.android.colormixer;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class ColorMixerDemo extends Activity {
    private TextView color=null;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        color=(TextView)findViewById(R.id.color);

        ColorMixer mixer=(ColorMixer)findViewById(R.id.mixer);

        mixer.setOnColorChangeListener(onColorChange);
    }

    private ColorMixer.OnColorChangeListener onColorChange=
        new ColorMixer.OnColorChangeListener() {
            public void onColorChange(int argb) {
                color.setText(Integer.toHexString(argb));
            }
        };
}
```

It gets access to both the ColorMixer and the TextView in the main layout, then registers an OnColorChangeListener with the ColorMixer. That listener, in turn, puts the value of the color in the TextView, so the user can see the hex value of the color along with the shade itself in the swatch.

ReverseChronometer: Simply a Custom Subclass

Sometimes, what you want to achieve only requires a basic subclass of an existing widget (or container), into which you can pour your business logic.

For example, Android has a Chronometer widget, which is used for denoting elapsed time of some operation. It works well, but it only counts up from zero. It cannot be used to display a countdown instead.

But, we can roll a ReverseChronometer that does, simply by subclassing TextView, as seen in the [Views/ReverseChronometer](#) sample project:

```
package com.commonware.android.revchron;

import android.content.Context;
import android.graphics.Color;
import android.os.SystemClock;
import android.util.AttributeSet;
import android.widget.TextView;

public class ReverseChronometer extends TextView implements Runnable {
    long startTime=0L;
    long overallDuration=0L;
    long warningDuration=0L;

    public ReverseChronometer(Context context, AttributeSet attrs) {
        super(context, attrs);

        reset();
    }

    @Override
    public void run() {
        long elapsedSeconds=
            (SystemClock.elapsedRealtime() - startTime) / 1000;

        if (elapsedSeconds < overallDuration) {
            long remainingSeconds=overallDuration - elapsedSeconds;
            long minutes=remainingSeconds / 60;
            long seconds=remainingSeconds - (60 * minutes);

            setText(String.format("%d:%02d", minutes, seconds));

            if (warningDuration > 0 && remainingSeconds < warningDuration) {
                setTextColor(0xFFFF6600); // orange
            }
            else {
                setTextColor(Color.BLACK);
            }
        }
    }
}
```

```
        postDelayed(this, 1000);
    }
    else {
        setText("0:00");
        setTextColor(Color.RED);
    }
}

public void reset() {
    startTime=SystemClock.elapsedRealtime();
    setText("--:--");
    setTextColor(Color.BLACK);
}

public void stop() {
    removeCallbacks(this);
}

public void setOverallDuration(long overallDuration) {
    this.overallDuration=overallDuration;
}

public void setWarningDuration(long warningDuration) {
    this.warningDuration=warningDuration;
}
}
```

ReverseChronometer is designed to show minutes and seconds remaining from some initial time. In the constructor, by means to a call to a `reset()` method, we set the text of the `TextView` to show a generic starting point (“--:--”), set its color to black, and note the current time (`SystemClock.elapsedRealtime()`) in a `startTime` data member.

ReverseChronometer also tracks two durations in seconds, with corresponding setter methods:

- `overallDuration` is how long the countdown should run from beginning to end
- `warningDuration` is how far from the end we should change the color of the `TextView` from black to orange, to hint to the viewer that time is running out

ReverseChronometer implements `Runnable`, and when its `run()` method is called, it determines how many seconds have elapsed since that `startTime` value. Depending on the amount of seconds remaining, we either:

- Just update the text to show the minutes and seconds remaining
- Update the text and set the color to black or orange

- Set the text to “o:oo” (time has run out) and set the text color to red

In either of the first two cases, we also call `postDelayed()` to schedule ourselves to run again in a second, where we can update the `TextView` contents once more. That continues until somebody calls `stop()`.

As with any custom `View`, we can reference this in a layout XML resource, fully-qualifying the class name used as the name of our XML element for the widget. And, since we inherit from `TextView`, we can set any of the attributes that we want on that `TextView`, in terms of styling the text, positioning it within a parent container, etc.:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context=".MainActivity">

    <com.commonware.android.revchron.ReverseChronometer
        android:id="@+id/chrono"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textSize="50sp"
        android:textStyle="bold"/>

</RelativeLayout>
```

All our activity needs to do is set the durations, then call `run()` and `stop()` at appropriate times, such as when the activity is resumed and paused:

```
package com.commonware.android.revchron;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    private ReverseChronometer chrono=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        chrono=(ReverseChronometer)findViewById(R.id.chrono);
        chrono.setOverallDuration(90);
        chrono.setWarningDuration(10);
    }

    @Override
    public void onResume() {
```

```
super.onResume();  
    chrono.run();  
}  
  
@Override  
public void onPause() {  
    chrono.stop();  
    super.onPause();  
}  
}
```

The result is much as you would expect: a countdown of the time remaining:

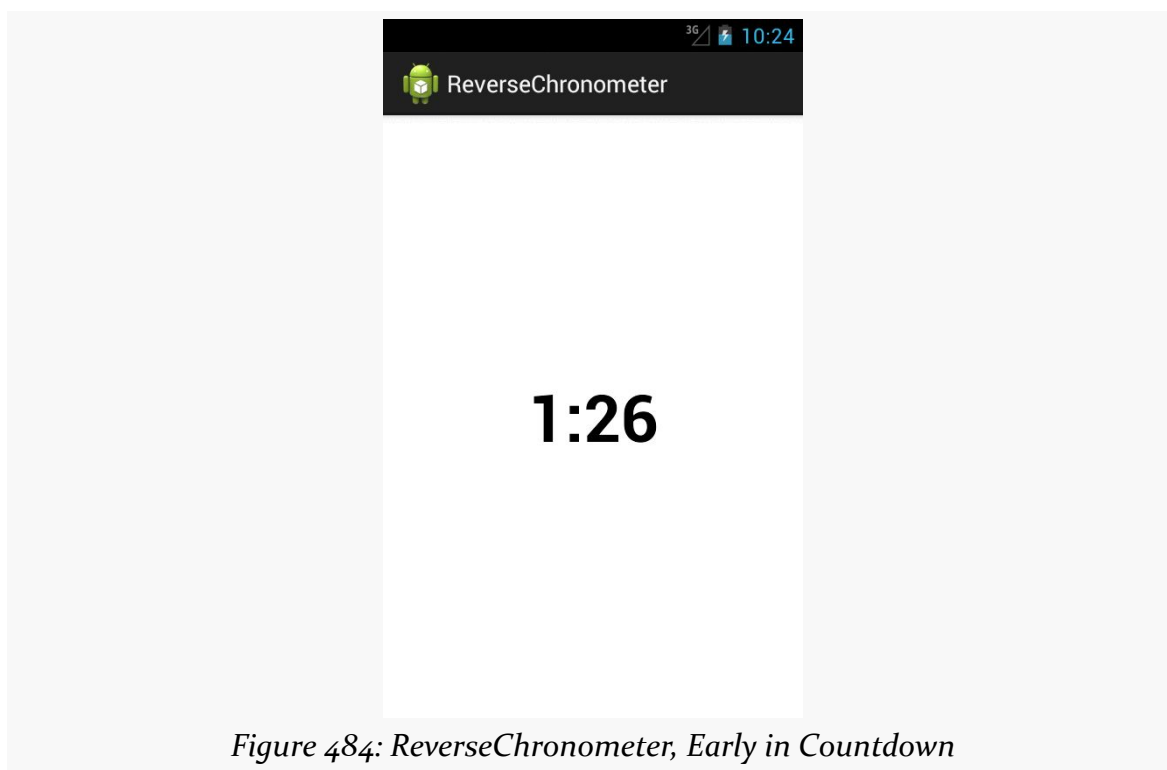

Figure 484: ReverseChronometer, Early in Countdown

...changing to orange when we are within the warning duration:

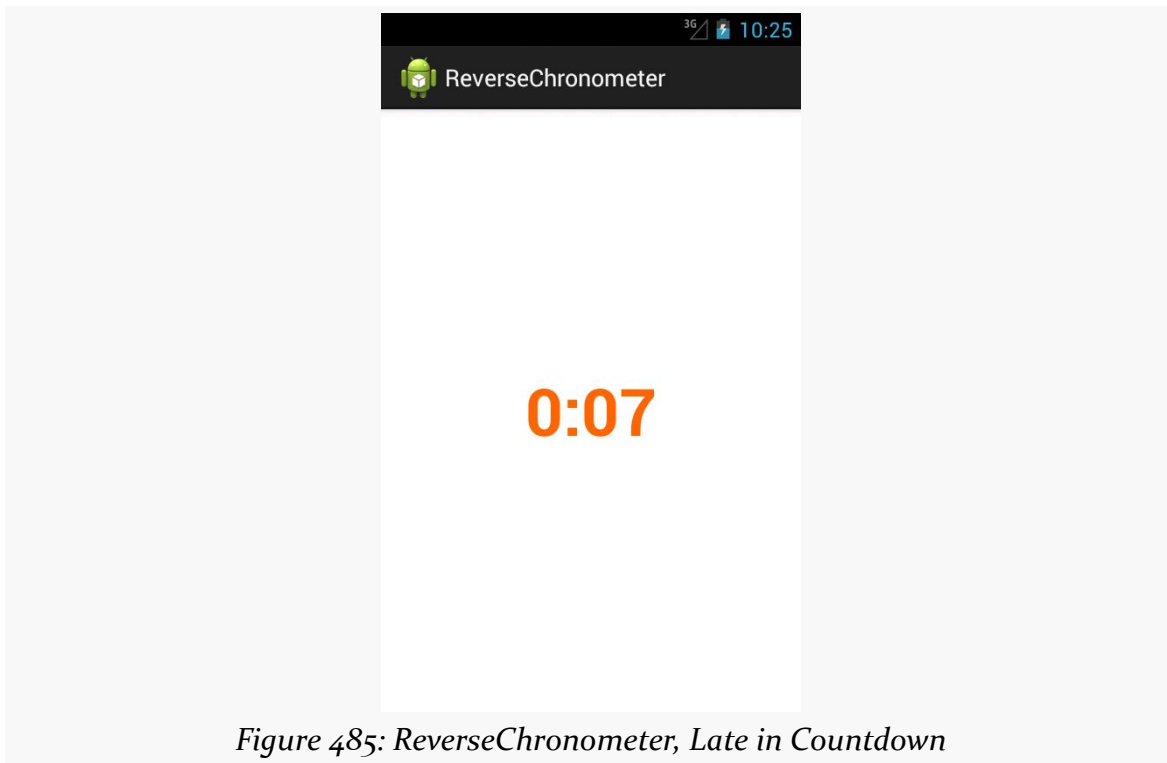

Figure 485: ReverseChronometer, Late in Countdown

...and changing to red when time has run out:

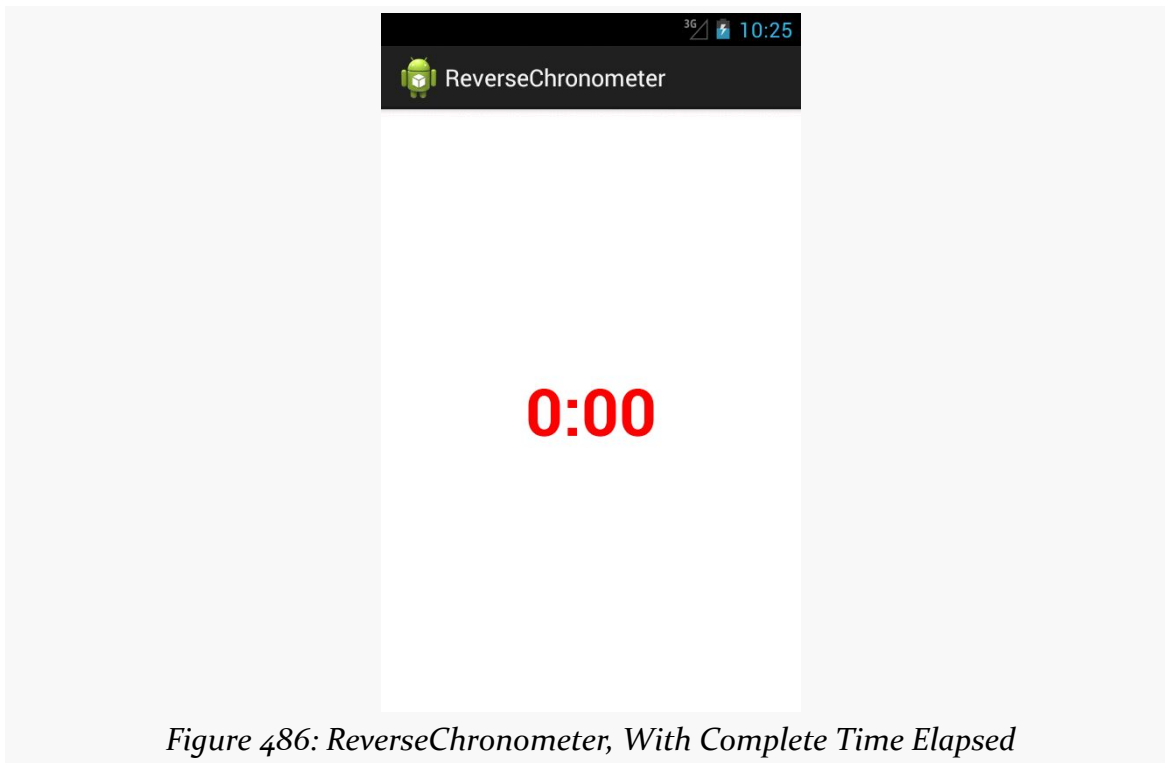

Figure 486: ReverseChronometer, With Complete Time Elapsed

Of course, much more could be done with this widget, if you chose:

- Support other constructors, beyond the two-argument constructor needed for layout inflation
- Support setting durations and colors via custom XML attributes
- Adding listeners for warning and expired events, so other things can be done at those points in time (e.g., play a sound, vibrate the device)

AspectRatioLockedFrameLayout: A Custom Container

You can also craft your own custom container classes, whether inheriting straight from `ViewGroup` to implement your own set of layout rules, or by extending an existing `ViewGroup` to merely augment its functionality.

For example, there may be cases where you want to control the aspect ratio of some set of widgets. This is important when working with preview frames off of the Camera to prevent distortion, for example.

AspectRatioLockedFrameLayout, therefore, is a custom extension of FrameLayout that ensures that its contents are kept within a particular aspect ratio, reducing the height or width of the contents to keep that aspect ratio.

AspectRatioLockedFrameLayout is published as part of the CWAC-Layouts project, with [its own GitHub repo](#). As with many of the CWAC projects, the reusable code is distributed as a JAR and as an Android library project, with a demo/ sub-project illustrating the use of some of the library's contents.

AspectRatioLockedFrameLayout holds onto two data members:

- A double (aspectRatio) that represents a specific aspect ratio to maintain, initialized to 0.0
- A View (aspectRatioSource) that represents some other widget whose aspect ratio should be matched, initialized to null

AspectRatioLockedFrameLayout has corresponding setters for each:

```
public void setAspectRatioSource(View v) {
    this.aspectRatioSource=new ViewAspectRatioSource(v);
}

public void setAspectRatioSource(AsspectRatioSource aspectRatioSource) {
    this.aspectRatioSource=aspectRatioSource;
}

// from com.android.camera.PreviewFrameLayout, with slight
// modifications

public void setAspectRatio(double aspectRatio) {
    if (aspectRatio <= 0.0) {
        throw new IllegalArgumentException(
            "aspect ratio must be positive");
    }

    if (this.aspectRatio != aspectRatio) {
        this.aspectRatio=aspectRatio;
        requestLayout();
    }
}
```

The “business logic” of maintaining the aspect ratio comes in onMeasure(). onMeasure() is called on a ViewGroup when it is time for it to determine its actual size, based upon things like the requested height and width and the sizes of its children. In our case onMeasure() needs to be tweaked to maintain the aspect ratio, assuming that we have an aspect ratio to work with:

CRAFTING YOUR OWN VIEWS

```
// from com.android.camera.PreviewFrameLayout, with slight
// modifications

@Override
protected void onMeasure(int widthSpec, int heightSpec) {
    double localRatio=aspectRatio;

    if (localRatio == 0.0 && aspectRatioSource != null
        && aspectRatioSource.getHeight() > 0) {
        localRatio=
            (double)aspectRatioSource.getWidth()
            / (double)aspectRatioSource.getHeight();
    }

    if (localRatio == 0.0) {
        super.onMeasure(widthSpec, heightSpec);
    }
    else {
        int lockedWidth=MeasureSpec.getSize(widthSpec);
        int lockedHeight=MeasureSpec.getSize(heightSpec);

        if (lockedWidth == 0 && lockedHeight == 0) {
            throw new IllegalArgumentException(
                "Both width and height cannot be zero
-- watch out for scrollable containers");
        }

        // Get the padding of the border background.
        int hPadding=getPaddingLeft() + getPaddingRight();
        int vPadding=getPaddingTop() + getPaddingBottom();

        // Resize the preview frame with correct aspect ratio.
        lockedWidth-=hPadding;
        lockedHeight-=vPadding;

        if (lockedHeight > 0 && (lockedWidth > lockedHeight * localRatio)) {
            lockedWidth=(int)(lockedHeight * localRatio + .5);
        }
        else {
            lockedHeight=(int)(lockedWidth / localRatio + .5);
        }

        // Add the padding of the border.
        lockedWidth+=hPadding;
        lockedHeight+=vPadding;

        // Ask children to follow the new preview dimension.
        super.onMeasure(MeasureSpec.makeMeasureSpec(lockedWidth,
                                                    MeasureSpec.EXACTLY),
                        MeasureSpec.makeMeasureSpec(lockedHeight,
                                                    MeasureSpec.EXACTLY));
    }
}
```

We start by determining what actually is the desired aspect ratio, held onto in a `localRatio` local variable. That will be `aspectRatio` if we do not have an `aspectRatioSource` that already knows its size, otherwise we will calculate the aspect ratio from the source. And, if `localRatio` turns out to be 0.0, indicating that we do not have an aspect ratio to maintain, we just chain to the superclass, so `AspectLockedFrameLayout` will behave just like a normal `FrameLayout`.

If we *do* have an aspect ratio to maintain, we start by determining our requested height and width. `onMeasure()` is passed a pair of “specs” that provides details about our requested size, and we can get the height and width from those by means of the `MeasureSpec` helper class. We remove any horizontal padding — padding is considered to be “outside” the locked area and therefore is ignored in aspect ratio calculations. We then adjust the height or the width, as needed, to maintain the aspect ratio. We add back in the padding, then chain to the superclass with revised height and width “specs” via `MeasureSpec`.

Note that much of this logic was derived from `com.android.camera.PreviewFrameLayout` from the AOSP Camera application, which is used to maintain the aspect ratio of the `SurfaceView` used to display preview frames.

To use an `AspectLockedFrameLayout`, just add it to your layout XML file, with an appropriate child widget/container representing the material that needs to maintain a particular aspect ratio. Since the `AspectLockedFrameLayout` is overriding its natural size, you can use `android:layout_gravity` to control its positioning within some parent widget, such as centering it:

```
<FrameLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <com.commonware.cwac.layouts.AspectLockedFrameLayout
        android:id="@+id/source"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center">

        <!-- children go here -->
    </com.commonware.cwac.layouts.AspectLockedFrameLayout>
</FrameLayout>
```

Mirror and MirroringFrameLayout: Draw It Yourself

Another scenario where aspect ratios matter is when you are presenting information on an external display via Presentation, as is covered [elsewhere in this book](#). Ideally, you fill the external display. And normally this will happen for you automatically, as your Presentation content view should fill the available screen space... assuming that the content has the right aspect ratio, or can be suitably stretched.

One scenario where this might be a problem is if you want *the same material* shown on both the main display and on the external display. For example, suppose that you are using Presentation to deliver... well... a presentation. The external display is probably some form of video projector, and you will want your slides or other materials shown there. However, it is useful for you to be able to see those same slides and such on the tablet, as typically the projector screen is behind, or to the side of, the presenter. If the presenter has to keep turning around to confirm what is shown on “the big screen”, it can detract from the presentation.

Moreover, you might not only want to *show* the same material, but have it stem *from the same source*, on the tablet, for interactivity reasons. Suppose that you want to display a Web page. You might just pop up a WebView in the Presentation. But... how do you scroll? The Presentation offers no touch interface — projector screens do not magically respond to pinch-to-zoom just because we happen to be projecting something onto them from an Android tablet.

In this case, ideally we would like to *mirror* something. Have the actual widgets shown on the tablet, which can then respond to touch events and the like. At the same time, capture what is shown on the tablet and reproduce it, verbatim, on the Presentation for the audience to see. Now everybody can see the same material, and the presenter can manipulate that material.

But now aspect ratios come into play. We want to fill the Presentation display space, without black bars or stretching or whatever. That only works if our source material — the widgets and containers to be mirrored — have the same aspect ratio as the Presentation’s Display itself.

With that in mind, the CWAC Layouts project also contains two classes to solve this problem:

- `MirroringFrameLayout` is an `AspectLockedFrameLayout` that also can mirror its content to...
- `Mirror`, a `View` that takes a `Bitmap` representing the `MirroringFrameLayout` contents and displays it

Technically, `MirroringFrameLayout` works with a `MirrorSink`, an interface that can receive updates to the content to be mirrored when that content changes. `Mirror` implements `MirrorSink`, and you could have other classes implement `MirrorSink` as well if that made sense for your app. The sections that follow focus on `MirroringFrameLayout` working with a `Mirror`, as that is the most likely scenario.

MirroringFrameLayout

`MirroringFrameLayout` extends `AspectLockedFrameLayout`, so that we can lock the aspect ratio of the to-be-mirrored contents to match the aspect ratio of the `Mirror`. The `Mirror` is designed to be projected by the `Presentation`, and so if the `Mirror` fills the `Presentation`'s `Display`, we want our `MirroringFrameLayout` to match the aspect ratio so the entire `Display` can indeed be filled.

Of course, a `ViewGroup` like `FrameLayout` normally just has its children draw to the screen. In our case, we need to capture what is drawn ourselves, to supply to the `Mirror` as needed. This is a bit tricky.

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.ViewTreeObserver.OnPreDrawListener;
import android.view.ViewTreeObserver.OnScrollChangedListener;

public class MirroringFrameLayout extends AspectLockedFrameLayout
    implements OnPreDrawListener, OnScrollChangedListener {
    private MirrorSink mirror=null;
    private Bitmap bmp=null;
    private Canvas bmpBackedCanvas=null;
    private Rect rect=new Rect();

    public MirroringFrameLayout(Context context) {
        this(context, null);
    }

    public MirroringFrameLayout(Context context, AttributeSet attrs) {
        super(context, attrs);
```

```
        setWillNotDraw(false);
    }

    public void setMirror(MirrorSink mirror) {
        this.mirror=mirror;

        if (mirror != null) {
            setAspectRatioSource(mirror);
        }
    }

    @Override
    public void onAttachedToWindow() {
        super.onAttachedToWindow();

        getViewTreeObserver().addOnPreDrawListener(MirroringFrameLayout.this);
        getViewTreeObserver().addOnScrollChangeListener(MirroringFrameLayout.this);
    }

    @Override
    public void onDetachedFromWindow() {
        getViewTreeObserver().removeOnPreDrawListener(this);
        getViewTreeObserver().removeOnScrollChangeListener(this);

        super.onDetachedFromWindow();
    }

    @Override
    public void draw(Canvas canvas) {
        if (mirror != null) {
            bmp.eraseColor(0);

            super.draw(bmpBackedCanvas);
            getDrawingRect(rect);
            canvas.drawBitmap(bmp, null, rect, null);
            mirror.update(bmp);
        }
        else {
            super.draw(canvas);
        }
    }

    @Override
    protected void onSizeChanged(int w, int h, int oldw, int oldh) {
        initBitmap(w, h);

        super.onSizeChanged(w, h, oldw, oldh);
    }

    @Override
    public boolean onPreDraw() {
        if (mirror != null) {
            if (bmp == null) {
                requestLayout();
            }
        }
    }
}
```

```
    }
    else {
        invalidate();
    }
}

return(true);
}

@Override
public void onScrollChanged() {
    onPreDraw();
}

private void initBitmap(int w, int h) {
    if (mirror != null) {
        if (bmp == null || bmp.getWidth() != w || bmp.getHeight() != h) {
            if (bmp != null) {
                bmp.recycle();
            }

            bmp=Bitmap.createBitmap(w, h, Bitmap.Config.ARGB_8888);
            bmpBackedCanvas=new Canvas(bmp);
        }
    }
}
```

Our one-argument constructor uses `this()` to chain to the two-argument constructor. The two-argument constructor calls `setWillNotDraw(false)` indicating to Android that we want this `ViewGroup` to participate in the drawing process like a regular `View` — normally, certain steps in the drawing process are skipped as being irrelevant to `View` classes that do not draw anything themselves.

We have a `setMirror()` method, where the activity or fragment can supply the `MirrorSink` that is connected to this `MirroringFrameLayout`. In addition to holding onto the `MirrorSink` in a `mirror` data member, we call `setAspectRatioSource()`, inherited from `AspectLockedFrameLayout`, so our contents will match the aspect ratio from that source.

`MirroringFrameLayout` overrides `onAttachedToWindow()` and `onDetachedFromWindow()`. As one might guess, these callbacks are called when views are attached and detached from some window. Usually, that window represents an activity, though it could represent a `Dialog` or a `Presentation`.

In those callbacks, we connect with the `ViewTreeObserver` of the `MirroringFrameLayout`. A `ViewTreeObserver` is a way to find out about events of a view tree, rooted at some `ViewGroup`. In our case, we want to find out when children

are going to be drawn (`addOnPreDrawListener()`) and when they are scrolled (`addOnScrollChangeListener()`).

We override `onSizeChanged()`. This is called on any `View` when its size may have changed, either because it is being sized initially when the UI is being set up, or because something else nearby changed size (e.g., its parent) and therefore the size of the `View` itself may now be different. In our case, we use `onSizeChanged()` to set up a `Bitmap` object, sized to match our size, and a `Canvas` object that wraps around that `Bitmap` object. As you will see, we will use this `Canvas` to capture what is being drawn on the screen, for later use by the `Mirror`.

We also override `draw()`. This is, in effect, the “entry point” into the logic that causes a `View` to render itself on the screen, by drawing to a supplied `Canvas` object. Most `View` classes do not override `draw()`, as the real rendering is done in an `onDraw()` method, as we will see with `Mirror` later in this chapter. However, in our case, we have to override `draw()` for one simple reason: we do not want to draw to the `Canvas` supplied by Android to the `draw()` method. We want to draw to our own `Canvas`, backed by that `Bitmap`.

To that end, if we have a `MirrorSink`, we:

- Make sure the `Bitmap` starts off blank by calling `eraseColor()`
- Chain to the superclass, replacing the `Canvas` given to us in `draw()` by our own `Bitmap`-backed `Canvas`
- Calculate a `Rect` object with our size and position, using `getDrawingRect()`
- Use that `Rect` and the `Bitmap` to render the `Bitmap` to the “real” `Canvas` supplied to us in `draw()`
- Call `update()` on the `MirrorSink`, to give it the new `Bitmap`

By rendering our contents to the `Bitmap`-backed `Canvas`, instead of the normal one, we capture a copy of the output, in the form of the `Bitmap`. Since the `Bitmap` has the same size as the “real” `Canvas` (courtesy of our `onSizeChanged()` work), when we draw the `Bitmap` onto the `Canvas`, we effectively “color in” the same pixels in the same spots as if we had skipped all of this and left the normal `draw()` logic alone. But, since we still hold onto our `Bitmap`, we can use those same pixels elsewhere... such as in our `Mirror`.

The problem with relying on `draw()` is that it is not always called when there are changes to widgets within the `MirroringFrameLayout`. In particular, `WebView` often does not trigger `draw()` on the `MirroringFrameLayout`. That’s where the pre-draw

and scroll-changed events from the `ViewTreeObserver` come into play: they give us more indication that we need to update our `Bitmap`.

The `onPreDraw()` method is called when a child of this `MirroringFrameLayout` is about to be drawn. If we have our `MirrorSink`, we then either call `requestLayout()` (if we have no `bitmap` yet) or `invalidate()` (if we do), to trigger Android to go through the draw process for the `MirroringFrameLayout` too, allowing us to update our `Bitmap`.

The `onScrollChanged()` method is called when a child of this `MirroringFrameLayout` has been scrolled. This delegates to `onPreDraw()`, to run through the same logic to force an update to the `Bitmap`.

Mirror

`Mirror` extends the base `View` class, and so it is the most “raw” of all the custom widgets and containers shown so far in this chapter. It has an `update()` method, used to connect the `MirroringFrameLayout` from which the `Mirror` can obtain what it is supposed to display:

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.View;

public class Mirror extends View implements MirrorSink {
    private Rect rect=new Rect();
    private Bitmap bmp=null;

    public Mirror(Context context) {
        super(context);
    }

    public Mirror(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    public Mirror(Context context, AttributeSet attrs, int defStyle) {
        super(context, attrs, defStyle);
    }

    @Override
    public void update(Bitmap bmp) {
        this.bmp=bmp;
    }
}
```

```
        invalidate();
    }

    @Override
    protected void onDraw(Canvas canvas) {
        super.onDraw(canvas);

        if (bmp != null) {
            getDrawingRect(rect);

            calcCenter(rect.width(), rect.height(), bmp.getWidth(),
                        bmp.getHeight(), rect);
            canvas.drawBitmap(bmp, null, rect, null);
        }
    }

    // based upon http://stackoverflow.com/a/14679729/115145

    static void calcCenter(int vw, int vh, int iw, int ih, Rect out) {
        double scale=
            Math.min((double)vw / (double)iw, (double)vh / (double)ih);

        int h=(int)(scale * ih);
        int w=(int)(scale * iw);
        int x=((vw - w) >> 1);
        int y=((vh - h) >> 1);

        out.set(x, y, x + w, y + h);
    }
}
```

The bulk of the “business logic” lies in `onDraw()`, plus a helper `calcCenter()` static method.

`onDraw()` is called on a `View` when it is time for that widget to actually draw its visual representation onto the supplied `Canvas`. Different widgets will use different drawing primitive methods offered by `Canvas`, to draw lines and text and whatnot. In our case, we:

- Calculate a `Rect` object with our size and position, using `getDrawingRect()`
- Get the `Bitmap` object from the `MirroringFrameLayout`, via a call to `getLastBitmap()` (which simply returns the `Bitmap` that the `MirroringFrameLayout` is using)
- Call `calcCenter` to adjust our `Rect` to take into account the fact that our size may be different than the size of the actual `Bitmap`
- Call `drawBitmap()` on our `Canvas`, to render the `Bitmap` into the location specified by the `Rect`, where `drawBitmap()` will automatically down-sample or up-sample the image as needed to fill the necessary space

Usage and Results

Normally, you would use the `Mirror` in a layout for a `Presentation` and the `MirroringFrameLayout` in an activity that controls the `Presentation`. However, it is possible to use both in the same layout file, for light testing. However, please do not put the `Mirror` inside of the `MirroringFrameLayout`, as this is likely to cause a rupture in the space-time continuum, and you really do not want to be responsible for that.

So, in the `SimpleMirrorActivity` from the demo/ sub-project, we use a layout that has both `Mirror` and `MirroringFrameLayout`, with the latter set to mirror a `WebView`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context=".SimpleMirrorActivity">

    <FrameLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1">

        <com.commonware.cwac.layouts.MirroringFrameLayout
            android:id="@+id/source"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center">

            <EditText
                android:id="@+id/editor"
                android:layout_width="match_parent"
                android:layout_height="match_parent"
                android:gravity="left|top"
                android:inputType="textMultiLine"/>
        </com.commonware.cwac.layouts.MirroringFrameLayout>
    </FrameLayout>

    <View
        android:layout_width="match_parent"
        android:layout_height="4dip"
        android:background="#FF000000"/>

    <com.commonware.cwac.layouts.Mirror
        android:id="@+id/target"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="2"/>
```

```
</LinearLayout>
```

In this case, we set the background of the `FrameLayout` holding our `MirroringFrameLayout` to green, to show how the `MirroringFrameLayout` size is changed to maintain our aspect ratio.

(or, perhaps we just like green)

Besides configuring the to-be-mirrored widgets, all you need to do is call `setMirror()` on the `MirroringFrameLayout` to enable the mirroring logic:

```
package com.commonware.cwac.layouts.demo;

import android.app.Activity;
import android.os.Bundle;
import com.commonware.cwac.layouts.Mirror;
import com.commonware.cwac.layouts.MirroringFrameLayout;

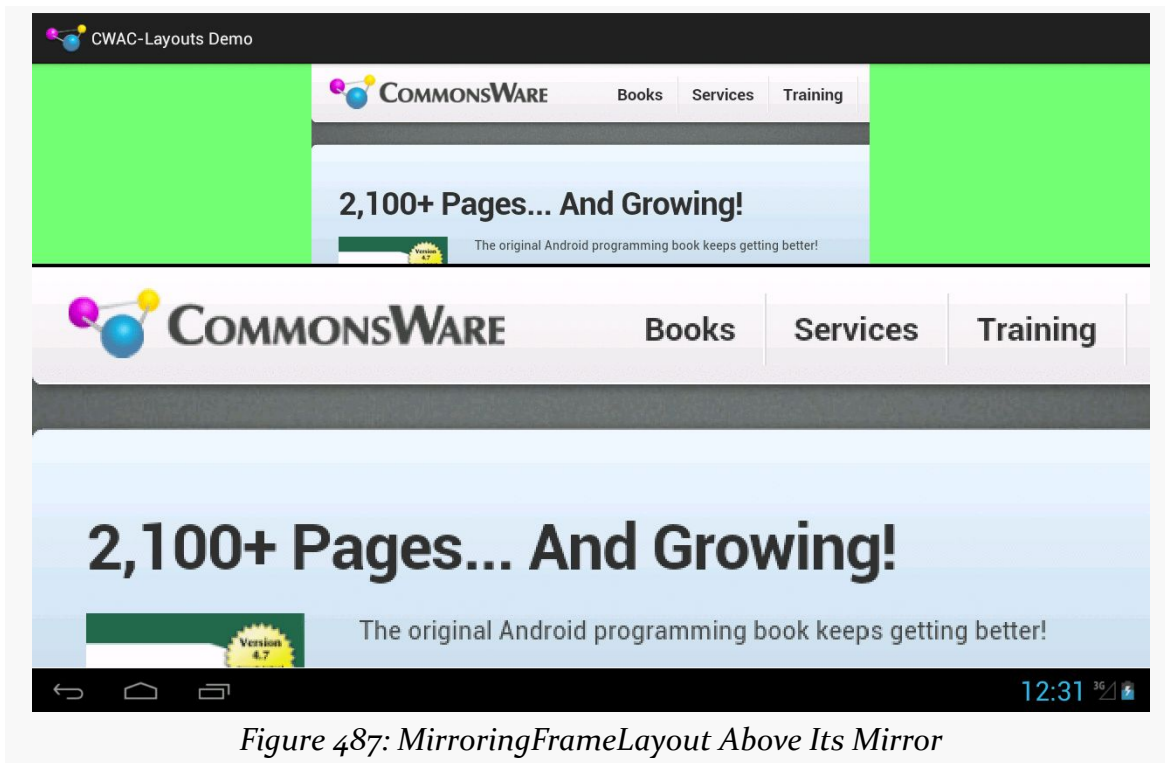

public class SimpleMirrorActivity extends Activity {
    MirroringFrameLayout source=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.simple_mirror);

        source=(MirroringFrameLayout)findViewById(R.id.source);
        Mirror target=(Mirror)findViewById(R.id.target);

        source.setMirror(target);
    }
}
```

CRAFTING YOUR OWN VIEWS

While the bottom portion is just the Mirror and therefore is non-interactive, the top is the real WebView, which can be scrolled, with the resulting changes reflected in the Mirror in real-time:

Figure 488: *MirroringFrameLayout and Mirror, Showing Scrolled Contents*

Limitations

`MirroringFrameLayout` only works for materials drawn in the Java layer, that therefore can be drawn to the Bitmap-backed Canvas. Content *not* drawn in the Java layer will not work with `MirroringFrameLayout`, notably anything involving a `SurfaceView`. This not only includes your own `SurfaceView` widgets, but anything else that depends upon `SurfaceView`, such as `VideoView` or the Maps V2 `MapView` and `MapFragment`.

Also, the re-sampling done by `Mirror` is not especially sophisticated and will cause jagged effects, particularly when up-sampling. Ideally, the `MirroredFrameLayout` will be the same size or larger than the `Mirror`. This may not always be possible, particularly with a `Mirror` shown on a 1080p external display, but the closer you can get will improve the output.

Custom Dialogs and Preferences

Android ships with a number of dialog classes for specific circumstances, like `DatePickerDialog` and `ProgressDialog`. Similarly, Android comes with a smattering of Preference classes for your `PreferenceActivity`, to accept text or selections from lists and so on.

However, there is plenty of room for improvement in both areas. As such, you may find the need to create your own custom dialog or preference class. This chapter will show you how that is done.

We start off by looking at creating a [custom `AlertDialog`](#), not by using `AlertDialog.Builder`, but via a custom subclass. Then, we show how to create your [own dialog-style Preference](#), where tapping on the preference pops up a dialog to allow the user to customize the preference value.

Prerequisites

Understanding this chapter requires that you have read [the chapter on dialogs](#), along with [the chapter on the preference system](#). Also, the samples here use the custom `ColorMixer` View described [in another chapter](#).

Your Dialog, Chocolate-Covered

For your own application, the simplest way to create a custom `AlertDialog` is to use `AlertDialog.Builder`, as described [in a previous chapter](#). You do not need to create any special subclass — just call methods on the Builder, then `show()` the resulting dialog.

However, if you want to create a reusable `AlertDialog`, this may become problematic. For example, where would this code to create the custom `AlertDialog` reside?

So, in some cases, you may wish to extend `AlertDialog` and supply the dialog's contents that way, which is how `TimePickerDialog` and others are implemented. Unfortunately, this technique is not well documented. This section will illustrate how to create such an `AlertDialog` subclass, as determined by looking at how the core Android team did it for their own dialogs.

The sample code is `ColorMixerDialog`, a dialog wrapping around the `ColorMixer` widget shown in a previous chapter. The implementation of `ColorMixerDialog` can be found in the [CWAC-ColorMixer](#) GitHub repository, as it is part of the CommonsWare Android Components.

Using this dialog works much like using `DatePickerDialog` or `TimePickerDialog`. You create an instance of `ColorMixerDialog`, supplying the initial color to show and a listener object to be notified of color changes. Then, call `show()` on the dialog. If the user makes a change and accepts the dialog, your listener will be informed.

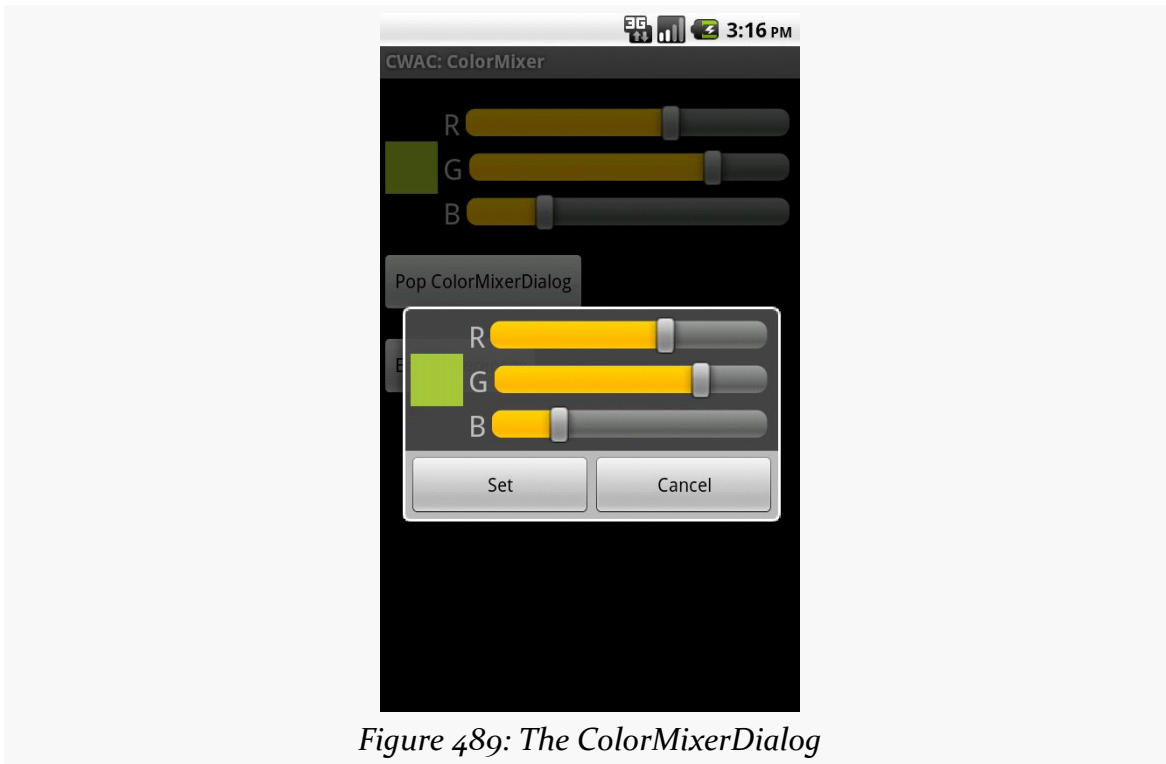

Figure 489: The ColorMixerDialog

Basic AlertDialog Setup

The ColorMixerDialog class is not especially long, since all of the actual color mixing is handled by the ColorMixer widget:

```
package com.commonsware.cwac.colormixer;

import android.app.AlertDialog;
import android.content.Context;
import android.content.DialogInterface;
import android.os.Bundle;

public class ColorMixerDialog extends AlertDialog
    implements DialogInterface.OnClickListener {
    static private final String COLOR="c";
    private ColorMixer mixer=null;
    private int initialColor;
    private ColorMixer.OnColorChangeListener onSet=null;

    public ColorMixerDialog(Context ctxt,
                           int initialColor,
                           ColorMixer.OnColorChangeListener onSet) {

        super(ctxt);

        this.initialColor=initialColor;
        this.onSet=onSet;

        mixer=new ColorMixer(ctxt);
        mixer.setColor(initialColor);

        setView(mixer);
        setButton(ctxt.getText(R.string.cwac_colormixer_set),
                  this);
        setButton2(ctxt.getText(R.string.cwac_colormixer_cancel),
                   (DialogInterface.OnClickListener)null);
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        if (initialColor!=mixer.getColor()) {
            onSet.onColorChange(mixer.getColor());
        }
    }

    @Override
    public Bundle onSaveInstanceState() {
        Bundle state=super.onSaveInstanceState();

        state.putInt(COLOR, mixer.getColor());

        return(state);
    }
}
```

```
@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
}
```

We extend the `AlertDialog` class and implement a constructor of our own design. In this case, we take in three parameters:

1. A `Context` (typically an `Activity`), needed for the superclass
2. The initial color to use for the dialog, such as if the user is editing a color they chose before
3. A `ColorMixer.OnColorChangeListener` object, just like `ColorMixer` uses, to notify the dialog creator when the color is changed

We then create a `ColorMixer` and call `setView()` to make that be the main content of the dialog. We also call `setButton()` and `setButton2()` to specify a “Set” and “Cancel” button for the dialog. The latter just dismisses the dialog, so we need no event handler. The former we route back to the `ColorMixerDialog` itself, which implements the `DialogInterface.OnClickListener` interface.

Handling Color Changes

When the user clicks the “Set” button, we want to notify the application about the color change...if the color actually changed. This is akin to `DatePickerDialog` and `TimePickerDialog` only notifying you of date or times if the user clicks Set and actually changed the values.

The `ColorMixerDialog` tracks the initial color via the `initialColor` data member. In the `onClick()` method — required by `DialogInterface.OnClickListener` — we see if the mixer has a different color than the `initialColor`, and if so, we call the supplied `ColorMixer.OnColorChangeListener` callback object:

```
@Override
public void onClick(DialogInterface dialog, int which) {
    if (initialColor != mixer.getColor()) {
        onSet.onColorChange(mixer.getColor());
    }
}
```

State Management

Dialogs use `onSaveInstanceState()` and `onRestoreInstanceState()`, just like activities do. That way, if the screen is rotated, or if the hosting activity is being evicted from RAM when it is not in the foreground, the dialog can save its state, then get it back later as needed.

The biggest difference with `onSaveInstanceState()` for a dialog is that the `Bundle` of state data is not passed into the method. Rather, you get the `Bundle` by chaining to the superclass, then adding your data to the `Bundle` it returned, before returning it yourself:

```
@Override
public Bundle onSaveInstanceState() {
    Bundle state=super.onSaveInstanceState();

    state.putInt(COLOR, mixer.getColor());

    return(state);
}
```

The `onRestoreInstanceState()` pattern is much closer to the implementation you would find in an `Activity`, where the `Bundle` with the state data to restore is passed in as a parameter:

```
@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
```

Preferring Your Own Preferences, Preferably

The Android Settings application, built using the Preference system, has lots of custom Preference classes. You too can create your own Preference classes, to collect things like dates, numbers, or colors. Once again, though, the process of creating such classes is not well documented. This section reviews one recipe for making a Preference — specifically, a subclass of `DialogPreference` – based on the implementation of other Preference classes in Android.

The result is `ColorPreference`, a Preference that uses the `ColorMixer` widget. As with the `ColorMixerDialog` from the previous section, the `ColorPreference` is from

the CommonsWare Android Components, and its source code can be found in the [CWAC-ColorMixer](#) GitHub repository.

One might think that `ColorPreference`, as a subclass of `DialogPreference`, might use `ColorMixerDialog`. However, that is not the way it works, as you will see.

The Constructor

A `Preference` is much like a [custom View](#), in that there are a variety of constructors, some taking an `AttributeSet` (for the preference properties), and some taking a default style. In the case of `ColorPreference`, we need to get the string resources to use for the names of the buttons in the dialog box, providing them to `DialogPreference` via `setPositiveButton()` and `setNegativeButton()`.

Here, we just implement the standard two-parameter constructor, since that is the one that is used when this preference is inflated from a preference XML file:

```
public ColorPreference(Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    setPositiveButton(ctxt.getText(R.string.cwac_colormixer_set));
    setNegativeButton(ctxt.getText(R.string.cwac_colormixer_cancel));
}
```

Creating the View

The `DialogPreference` class handles the pop-up dialog that appears when the preference is clicked upon by the user. Subclasses get to provide the `View` that goes inside the dialog. This is handled a bit reminiscent of a `CursorAdapter`, in that there are two separate methods to be overridden:

- `onCreateDialogView()` works like `newView()` of `CursorAdapter`, returning a `View` that should go in the dialog
- `onBindDialogView()` works like `bindView()` of `CursorAdapter`, where the custom `Preference` is supposed to configure the `View` for the current preference value

In the case of `ColorPreference`, we use a `ColorMixer` for the `View`:

```
@Override
protected View onCreateDialogView() {
    mixer=new ColorMixer(getContext());
}
```

```
        return(mixer);  
    }
```

Then, in `onBindDialogView()`, we set the mixer's color to be `lastColor`, a private data member:

```
@Override  
protected void onBindDialogView(View v) {  
    super.onBindDialogView(v);  
  
    mixer.setColor(lastColor);  
}
```

We will see later in this section where `lastColor` comes from – for the moment, take it on faith that it holds the user's chosen color, or a default value.

Dealing with Preference Values

Of course, the whole point behind a Preference is to allow the user to set some value that the application will then use later on. Dealing with values is a bit tricky with `DialogPreference`, but not too bad.

Getting the Default Value

The preference XML format has an `android:defaultValue` attribute, which holds the default value to be used by the preference. Of course, the actual data type of the value will differ widely — an `EditTextPreference` might expect a `String`, while `ColorPreference` needs a color value.

Hence, you need to implement `onGetDefaultValue()`. This is passed a `TypedArray` — similar to how a custom `View` uses a `TypedArray` for getting at its custom attributes in an XML layout file. It is also passed an index number into the array representing `android:defaultValue`. The custom Preference needs to return an `Object` representing its interpretation of the default value.

In the case of `ColorPreference`, we simply get an integer out of the `TypedArray`, representing the color value, with an overall default value of `0xFFA4C639` (a.k.a., Android green):

```
@Override  
protected Object onGetDefaultValue(TypedArray a, int index) {  
    return(a.getInt(index, 0xFFA4C639));  
}
```

Setting the Initial Value

When the user clicks on the preference, the `DialogPreference` supplies the last-known preference value to its subclass, or the default value if this preference has not been set by the user to date.

The way this works is that the custom `Preference` needs to override `onSetInitialValue()`. This is passed in a boolean flag (`restoreValue`) indicating whether or not the user set the value of the preference before. It is also passed the `Object` returned by `onGetDefaultValue()`. Typically, a custom `Preference` will look at the flag and choose to either use the default value or load the already-set preference value.

To get the existing value, `Preference` defines a set of type-specific getter methods — `getPersistedInt()`, `getPersistedString()`, etc. So, `ColorPreference` uses `getPersistedInt()` to get the saved color value:

```
@Override
protected void onSetInitialValue(boolean restoreValue, Object defaultValue) {
    lastColor=(restoreValue ? getPersistedInt(lastColor) :
(Integer)defaultValue);
}
```

Here, `onSetInitialValue()` stores that value in `lastColor` — which then winds up being used by `onBindDialogView()` to tell the `ColorMixer` what color to show.

Closing the Dialog

When the user closes the dialog, it is time to persist the chosen color from the `ColorMixer`. This is handled by the `onDialogClosed()` callback method on your custom `Preference`:

```
@Override
protected void onDialogClosed(boolean positiveResult) {
    super.onDialogClosed(positiveResult);

    if (positiveResult) {
        if (callChangeListener(mixer.getColor())) {
            lastColor=mixer.getColor();
            persistInt(lastColor);
        }
    }
}
```

The passed-in boolean indicates if the user accepted or dismissed the dialog, so you can elect to skip saving anything if the user dismissed the dialog. The other `DialogPreference` implementations also call `callChangeListener()`, which is somewhat ill-documented. Assuming both the flag and `callChangeListener()` are true, the Preference should save its value to the persistent store via `persistInt()`, `persistString()`, or `kin`.

Using the Preference

Given all of that, using the custom Preference class in an application is almost anticlimactic. You simply add it to your preference XML, with a fully-qualified class name:

```
<PreferenceScreen
  xmlns:android="http://schemas.android.com/apk/res/android">
  <com.commonware.cwac.colormixer.ColorPreference
    android:key="favoriteColor"
    android:defaultValue="0xFFA4C639"
    android:title="Your Favorite Color"
    android:summary="Blue. No yel-- Auuuuuuuugh!" />
</PreferenceScreen>
```

At this point, it behaves no differently than does any other Preference type. Since `ColorPreference` stores the value as an integer, your code would use `getInt()` on the `SharedPreferences` to retrieve the value when needed.

The user sees an ordinary preference entry in the `PreferenceActivity`:

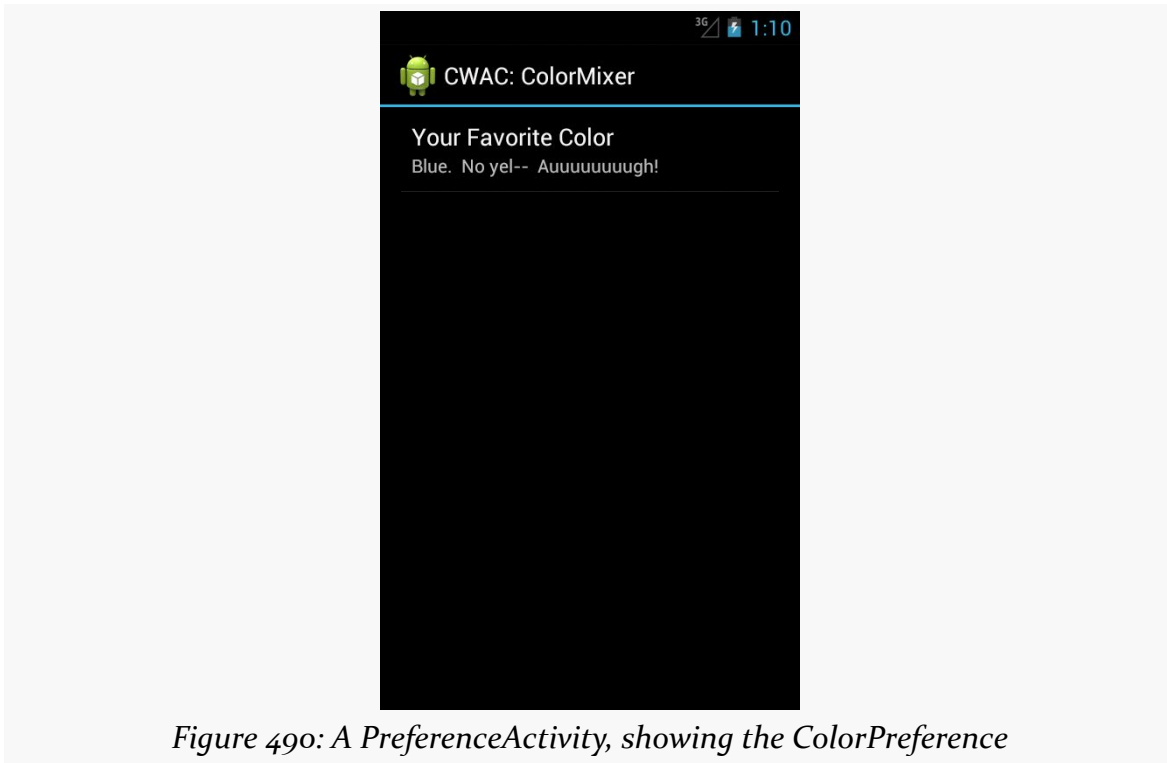

Figure 490: A PreferenceActivity, showing the ColorPreference

When tapped, it brings up the mixer:

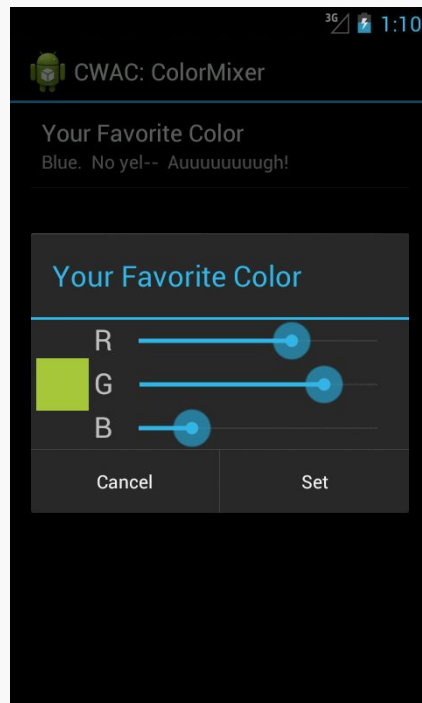

Figure 491: The ColorMixer in a custom DialogPreference

Choosing a color and clicking “Set” persists the color value as a preference.

Progress Indicators

Sometimes, we make the user wait. And wait. And wait some more.

Often, in these cases, it is useful to let the user know that something they requested is something that we are diligently working on. To do this, we can use some form of progress indicator. We saw basic use of a `ProgressBar` in the tutorials earlier in this book — now is the time to take a much closer look at `ProgressBar` and other means of displaying progress.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapters on [dialogs](#), [custom drawables](#), and [animators](#) is also a good idea.

Progress Bars

The classic way to tell the user that we are doing something for them is to use a `ProgressBar` widget, much as we briefly displayed one in the `EmPubLite` sample app in the tutorials.

However, a `ProgressBar` is much more than a simple spinning image. We can use it to display either indeterminate progress (“we will be done... sometime”) or specific progress (“we are 34% complete”). We can use it either as a circle or as a classic horizontal bar, the latter typically used for specific progress. And, for specific progress, we can actually show two tiers of progress, known as “primary” and “secondary” (e.g., primary for the progress in copying a directory’s worth of files, secondary for the progress on a specific file).

In this section, we will take a look at these different ways of using ProgressBar.

Circular vs. Horizontal

As the name suggests, a ProgressBar denotes progress. As the name does not suggest, a ProgressBar is not a bar, by default — it is a circle. Hence, the following element from an XML layout resource:

```
<ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
    android:layout_marginTop="20dp"/>
```

gives us:

Figure 492: Android 4.0 ProgressBar, Default Style

However, referencing `style="?android:attr/progressBarStyleHorizontal"` in the element:

```
<ProgressBar
    android:id="@+id/progressHI"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="true"/>
```

gives us a horizontal bar:

Figure 493: Android 4.0 ProgressBar, Horizontal Style

Note that the look-and-feel of these widgets have changed over the years. On Android 1.x and 2.x, they will look like this:

Figure 494: Android 2.3.3 ProgressBar, Both Styles

Specific vs. Indeterminate

Typically, you use the circular ProgressBar style for indeterminate progress, where the circle simply spins in place to let the user know that work is proceeding and the device (or activity) has not frozen. The horizontal ProgressBar style is used to illustrate specific amounts of progress, from 0 to a value you choose.

However, while those patterns are typical, the choice of whether to use indeterminate or some specific amount of progress is independent of the style of the widget.

The `android:indeterminate` attribute controls whether the ProgressBar will render an indeterminate look or a specific look. For the latter, calls to `setMax()` (or the `android:max` attribute) will set the upper end of the progress range (the default is 100), and `setProgress()` or `incrementProgressBy()` will set how much progress along that range is illustrated.

Figure 495: Android 4.0 ProgressBar, Horizontal Style, Indeterminate and Specific

Figure 496: Android 2.3.3 ProgressBar, Horizontal Style, Indeterminate and Specific

Primary vs. Secondary

For specific progress, you actually have two independent amounts of progress. `setProgress()`, `incrementProgressBy()`, and `android:progress` control the primary progress, while `setSecondaryProgress()`, `incrementSecondaryProgressBy()`, and `android:secondaryProgress` control the secondary progress. Here, “primary progress” refers to the progress along an entire piece of work (e.g., copying a folder’s worth of files), while “secondary progress” refers the progress along a discrete chunk of the overall work (e.g., copying an individual file).

A `ProgressBar` will render these with different colors, though primary trumps secondary, and so the secondary progress will only be visible when its value exceeds that of the primary progress:

Figure 497: Android 4.0 `ProgressBar`, Horizontal Style, Primary-Only and Primary-Plus-Secondary

Figure 498: Android 2.3.3 `ProgressBar`, Horizontal Style, Primary-Only and Primary-Plus-Secondary

ProgressBar and Threads

Normally, you cannot update the UI of a widget from a background thread.

`ProgressBar` is an exception. You *can* safely call `setProgress()` and `incrementProgressBy()` from a background thread to update the primary progress, and you can safely call `setSecondaryProgress()` and `incrementSecondaryProgressBy()` from a background thread to update the secondary progress.

To see this in action, take a look at the [Progress/BarSampler](#) sample project.

This project has a single activity (`MainActivity`), whose layout (`activity_main.xml`) contains four `ProgressBar` widgets, two indeterminate and two for specific progress:

PROGRESS INDICATORS

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <ProgressBar
        android:id="@+id/progressCI"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_marginBottom="20dp"
        android:layout_marginTop="20dp"/>

    <ProgressBar
        android:id="@+id/progressHI"
        style="?android:attr/progressBarStyleHorizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="20dp"
        android:indeterminate="true"/>

    <ProgressBar
        android:id="@+id/progressHS"
        style="?android:attr/progressBarStyleHorizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="20dp"
        android:indeterminate="false"
        android:max="100"/>

    <ProgressBar
        android:id="@+id/progressHS2"
        style="?android:attr/progressBarStyleHorizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:max="100"/>

</LinearLayout>
```

The activity gets access to the latter two `ProgressBar` widgets and sets up a `ScheduledThreadPoolExecutor` to get control every second in a background thread, which calls our `run()` method. The `run()` method will increment both `ProgressBar` widgets primary progress by 2 each time, and the secondary progress by 10 (dropping back to the starting point when the secondary progress reaches the maximum of 100). When the primary progress gets to 100, we cancel our scheduled work in the `ScheduledThreadPoolExecutor`:

```
package com.commonsware.android.progress;

import android.app.Activity;
```

PROGRESS INDICATORS

```
import android.os.Bundle;
import android.widget.ProgressBar;
import java.util.concurrent.ScheduledThreadPoolExecutor;
import java.util.concurrent.TimeUnit;

public class MainActivity extends Activity implements Runnable {
    private static final int PERIOD_SECONDS=1;
    private ScheduledThreadPoolExecutor executor=
        new ScheduledThreadPoolExecutor(1);
    private ProgressBar primary=null;
    private ProgressBar secondary=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        primary=(ProgressBar)findViewById(R.id.progressHS);
        secondary=(ProgressBar)findViewById(R.id.progressHS2);

        executor.setExecuteExistingDelayedTasksAfterShutdownPolicy(false);
        executor.scheduleAtFixedRate(this, 0, PERIOD_SECONDS,
                                     TimeUnit.SECONDS);
    }

    @Override
    public void onDestroy() {
        executor.shutdown();

        super.onDestroy();
    }

    @Override
    public void run() {
        if (primary.getProgress() < 100) {
            primary.incrementProgressBy(2);
            secondary.incrementProgressBy(2);

            if (secondary.getSecondaryProgress() == 100) {
                secondary.setSecondaryProgress(10);
            }
            else {
                secondary.incrementSecondaryProgressBy(10);
            }
        }
        else {
            executor.remove(this);
        }
    }
}
```

The net effect is that you see the progress march across the screen, with the secondary progress going through five passes for the primary progress' single pass through the 0–100 range.

Tailoring Progress Bars

The stock `ProgressBar` look and feel is decent, if perhaps not spectacular. Often times, the stock look is sufficient for your needs. If you wish to have greater control over the look of your `ProgressBar`, the following sections will demonstrate some possibilities.

Changing the Progress Colors

The `ProgressBar` uses different colors for primary and secondary specific progress. By default, those colors are defined by the theme you are using, and the stock themes have firmware-defined colors (e.g., yellows for Android 1.x and 2.x, blues for Android 3.x and higher).

However, you can change the colors by using a [LayerListDrawable](#) and associating it with a `ProgressBar` by means of the `android:progressDrawable` attribute.

The `ProgressBar` background image needs to be a `LayerListDrawable` with three specific layers:

- `android:id="@android:id/background"` for the background color of the bar
- `android:id="@android:id/progress"` for the primary progress
- `android:id="@android:id/secondaryProgress"` for the secondary progress

Whether those layers are defined as [ShapeDrawable structures](#), or as [nine-patch PNG files](#) is up to you, but they will need the ability to stretch to fit however big your bar winds up being.

To see what this means, let's take a look at the [Progress/Styled](#) sample project. This is a near-clone of the `Progress/BarSampler` project from earlier, using custom backgrounds for the bars. Here, we will look at the horizontal `ProgressBar` widgets — in [the next section](#), we will look at how to change the background of a circular indefinite `ProgressBar`.

PROGRESS INDICATORS

For the first horizontal ProgressBar (progressHS), we will use a custom style created by Jérôme Van Der Linden's [Android Holo Colors Generator](http://android-holo-colors.com), a Web site set up to help us create custom versions of the holographic widget theme.

When you visit this site in Google Chrome (note: other browsers are not supported at this time), you can fill in a name for your theme (e.g., "AppTheme"), the color scheme to use for the theme, and the foundation theme to use (light or dark):

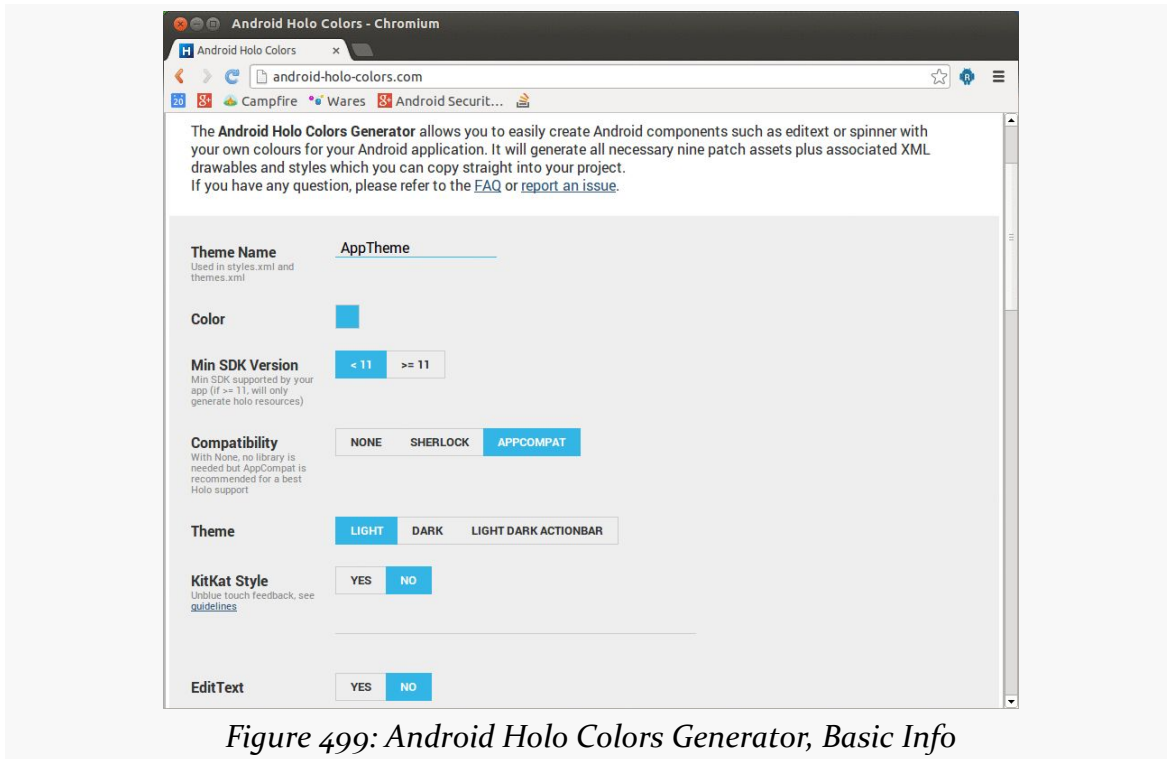

Figure 499: Android Holo Colors Generator, Basic Info

You can then toggle on and off which widgets you intend to use, so the generator will create custom styles for them:

PROGRESS INDICATORS

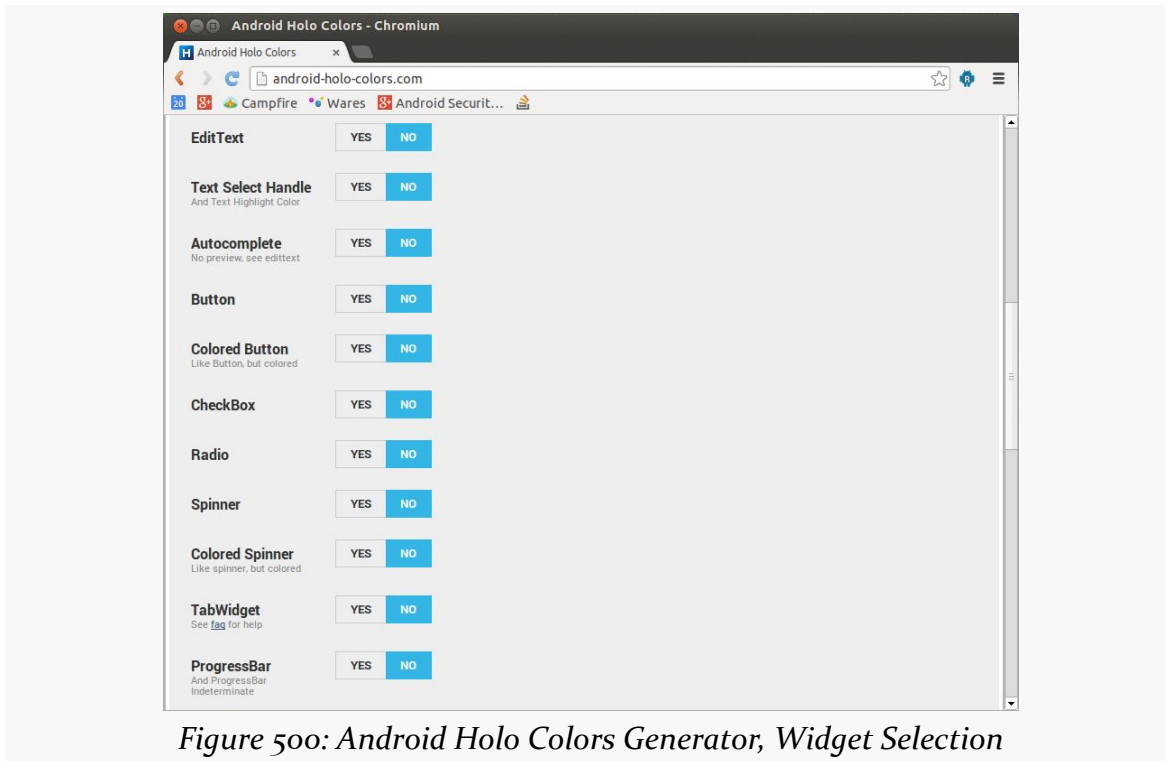

Figure 500: Android Holo Colors Generator, Widget Selection

Then, the generator will create a ZIP file that you can download that contains the generated resources for your custom styles.

The Progress/Styled project contains the files generated by the generator, replacing the original style resources. Note that the generator does not create a .DarkActionBar version of the style resource, so the values-v14 resource directory in the project has one hand-crafted based upon a regular generated style resource.

Our manifest points to our AppTheme as being how we wish to style widgets in this application:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.progress"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="8"
        android:targetSdkVersion="15"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
```

PROGRESS INDICATORS

```
    android:theme="@style/AppTheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/title_activity_main">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
        </activity>
    </application>
</manifest>
```

That theme, defined in `apptheme_themes.xml`, points to style resources for horizontal `ProgressBar` widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated (in part) with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="AppTheme" parent="android:Theme.Holo.Light.DarkActionBar">

        <item name="android:progressBarStyleHorizontal">@style/
ProgressBarAppTheme</item>

    </style>
</resources>
```

The `ProgressBarAppTheme` style resource is defined in a separate `apptheme_styles.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="ProgressBarAppTheme"
        parent="android:Widget.Holo.Light.ProgressBar.Horizontal">
        <item name="android:progressDrawable">@drawable/
progress_horizontal_holo_light</item>
        <item name="android:indeterminateDrawable">@drawable/
progress_indeterminate_horizontal_holo_light</item>
    </style>
</resources>
```

Here, we say that we want the `android:progressDrawable` property to be a `progress_horizontal_holo_light` drawable resource. We also set the

PROGRESS INDICATORS

`android:indeterminateDrawable` property — used for indeterminate bars — to a `progress_indeterminate_horizontal_holo_light` drawable resource.

Those are defined as XML-based drawables, in the `res/drawable/` directory in the project. The `progress_horizontal_holo_light` resource is defined as:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2010 The Android Open Source Project

limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background"
        android:drawable="@drawable/progress_bg_holo_light" />

    <item android:id="@android:id/secondaryProgress">
        <scale android:scaleWidth="100%"
            android:drawable="@drawable/progress_secondary_holo" />
    </item>

    <item android:id="@android:id/progress">
        <scale android:scaleWidth="100%"
            android:drawable="@drawable/progress_primary_holo" />
    </item>

</layer-list>
```

The generator creates our `LayerListDrawable` resource with our three layers, each pointing to a nine-patch PNG file (with different versions for different densities) that contains our desired custom color. The `progress` and `secondaryProgress` layers use [ScaleDrawable definitions](#) to ensure that the images are measured against the complete width of the background layer, which in turn will be sized according to the size of the `ProgressBar` itself.

We will take a look at the `progress_indeterminate_horizontal_holo_light` drawable resource in [the next section](#).

PROGRESS INDICATORS

Note that you could skip the custom theme and style if you wished, and simply add the `android:progressDrawable` attribute to the `ProgressBar` widget definition in its layout XML resource.

Regardless, the result is that our progress bars have the desired purple color scheme:

Figure 501: Custom ProgressBar Style, Primary and Secondary

Also, you can have your `LayerListDrawable` use `ShapeDrawable` layers, to avoid creating nine-patch PNG files, if you prefer, using a resource like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:id="@android:id/background">
    <shape>
      <stroke android:width="1dip" android:color="#FF333333" />
      <gradient
        android:startColor="#FF9C9E9C"
        android:centerColor="#FF5A5D5A"
        android:centerY="0.71"
        android:endColor="#FF6B716B"
        android:angle="270"
      />
    </shape>
  </item>
  <item android:id="@android:id/secondaryProgress">
    <clip>
      <shape>
        <stroke android:width="1dip" android:color="#FF333333" />
        <gradient
          android:startColor="#4cffffff"
          android:centerColor="#4cE7E7E7"
          android:centerY="0.71"
          android:endColor="#4cFFFBFF"
          android:angle="270"
        />
      </shape>
    </clip>
  </item>
  <item android:id="@android:id/progress">
    <clip>
      <shape>
        <stroke android:width="1dip" android:color="#FF333333" />
        <gradient
          android:startColor="#FFFFFFFF"
          android:centerColor="#FFE7E7E7"
        />
      </shape>
    </clip>
  </item>
</layer-list>
```

```
        android:centerY="0.71"
        android:endColor="#FFFFFFBFF"
        android:angle="270"
    />
</shape>
</clip>
</item>
</layer-list>
```

Changing the Indeterminate Animation

Similarly, for indefinite progress “bars”, changing the progress drawable will let you change the way they look. However, in this case, the drawable also needs to implement the animation itself. You can accomplish this either by using an [AnimationDrawable](#) or by using some other type of drawable wrapped in an animation, such as [a ShapeDrawable wrapped in a <rotate> animation](#).

For example, the custom theme created by the Android Holo Colors Generator assigns the following drawable resource to `android:indeterminateDrawable` in the theme:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/*
** Copyright 2011, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/progressbar_indeterminate_holo1"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo2"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo3"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo4"
android:duration="50" />
```

PROGRESS INDICATORS

```
<item android:drawable="@drawable/progressbar_indeterminate_holo5"
android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo6"
android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo7"
android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo8"
android:duration="50" />
</animation-list>
```

Hence, every horizontal indeterminate ProgressBar will use that AnimationDrawable. The individual images in the animation are PNG files, with different versions for different densities.

Circular ProgressBar widgets also need a custom progress drawable, though obviously the image will need to be circular, not a bar. You can certainly use an AnimationDrawable for this, or you can use a ShapeDrawable, such as the res/drawable/progress_circular.xml resource shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rotate xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromDegrees="0"
    android:pivotX="50%"
    android:pivotY="50%"
    android:toDegrees="360">

    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thicknessRatio="8"
        android:useLevel="false">
        <gradient
            android:centerColor="#4c737373"
            android:centerY="0.50"
            android:endColor="#ff9933CC"
            android:startColor="#4c737373"
            android:type="sweep"
            android:useLevel="false" />
        </shape>
    </rotate>
```

Here, we have a ring ShapeDrawable, with a certain thickness and radius, filled with a gradient. Half of the fill is actually a solid color (#4c737373), as the start and center colors are the same. The other half is a sweep gradient from the starting color to the same purple shade that is used by the other bar styles. This ring is then wrapped in a rotate animation. This yields a simple gradient-filled ring, that rotates smoothly to indicate progress:

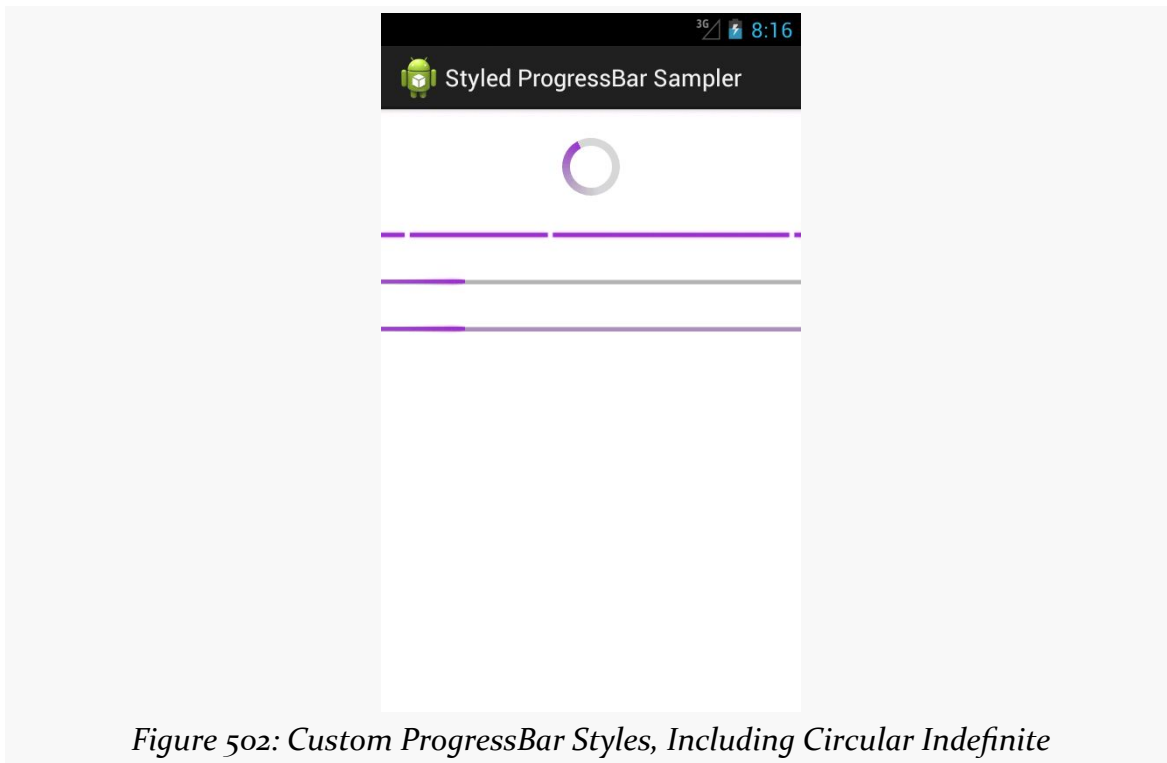

Figure 502: Custom ProgressBar Styles, Including Circular Indefinite

Note that the Android Holo Colors Generator does not generate circular indefinite ProgressBar resources as of the time of this writing.

Progress Dialogs

One use of a ProgressBar is to have it wrapped in a ProgressDialog. Like all dialogs, ProgressDialog is modal, preventing the user from interacting with an underlying activity while the dialog is displayed. From a UI design standpoint, a ProgressDialog is an easy way to temporarily show progress without having to find a spot for a ProgressBar widget somewhere in the UI. Also, since usually there are things in the activity that are dependent upon the work being done in the background, having the dialog in place prevents anyone from trying to use things that are not yet ready.

However, modal dialogs are not a great design approach, as they aggressively limit the user's options. ProgressDialog is perhaps the worst in this regard, as the user can do nothing except wait. While *part* of your app may not yet be ready, other parts surely are, such as reading the documentation, or adjusting settings, or clicking on

your ad banners. Hence, using *anything* else other than `ProgressDialog`, while perhaps a bit more work, will be an improvement in the usability of your app.

That being said, let us see how to set up a `ProgressDialog`. The [Progress/Dialog](#) sample project is a near-clone of the [Dialogs/DialogFragment](#) sample project from [the chapter on dialogs](#). The only difference is the `onCreateDialog()` method of our `DialogFragment`, where we directly create a `ProgressDialog` instead of using an `AlertDialog.Builder` to create an `AlertDialog` as before:

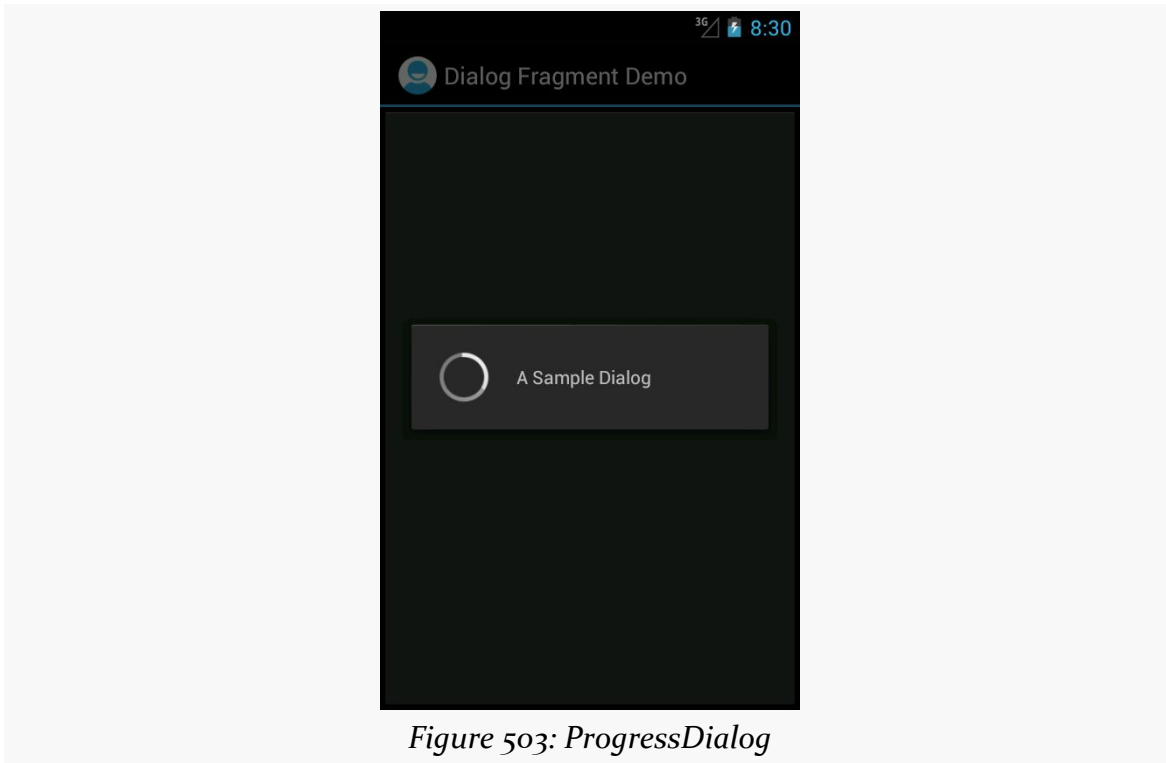

```
@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    ProgressDialog dlg=new ProgressDialog(getActivity());

    dlg.setMessage(getActivity().getString(R.string.dlg_title));
    dlg.setIndeterminate(true);
    dlg.setProgressStyle(ProgressDialog.STYLE_SPINNER);

    return(dlg);
}
```

We create the `ProgressDialog` via its constructor, set the message explaining what we are waiting for via `setMessage()`, indicate that the `ProgressBar` should be an indeterminate one via `setIndeterminate()`, and indicate that we want a circular “spinner” `ProgressBar` rather than a horizontal one by calling `setProgressStyle(ProgressDialog.STYLE_SPINNER)`. There are a variety of other things you could configure on the `ProgressDialog` if desired, and `ProgressDialog` inherits from `AlertDialog`, so some things you could configure on an `AlertDialog` will also be available on the `ProgressDialog`.

The result is a dialog that you may have seen from other apps in Android:

Title Bar and Action Bar Progress Indicators

Another place to let users know that you are doing something on their behalf is to put a progress indicator in the title bar or action bar of your activity. This avoids your having to put an indeterminate `ProgressBar` somewhere in your activity's UI. It is also very simple to set up, as we can see in the [Progress/TitleBar](#) sample project.

```
package com.commonware.android.titleprog;

import android.app.Activity;
import android.os.Bundle;
import android.view.Window;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
        super.onCreate(savedInstanceState);

        setContentView(R.layout.activity_main);
        setProgressBarIndeterminateVisibility(true);
    }
}
```

PROGRESS INDICATORS

Up front, as the first thing that you do in your `onCreate()` call, you need to call:

```
getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
```

This tells Android to reserve space in your title bar or action bar for an indeterminate progress indicator, though the indicator does not appear at this point.

Later on, when you want the indicator to actually appear, call `setProgressBarIndeterminateVisibility(true)` on your activity, and later call `setProgressBarIndeterminateVisibility(false)` to make the indicator go away.

This particular application has `android:targetSdkVersion` set to 11 or higher, but it is not using an action bar backport like [ActionBarSherlock](#). Hence, when you run it on an older Android environment, you get a classic title bar with the progress indicator on the right:

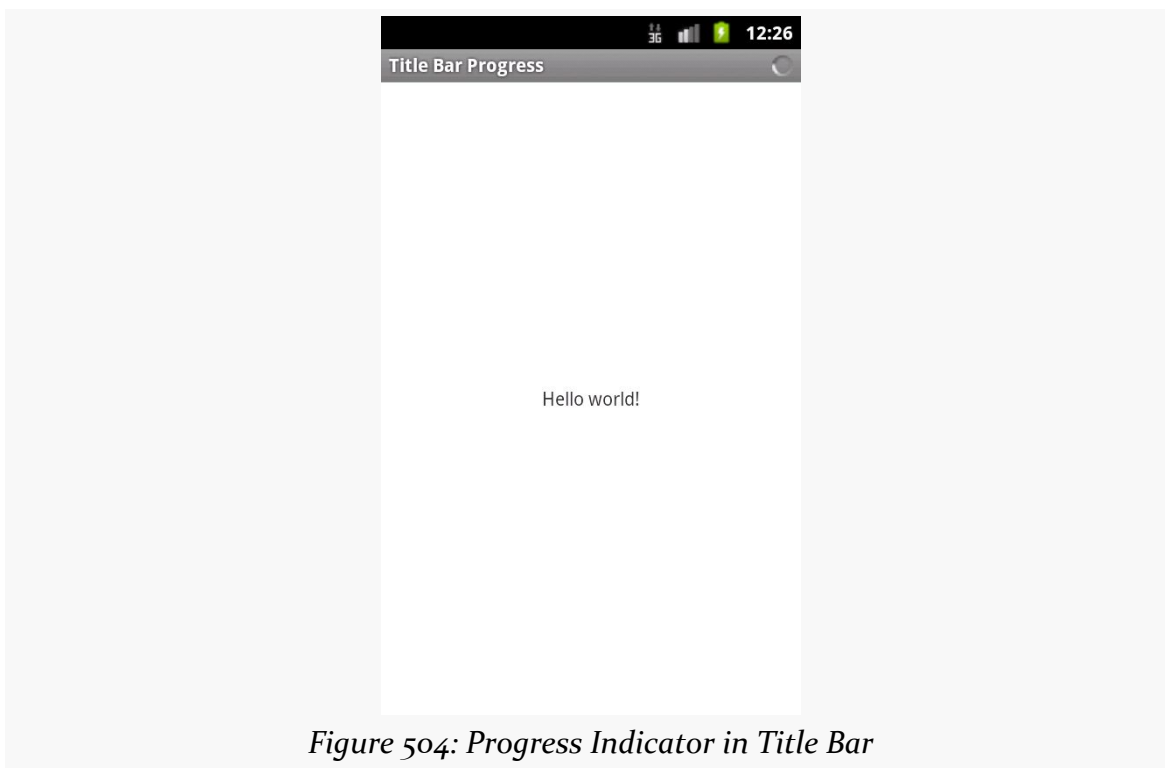

Figure 504: Progress Indicator in Title Bar

When you have an action bar, you get the same basic effect, albeit with a larger indicator to match the larger bar:

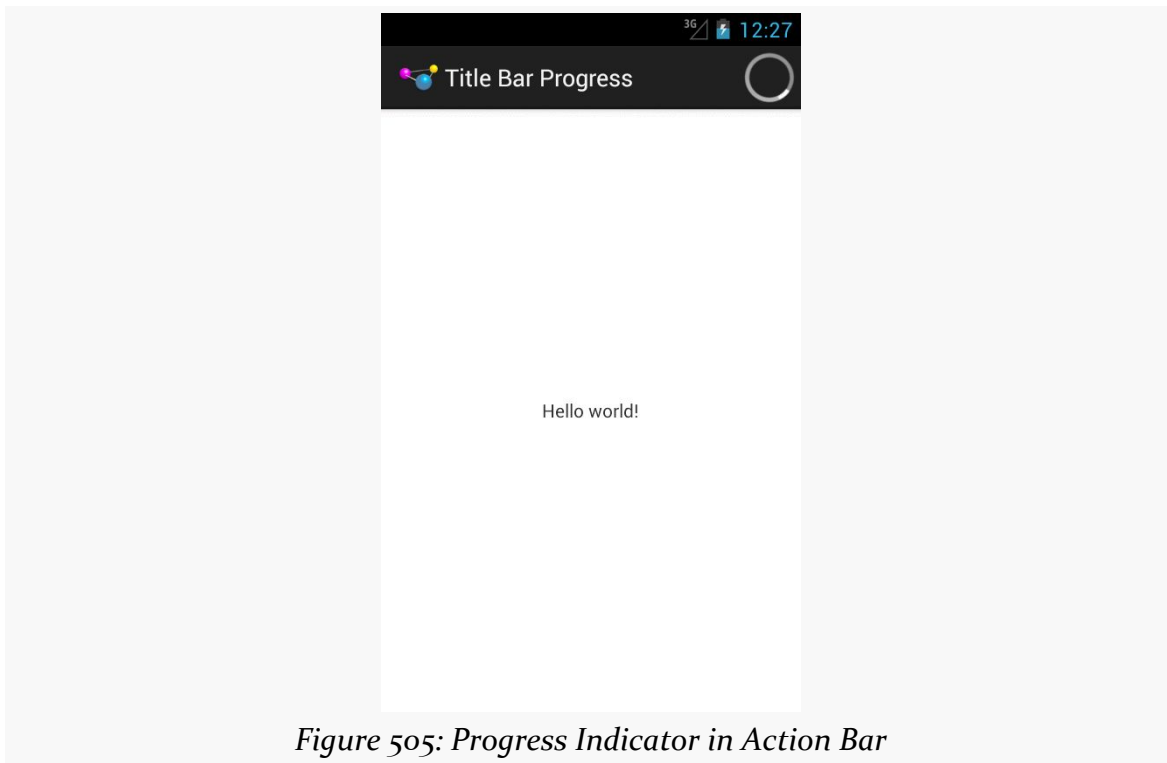

Figure 505: Progress Indicator in Action Bar

Direct Progress Indication

Sometimes, the best way to let the user know about updates is to simply update the data in place. Rather than have some separate indicator, let the core UI itself convey the work being done.

We saw this in [the chapter on threads](#), where we populated a `ListView` in “real time” as we loaded in data into its adapter. Other variations on this theme include:

- Updating a page count `TextView` to show the number of downloaded pages, while the user is reading earlier pages, perhaps with some sort of style (e.g., italics) or color coding (e.g., red) to indicate data that is being loaded.
- Simply disabling the buttons, action bar items, and other ways that the user could navigate to a point in your app where you need the data that is being loaded in the background. The key here is to make sure that users understand *why* those items are disabled, and sometimes that is not obvious. Hence, while this step may be necessary, it is often tied in with progress indicators in the title bar or action bar or other means of indicating to the user the *reason* they cannot perform certain operations.

Advanced Notifications

Notifications are those icons that appear in the status bar (or system bar on tablets), typically to alert the user of something that is going on in the background or has completed in the background. Many apps use them, to let the user know of new email messages, calendar reminders, and so on. Foreground services, such as music players, also use notifications, to tell the OS that they are part of the foreground user experience and to let the user rapidly return to the apps to turn the music off.

There are other tricks available with the Notification object beyond those originally discussed [in an earlier chapter](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on basic notifications](#) and [the section on RemoteViews in the chapter on basic app widgets](#).

Being a Good Citizen

Users have a love/hate relationship with apps that use notifications:

- They love apps that raise notifications for events that the user cares about...
- ...but they hate apps that raise notifications for events that the user does not care about (e.g., Evernote’s “please confirm your email” notifications)
- They love apps that provide control over when and how notifications appear...
- ...but they hate apps that display notifications solely because the developer wanted them (e.g., ads in notifications)

- They love apps that use notifications to let the user control some background operation, like media playback...
- ...but they hate apps that have ongoing notifications for no obvious reason (e.g., developers trying to use a foreground service to keep their process around, rather than using `AlarmManager`, `JobScheduler`, or other means of doing work periodically)
- They love apps that set up notifications for use in different scenarios, such as supporting Android Wear devices...
- ...but they hate apps that wind up flooding their wrist (or eyes, or other wearable locations) with notifications that have to be individually dismissed

And so on.

Users' discomfort with how apps handle notifications is why Android allows users to [disable notifications](#).

Some of the items in this chapter, particularly those surrounding Android Wear, can help you improve user satisfaction with your notification strategy and tactics. Yet, at the same time, misuse of notifications is magnified by Wear, as Wear takes extra steps to get the user to pay attention to the notifications, with possibly disastrous results for your Play Store reviews.

In short, your objective with notifications is to be a good citizen:

- Have a reasonable default mode for your notifications
- Allow users to tailor that mode to better suit their needs, where practical

Wear? There!

The humble `Notification` has been steadily advancing over the past few years, with “big” styles and the like adding new capabilities for newer devices.

Android Wear takes notifications to a new level, by having the notification not only appear on the user's device, but also on wearables connected to that device.

The good news is that this works “out of the box”. There is nothing you absolutely need to do in your app to get your notifications to appear on a Wear device.

The bad news is that the “out of the box” experience may be poor, as a Notification approach that is fine for devices that reside in pockets and backpacks might be inappropriate for wrists and eyes.

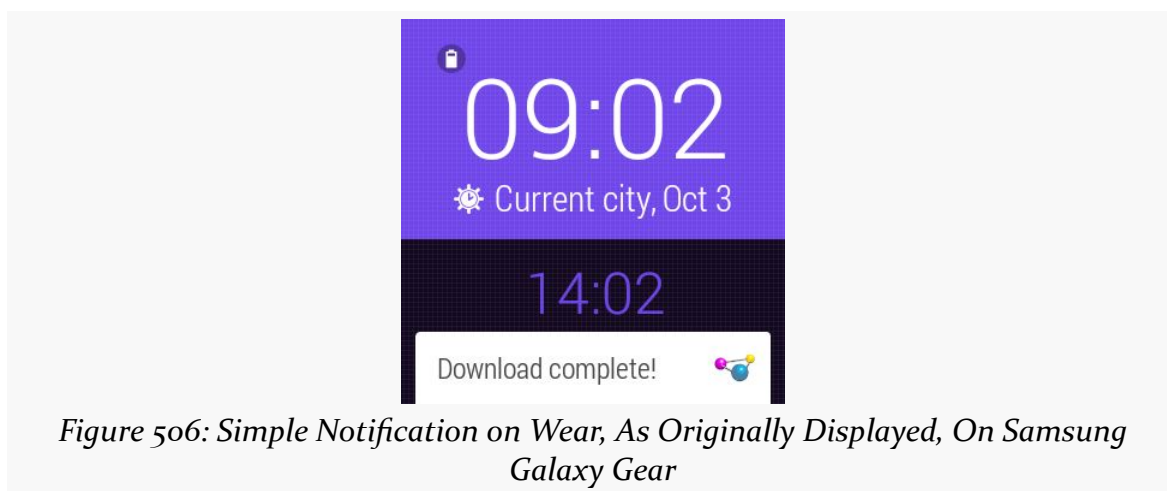

With that in mind, let’s see what some notification samples from earlier in the book behave like when they are run on a phone connected to a Wear device.

NOTE: For this section, and the rest of this chapter, “primary device” will refer to the user’s phone or tablet that the “Wear device” will be connected to.

Simple Notification

The [Notifications/DownloadNotify](#) sample project allows the user to download a PDF file, raising a Notification when that download is complete.

With a Wear device paired with the phone, the Notification also appears on the device, first as a “mini card”:

Swiping up on that will bring up the full card:

Figure 507: Simple Notification on Wear, Full, On Samsung Galaxy Gear

Swiping to the right will bring up the action associated with `setContentIntent()` on the `NotificationCompat.Builder`:

Figure 508: Simple Notification on Wear, Default Action, On Samsung Galaxy Gear

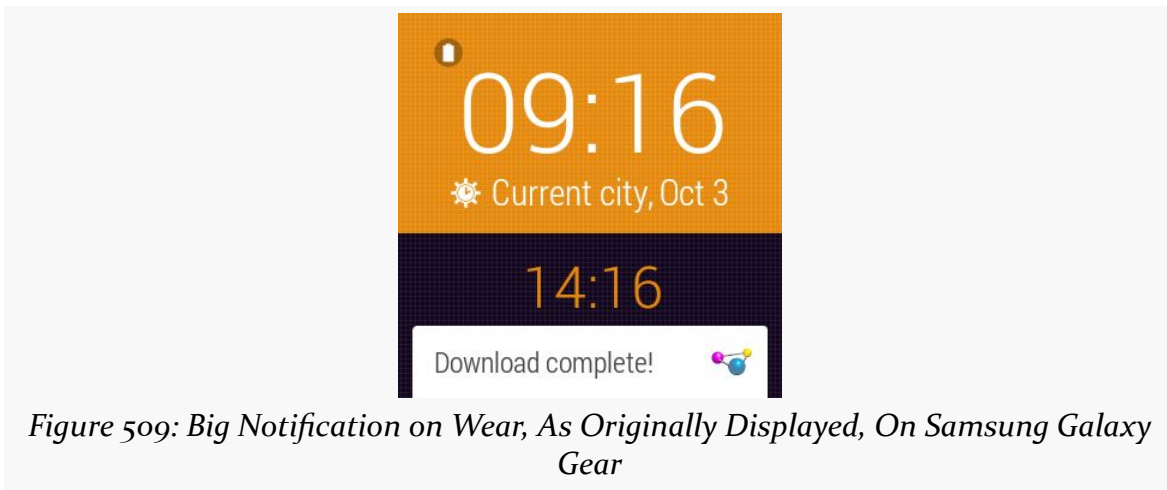

Tapping on that dismisses the Notification on the Wear device and the primary device, plus it invokes the `PendingIntent` on the phone itself (in this case, opening up the PDF file).

This is a fine example of a Notification that perhaps should *not* appear on the Wear device. The fact that the download completed is interesting but not all that important. Furthermore, the user cannot do anything about this download other than to pull out the primary device to see the PDF. Low-priority primary-device-centric notifications generally should be shown on the primary device alone, not on the Wear device. We will see how to do that [later in this chapter](#).

“Big” Style and Action Button

The [Notifications/BigNotify](#) sample application wrapped a regular Notification in a NotificationCompat.InboxStyle “big” Notification, one with both a regular action and a separate “Play” action button.

As before, with a Wear device paired with the phone, the Notification also appears on the device, first as a “mini card”:

However, this time, when the user swipes up to show the full card, it is the InboxStyle version that appears, albeit without the summary text:

Swiping to the right shows our actions, starting with the custom “Play” action:

...followed by the default action:

Tapping on either action will cause the primary device to invoke its `PendingIntent`, but only the default action dismisses the `Notification` from both devices. The custom “Play” action does not.

Foreground Service

The [Notifications/Foreground](#) sample project is another version of the download-the-file sample, but this time uses a `Notification` and `startForeground()` to mark the service as a foreground service while it is downloading things.

This particular sample does not spend much time in the foreground state, so for testing purposes, you may want to add a `SystemClock.sleep()` call to the service,

between the `startForeground()` and `stopForeground()` calls, to better examine the behavior while the foreground service `Notification` is around.

However, in truth, that modification is probably not necessary... as the foreground service `Notification` is not displayed on the Wear device, only on the primary device. This is by design. The expectation is that you would use a Wear app to control your service from the Wear device, not some un-dismissable card.

Stacking Notifications

If you are writing an email client, and you want to use a `Notification` to let the user know about new email messages, you do *not* want to raise a separate `Notification` for each email. Users will come to your home with pitchforks and torches... and not to help you with farming.

Instead, the vision is that you update an existing `Notification` with new content. For example, you might start with a regular `Notification` for the first received email. Then, when the second one comes in, you replace that `Notification` with one that has a simple summary (“2 messages are in your inbox!”), plus perhaps an `InboxStyle` “big” `Notification` variant that could show the subject lines for both of those messages.

Android Wear devices, however, add an interesting wrinkle: you want the `Notification` to be informative about the event itself. You want the user to be able to make an informed decision about whether they should pull out their primary device to read the new messages, and that decision is only partly based on how many messages there are. Users will want to know more about the outstanding messages (sender and/or subject line) to help them make that decision... at least to a point. If there are 57 unread messages, users may get frustrated dealing with all of those as individual items on the wearable itself.

The pattern here, then, takes advantage of some “group” capabilities added to `NotificationCompat`:

- Raise one “summary” `Notification`, that will only be shown on the primary device, with the same sort of “2 messages are in your inbox!” information that you would have used without considering Wear
- Raise individual notifications for individual messages that will appear on the Wear device

- Collect all of those in a “group”, so the primary device shows only the summary and the Wear device shows only the individual ones

This can be seen in action in the [Notifications/Stacked](#) sample project.

The setup is reminiscent of the “big” style one from [the original chapter on Notification](#). However, this time, there are a total of three Notification objects created: two for individual events for the Wear device, and one summary one for the primary device.

However, to make this work, we need a new version of the support-v13 library from the Android Support package: 20.0.0 (or higher), as it is where the extra compatibility smarts were added to support this whole group-and-summary construct. Hence, in build.gradle, we have compile 'com.android.support:support-v13:20.0.0', and for Eclipse, we have the corresponding JAR in libs/.

Similarly, while we will still use NotificationCompat for creating the Notification objects, we will *not* use NotificationManager for displaying them. Instead, we need to use NotificationManagerCompat from the Android Support package. While the NotificationManager API has not changed to support the group-and-summary pattern, the *implementation* has, and NotificationManagerCompat gives us a version of that implementation that can work on compatible devices and gracefully degrade on older ones. However, since the API did not change, it is easy to miss this requirement, use NotificationManager, and not quite get the desired results. Notably, the primary device will wind up showing all three notifications, not just the summary as we want.

Hence, our MainActivity will hold onto a NotificationManagerCompat as a data member, initialized in onCreate():

```
private NotificationManagerCompat mgr=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    mgr=NotificationManagerCompat.from(this);

    showWearOne();
    showWearTwo();
    showSummary();
}
```

```
    finish();  
}
```

The three `show...()` methods are each responsible for raising one Notification: `showWearOne()` and `showWearTwo()` are ones that will wind up on the Wear device, and `showSummary()` will show the summary Notification for use on the primary device.

Beyond using `NotificationManagerCompat` instead of `NotificationManager`, the only substantial difference is the use of `setGroup()` and `setGroupSummary()` methods on the `NotificationCompat.Builder`.

`setGroup()` associates the Notification with a group, identified by a String key. On a Wear device, notifications that are part of a group will be shown stacked as part of a single card by default. So, the two `showWear...()` methods call `setGroup()` as part of building the Notification:

```
private void showWearOne() {  
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);  
  
    b.setAutoCancel(true)  
        .setDefaults(Notification.DEFAULT_ALL)  
        .setContentTitle(getString(R.string.entry))  
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))  
        .setSmallIcon(android.R.drawable.stat_sys_download_done)  
        .setTicker(getString(R.string.download_complete))  
        .setGroup(GROUP_SAMPLE);  
  
    mgr.notify(NOTIFY_ID2, b.build());  
}  
  
private void showWearTwo() {  
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);  
  
    b.setAutoCancel(true)  
        .setDefaults(Notification.DEFAULT_ALL)  
        .setContentTitle(getString(R.string.another_entry))  
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))  
        .setSmallIcon(android.R.drawable.stat_sys_download_done)  
        .setTicker(getString(R.string.download_complete))  
        .setGroup(GROUP_SAMPLE);  
  
    mgr.notify(NOTIFY_ID3, b.build());  
}  
  
private PendingIntent buildPendingIntent(String action) {  
    Intent i=new Intent(action);  
  
    return(PendingIntent.getActivity(this, 0, i, 0));  
}
```

ADVANCED NOTIFICATIONS

`setGroupSummary()` indicates a particular Notification that should serve as the summary for its group. This Notification will not be passed to the Wear device, and it replaces all other notifications for this group on the primary device. Hence, `showSummary()` (or, more accurately, the `buildNormal()` method that creates the base Notification for the summary) uses `setGroupSummary()`:

```
private void showSummary() {
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle();

    big.setSummaryText(getString(R.string.summary))
        .addLine(getString(R.string.entry))
        .addLine(getString(R.string.another_entry));

    mgr.notify(NOTIFY_ID, normal.setStyle(big).build());
}

private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
        .setContentTitle(getString(R.string.download_complete))
        .setContentText(getString(R.string.fun))
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.download_complete))
        .setGroup(GROUP_SAMPLE)
        .setGroupSummary(true);

    return(b);
}
```

Note that you need to use `setGroupSummary()` on a `NotificationCompat.Builder` on which you have also called `setGroup()`, to identify the group for which this Notification is a summary.

When you run this, the primary device shows the summary Notification:

ADVANCED NOTIFICATIONS

Figure 513: Stacked Notifications, Summary on Primary Device

On the Wear device, you will see the two original notifications as part of a single card at the outset:

Figure 514: Stacked Notifications, Stacked on Wear Device

Tapping on the stack brings up separate mini cards for each individual Notification:

...And the Passage of Time

Of course, this sample is artificially simple, like most of the samples in this book.

In the sample, we are raising all three notifications all at once. That is certainly conceivable, but it is not especially likely. A more likely scenario is that the mix of notifications needs to change over time, based upon continuing events, such as a trickle of new unread email messages for an email client.

This adds a few complexities to what you need to implement all of this properly.

The big thing is that your persistent data model (e.g., database) needs to have enough information for you to know how to notify the user about the next event, when that event occurs. Using the email client as an example:

- We start off in the “steady state” of no unread email messages and, therefore, no notifications from our app.
- A new email message arrives. At this point, we want to show a regular Notification on both the Wear device and the primary device, with the sender and subject line of the unread message.
- A second new email message arrives later. At this point, we want to show another regular Notification (requiring a separate notification ID) for the Wear device, but also show a summary Notification for the primary device. For all that to work, we need to know this *is* a second unread message, and that the user has not read the first message in between the two incoming messages. And, we need to know enough details about the unread messages to format the summary properly.

This gets even more complex when events “stack themselves” (e.g., one poll of the mail server results in two unread messages), in addition to having to deal with user input (e.g., user clears the notification stack from either device, yet does not read the messages).

Among other things, you cannot rely upon static data members as being the sole source of your Notification-related data, as your process may be terminated in between events. You are welcome to use it as a cache, in case your process does happen to survive long enough to process more than one event, but you will need to also save this data to a persistent store, so that you can properly handle new events requiring Notification changes with your process having been terminated since the last Notification-related event.

Avoiding Wear

Sometimes, you will want to raise a Notification that does not make sense to show on a Wear device, only on the primary device. In the case of the group summary for the stacked notifications, this primary-only behavior happens automatically. In other cases, though, you will need to call `setLocalOnly()` on the `NotificationCompat.Builder` to tell the framework that this Notification should only be displayed on the current device.

The [Notifications/BigLocal](#) sample project demonstrates this, through a clone of the `Notifications/BigNotify` sample that has just two changes:

1. It switches to the 20.0.0 version of the `support-v13` library, to get a version of `NotificationCompat.Builder` that offers `setLocalOnly()`
2. It calls `setLocalOnly(true)` as part of configuring the Notification:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setTitle(getString(R.string.download_complete))
      .setText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setPriority(Notification.PRIORITY_HIGH)
      .setLocalOnly(true)
      .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));
}
```

```
return(b);  
}
```

Note that we do not need to use `NotificationManagerCompat` for local-only behavior — simply calling `setLocalOnly(true)` on an up-to-date `NotificationCompat.Builder` will suffice.

Running this sample provides the same behavior as `Notifications/BigNotify`, except that the Notification only appears on the primary device, not the Wear device.

Other Wear-Specific Notification Options

Configuring stacked notifications, and opting into local-only behavior when needed, should give you Wear behavior that is acceptable. Right now, Android Wear is fairly nascent, and therefore it may not behoove you to do much more than this, as you decide how to prioritize your engineering time.

However, there are other things that you can do to further tailor your notifications on Wear that can improve user satisfaction, if you wish for Wear to be a key part of your marketing message.

Pages

On the primary device, the amount of information you can provide in a Notification is intentionally capped. This prevents a Notification from drowning out its peers. The cap is not a big problem, simply because the whole UI for the app raising the Notification is usually just a tap away.

With a Wear device, though, the whole UI for the app raising the Notification involves pulling out the primary device.

Hence, it might be nice to provide some additional information to the Wear user, so that perhaps they can make a more informed decision as to whether it is worthwhile to open up their primary device. In Wear terms, this involves adding more “pages” to a Notification.

To do this, you must:

ADVANCED NOTIFICATIONS

- Create the second (and additional) pages as their own separate Notification objects, probably via a NotificationCompat.Builder
- Use a NotificationCompat.WearableExtender to teach the primary Notification about the additional pages
- Raise the primary Notification using a NotificationManagerCompat variant of the system service

We can see this in action in the [Notifications/Pages](#) sample project. This is a clone of Notifications/BigNotify, where we make the “big” content be on a second page.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManagerCompat mgr=
        NotificationManagerCompat.from(this);
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle();

    big.setSummaryText(getString(R.string.summary))
        .addLine(getString(R.string.entry))
        .addLine(getString(R.string.another_entry))
        .addLine(getString(R.string.third_entry))
        .addLine(getString(R.string.yet_another_entry))
        .addLine(getString(R.string.low));

    NotificationCompat.Builder bigPage=
        new NotificationCompat.Builder(this)
            .setStyle(big);
    NotificationCompat.Builder twoPages=
        new NotificationCompat.WearableExtender()
            .addPage(bigPage.build())
            .extend(normal);

    mgr.notify(NOTIFY_ID, twoPages.build());

    finish();
}
```

Here, we:

- Create a NotificationManagerCompat instance
- Create the primary (“normal”) Notification, using the same process as before
- Create the InboxStyle structure with our expanded content

ADVANCED NOTIFICATIONS

- Wrap that “big” style in another Notification via a NotificationCompat.Builder, using the `setStyle()` method to associate the “big” style with the Notification
- Create a NotificationCompat.WearableExtender, tell it to add the second page using `addPage()`, and tell it to apply that second page to the primary Notification via the `extend()` method
- Use `notify()` as normal to raise the Notification, using the already-created NotificationManagerCompat instance

On the primary device, we just see the primary Notification content:

Figure 516: Pages Demo, on a Galaxy Nexus

On the Wear device, we see the main Notification and the second page as separate pages on the wearable:

Figure 517: Pages Demo, on a Samsung Galaxy Wear, Showing Initial Notification

Figure 518: Pages Demo, on a Samsung Galaxy Wear, Showing Second Page

Note that you cannot use `addAction()` to define a custom action on the extra pages added to the primary Notification. Instead, use `addAction()` and `setContentAction()` on the `WearableExtender` to define actions associated with those extra pages. We will see this in use in the next section.

Wear-Only Actions

Sometimes, you may want certain actions to only be available on the Wear device, and not on the primary device. We will see a specific example of this coming up in [the next section](#), when we cover voice input actions.

Sometimes, you may want a different mix of actions on the primary device versus the Wear device — some in common, some only on the primary device, some only on the Wear device.

ADVANCED NOTIFICATIONS

To set up Wear-only actions, use `addAction()` on `WearableExtender`, as opposed to (or in addition to) `addAction()` on `NotificationCompat.Builder`. This takes an action as a parameter, which you create using `NotificationCompat.Action.Builder`, a custom builder for building Notification actions.

This is illustrated in the [Notifications/WearActions](#) sample project, yet another variation on the “launch an activity, show a Notification” samples that we have been using. This time, though, we will apply an action to the Wear device:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManagerCompat mgr=
        NotificationManagerCompat.from(this);
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.Action.Builder wearActionBuilder=
        new NotificationCompat.Action.Builder(android.R.drawable.ic_media_pause,
                                                getString(R.string.pause),
                                                buildPendingIntent(Settings.ACTION_DATE_SETTINGS));

    NotificationCompat.Builder extended=
        new NotificationCompat.WearableExtender()
            .addAction(wearActionBuilder.build())
            .extend(normal);

    mgr.notify(NOTIFY_ID, extended.build());
    finish();
}
```

Here, we:

- Create a `NotificationManagerCompat` instance
- Create the primary (“normal”) Notification, using the same process as before
- Create an instance of `NotificationCompat.Action.Builder`, providing it the icon, label, and `PendingIntent` to be invoked for this action
- Create an instance of `NotificationCompat.WearableExtender`, adding the newly-defined action to it, and using the `WearableExtender` to `extend()` the primary Notification
- Show that extended Notification using the `NotificationManagerCompat` instance

However, note that we have also defined an action on the primary Notification:

ADVANCED NOTIFICATIONS

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentType(getString(R.string.download_complete))
      .setContentTitle(getString(R.string.fun))
      .setContentText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));

    return(b);
}
```

`addAction()` on `WearableExtender` *replaces*, for the Wear device, any actions defined on the Notification itself using `addAction()`, but not the action defined via `setContentIntent()`.

On the primary device, we do not see the wear-only action:

Figure 519: WearActions Demo, on a Galaxy Nexus

ADVANCED NOTIFICATIONS

On a Wear device, though, we see both the wear-only and the main content action, but not the device-only action added via `addAction()` on the `NotificationCompat.Builder`:

Figure 520: WearActions Demo, on a Samsung Galaxy Wear, Showing Notification

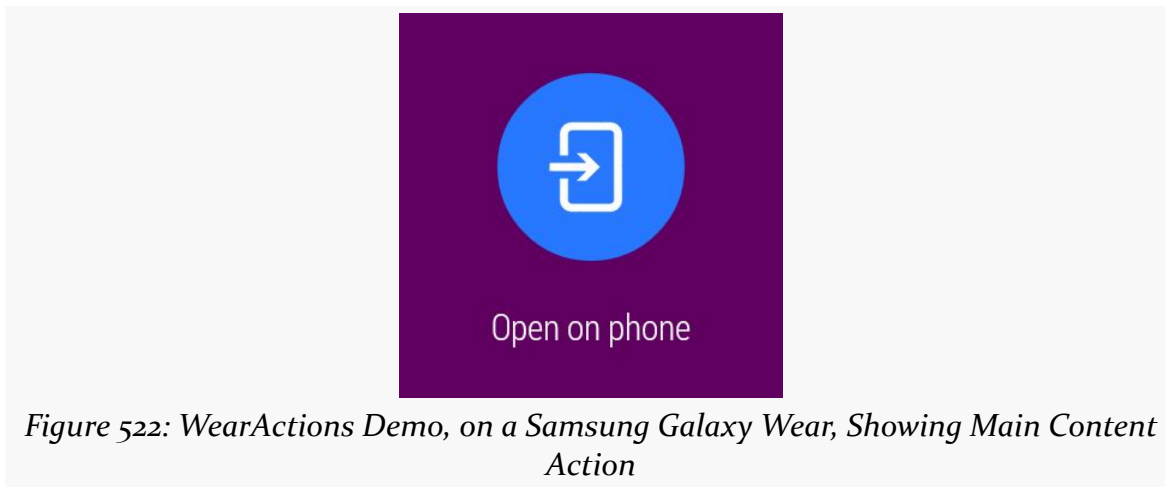

Figure 521: WearActions Demo, on a Samsung Galaxy Wear, Showing Wear-Only Action

Hence:

- If you want actions only on the primary device, define those before applying a `WearableExtender` and its `addAction()`
- If you want actions only on the Wear device, define those using a `WearableExtender` and its `addAction()`
- If you want the same actions on both devices, define those using both flavors of `addAction()` (on `NotificationCompat.Builder` for the primary device and on `WearableExtender` for the Wear device)

Voice Input

In the spirit of [Dick Tracy's](#) two-way wrist radio, Android Wear allows you to talk to your wrist and not seem like you are completely insane.

In particular, your `Notification`, when presented on the Wear, can request that the user provide you with a response, via voice input or via canned responses. This can be very handy:

- Responding to a text message without pulling out one's phone
- Directing your app to file an incoming email message into a particular folder or label
- Responding to a police alert, requesting your assistance, by indicating that you will be on your way as soon as you can find your bright yellow trenchcoat
- And so on

In many cases, with a regular Notification, the result of the user choosing an action is for us to display an activity. Sometimes, though, that's not what we want, such as a music player's Notification handling "pause" and similar events via its background service. Similarly, actions from a Notification seen on a Wear device will sometimes need to perform operations in the background, as the user may not be in position to look at your UI. This is especially true with voice input — usually, if we are bothering to dictate words to our wrist, that should happen instead of opening up the primary device. As a result, our flow for responding to the action is a little bit different, as is illustrated in the [Notifications/VoiceInput](#) sample project.

The Activity and Notification

Let's walk through the MainActivity that sets up our Notification:

```
package com.commonware.android.wearvoice;

import android.app.Activity;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;

public class MainActivity extends Activity {
    private static final int NOTIFY_ID=1337;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Intent i=new Intent(this, VoiceReceiver.class);
        PendingIntent pi=
            PendingIntent.getBroadcast(this, 0, i,
                PendingIntent.FLAG_UPDATE_CURRENT);

        RemoteInput remoteInput=
            new RemoteInput.Builder(VoiceReceiver.EXTRA_SPEECH)
                .setLabel(getString(R.string.talk))
                .setChoices(getResources().getStringArray(R.array.replies))
                .build();

        NotificationCompat.Action wearAction=
            new NotificationCompat.Action.Builder(
                android.R.drawable.ic_btn_speak_now,
                getString(R.string.talk),
                pi).addRemoteInput(remoteInput).build();

        NotificationCompat.WearableExtender wearExtender=
```

```
        new NotificationCompat.WearableExtender()
            .addAction(wearAction);

    NotificationCompat.Builder builder=
        new NotificationCompat.Builder(this)
            .setSmallIcon(android.R.drawable.stat_sys_download_done)
            .setContentTitle(getString(R.string.title))
            .setContentText(getString(R.string.talk))
            .extend(wearExtender);

    NotificationManagerCompat
        .from(this)
        .notify(NOTIFY_ID, builder.build());

    finish();
}
```

We start by creating a broadcast `PendingIntent`, pointing to a `VoiceReceiver` that will respond to the voice input. We will examine this `VoiceReceiver` later in this example.

We then set up a `RemoteInput.Builder`. This is a builder-style API for defining a `RemoteInput` configuration to attach to a Wear-only action. Here, we configure it with:

- the key for retrieving the response in our `VoiceReceiver` (`VoiceReceiver.EXTRA_SPEECH`)
- the label to prompt the user for what we are looking for them to provide (an `R.string.talk` string resource)
- a `String` array of canned responses that the user can choose from rather than dictate their own answer and go through speech-to-text conversion (pulled from an `R.array.replies <string-array>` resource)

That `RemoteInput` is then applied to a `NotificationCompat.Action`, via its `NotificationCompat.Action.Builder` and the `addRemoteInput()` method. That `Action`, in turn, is wrapped in a `NotificationCompat.WearableExtender`, which is used to `extend()` a `NotificationCompat.Builder`.

Finally, the resulting `Notification` is raised using a `NotificationManagerCompat` instance.

The Receiver

Our VoiceReceiver, registered in the manifest, is set up to respond to the voice action:

```
package com.commonware.android.wearvoice;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.RemoteInput;
import android.util.Log;
import android.widget.TextView;

public class VoiceReceiver extends BroadcastReceiver {
    static final String EXTRA_SPEECH="speech";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        Bundle input=RemoteInput.getResultsFromIntent(i);

        if (input!=null) {
            CharSequence speech=input.getCharSequence(EXTRA_SPEECH);

            if (speech!=null) {
                Log.d(getClass().getSimpleName(), speech.toString());
            }
            else {
                Log.e(getClass().getSimpleName(), "No voice response speech");
            }
        }
        else {
            Log.e(getClass().getSimpleName(), "No voice response Bundle");
        }
    }
}
```

It uses `RemoteInput.getResultsFromIntent(i)` to pick out the response we got from the user for this action. There are three major possibilities:

1. We did not get any response (should not happen)
2. We got a response, but for whatever reason, the decoded Bundle is missing our `VoiceReceiver.EXTRA_SPEECH` key (also should not happen)
3. The `CharSequence` from the `VoiceReceiver.EXTRA_SPEECH` key in the decoded Bundle is the user's response, whether from speech recognition or from choosing one of our canned responses

In this case, we just log the message to LogCat, but in principle you could do whatever you wanted. Just bear in mind that your UI may not be in the foreground, and that the device screen may be off entirely. It is also possible that your process will have been terminated between the time you raised the Notification and the user got around to responding to it from the Wear device. Hence, you should be making few assumptions about the environment at the point when you get the voice response.

The Results

The Wear device starts off with a typical action:

Figure 523: VoiceInput Demo, on a Samsung Galaxy Wear, Showing Voice Action

Tapping it brings up a voice input screen, where the user can dictate some text:

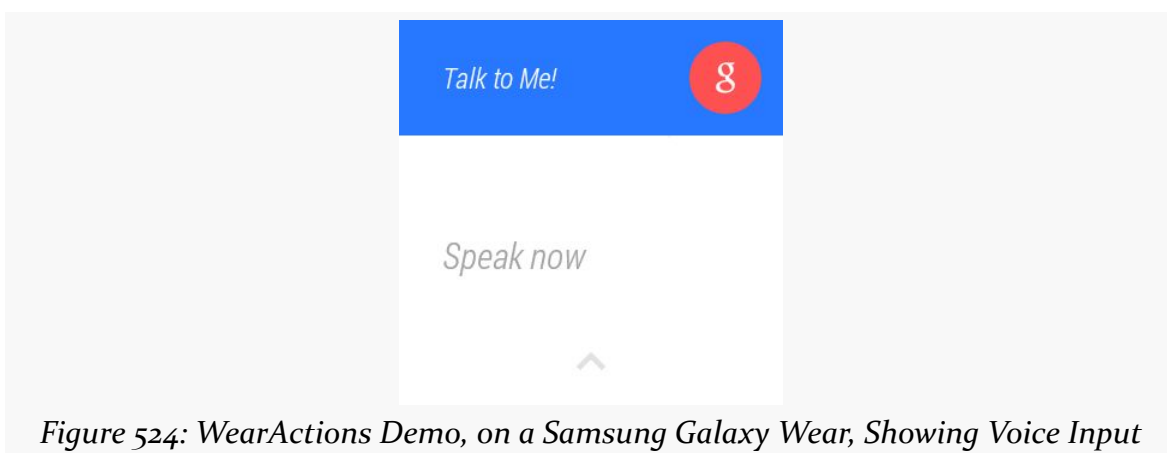

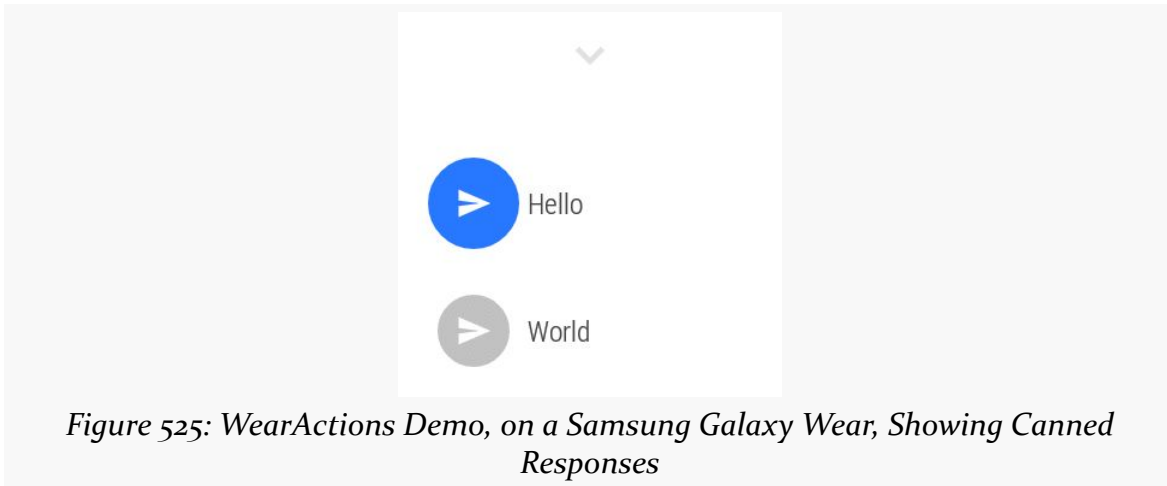

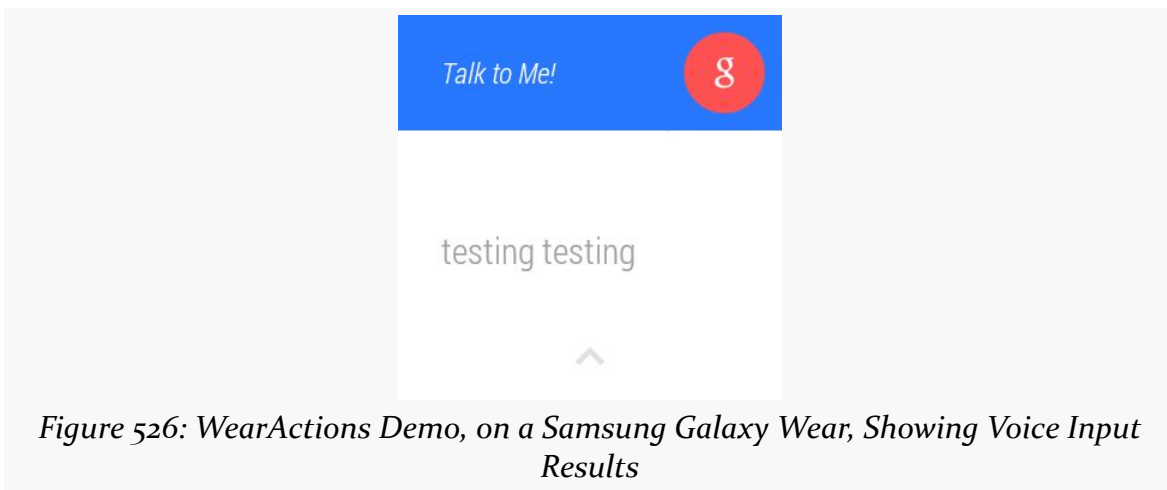

Figure 524: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input

ADVANCED NOTIFICATIONS

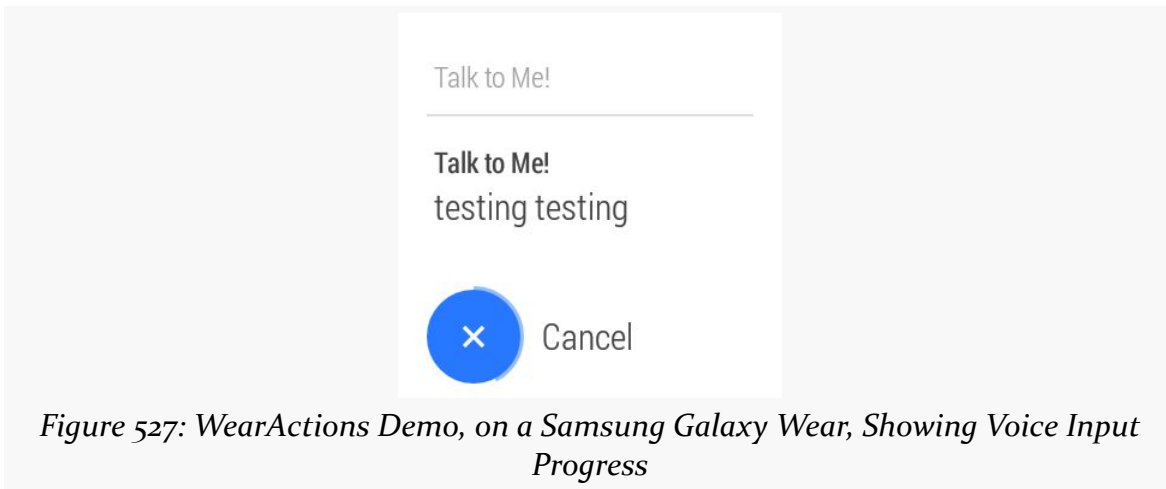

If the user delays too long without saying anything recognizable, or if the user swipes up the screen, they are taken to our list of canned responses:

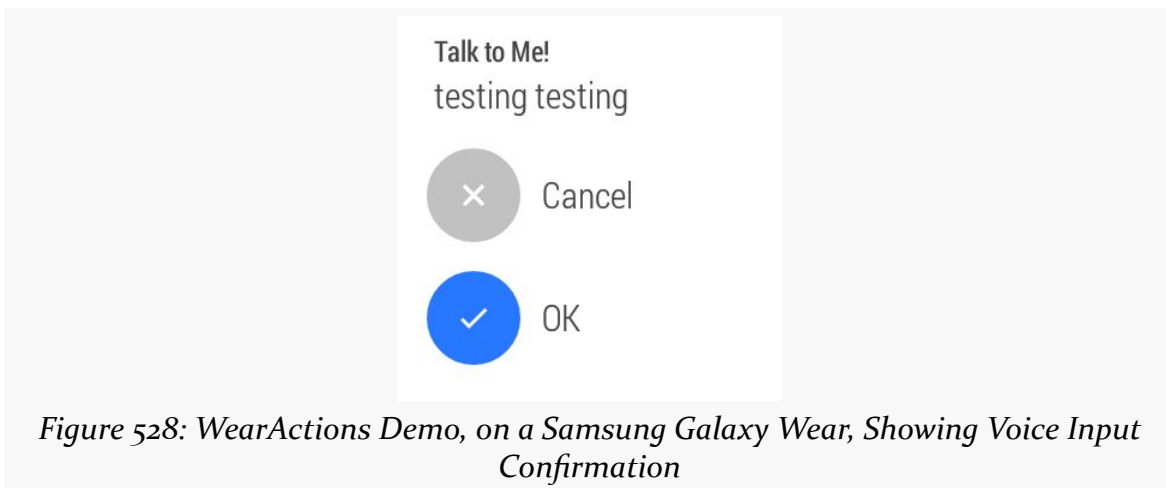

If the user instead does dictate some text, initially they are shown just the interpreted text:

Then a cancel button with a progress indicator around the edge appears:

If the user taps the cancel button before the progress indicator elapses, they are prompted to confirm or reject the input:

Lockscreen Notifications

Historically, notification icons would be visible on the user's lockscreen, but that was it. This would give the user an indication of what apps need attention, but no additional context.

Android 5.0 now shows notifications on the lockscreen, to help provide that missing context. Now users can have more details about the notifications, to determine whether it is necessary to unlock the device right now to deal with them.

ADVANCED NOTIFICATIONS

However, this also raises privacy concerns, as now notification text can be seen by anyone with access to the phone. As such, Android 5.0 has introduced the concept of *visibility* to notifications, so developers can help control what is shown on the lockscreen versus what is shown only past the lockscreen.

However, these visibility options are only useful if:

- The device has a pattern, PIN, or password set, so it is not merely some swipe-to-unlock approach
- The user has indicated that the system should “hide sensitive notification content”, either when they set up the pattern/PIN/password:

Figure 529: Choosing Notification Control, When Securing the Lockscreen

or in the “Sound & notification” portion of the Settings app:

ADVANCED NOTIFICATIONS

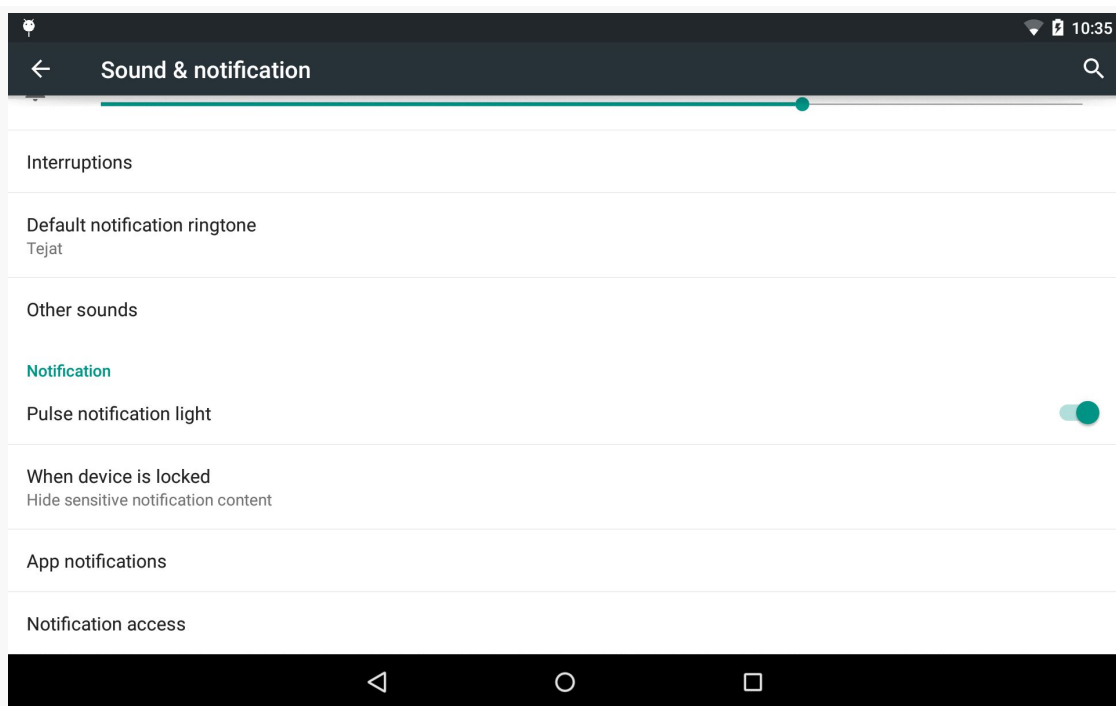

Figure 530: “Sound & notification” Settings

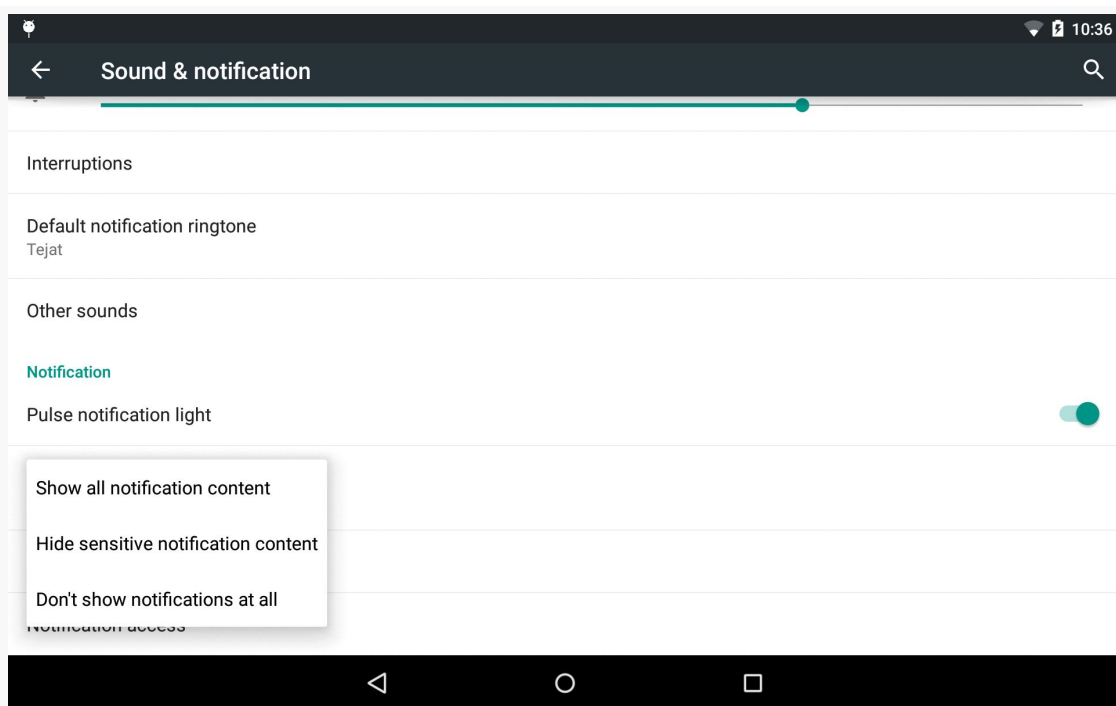

Figure 531: Notification Control Options in “Sound & notification” in Settings

Given that the user has enabled “hide sensitive notification content” mode, you as a developer can choose a visibility to apply to your notifications. There are three such visibility options — private, public, and secret — covered in the following sections.

Private Notifications

The default behavior is a “private” Notification. Basic information appears on the lockscreen, but not the whole Notification. However, you as a developer can also provide a *separate* Notification that *will* be shown on the lockscreen, so you can choose what information appears publicly and what information does not.

The sample app for this section has a “public” edition of the Notification that shows up on the lockscreen:

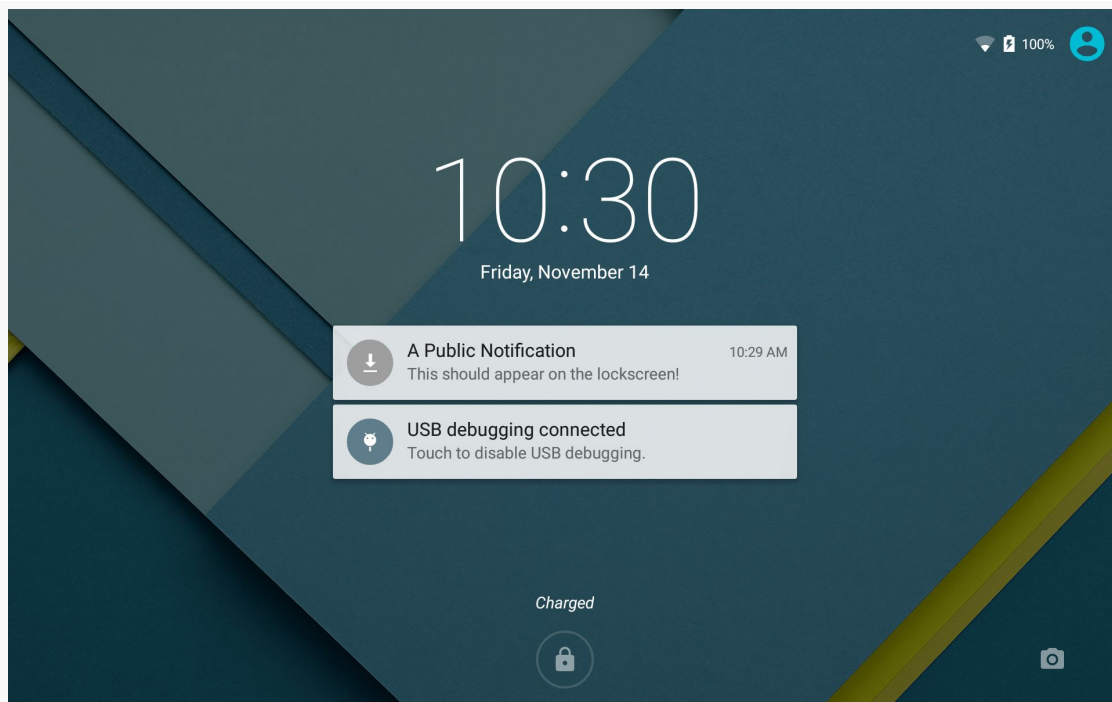

Figure 532: Public Edition of Private Lockscreen Notification, on a Nexus 7

Public Notifications

Instead of creating a separate Notification for public visibility on the lockscreen, you could flag your main Notification as having public visibility. This is suitable for notifications where there is little to no privacy implications for having the information appear on the lockscreen.

Secret Notifications

A Notification with visibility set to “secret” will not show up on the lockscreen at all. The ringtone, etc. will occur, as requested (and based on device settings, like it being muted), but otherwise there is no visible indication on the lockscreen that your Notification exists. Only when the user gets past the lockscreen will your Notification appear, in the status bar.

A Visibility Sample

The [Notifications/Lollipop](#) sample project demonstrates the use of these visibility values. It also demonstrates heads-up notifications, covered [later in this chapter](#).

The user interface consists of a Spinner of possible Notification variants, a SeekBar to allow the user to specify a delay period in seconds before showing the Notification, and a Button to trigger showing the Notification:

```
<?xml version="1.0" encoding="utf-8"?>

<TableLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:stretchColumns="1">

    <TableRow>
        <TextView
            android:text="@string/type_label"/>

        <Spinner
            android:id="@+id/type"/>
    </TableRow>

    <TableRow>
        <TextView
            android:text="@string/delay_label"/>

        <SeekBar
            android:id="@+id/delay"
            android:progress="5"
            android:max="30"/>
    </TableRow>

    <Button
        android:text="@string/notify_button"
        android:id="@+id/download">
```

ADVANCED NOTIFICATIONS

```
        android:onClick="notifyMe"/>  
</TableLayout>
```

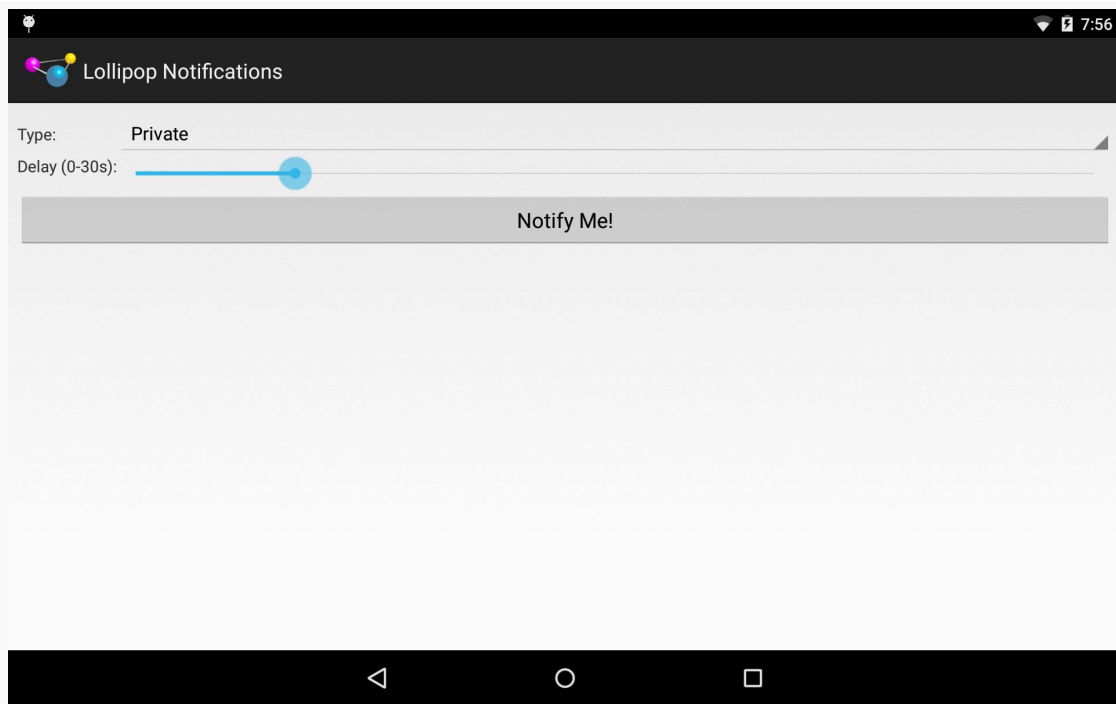

Figure 533: Lollipop Notifications Demo, on a Nexus 7

The `onCreate()` method of our launcher activity (`MainActivity`) initializes the UI:

```
package com.commonware.android.lollipopnotify;  
  
import android.app.Activity;  
import android.app.AlarmManager;  
import android.app.PendingIntent;  
import android.content.Intent;  
import android.os.Bundle;  
import android.os.SystemClock;  
import android.view.View;  
import android.widget.AdapterView;  
import android.widget.SeekBar;  
import android.widget.Spinner;  
  
public class MainActivity extends Activity {  
    private Spinner type=null;  
    private SeekBar delay=null;  
  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.main);  
    }  
}
```

```
type=(Spinner)findViewById(R.id.type);

ArrayAdapter<String> types=
    new ArrayAdapter<String>(this,
        android.R.layout.simple_spinner_item,
        getResources().getStringArray(R.array.types));

types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
type.setAdapter(types);

delay=(SeekBar)findViewById(R.id.delay);
}

public void notifyMe(View v) {
    Intent i=new Intent(this, AlarmReceiver.class)
        .putExtra(AlarmReceiver.EXTRA_TYPE, type.getSelectedItemPosition());
    PendingIntent pi=PendingIntent.getBroadcast(this, 0, i,
PendingIntent.FLAG_UPDATE_CURRENT);
    AlarmManager mgr=(AlarmManager)getSystemService(ALARM_SERVICE);

    mgr.set(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+(1000*delay.getProgress()),
        pi);
}
}
```

In particular, onCreate() populates the Spinner based on a <string-array> resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="types">
        <item>Private</item>
        <item>Public</item>
        <item>Secret</item>
        <item>Heads-Up</item>
    </string-array>
</resources>
```

When the button is clicked, the notifyMe() method on MainActivity is called. Here, we:

- Create an Intent pointing at an AlarmReceiver
- Package an extra on the Intent that contains the selected position of the Spinner
- Wrap the Intent in a getBroadcast() PendingIntent
- Use set() on AlarmManager to invoke the PendingIntent after the delay period specified via the SeekBar

ADVANCED NOTIFICATIONS

Since the `targetSdkVersion` of this project is below 19, the `set()` method will behave in an exact fashion, triggering our `AlarmReceiver` at the designated time.

`AlarmReceiver`, in turn, uses a switch statement to call out to different private methods based upon which Spinner item was selected:

```
package com.commonware.android.lollipopnotify;

import android.app.Notification;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.provider.Settings;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;

public class AlarmReceiver extends BroadcastReceiver {
    private static final int NOTIFY_ID=1337;
    static final String EXTRA_TYPE="type";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        NotificationManagerCompat mgr=NotificationManagerCompat.from(ctxt);

        switch (i.getIntExtra(EXTRA_TYPE, -1)) {
            case 0:
                notifyPrivate(ctxt, mgr);
                break;

            case 1:
                notifyPublic(ctxt, mgr);
                break;

            case 2:
                notifySecret(ctxt, mgr);
                break;

            case 3:
                notifyHeadsUp(ctxt, mgr);
                break;
        }
    }

    private void notifyPrivate(Context ctxt, NotificationManagerCompat mgr) {
        Notification pub=buildPublic(ctxt).build();

        mgr.notify(NOTIFY_ID, buildNormal(ctxt).setPublicVersion(pub).build());
    }

    private void notifyPublic(Context ctxt, NotificationManagerCompat mgr) {
```

ADVANCED NOTIFICATIONS

```
        buildNormal(ctxt)
            .setVisibility(NotificationCompat.VISIBILITY_PUBLIC)
            .build());
    }

    private void notifySecret(Context ctxt, NotificationManagerCompat mgr) {
        mgr.notify(NOTIFY_ID,
            buildNormal(ctxt)
                .setVisibility(NotificationCompat.VISIBILITY_SECRET)
                .build());
    }

    private void notifyHeadsUp(Context ctxt, NotificationManagerCompat mgr) {
        mgr.notify(NOTIFY_ID,
            buildNormal(ctxt)
                .setPriority(NotificationCompat.PRIORITY_HIGH)
                .build());
    }

    private NotificationCompat.Builder buildNormal(Context ctxt) {
        NotificationCompat.Builder b=new NotificationCompat.Builder(ctxt);

        b.setAutoCancel(true)
            .setDefaults(Notification.DEFAULT_ALL)
            .setContentTitle(ctxt.getString(R.string.download_complete))
            .setContentText(ctxt.getString(R.string.fun))
            .setContentIntent(buildPendingIntent(ctxt,
Settings.ACTION_SECURITY_SETTINGS))
            .setSmallIcon(android.R.drawable.stat_sys_download_done)
            .setTicker(ctxt.getString(R.string.download_complete))
            .addAction(android.R.drawable.ic_media_play,
                ctxt.getString(R.string.play),
                buildPendingIntent(ctxt, Settings.ACTION_SETTINGS));

        return(b);
    }

    private NotificationCompat.Builder buildPublic(Context ctxt) {
        NotificationCompat.Builder b=new NotificationCompat.Builder(ctxt);

        b.setAutoCancel(true)
            .setDefaults(Notification.DEFAULT_ALL)
            .setContentTitle(ctxt.getString(R.string.public_title))
            .setContentText(ctxt.getString(R.string.public_text))
            .setContentIntent(buildPendingIntent(ctxt,
Settings.ACTION_SECURITY_SETTINGS))
            .setSmallIcon(android.R.drawable.stat_sys_download_done)
            .addAction(android.R.drawable.ic_media_play,
                ctxt.getString(R.string.play),
                buildPendingIntent(ctxt, Settings.ACTION_SETTINGS));

        return(b);
    }
}
```

```
private PendingIntent buildPendingIntent(Context ctxt, String action) {  
    Intent i=new Intent(action);  
  
    return(PendingIntent.getActivity(ctxt, 0, i, 0));  
}
```

If the user chooses the “Private” option in the Spinner, we call `notifyPrivate()`. That method builds two `Notification` objects: the regular one and a separate public edition. We attach the public edition to the regular `Notification` via a call to `setPublicVersion()` on the `NotificationCompat.Builder`. Then, we raise the regular `Notification`. This will show the public edition if the lockscreen is locked; otherwise, it will show the regular edition.

If the user chooses the “Public” option, we call `notifyPublic()`. That, in turn, calls `setVisibility(NotificationCompat.VISIBILITY_PUBLIC)` on the `NotificationCompat.Builder`, causing our `Notification` to appear normally both on the lockscreen and past the lockscreen.

If the user chooses the “Secret” option, we call `notifySecret()`. That uses `setVisibility(NotificationCompat.VISIBILITY_SECRET)` to configure the `Notification` to only appear once the user has gotten past the lockscreen.

The “Heads-Up” option — fourth in the Spinner — is covered in the next section.

Priority, and Heads-Up Notifications

Notifications can have a priority associated with them. Normally, notifications with higher priority will appear higher in the list of notifications in the notification tray than will notifications with lower priority.

Android 5.0 takes this a step further, showing high-priority notifications in a “heads-up” style, popping up a small dialog-like window over the main screen, with the same basic content as would appear for the `Notification` in its tile in the notification tray:

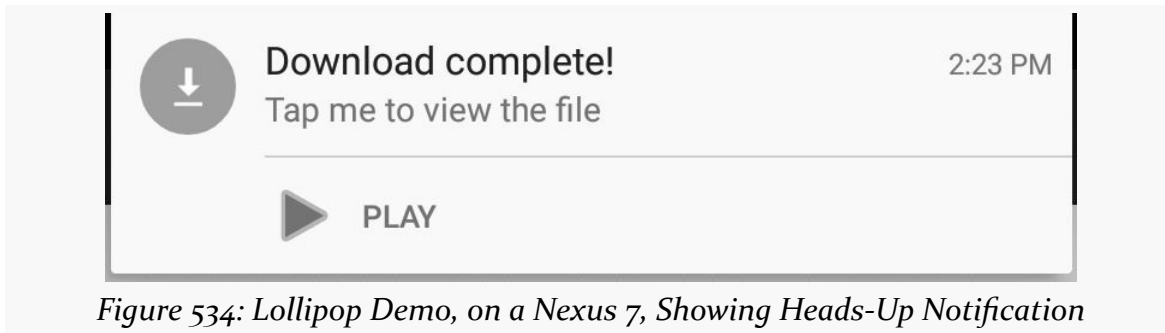

Figure 534: Lollipop Demo, on a Nexus 7, Showing Heads-Up Notification

Users can interact with the heads-up Notification or ignore it; in the latter case, the Notification will move into the status bar and the “heads-up” display will disappear from the screen.

Note that the “priority” concept being described here seems to be independent of the notion of “priority notifications” in the user’s interruption configuration in Settings. There, “priority notifications” is tied to the app, not tied to any sort of configuration of the Notification itself.

Specifying the Priority

`NotificationCompat.Builder` has a `setPriority()` method that allows you to specify your requested priority. There are five priority values accepted as a parameter, all defined as constants out on the `NotificationCompat` class:

- `PRIORITY_MAX`
- `PRIORITY_HIGH`
- `PRIORITY_DEFAULT`
- `PRIORITY_LOW`
- `PRIORITY_MIN`

The actual priority applied to the Notification will depend upon other factors, and so you should not assume that your requested value will be accepted and applied as-is.

Results on Android 5.0 Devices

The heads-up Notification appears as shown in the above screenshot. The pop-up itself is centered across the top of the screen, as shown below:

ADVANCED NOTIFICATIONS

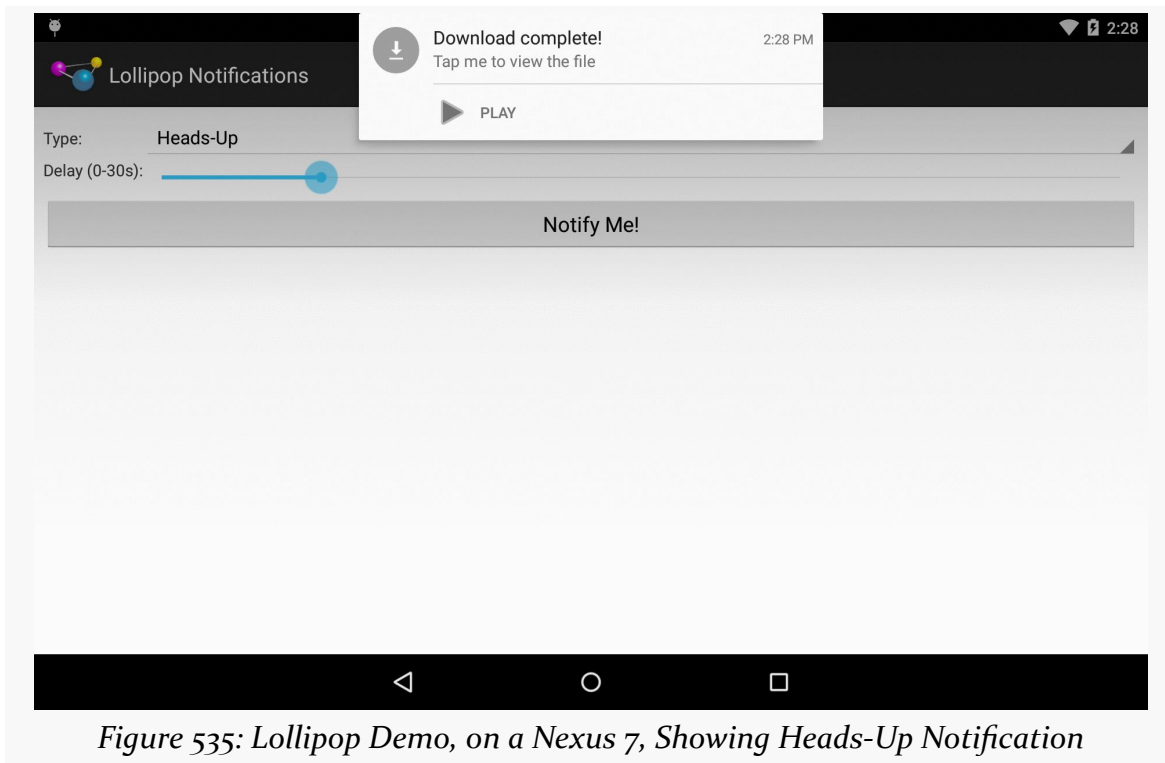

Figure 535: Lollipop Demo, on a Nexus 7, Showing Heads-Up Notification

After a few seconds of inactivity, the pop-up vanishes, and the Notification goes into the status bar.

Results on Older Devices

The concept of priority was introduced in API Level 16 (Android 4.1). On Android 4.1 through 4.4, the only effect of priority was to help influence the sort order of notifications in the notification tray, with higher-priority items drifting towards the top.

While `NotificationCompat.Builder` will allow you to specify a priority even on devices running older versions of Android than 4.1, the requested priority will be ignored, simply because priority did not exist back then. Hence, while your code will still work, it will have no effect on such old devices.

Full-Screen Notifications

Before Android 5.0 added heads-up notifications, while priority would influence things like sort order, it would have no real impact on how the user would be

informed about whatever event triggered the Notification. The user would still just get an icon in the status bar, and perhaps a ringtone and other hardware output.

However, sometimes we need to be somewhat more “in the user’s face”, such as for a calendar event reminder, or for an incoming phone call from our VOIP app.

It is tempting to launch an activity in these cases. In fact, that is what the user tends to perceive as happening, on Android 4.4 and older devices. And some apps no doubt actually do launch an activity.

A “middle ground” between showing a Notification and launching an activity is to use a full-screen Notification. Here, we provide a `PendingIntent` that should be invoked if the user is actively using the device at the time of the Notification. Typically, that `PendingIntent` will display an activity. However, on Android 5.0, the behavior has changed, where a full-screen Notification actually just triggers a heads-up notification, as would a high-priority Notification.

Requesting Full-Screen Output

All you need to do to set up a Notification to be full-screen is to call `setFullScreenIntent()` on your `NotificationCompat.Builder`, supplying two values:

1. A `PendingIntent` to be invoked when the notification is added to the screen
2. A boolean, where `true` indicates that even if the user has blocked notifications, you want this one to appear

For example, in the [Notifications/FullScreen](#) sample project, `MainActivity` shows a Notification constructed via the `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.download_complete))
      .setContentText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setFullScreenIntent(buildPendingIntent(Settings.ACTION_DATE_SETTINGS),
true)
      .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));
}
```

```
return(b);  
}
```

Here, the `PendingIntent` is created using the same `buildPendingIntent()` method as before, this time opening up a distinct screen from the Settings app.

Results on Android 5.0 Devices

On Android 5.0, the “full screen” Notification appears as a heads-up Notification:

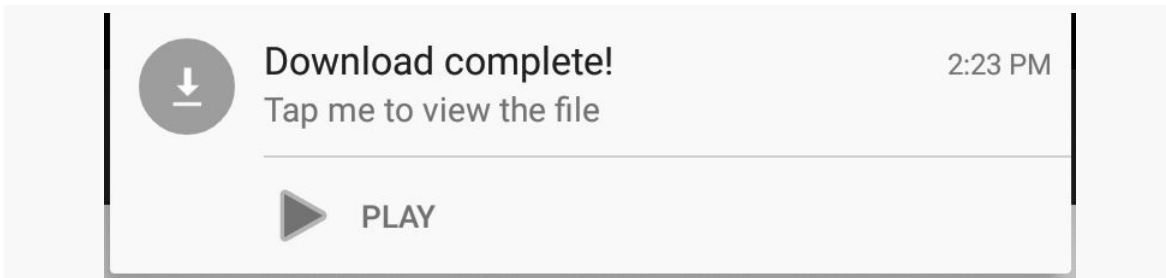

Figure 536: FullScreen Demo, on a Nexus 7, Showing “Full Screen” Notification

Note that there is no obvious way to actually invoke the `PendingIntent` associated with the `setFullScreenIntent()` method. Hence, you need to make sure that the Notification has some other means of getting the user to the right place in your UI, such as via `setContentIntent()` or an action.

Results on Android 3.0–4.4 Devices

On API Levels 11 through 19 (Android 3.0 through 4.4), the effect of a full-screen `PendingIntent` is to invoke the `PendingIntent` when the Notification is added to the screen. This will happen regardless of whether the user is using the device or not, though if the device is asleep, the activity triggered by the `PendingIntent` will only be visible once the user gets past their lockscreen.

Note that the Notification is *also* shown, along with whatever the `PendingIntent` does. That Notification is not automatically cleared when the user exits out of that activity via `BACK`, `HOME`, etc. Hence, it is up to you to clear that Notification if and when it is no longer relevant. The primary value of the Notification is to have the icon appear in the status bar on the lockscreen — even though the user cannot interact with your Notification then, the user may recognize your icon and therefore elect to unlock their device to see what all the fuss is about.

Results on Older Devices

Full-screen notifications were not supported prior to Android 3.0. While `NotificationCompat.Builder` will allow you to call `setFullScreenIntent()`, the value will be ignored prior to API Level 11.

In theory, there is nothing stopping `NotificationCompat` from launching an activity itself, in addition to displaying the `Notification`. However, at least at this time, it is not doing so, and it is fairly likely that Google will not add this in at this point.

Hence, the only way to do a “full-screen notification” is for your app to launch the desired activity, in addition to (or instead of) showing the `Notification`.

Custom Views: or How Those Progress Bars Work (Sometimes)

Some applications have specific tasks that take a chunk of time. The most common situation for these is a download — while downloading a file should not take forever, it may take several seconds or minutes, depending on the size of the file and the possible download speed.

You may have noticed that some applications, such as the Android Market, have a `Notification` for a download that shows the progress of the download itself. Visually, it's obvious how they accomplish this: they use a `ProgressBar`. But normally you create `Notification` objects with just a title and description as text. How do they get the `ProgressBar` in there? And, perhaps more importantly, how are they continuously updating it?

This section will explain how that works, along with a related construct added in Android 3.0: the custom ticker.

Custom Content

When you specify a title and a description for a `Notification`, you are implicitly telling Android to use a stock layout for the structure of the `Notification` object's entry in the notification drawer. However, instead, you can provide Android with the layout to use and the contents of all the widget, by means of a `RemoteViews`. In other words, by using the same techniques that you use to create [app widgets](#), you can

create tailored notification drawer content. Just create the RemoteViews and put it in the contentView data member of the Notification.

To update the notification drawer content — such as updating a ProgressBar to show download progress — you update your RemoteViews in your Notification and re-raise the Notification via a call to `notify()`. Android will apply your revised RemoteViews to the notification drawer content, and the user will see the changed widgets. However, you will also want to remove requested features from the Notification that you do not want to occur every time you update the RemoteViews. For example, if you keep the `tickerText` in place, every time you update the RemoteViews, the ticker text will be re-displayed, which can get annoying.

We will see an example of this in action [later in this chapter](#).

Custom Tickers

Traditionally, the “ticker” is a piece of text that is placed in the status bar when the Notification is raised, so that if the user happens to be looking at the phone at that moment (or glances at it quickly, cued by a vibration or ringtone), they get a bit more contextual information about the Notification and why it is there.

On API Level 11+ tablets, you also have the option of creating a custom ticker, once again using a RemoteViews. Create the RemoteViews to be what you want to show as the ticker, and assign it to the `tickerView` data member of the Notification. On devices with room (e.g., tablets), your RemoteViews will be displayed instead of the contents of the `tickerText` data member. However, it is a good idea to also fill in the `tickerText` value, for devices that elect to show that instead of your custom view.

Seeing It In Action

To see custom tickers and custom content in a complete project, take a peek at the [Notifications/HCNotifyDemo](#) sample project. This is perhaps the smallest possible project that uses all of these features, so do not expect much elaborate business logic.

The Activity

The launcher icon for this application is tied to an activity named `HCNotifyDemoActivity`. All it does is spawn a background service named

SillyService, that will simulate doing real work in the background and maintaining a Notification along the way:

```
package com.commonware.android.hcnotify;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import com.commonware.android.hcnotify.R;

public class HCNotifyDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        startService(new Intent(this, SillyService.class));

        finish();
    }
}
```

The IntentService

SillyService is an IntentService, to take advantage of the two key features of an IntentService: the supplied background thread, and automatically being destroyed when the work being done in the background is finished.

Since SillyService is an IntentService, and IntentService requires a constructor, supplying a display name for the service, we oblige:

```
public SillyService() {
    super("SillyService");
}
```

All of the rest of the business logic is in `onHandleIntent()`, which will be described in pieces below.

The Builder

In theory, SillyService is going to do some real long-running work, updating a ProgressBar in a Notification along the way. To keep the example simple — and not to violate “truth in advertising” laws given the service’s name — SillyService will emulate doing real work by sleeping.

ADVANCED NOTIFICATIONS

Hence, the first thing SillyService does in `onHandleIntent()` is get a `NotificationManager` and a `NotificationCompat.Builder`, then configure the builder to get the base `Notification` to use:

```
NotificationManager
mgr=(NotificationManager)getSystemService(NOTIFICATION_SERVICE);
NotificationCompat.Builder builder=new NotificationCompat.Builder(this);

builder
    .setContent(buildContent(0))
    .setTicker(getText(R.string.ticker), buildTicker())
    .setContentIntent(buildContentIntent())
    .setLargeIcon(buildLargeIcon())
    .setSmallIcon(R.drawable.ic_stat_notif_small_icon)
    .setOngoing(true);

Notification notif=builder.build();
```

Configuring the builder, in this case, involves calling the following setters:

1. `setContent()`, to provide the `RemoteViews` for the notification drawer entry, here delegated to a `buildContent()` method we will examine in a bit
2. `setTicker()`, to provide the material to be displayed as the ticker, in this case using a `setTicker()` variant that takes a `CharSequence` (e.g., a `String`, or the result of `getText()` on a string resource ID) and a `RemoteViews` to use in cases where the device supports custom tickers (delegated here to `buildTicker()`)
3. `setContentIntent()`, to provide the `PendingIntent` to be invoked if the user taps on our custom content `RemoteViews`, here delegated to `buildContentIntent()`
4. `setLargeIcon()`, used on some devices for a larger representation of our notification icon for use in tickers and non-custom notification drawer contents, here delegated to `buildLargeIcon()`
5. `setSmallIcon()`, use for the status bar/system bar icon and, on some devices, for non-custom notification drawer contents
6. `setOngoing()`, which sets `FLAG_ONGOING_EVENT`, preventing this `Notification` from being deleted by the user

Finally, we call `build()` to retrieve the `Notification` object as configured by the builder. Note that previous versions of `NotificationBuilder` used `getNotification()` instead of `build()`, but `getNotification()` is now officially deprecated.

The ProgressBar

Our buildContent() method just returns a RemoteViews object:

```
private RemoteViews buildContent(int progress) {
    RemoteViews content=new RemoteViews(this.getPackageName(),
                                       R.layout.content);

    return(content);
}
```

The RemoteViews object, in turn, is based on a trivial layout (res/layout/content.xml) containing a ProgressBar:

```
<ProgressBar xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/progress"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:indeterminate="false">
</ProgressBar>
```

The simplest way to update a ProgressBar in a Notification is to simply hold onto the Notification object and update the ProgressBar in the RemoteViews as needed.

SillyService takes this approach, looping 20 times for 1000-millisecond naps, updating the ProgressBar on each pass of the loop:

```
for (int i=0;i<20;i++) {
    notif.contentView.setProgressbar(android.R.id.progress,
                                     100, i*5, false);
    mgr.notify(NOTIFICATION_ID, notif);

    if (i==0) {
        notif.tickerText=null;
        notif.tickerView=null;
    }

    SystemClock.sleep(1000);
}
```

You update the progress of a ProgressBar by calling setProgressbar() on the RemoteViews, and you get your content RemoteViews from the contentView data member of the configured Notification. SillyService has the ProgressBar run from 0 to 100 and sets the progress to be 5 times our loop counter. Each time we update the RemoteViews, we call notify() to raise or update the Notification.

The key is that the first time we do this, we want to display our ticker, but not every time the `ProgressBar` updates, as that would really aggravate the user. So, after we raise the `Notification` in the first pass of our loop, we set the `tickerText` and `tickerView` data members of the `Notification` to null, to suppress further tickers from being displayed.

When the loop is finished, we just `cancel()` the `Notification`, to remove it from the screen.

The Rest of the Story

The `buildTicker()` method also returns a `RemoteViews`:

```
private RemoteViews buildTicker() {
    RemoteViews ticker=new RemoteViews(this.getPackageName(),
                                      R.layout.ticker);

    ticker.setTextViewText(R.id.ticker_text,
                          getString(R.string.ticker));

    return(ticker);
}
```

It, in turn, is based off of a `res/layout/ticker.xml` resource:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/ticker_text"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="TextView">

</TextView>
```

There is nothing requiring the ticker (or the content, for that matter) to be completely static. You might well customize `TextView` or other widgets at runtime with details about the work being done. Here, `buildTicker()` does that via `setTextViewText()`, albeit just pulling in a string resource.

The `buildContentIntent()` method returns a `PendingIntent` to be invoked when the user taps on our `ProgressBar`-laden notification drawer entry. Here, lacking any better ideas and being generally lazy, we return a `PendingIntent` designed to bring up the `Settings` application:

```
private PendingIntent buildContentIntent() {
    Intent i=new Intent(Settings.ACTION_SETTINGS);
```

```
return(PendingIntent.getActivity(this, 0, i, 0));  
}
```

While small icons in a Notification must be resources, large icons are bitmaps. Presumably, that is to support the large icon holding contact photos, chat avatars, album art for music players, and whatnot. Hence, `buildLargeIcon()` needs to return a `Bitmap` object. In our case, it is simply a drawable resource, so we use `BitmapFactory` and `decodeResource()` to get a `Bitmap` from the PNG:

```
private Bitmap buildLargeIcon() {  
    Bitmap raw=BitmapFactory.decodeResource(getResources(),  
                                           R.drawable.icon);  
  
    return(raw);  
}
```

The Results

When we launch `HCNotifyDemoActivity`, which in turns starts up `SillyService`, we initially get our custom ticker on a tablet:

Figure 537: The custom ticker in our Notification, as seen on a Honeycomb tablet

Eventually, the ticker vanishes, leaving us with the traditional system bar icon:

Figure 538: The system bar icon for our Notification, as seen on a Honeycomb tablet

Tapping on the icon brings up the notification drawer, with our custom content, including our `ProgressBar`:

Figure 539: Notification ProgressBar, on Android 3.x Tablet

On an Android 4.0 phone, the status bar and ticker are no different than their Android 1.x/2.x counterparts, though we still get our custom content:

Figure 540: Notification ProgressBar, on Android 4.x Phone

How You *Really* Do Progress Notifications

While it is entirely possible to have a Notification with a ProgressBar using RemoteViews, there is a far simpler solution: use `setProgress()` on the `Notification.Builder` (or `NotificationCompat.Builder`). This is illustrated in the [Notifications/Progress](#) sample project, which is a simplified clone of the `HCNotifyDemo` project.

The `SillyService.onHandleIntent()` method now eschews the RemoteViews in favor of `setProgress()`:

```
@Override
protected void onHandleIntent(Intent intent) {
    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);
```

ADVANCED NOTIFICATIONS

```
NotificationCompat.Builder builder=
    new NotificationCompat.Builder(this);

builder.setTicker(getText(R.string.ticker))
    .setContentTitle(getString(R.string.progress_notification))
    .setContentText(getString(R.string.busy))
    .setContentIntent(buildContentIntent())
    .setSmallIcon(R.drawable.ic_stat_notif_small_icon)
    .setOngoing(true);

for (int i=0; i < 20; i++) {
    builder.setProgress(20, i, false);
    mgr.notify(NOTIFICATION_ID, builder.build());

    SystemClock.sleep(1000);
}

builder.setContentText(getString(R.string.done))
    .setProgress(0, 0, false).setOngoing(false);

mgr.notify(NOTIFICATION_ID, builder.build());
}
```

After initializing the stock data for the `NotificationCompat.Builder`, we enter the same sort of loop—20-times-sleeping-a-second loop as was seen in the previous demo. This time, though, we call `setProgress()` on the Builder to set the current progress, then have it `build()` a Notification object to use with the `NotificationManager`.

`setProgress()` takes three parameters:

- the maximum value of the `ProgressBar`, which eventually routes to `setMax()` on the `ProgressBar` itself
- the current progress of the `ProgressBar`, which eventually routes to `setProgress()` on the `ProgressBar` itself
- true if the progress is indeterminate, false otherwise

In this case, we set the maximum to be 20 and the progress to be the value of our loop counter `i`.

When the loop is finished, we update the Builder to:

- Provide an alternative piece of text to show below the `ProgressBar`
- Remove the `ProgressBar` via `setProgress(0, 0, false)`
- Use `setOngoing(false)` to allow the user to get rid of the Notification

Figure 542: Notification with ProgressBar, When Done

Life After Delete

Most of the time, you do not care about your Notification being dismissed by the user from the notification drawer (e.g., pressing the Clear button on Android 1.x/2.x devices). If you do care about the Notification being deleted this way, you can supply a `PendingIntent` in the `deleteIntent` data member of the Notification — this will be executed when the user gets rid of your Notification. Usually, this will be a `getService()` or `getBroadcast()` `PendingIntent`, to have you do something in the background related to the dismissal. Users are likely to get rather irritated with you if you pop up an activity because they got rid of your Notification.

Note that this only works for Notification objects that can be cleared. If you have `FLAG_ONGOING_EVENT` set on the Notification, it will remain on-screen until you get rid of it.

The Mysterious Case of the Missing Number

The `Notification` class has a number data member. On Android 1.x and 2.x, setting that data member would cause a number to be super-imposed on top of your icon in the status bar. That data member no longer works as of Android 3.0.

However, `Notification.Builder` has a `setNumber()` method which *does* work on API Level 11 and higher, though with slightly different behavior. Instead of putting the number on top of your status bar icon, the number will appear in your notification drawer entry. This only works if you do not use `setContent()` with `Notification.Builder` to define your own notification drawer entry layout — in that case, you could put your own number in wherever you would like.

More Fun with Pagers

In earlier chapters, we saw [basic uses of ViewPager](#), along with ways to [show multiple pages at a time on larger screens](#). However, there are other ways to apply ViewPager and integrate it into the rest of your application, some of which we will examine in this chapter.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the one showing [how to use ViewPager](#).

Hosting ViewPager in a Fragment

Classically, the primary restriction on ViewPager was that you could not both have ViewPager be in a fragment *and* have ViewPager host fragments as its pages. You could do one or the other, but not both simultaneously.

As noted [in a previous chapter](#), Android 4.2 supports nested fragments natively, and the latest Android Support package backport also supports nested fragments. With those, you can have ViewPager be in a fragment and host fragments as its pages. However, it requires a minor modification to the way we set up a PagerAdapter, as is illustrated in the [ViewPager/Nested](#) sample project. This is the same project as ViewPager/Indicator, with the twist that the pages are fragments and the ViewPager is inside a fragment.

Our activity now implements the standard add-the-fragment-if-it-does-not-exist pattern that we have seen previously:

MORE FUN WITH PAGERS

```
package com.commonware.android.pagnested;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class ViewPagerIndicatorActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) ==
null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PagerFragment()).commit();
        }
    }
}
```

This loads a PagerFragment, which contains most of the logic from our original activity:

```
package com.commonware.android.pagnested;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PagerFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.pager, container, false);
        ViewPager pager=(ViewPager)result.findViewById(R.id.pager);

        pager.setAdapter(buildAdapter());

        return(result);
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(getActivity(), getChildFragmentManager()));
    }
}
```

The biggest difference is that our call to the constructor of SampleAdapter no longer uses getSupportFragmentManager(). Instead, it uses getChildFragmentManager().

This allows `SampleAdapter` to use fragments hosted by `PagerFragment`, rather than ones hosted by the activity as a whole.

No other code changes are required, and from the user's standpoint, there is no visible difference.

Pages and the Action Bar

Fragments that are pages inside a `ViewPager` can participate in the action bar, supplying items to appear as toolbar buttons, in the overflow menu, etc. This is not significantly different than [how any fragment participates in the action bar](#):

- Call `setHasOptionsMenu()` early in the fragment lifecycle (e.g., `onCreateView()`) to state that the fragment wishes to contribute to the action bar contents
- Override `onCreateOptionsMenu()` and `onOptionsItemSelected()`, much as you would with an activity

`ViewPager` and `FragmentManager` will manage the contents of the action bar, based upon the currently-visible page. That page's contributions will appear in the action bar, then will be removed when the user switches to some other page.

To see this in action, take a look at the [ViewPager/ActionBar](#) sample project. This is the same as the `ViewPager/Indicator` project from before, except:

- In `onCreateView()`, for even-numbered page positions (0, 2, etc.), we call `setHasOptionsMenu(true)`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);

    position=getArguments().getInt(KEY_POSITION, -1);
    editor.setHint(getTitle(getActivity(), position));

    if ((position % 2)==0) {
        setHasOptionsMenu(true);
    }

    return(result);
}
```

MORE FUN WITH PAGERS

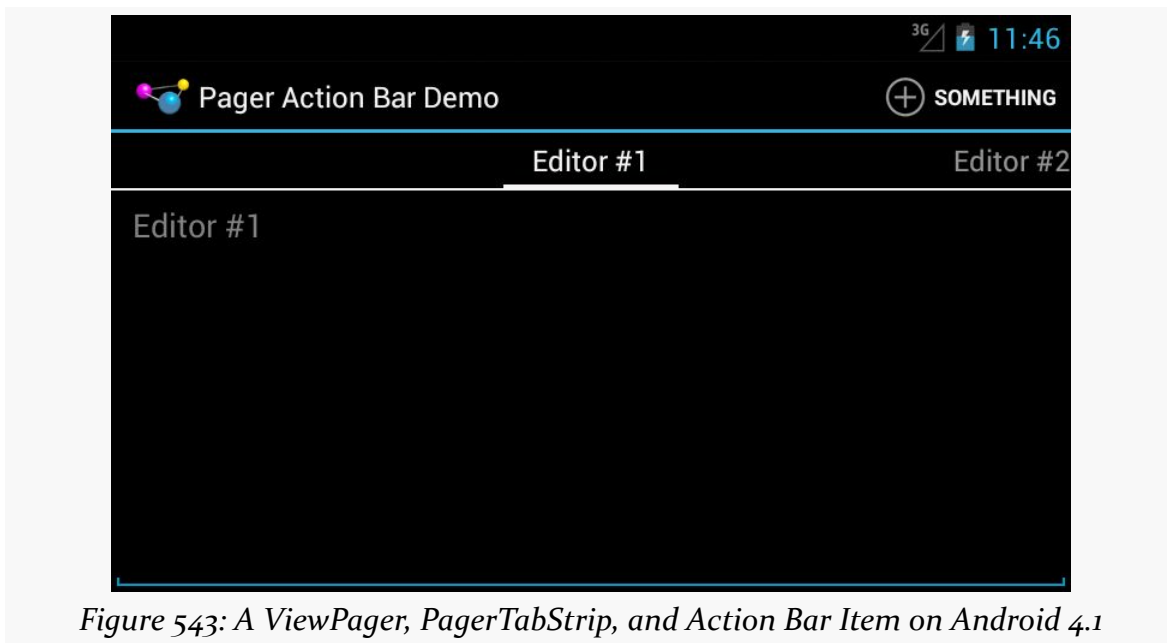

- In `onCreateOptionsMenu()`, we inflate a `res/menu/actions.xml` menu resource:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

Normally, we would also implement `onOptionsItemSelected()`, to find out when the action bar item was tapped, though this is skipped in this sample.

The result is that when we have an even-numbered page position — equating to an odd-numbered title and hint — we have items in the action bar:

...but as soon as we swipe to an odd-numbered page position — equating to an even-numbered title and hint — our action bar item is removed, as that fragment did not call `setHasOptionsMenu(true)`:

Figure 544: A ViewPager and PagerTabStrip, Sans Action Bar Item on Android 4.1

ViewPagers and Scrollable Contents

There are other things in Android that can be scrolled horizontally, besides a ViewPager:

- `HorizontalScrollView`
- `WebView`, for content that is wider than the width of the screen
- the deprecated `Gallery` widget
- maps from many mapping engines, such as Google Maps
- various third-party widgets

The challenge then comes in terms of dealing with horizontal swipe events. The ideal situation is for you to be able to swipe horizontally on the material inside the page, until you hit some edge (e.g., end of the `HorizontalScrollView`), then have swipe events move you to the adjacent page.

You can assist `ViewPager` in handling this scenario by subclassing it and overriding the `canScroll()` method. This will be called on a horizontal swipe, and it is up to you to indicate if the contents can be scrolled (returning `true`) or not (returning `false`). If the built-in logic is insufficient, tailoring `canScroll()` to your particular needs can help.

We will see an example of this later in the book, when [we put some maps into a ViewPager](#).

Using ViewPagerIndicator

In addition to using PagerTitleStrip or PagerTabStrip to indicate context for the user, there are a plethora of other UI alternatives. Embodiments of many such patterns can be found in the [ViewPagerIndicator library](#) (VPI).

ViewPagerIndicator offers a variety of different indicator styles:

- A set of circles, colored lines, or your own icons to indicate different pages
- Another approach for implementing tabs, more readily customized for your needs (e.g., replacing the bar indicating the selected tab with an arrowhead)

ViewPagerIndicator is open source, released under the Apache Software License 2.0.

Downloading VPI

ViewPagerIndicator is distributed as an Android library project. On [the ViewPagerIndicator home page](#) you will find buttons to download a ZIP or a TGZ containing the library and sample code.

Android Studio users are a bit out of luck, in that there is no official AAR for this library. An unofficial AAR is available that you can use if you wish, using the following configuration of your top-level repositories and dependencies closures:

```
repositories {  
    maven {  
        url "http://dl.bintray.com/populov/maven"  
    }  
}  
  
dependencies {  
    compile 'com.viewpagerindicator:library:2.4.1@aar'  
    compile 'com.android.support:support-v13:19.1.0'  
}
```

The above example also shows loading in support-v13, as that (or support-v4) is needed for ViewPager itself.

If you are using Eclipse, you will need to import the project into your workspace, via File > Import, then choosing Android > Existing Android Code Into Workspace from

the import wizard. Then you will need to attach the library to your main project, via Project > Properties > Android. This process is covered in greater detail in [the chapter on library projects](#).

Replacing PagerTabStrip with TabPageIndicator

[Earlier in the book](#), we looked at PagerTabStrip. The differences between using PagerTabStrip and one of the ViewPagerIndicator (VPI) classes, like TabPageIndicator, are fairly minor. The [ViewPager/VPI](#) sample project is a straight conversion of the PagerTabStrip sample to use TabPageIndicator.

First, your layout file will need to reference the VPI class instead of PagerTabStrip. The VPI indicators do not go as children of ViewPager; instead, you position them wherever makes sense using ordinary containers and layout rules. So, for example, you could have a classic vertical LinearLayout for stacking a TabPageIndicator atop the ViewPager:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <com.viewpagerindicator.TabPageIndicator
        android:id="@+id/titles"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>

</LinearLayout>
```

You also have to wire the indicator to the ViewPager, something that happens for you automatically when you use PagerTabStrip. This simply involves passing the ViewPager to the indicator via a `setViewPager()` method:

```
package com.commonware.android.pager3;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import com.viewpagerindicator.TabPageIndicator;
```

```
public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);
        TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

        pager.setAdapter(buildAdapter());
        tabs.setViewPager(pager);
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(this, getFragmentManager()));
    }
}
```

For this sample, those are the only two required changes. However, if you were using an `OnPageChangeListener` with your `ViewPager`, you now need to attach it to the *indicator*, rather than the pager, so you find out about page changes triggered by the indicator. This is accomplished by calling `setOnPageChangeListener()` on your indicator object.

Styling the Indicator

It is also reasonably likely that you will want to style the indicator to meet your needs. In the case of the `TabPageIndicator`, you can control things like the font used for the tab title (size, color, style, etc.), the amount of padding to have to the left and right of the title to form the overall “tab”, etc.

To do this, you will need to set up a custom theme for your project, if you do not already have one. That would involve creating a style resource, inheriting from whatever stock theme you want (e.g., `@android:style/Theme.Holo.Light.DarkActionBar`), and referencing your custom theme in your manifest:

```
<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>
```

```
<category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
</activity>
</application>
```

In addition to any other theme customizations you want to make, you will need to have an item, named based upon the indicator class that you are using, that will point to a style resource to use for styling instances of that indicator class. In the case of `TabPageIndicator`, the name is `vpiTabPageIndicatorStyle`:

```
<style name="AppTheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  <item name="vpiTabPageIndicatorStyle">@style/TabStyle</item>
</style>
```

Of course, you need to declare another style resource, using the name you supplied to the `vpiTabPageIndicatorStyle` item, where you tailor the look and feel of your indicator:

```
<style name="TabStyle" parent="Widget.TabPageIndicator">
  <item name="android:textColor">#FF33AA33</item>
  <item name="android:textSize">14sp</item>
  <item name="android:textStyle">italic</item>
  <item name="android:paddingLeft">16dp</item>
  <item name="android:paddingRight">16dp</item>
  <item name="android:fadingEdge">horizontal</item>
  <item name="android:fadingEdgeLength">8dp</item>
</style>
```

The easiest way to see what some of the options are is to look at [the sample code for ViewPagerIndicator](#) and [the various custom styles](#) that it defines.

With the custom style as defined above — specifying green italicized tab titles – we get tabs that look like these:

Figure 545: ViewPager with Customized TabPagerIndicator

Columns for Large, Pages for Small

In some cases, you can take better advantage of larger screens by using ViewPager more judiciously. In [a previous chapter](#), we explored having ViewPager itself display more than one page at a time. A variation on that same theme is to only use a ViewPager on screen sizes where you lack sufficient room for everything, and to put those same pages on the screen at the same time when you have room for all of them.

The Plume Example

Plume is a Twitter client for Android. It uses the columns-or-pages support for displaying various streams of tweets: your timeline, your @ mentions, hashtags you follow, etc.

Each stream is represented by a typical ListView, with one row per tweet. On a phone, since screen space is at a premium, those ListView widgets are set up in a ViewPager, with one list per page. Users can swipe between the lists, or use tabs to navigate the available lists.

However, tablets offer more room, so they will show three `ListView` widgets side-by-side in landscape mode, so you can take in three sets of content without further interaction with the screen.

The [ViewPager/Columns1](#) sample project will demonstrate how you can accomplish the same basic approach in your own app... with some limitations. This is a clone of the `ViewPagerIndicator` sample from [the previous section](#).

The Layouts

Our main activity layout — cunningly named `main` — has a `ViewPager`-based definition in `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <com.viewpagerindicator.TabPageIndicator
        android:id="@+id/titles"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>

</LinearLayout>
```

However, in `res/layout-large/`, for 5-inch devices on up, we have a horizontal `LinearLayout` with three `FrameLayout` containers, each representing an equal-sized slot for one of our “pages”:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:baselineAligned="false"
    android:orientation="horizontal">

    <FrameLayout
        android:id="@+id/editor1"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>
```

```
<FrameLayout
    android:id="@+id/editor2"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

<FrameLayout
    android:id="@+id/editor3"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</LinearLayout>
```

Android will automatically inflate the proper layout when we call `setContentView(R.layout.main)`.

The Activity

However, while Android handles the inflation for us, we obviously need to populate the contents a bit differently. In this sample, though, we are relying upon the fact that screen size will not change on the fly. Hence, an instance of our application will either show a `ViewPager` or show the horizontal `LinearLayout`, and not have to switch between those at runtime.

Our `SampleAdapter`, therefore, can remain unchanged, except for reducing the page count to 3:

```
package com.commonware.android.pagercolumns;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(3);
    }
}
```

```
@Override
public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
}

@Override
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}
}
```

Our MainActivity will still use the SampleAdapter, and if we have a ViewPager, it will use it the same way as before. However, if we do *not* have a ViewPager, we must be showing three panes of content side by side, in which case we just execute a FragmentTransaction to populate the three FrameLayout containers with the three items created by the SampleAdapter:

```
package com.commonware.android.pagercolumns;

import android.app.Activity;
import android.os.Bundle;
import android.support.v13.app.FragmentPagerAdapter;
import android.support.v4.view.ViewPager;
import com.viewpagerindicator.TabPageIndicator;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        if (pager == null) {
            if (getFragmentManager().findFragmentById(R.id.editor1) == null) {
                FragmentPagerAdapter adapter=buildAdapter();

                getFragmentManager().beginTransaction()
                    .add(R.id.editor1,
                        adapter.getItem(0))
                    .add(R.id.editor2,
                        adapter.getItem(1))
                    .add(R.id.editor3,
                        adapter.getItem(2)).commit();
            }
        }
        else {
            TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

            pager.setAdapter(buildAdapter());
            tabs.setViewPager(pager);
        }
    }
}
```

```
}  
  
private FragmentPagerAdapter buildAdapter() {  
    return(new SampleAdapter(this, getFragmentManager()));  
}  
}
```

Of course, we skip the `FragmentManagerTransaction` if the fragments already exist, such as due to a screen rotation configuration change.

The Results

On a phone, the `ViewPager`-based layout looks pretty much as it did before:

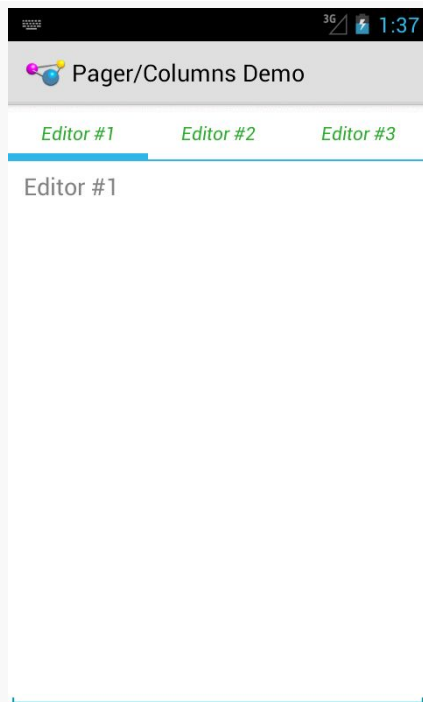

Figure 546: ViewPager with Customized TabPagerIndicator. Again.

However, on a tablet, we get our three editors side-by-side:

The Limitations

The simplified large-screen layout does not contain any indicators above the three editors. This could be added by simple changes to the `res/layout-large/main.xml` layout resource, if desired.

The bigger limitation is that this only works if you want the same look in all configurations *except* screen size, and if the screen size never changes. However, it is eminently possible that you will want to have a different mix than that, such as using the three-column approach only on large-screen *landscape* layouts, using `ViewPager` everywhere else. In that case, our approach breaks down, as we will have different fragments inside the pager and outside the pager, meaning that we will lose our data on a configuration change. Addressing this issue is covered in the next two sections.

Introducing ArrayPagerAdapter

The flexibility of ViewPager is governed, to a large extent, by the implementation of its PagerAdapter. Inflexible PagerAdapter implementations lead to inflexible uses of ViewPager.

Notably, the two concrete PagerAdapter implementations shipped in the Android Support package — FragmentPagerAdapter and FragmentStatePagerAdapter — have their limitations when it comes to things like:

- Using fragments created by those adapters in other fashions, such as in the columns-or-pager scenario from the previous section
- Handling dynamically-changing contents, such as adding pages, removing pages, or reordering pages

The ArrayPagerAdapter is an attempt to provide a more flexible PagerAdapter implementation that still feels a lot like FragmentPagerAdapter in terms of its use of fragments. It also bears some resemblance to the ArrayAdapter used for AdapterView implementations like ListView, giving rise to its name.

ArrayPagerAdapter is part of [the CWAC-Pager project](#) and is available for use in any Android project compatible with the Apache License 2.0.

We will review the implementation of ArrayPagerAdapter [later in this chapter](#). This section reviews how you can use ArrayPagerAdapter in your projects.

Adding the JAR

As the CWAC-Pager project does not need its own resources, it is packaged in the form of [a simple JAR file](#).

Eclipse users can download the JAR and add to their projects by conventional means (e.g., putting it in the `libs/` directory). Android Studio users can use the repositories and dependencies closures outlined on [the CWAC-Pager project home page](#):

```
repositories {  
    maven {  
        url "https://repo.commonsware.com.s3.amazonaws.com"  
    }  
}
```

```
dependencies {  
    compile 'com.commonware.cwac:pager:0.2.+'  
}
```

Choosing the Package

There are two implementations of `ArrayPagerAdapter`. One, in the `com.commonware.cwac.pager` package, is designed for use with native API Level 11 fragments. The other, in the `com.commonware.cwac.pager.v4` package, is designed for use with the Android Support package's backport of fragments. You will need to choose the right `ArrayPagerAdapter` for the type of fragments that you are using.

However, other than choosing suitable versions of classes for `Fragment`, etc., there is no real public API difference between the two. Hence, the documentation that follows is suitable for either implementation of `ArrayPagerAdapter`, so long as you use the one that matches the source of your fragment implementation.

Note that only `ArrayPagerAdapter` lives in the `com.commonware.cwac.pager.v4` package. The classes and interfaces that support `ArrayPagerAdapter`, like `PageDescriptor`, are implemented in `com.commonware.cwac.pager` and used by both implementations of `ArrayPagerAdapter`.

Creating PageDescriptors

You might think that `ArrayPagerAdapter` would take an array of pages, much like `ArrayAdapter` takes an array of models.

That's not how it works.

Instead, `ArrayPagerAdapter` wants an `ArrayList` of `PageDescriptor` objects. `PageDescriptor` is an interface, requiring you to supply implementations of two methods:

- `getTitle()`, which will be the title used for this page, for things like `PagerTabStrip` and the `ViewPagerIndicator` family of indicators
- `getFragmentTag()`, which is a unique tag for this page's fragment

Also, `PageDescriptor` extends the `Parcelable` interface, and so any implementation of `PageDescriptor` must also implement the methods and `CREATOR` required by `Parcelable`.

You are welcome to create your own `PageDescriptor` if you wish. However, there is a built-in implementation, `SimplePageDescriptor`, which probably meets your needs. You just pass the tag and title into the `SimplePageDescriptor` constructor, and it handles everything else, including the `Parcelable` implementation.

Creating and Populating the Adapter

To work with `ArrayPagerAdapter`, you start by creating an `ArrayList` of `PageDescriptor` objects, one for each page that is to be in your pager.

Then, create a subclass of `ArrayPagerAdapter`. `ArrayPagerAdapter` uses Java generics, requiring you to declare the type of fragment the adapter is serving up to the `ViewPager`. So, for example, if you have a `ViewPager` that will have each page be an `EditorFragment`, you would declare your custom `ArrayPagerAdapter` like so:

```
static class SamplePagerAdapter extends
```

If you will have pages come from a variety of fragments, just use the `Fragment` base class appropriate for your fragment source (e.g., `android.app.Fragment`).

Your custom `ArrayPagerAdapter` subclass will need to override (at minimum) one method: `createFragment()`. This method is responsible for instantiating fragments, as requested. You are passed the `PageDescriptor` for the fragment to be created — you simply create and return that fragment.

Hence, a custom `ArrayPagerAdapter` can be as simple as:

```
static class SamplePagerAdapter extends
    ArrayPagerAdapter<EditorFragment> {
    public SamplePagerAdapter(FragmentManager fragmentManager,
        ArrayList<PageDescriptor> descriptors) {
        super(fragmentManager, descriptors);
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
        return(EditorFragment.newInstance(desc.getTitle()));
    }
}
```

Then, you can create an instance of your custom `ArrayPagerAdapter` subclass as needed, supplying the constructor with a suitable `FragmentManager` and your `ArrayList` of `PageDescriptor` objects. Once attached to a `ViewPager`, `ArrayPagerAdapter` behaves much like a `FragmentPagerAdapter` by default.

There is another flavor of the `ArrayPagerAdapter` constructor, one that takes a `RetentionPolicy` as a parameter, as is described [later in this chapter](#).

Modifying the Contents

`ArrayPagerAdapter` offers several methods to allow you to change the contents of the `ViewPager`:

- `add()` takes a `PageDescriptor` and adds a new page at the end of the current roster of pages
- `insert()` takes a `PageDescriptor` and an insertion point and inserts a new page before the current page at that insertion point
- `remove()` takes a position and removes the page at that position
- `move()` takes an old and new position and moves the page from the old position to the new position (effectively combining a `remove()` from the old position and an `insert()` of the same page into the new position)

Other Useful Methods

`getExistingFragment()`, given a position, returns the existing fragment for that position in the `ViewPager`, if that fragment exists. Otherwise, it returns `null`.

`getCurrentFragment()` is like `getExistingFragment()`, but returns the fragment for the currently-viewed page in the `ViewPager`.

Columns for Large *Landscape*, Pages for the Rest

[Earlier in this chapter](#), we saw how you could conditionally use a `ViewPager` in some circumstances, but not others, such as using a `ViewPager` on smaller screens and a set of columns for the “pages” on larger screens. The limitation noted at that time was that you were stuck with one pattern for the lifetime of the activity, meaning that in any configuration change, you had to stick with the `ViewPager` or the columns that you started with.

However, while the columnar approach for larger screens works well in landscape, you may find the columns to be too tall and too skinny in portrait. Hence, a better solution would be to use columns only on larger screens in landscape, and to use the `ViewPager` everywhere else.

This is annoyingly tricky to do, assuming that you want to use the same fragments in each case, so you can arrange to hold onto the contents of their widgets.

Jake Wharton — author of ViewPagerIndicator and a seemingly infinite number of other Android open source libraries — raised this issue in [a Google+ post](#). He also posted [a sample solution](#), but one that was limited to only two fragments. Quoting Mr. Wharton:

Due the shenanigans performed by FragmentPagerAdapter we're forced to write a custom PagerAdapter which handles the instances our selves.

However, while two pages is reasonable, having some flexibility for a few more pages would be useful. So, let's see how we can accomplish the same aims, using ArrayPagerAdapter, in the [ViewPager/FlexColumns](#) sample project.

Fragments Inside and Outside the ViewPager

A fragment cannot be in two containers at once. The ViewPager, where we have one, is a different container than one of our columns, when we have one.

Hence, if the container is not changing during the operation of our activity — such as using a ViewPager in both portrait and landscape on smaller screens — we have no problem. But, if the container *is* changing — such as switching between columns and a ViewPager on larger screens — we need to take steps.

One option for those “steps”, of course, is to simply run a separate set of fragments. One set serves as pages of the ViewPager; the other serves as the columns. However, then we have to do work to synchronize those on configuration changes, as from the *user's* perspective, the fact that we happen to render things in pages or columns should not cause the user to lose data they entered in one form when switching to the other.

If we want to use the same fragment instances, then we can use normal configuration-change logic, like `onSaveInstanceState()`, to ensure that we hold onto user-entered data during the change. However, we have to arrange to move the fragment from one container to another. This will involve running a `FragmentTransaction` to `remove()` the fragment from the old container and `add()` it to its new container.

Making this more complicated is that the `PagerAdapter` should be handling the `add()` part, when the fragment is being put into a page, as that is how fragment-based `PagerAdapter` implementations like `FragmentPagerAdapter` work.

Adding to the fun is a matter of timing. By default, a `FragmentTransaction` is committed asynchronously. Attempting to `remove()` a fragment and `add()` the same fragment in the same transaction will fail, because the `add()` will complain that the fragment is already in another container, because the `remove()` will not have happened. Even doing the `remove()` and `add()` in separate normal transactions will not help. Instead, we need to ensure that the `remove()` has completed processing first, before we try to `add()`. To help with this, `FragmentManager` has a `executePendingTransactions()` method we can call, to have it complete its own processing on committed `FragmentTransactions` synchronously. Committing the `remove()` transaction and calling `executePendingTransactions()` before committing the `add()` transaction works.

The Revised PagerAdapter

With all that in mind, let's look at how this revised sample behaves. The core functionality is the same as with the earlier pager-or-columns sample, but now we will only use the columns on -large screen devices in -land orientation, by simply renaming `res/layout-large/` to `res/layout-large-land/`.

Our `PagerAdapter` is still called `SamplePagerAdapter`, but this time it is a `ArrayPagerAdapter` for our `EditorFragment` pages:

```
static class SamplePagerAdapter extends
    ArrayPagerAdapter<EditorFragment> {
    public SamplePagerAdapter(FragmentManager fragmentManager,
        ArrayList<PageDescriptor> descriptors) {
        super(fragmentManager, descriptors);
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
        return(createFragment(desc.getTitle()));
    }

    EditorFragment createFragment(String title) {
        return(EditorFragment.newInstance(title));
    }
}
```

The Revised Activity

The `onCreate()` method of the earlier example would see if we had a `ViewPager`, then either populate the columns or populate the `ViewPager` from our `PagerAdapter`. The `onCreate()` method of the new example does the same basic thing, except that it delegates most of the work for actually filling in the columns to a private `populateColumn()` method:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    if (pager == null) {
        if (getFragmentManager().findFragmentById(R.id.editor1) == null) {
            SamplePagerAdapter adapter=buildAdapter();
            FragmentTransaction ft=
                getFragmentManager().beginTransaction();

            populateColumn(getFragmentManager(), ft, adapter, 0,
                           R.id.editor1);
            populateColumn(getFragmentManager(), ft, adapter, 1,
                           R.id.editor2);
            populateColumn(getFragmentManager(), ft, adapter, 2,
                           R.id.editor3);
            ft.commit();
        }
    }
    else {
        SamplePagerAdapter adapter=buildAdapter();
        TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

        pager.setAdapter(adapter);
        tabs.setViewPager(pager);
    }
}
```

The `buildAdapter()` method changes a bit, to create our `ArrayPagerAdapter` subclass using an array of `SimplePageDescriptor` objects:

```
private SamplePagerAdapter buildAdapter() {
    ArrayList<PageDescriptor> pages=new ArrayList<PageDescriptor>();

    for (int i=0; i < 3; i++) {
        pages.add(new SimplePageDescriptor(buildTag(i), buildTitle(i)));
    }
}
```

MORE FUN WITH PAGERS

```
    return(new SamplePagerAdapter(getFragmentManager(), pages));
}
```

buildAdapter(), in turn, uses buildTag() and buildTitle() methods to retrieve the tag and title to use given a position:

```
private String buildTag(int position) {
    return("editor" + String.valueOf(position));
}

private String buildTitle(int position) {
    return(String.format(getString(R.string.hint), position + 1));
}
```

Finally, our populateColumn() method handles the work to fill in one of our columns, if we are in column mode:

```
private void populateColumn(FragmentManager fm,
                           FragmentTransaction ft,
                           SamplePagerAdapter adapter, int position,
                           int slot) {
    EditorFragment f=adapter.getExistingFragment(position);

    if (f == null) {
        f=adapter.createFragment(buildTitle(position));
    }
    else {
        fm.beginTransaction().remove(f).commit();
        fm.executePendingTransactions();
    }

    ft.add(slot, f, buildTag(position));
}
```

First, we ask our ArrayPagerAdapter to retrieve for us the existing fragment, if any, for this given column/page, based on its position. This may return null, if this is the first time we have run our app, in which case we ask our ArrayPagerAdapter to create the fragment for us (using the same logic that it would when functioning inside of a ViewPager, via createFragment()).

Otherwise, getExistingFragment() should return an existing EditorFragment instance, one probably formerly managed by a ViewPager. So, we create, commit, and execute a FragmentTransaction to remove() this fragment from its existing container.

The net is that, in either case, we have an EditorFragment, set up for use in this column, that does not have a current container. To add it to our column, we simply

call `add()` on the supplied `FragmentTransaction`, which is committed by our activity's `onCreate()` method. However, we use the three-parameter form of `add()`, which allows us not only to put the fragment into a container, but to assign it a tag as well. The tag is how `ArrayPagerAdapter` identifies the various fragments — by using the same tag, this fragment can be picked up by future instances of `ArrayPagerAdapter` in case of a configuration change.

You will notice that while we `remove()` the `EditorFragment` from the `ViewPager` and `add()` it to the column, we are not handling the reverse case, where we would `remove()` the fragment from the column and/or `add()` it to the `ViewPager`. That little bit of logic is supplied to us by `ArrayPagerAdapter`, as we will see when we examine the implementation of `ArrayPagerAdapter` [later in this chapter](#).

The resulting activity works exactly the same as the previous one, except that we use the `ViewPager` in portrait mode on larger-screen devices. Rotating a large-screen device will show our fragments moving between pages and columns, with their contents (whatever you type into the `EditorFragment` instances) being maintained via the built-in `onSaveInstanceState()` support for `EditText` widgets.

Adding, Removing, and Moving Pages

`ArrayPagerAdapter` also supports modifying the roster of pages at runtime: adding, inserting, removing, and moving pages. For example, a Twitter client might:

- Allow users to add pages for new monitored hashtags or search results
- Allow users to reorder the pages, putting more frequently-used ones towards the “front”, for easier access when the app starts from scratch
- Allow users to remove pages they do not use, such as ones they added earlier

To see how this works in practice, we can examine the demo project for the CWAC-Pager library. There are two versions of this demo, [one for the “v4” fragments](#) from the Android Support package, and [one for native API Level 11 fragments](#). Here, we will take a look at the latter project.

Reviewing the Core Functionality

This project is yet another rendition of our bunch-of-`EditorFragment`-pages sample that we have been examining for various ways of using `ViewPager`. This one sets up 10 pages at the start. However, it also inflates a menu resource to add four actions to the action bar: add, split, remove, and swap:

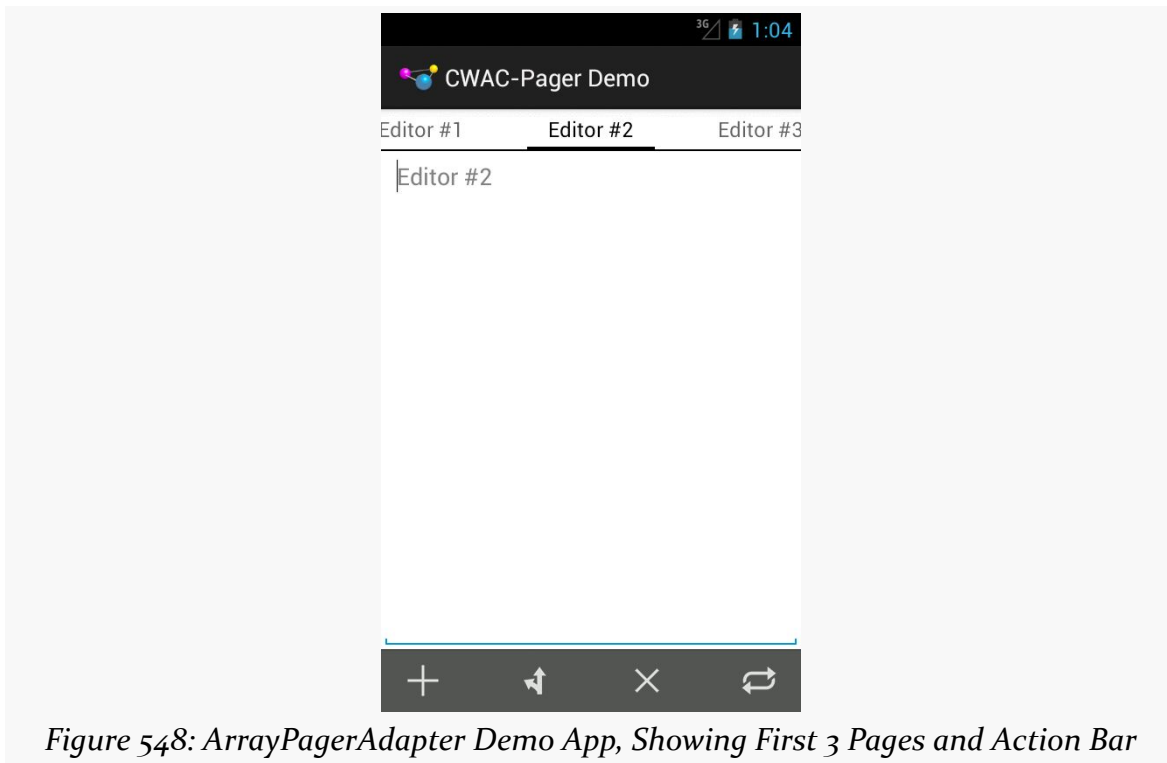

Figure 548: ArrayPagerAdapter Demo App, Showing First 3 Pages and Action Bar

`onOptionsItemSelected()` in our activity routes those four action items to three methods: `add()` (for add and split), `remove()`, and `swap()`.

Add and Split

Tapping the “add” action bar item will add a new page before the current one, with a title and hint based upon the number of existing pages (e.g., tapping “add” with 10 pages will add “Editor #11”):

Figure 549: ArrayPagerAdapter Demo App, Showing Result of “Add” From Second Page

Tapping the “split” action bar item will add a new page after the currently-selected one.

Since both of these involve adding pages, this sample consolidates their work into a single `add()` method, taking a boolean parameter to indicate if we are inserting a page before the current one or after:

```
private void add(boolean before) {
    int current=pager.getCurrentItem();
    SimplePageDescriptor desc=
        new SimplePageDescriptor(buildTag(adapter.getCount()),
                                buildTitle(adapter.getCount()));

    if (before) {
        adapter.insert(desc, current);
    }
    else {
        if (current < adapter.getCount() - 1) {
            adapter.insert(desc, current + 1);
        }
        else {
            adapter.add(desc);
        }
    }
}
```

```
}  
}
```

We call `getCurrentItem()` on the `ViewPager` to determine what the position index is of the currently-selected page. From there, we set up our `SimplePageDescriptor` for the page that we will be adding, giving it a title based upon our hint string resource and a tag based upon the number of pages. We then call `add()` (if we are on the last page and the user clicked on “split”) or `insert()` (for all other scenarios) to inject the new page. The `ArrayPagerAdapter` will be responsible for creating this page, just as it did for all previous pages.

Remove

Tapping “remove” will remove the currently-selected page, so long as we will still have at least one page remaining (just to keep the example simpler, so we do not have to worry about not having a “current page”).

This is handled by the `remove()` method on our activity, which turns around and calls `remove()` on the `ArrayPagerAdapter`:

```
private void remove() {  
    if (adapter.getCount() > 1) {  
        adapter.remove(pager.getCurrentItem());  
    }  
}
```

Swap

Tapping “swap” will swap the positions of the current page and the one immediately after it. The exception is if you are on the last page, in which case we will swap the current page with the one immediately before it:

```
private void swap() {  
    int current=pager.getCurrentItem();  
  
    if (current < adapter.getCount() - 1) {  
        adapter.move(current, current + 1);  
    }  
    else {  
        adapter.move(current, current - 1);  
    }  
}
```

This is handled by the `swap()` method on our activity, which calls `move()` on the `ArrayPagerAdapter`. `move()` takes the position of the page to be moved and the

position it should wind up in after the move, so we call `move(current, current + 1)` to swap the current page with the one after it or `move(current, current - 1)` to swap the current page with the one before it.

Inside `ArrayPagerAdapter`

`ArrayPagerAdapter` is a relatively large implementation of the `PagerAdapter` interface, and it helps to demonstrate some of the challenges faced when trying to create alternative fragment-based `PagerAdapter` implementations. Hence, this section will dive into portions of the innards of `ArrayPagerAdapter`, to explain how (and, sometimes, why) it does what it does.

Note that `ArrayPagerAdapter` will continue to expand over time, and so the copy in the master branch of the GitHub repo may be newer than the one profiled in this chapter. This chapter covers v0.1.1.

Also note that some of the code in `ArrayPagerAdapter` comes from `FragmentPagerAdapter` — as little of this code was altered as was practical, to help make it easier to integrate changes made to `FragmentPagerAdapter` over time.

Also, to simplify the discussion, this section will demonstrate the `ArrayPagerAdapter` set up for native API Level 11 fragments, in the `com.commonware.cwac.pager` package.

PageDescriptor and PageEntry

`ArrayPagerAdapter` works with two representations of pages: `PageDescriptor` and `PageEntry`.

`PageDescriptor` is a simple interface, supplying the unique tag (`getFragmentTag()`) and indicator title (`getTitle()`) to use for a page:

```
package com.commonware.cwac.pager;

import android.os.Parcelable;

public interface PageDescriptor extends Parcelable {
    String getFragmentTag();

    String getTitle();
}
```

MORE FUN WITH PAGERS

Developers can use SimplePageDescriptor as an implementation of PageDescriptor in most cases. SimplePageDescriptor just holds onto those two strings, plus handles the implementation of the Parcelable interface:

```
package com.commonware.cwac.pager;

import android.os.Parcel;
import android.os.Parcelable;

public class SimplePageDescriptor implements PageDescriptor {
    private String tag=null;
    private String title=null;

    public static final Parcelable.Creator<SimplePageDescriptor> CREATOR=
        new Parcelable.Creator<SimplePageDescriptor>() {
            public SimplePageDescriptor createFromParcel(Parcel in) {
                return new SimplePageDescriptor(in);
            }

            public SimplePageDescriptor[] newArray(int size) {
                return new SimplePageDescriptor[size];
            }
        };

    public SimplePageDescriptor(String tag, String title) {
        this.tag=tag;
        this.title=title;
    }

    private SimplePageDescriptor(Parcel in) {
        tag=in.readString();
        title=in.readString();
    }

    @Override
    public int describeContents() {
        return(0);
    }

    @Override
    public void writeToParcel(Parcel out, int flags) {
        out.writeString(tag);
        out.writeString(title);
    }

    public String getTitle() {
        return(title);
    }

    public String getFragmentTag() {
        return(tag);
    }
}
```

MORE FUN WITH PAGERS

However, the actual data model held by `ArrayPagerAdapter` is not the `PageDescriptor`, but rather a `PageEntry`, that holds onto its corresponding `PageDescriptor` *plus* a `Fragment.SavedState` object:

```
private static class PageEntry implements Parcelable {
    private PageDescriptor descriptor=null;
    private Fragment.SavedState state=null;

    public static final Parcelable.Creator<PageEntry> CREATOR=
        new Parcelable.Creator<PageEntry>() {
            public PageEntry createFromParcel(Parcel in) {
                return new PageEntry(in);
            }

            public PageEntry[] newArray(int size) {
                return new PageEntry[size];
            }
        };

    PageEntry(PageDescriptor descriptor) {
        this.descriptor=descriptor;
    }

    PageEntry(Parcel in) {
        this.descriptor=in.readParcelable(getClass().getClassLoader());
        this.state=in.readParcelable(getClass().getClassLoader());
    }

    PageDescriptor getDescriptor() {
        return(descriptor);
    }

    @Override
    public int describeContents() {
        return(0);
    }

    @Override
    public void writeToParcel(Parcel out, int flags) {
        out.writeParcelable(descriptor, 0);
        out.writeParcelable(state, 0);
    }
}
```

`Fragment.SavedState` is a `Parcelable` object we can request from a `Fragment` at any point, representing the saved state of that fragment, as obtained via `onSaveInstanceState()` and related code. At present, that `Fragment.SavedState` is unused, as will be explained in the next section.

RetentionStrategy

ArrayPagerAdapter also uses a RetentionStrategy, designed to abstract the logic for manipulating the fragments themselves as pages come and go within the ViewPager. RetentionStrategy is an interface, with methods to attach() a fragment to be in the pager and to detach() the fragment from the pager:

```
public interface RetentionStrategy {  
    void attach(Fragment fragment, FragmentTransaction currTransaction);  
  
    void detach(Fragment fragment, FragmentTransaction currTransaction);  
}
```

There is only one stock implementation of this strategy at this time, in the form of a static data member named KEEP. This strategy is designed to replicate the behavior of FragmentPagerAdapter, keeping all fragments around once created, and merely attach()-ing and detach()-ing them from the FragmentManager as dictated:

```
    }  
}  
  
public static final RetentionStrategy KEEP=new RetentionStrategy() {  
    @TargetApi(Build.VERSION_CODES.HONEYCOMB_MR2)  
    public void attach(Fragment fragment,  
        FragmentTransaction currTransaction) {  
        currTransaction.attach(fragment);  
    }  
  
    @TargetApi(Build.VERSION_CODES.HONEYCOMB_MR2)  
    public void detach(Fragment fragment,  
        FragmentTransaction currTransaction) {
```

A future implementation of ArrayPagerAdapter should include another strategy that behaves more like FragmentStatePagerAdapter, removing the fragments entirely and allowing them to be garbage collected, while using PageEntry to hold onto their Fragment.SavedState structures to repopulate them later on if the user swipes back to that page.

Class Declaration and Generics

ArrayPagerAdapter uses Java generics to allow developers to state what Fragment subclass the pages are. This is for use with convenience methods — getExistingFragment() and getCurrentFragment() — to help reduce the developer's need to downcast those Fragment instances to some subclass. If the pages in the ViewPager will all come from a single Fragment subclass, the developer

would use that class as the T in the declaration; otherwise, the developer would just use Fragment:

```
abstract public class ArrayPagerAdapter<T extends Fragment> extends
```

Constructors

ArrayPagerAdapter offers two constructors. The simpler two-parameter constructor, taking the FragmentManager and the desired pages as an ArrayList of PageDescriptor objects, just chains to the three-parameter constructor. That third parameter is an instance of a RetentionStrategy, allowing reusers of ArrayPagerAdapter to try their own hand at implementing such a strategy. null — the default strategy from the standpoint of the constructors — is replaced with the default KEEP strategy, and the PageDescriptor objects are wrapped in PageEntry objects as the actual data model (an entries ArrayList):

```
public ArrayPagerAdapter(FragmentManager fragmentManager,
                        List<PageDescriptor> descriptors,
                        RetentionStrategy retentionStrategy) {
    this.fm=fragmentManager;
    this.entries=new ArrayList<PageEntry>();

    for (PageDescriptor desc : descriptors) {
        validatePageDescriptor(desc);

        entries.add(new PageEntry(desc));
    }

    this.retentionStrategy=retentionStrategy;

    if (this.retentionStrategy == null) {
        this.retentionStrategy=KEEP;
    }
}
```

Core PagerAdapter Methods

All PagerAdapter implementations have some core methods that they must handle. When you create a subclass of FragmentPagerAdapter and FragmentStatePagerAdapter, you only need to worry about getCount() and getPageTitle(). However, if you are creating your own replacement for those fragment-based adapters, there are a few more standard PagerAdapter methods that you will need to override.

getCount()

`getCount()` is easy: all we need to do is return our desired number of pages. That is based on the number of `PageDescriptor` objects supplied to our adapter, which we wrapped into `PageEntry` objects and hold onto in entries:

```
@Override
public int getCount() {
    return(entries.size());
}
```

getPageTitle()

Similarly, `getPageTitle()` just needs to find the appropriate `PageDescriptor` and call `getTitle()` on it, to supply the title for a given page for use by an indicator like `PagerTabStrip`:

```
    }
}

@Override
```

instantiateItem() and destroyItem()

The `instantiateItem()` method on `PagerAdapter` is responsible for setting up the user interface for a given page (indicated by position) and adding those widgets to a `ViewGroup` supplied as a parameter. It returns an `Object` that represents a “handle” to the page that `ViewPager` will return to the `PagerAdapter` in future calls, such as to `destroyItem()`.

A `Fragment`-based `PagerAdapter` can use the `fragment` itself as the “handle”, and the `fragment`’s `onCreateView()` as the means of obtaining the UI to pour into the `ViewGroup`.

Hence, the `ArrayPagerAdapter` implementation of `instantiateItem()` does the following:

- First, starts a `FragmentTransaction`, if there is not one already in progress
- Then, tries to find an existing `Fragment` for this position, using a `getExistingFragment()` helper method (described later in this chapter)
- If an existing `fragment` exists, `instantiateItem()` uses the `RetentionPolicy` to re-attach the UI

- If an existing fragment does not exist, `instantiateItem()` calls the abstract `createFragment()` method, to allow the subclass to return the actual `Fragment` object given the `PageDescriptor`, then `add()` that fragment to the UI
- If the fragment is not already the current page, make sure that its action bar contributions are hidden via `setMenuVisibility()` and `setUserVisibleHint()`
- Return the fragment itself as the “handle”

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@Override
public Object instantiateItem(ViewGroup container, int position) {
    if (currTransaction == null) {
        currTransaction=fm.beginTransaction();
    }

    Fragment fragment=getExistingFragment(position);

    if (fragment != null) {
        retentionStrategy.attach(fragment, currTransaction);
    }
    else {
        fragment=createFragment(entries.get(position).getDescriptor());
        currTransaction.add(container.getId(), fragment,
                            getFragmentTag(position));
    }

    if (fragment != currPrimaryItem) {
        fragment.setMenuVisibility(false);

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
            fragment.setUserVisibleHint(false);
        }
    }

    return(fragment);
}
```

Conversely, `destroyItem()` is responsible for cleaning up anything from a page that the `PagerAdapter` thinks is no longer needed. The `destroyItem()` method on `ArrayPagerAdapter` starts a transaction if there is none, then delegates the actual work to the `RetentionStrategy`:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void destroyItem(ViewGroup container, int position,
                        Object object) {
    if (currTransaction == null) {
        currTransaction=fm.beginTransaction();
    }
}
```

```
retentionStrategy.detach((Fragment)object, currTransaction);
```

startUpdate() and finishUpdate()

The `startUpdate()` method will be called before any calls to `instantiateItem()` or `destroyItem()`, and so, if desired, we can do some initialization work there. In the case of `ArrayPagerAdapter`, all initialization is done lazily, and so `startUpdate()` is not needed. However, since `FragmentPagerAdapter` overrides `startUpdate()` with an empty implementation, we keep that for maximum fidelity with the stock implementation:

```
@Override
public void startUpdate(ViewGroup container) {
```

The `finishUpdate()` method will be called after any calls to `instantiateItem()` or `destroyItem()`, where we can do some cleanup work. `ArrayPagerAdapter` creates a `FragmentTransaction` as part of its work in `instantiateItem()` and `destroyItem()`, and so we need to commit that transaction in `finishUpdate()`. Once again, we reproduce the implementation from `FragmentPagerAdapter`, which uses `commitAllowingStateLoss()` (so we are not concerned with the timing of any state-saving being done at the activity level) and `executePendingTransactions()` (so all of the fragment work is done directly, rather than being posted to the end of the main application thread's work queue):

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void finishUpdate(ViewGroup container) {
    if (currTransaction != null) {
        currTransaction.commitAllowingStateLoss();
        currTransaction=null;
        fm.executePendingTransactions();
    }
}
```

setPrimaryItem()

`ViewPager` will call `setPrimaryItem()` on the `PagerAdapter` when a new page is being brought into view, based on gestures or other calls on `ViewPager` itself (e.g., `setCurrentItem()`). Some `PagerAdapter` implementations will have nothing much to do here. Fragment-based `PagerAdapter` implementations, though, need to ensure that the right fragment's action bar items are shown. Hence, `ArrayPagerAdapter` removes the action bar items from the previously-current page and adds the action bar items of the newly-current page:

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@SuppressWarnings("unchecked")
@Override
public void setPrimaryItem(ViewGroup container, int position,
                           Object object) {
    T fragment=(T)object;

    if (fragment != currPrimaryItem) {
        if (currPrimaryItem != null) {
            currPrimaryItem.setMenuVisibility(false);

            if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
            {
                currPrimaryItem.setUserVisibleHint(false);
            }
        }

        if (fragment != null) {
            fragment.setMenuVisibility(true);

            if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
            {
                fragment.setUserVisibleHint(true);
            }
        }

        currPrimaryItem=fragment;
    }
}
```

isViewFromObject()

`isViewFromObject()` helps `ViewPager` keep track of the UI for pages and how it maps back to a page's "handle". In our case, since the "handle" is a `Fragment`, we need to see if the supplied `View` is the `View` from the supplied `Fragment`:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public boolean isViewFromObject(View view, Object object) {
    return ((Fragment)object).getView() == view;
}
```

State Management

Our `PagerAdapter` is called with `saveState()` and `restoreState()` methods, to have us save the state of our data model and restore it, for configuration changes. `saveState()` returns a `Parcelable` which will form part of the state saved by the `ViewPager`, while `restoreState()` is handed back that `Parcelable` (or a copy).

The state of the *fragments* is handled by `FragmentManager`, no different than with any other fragments we might use in an activity. The mere fact that we happen to coordinate those fragments with a `PagerAdapter` does not change this. Hence, the “state” that we are dealing with in `saveState()` and `restoreState()` is solely the state of the `PagerAdapter` data model — in our case, the roster of pages.

To future-proof the implementation a bit, the state is represented as a `Bundle`, into which we can store other `Parcelable` objects. Since `Bundle` knows how to save an `ArrayList` of `Parcelable` objects, we can just call `putParcelableArrayList()` to save our `ArrayList` of `PageEntry` objects, restoring them in `restoreState()` via `getParcelableArrayList()`:

```
@Override
public Parcelable saveState() {
    Bundle state=new Bundle();

    state.putParcelableArrayList(KEY_DESCRIPTOR, entries);

    return(state);
}
```

Content Manipulation and Position Management

Perhaps the trickiest method on `PagerAdapter` that we have to worry about is innocuously named `getItemPosition()`. We are given the Object “handle” for a page, and we need to return the position of that page.

However, that’s not really what is going on here.

`getItemPosition()` is used when we call `notifyDataSetChanged()` to indicate a structural change in our data model, such as an added or removed page. `ViewPager` is looking for `getItemPosition()` to tell us the *new* position of pages for this `notifyDataSetChanged()` call. So, as we manipulate our pages, we need to track what is going on with page positions, so `getItemPosition()` can return the correct data.

The actual value returned by `getItemPosition()` is either:

- The actual numerical position of the page, from 0 to `getCount()-1`, if the page moved to another position (where we return the new position)
- `PagerAdapter.POSITION_UNCHANGED`, if the page has not moved
- `PagerAdapter.POSITION_NONE`, if the page no longer exists (e.g., was removed)

MORE FUN WITH PAGERS

ArrayPagerAdapter simply holds a HashMap (positionDelta), mapping our Fragment “handle” to the page to an Integer representing any change to the position of that page made by methods like add(). When getItemPosition() is called, we return the value for that page out of the HashMap, or POSITION_UNCHANGED if the page does not appear in the HashMap, indicating that the page has not been affected:

```
        return(entries.get(position).getDescriptor().getTitle());
    }

    @Override
    public int getItemPosition(Object o) {
        Integer result=positionDelta.get(o);

        if (result == null) {
            return(PagerAdapter.POSITION_UNCHANGED);
        }
    }
```

The add() method needs to add a new page to the data model, given the PageDescriptor. We clear() our positionDelta HashMap (as any previous changes should already have been picked up), add() a new PageEntry to our data model based on the supplied PageDescriptor, then call notifyDataSetChanged():

```
        return(result);
    }

    public void add(PageDescriptor desc) {
        validatePageDescriptor(desc);

        positionDelta.clear();
```

In this case, we did not need to add an entry to positionDelta, as ViewPager will use the natural position (based on where it appears in our data model) if we return POSITION_UNCHANGED.

The insert() method needs to do much the same thing, except rather than adding the new page to the end, we are adding it somewhere in the middle. This requires us to do everything we did in add(), plus add entries to the positionDelta map to indicate the new positions for every page that appears after the one being inserted:

```
        notifyDataSetChanged();
    }

    public void insert(PageDescriptor desc, int position) {
        validatePageDescriptor(desc);

        positionDelta.clear();
```

MORE FUN WITH PAGERS

```
for (int i=position; i < entries.size(); i++) {
    Fragment f=getExistingFragment(i);

    if (f != null) {
        positionDelta.put(f, i + 1);
    }
}
```

The `remove()` method needs to get rid of an existing page, given its position. Here, we are not given the “handle”, so we look it up via `getExistingFragment()`, then use that to put `POSITION_NONE` in the `positionDelta` map. We also update `positionDelta` to indicate the new positions for every page that appeared after the one being removed:

```
notifyDataSetChanged();
}

public void remove(int position) {
    positionDelta.clear();

    Fragment f=getExistingFragment(position);

    if (f != null) {
        positionDelta.put(f, PagerAdapter.POSITION_NONE);
    }

    for (int i=position + 1; i < entries.size(); i++) {
        f=getExistingFragment(i);

        if (f != null) {
            positionDelta.put(f, i - 1);
        }
    }
}
```

Finally, a `move()` is simply treated as a `remove()` from the old position and an `insert()` of the same page into the new position:

```
notifyDataSetChanged();
}

public void move(int oldPosition, int newPosition) {
    if (oldPosition != newPosition) {
        PageDescriptor desc=entries.get(oldPosition).getDescriptor();

        remove(oldPosition);
```

Miscellany

One headache with `FragmentPagerAdapter` and `FragmentStatePagerAdapter` is that they like to manage the fragments themselves, making it annoying for you to get at those fragments independently later on. Some developers have resorted to holding onto fragments in their own array, which works, but then you run into problems when it comes to garbage collection with `FragmentStatePagerAdapter`.

`ArrayPagerAdapter` provides two convenience methods to address this:

- `getExistingFragment()` simply returns the fragment for a given position, by finding the tag for that fragment from the `PageDescription`, then looking up the fragment by that tag. This way, if the fragment does not exist due to garbage collection, we can return null
- `getCurrentFragment()` returns the `currPrimaryItem` value, indicating the page that we are presently on

```
return (T)(fm.findFragmentByTag(getFragmentTag(position)));  
}
```

Both are set to return the generic type `T` that the developer uses when creating a subclass of `ArrayPagerAdapter`.

Focus Management and Accessibility

As developers, we are very used to creating apps that are designed to be navigated by touch, with users tapping on widgets and related windows to supply input.

However, not all Android devices have touchscreens, and not all Android users use touchscreens.

Internationalization (i18n) and localization (L10n) give you opportunities to expand your user base to audiences beyond your initial set, based on language. Similarly, you can expand your user base by offering support for non-touchscreen input and output. Long-term, the largest user base of these features may be those with televisions augmented by Android, whether via Android TV, OUYA consoles, or whatever. Short-term, the largest user base of these features may be those for whom touchscreens are rarely a great option, such as the blind. Supporting those with unusual requirements for input and output is called *accessibility* (any), and represents a powerful way for you to help your app distinguish itself from competitors.

In this chapter, we will first examine how to better handle focus management, and then segue into examining what else, beyond supporting keyboard-based input, can be done in the area of accessibility.

Prerequisites

Understanding this chapter requires that you have read the core chapters and are familiar with the concept of widgets having focus for user input.

Prepping for Testing

To test focus management, you will need an environment that supports “arrow key” navigation. Here, “arrow key” also includes things like D-pads or trackballs – basically, anything that navigates by key events instead of by touch events.

Examples include:

- The Android emulator, with the `DPad` support hardware property set to yes
- Phones that have actual D-pads, trackballs, arrow keys, or the like
- Television-based Android environments, such as Android TV or the OUYA console
- Devices that have dedicated keyboard accessories, such as the keyboard “slice” available for the ASUS Transformer series of tablets
- A standard Android device accessed via a Bluetooth keyboard, gamepad, or similar sort of pointing device

Hence, even if the emulator will be insufficient for your needs, you should be able to set up a hardware test environment relatively inexpensively. Most modern Android devices support Bluetooth keyboards, and such keyboards frequently can be obtained at low relative cost.

For accessibility beyond merely focus control, you will certainly want to enable TalkBack, via the Accessibility area of the Settings app. This will cause Android to verbally announce what is on the screen, by means of its text-to-speech engine.

On Android 4.0 and higher devices, enabling Talkback will also optionally enable “Explore by Touch”. This allows users to tap on items (e.g., icons in a `GridView`) to have them read aloud via TalkBack, with a double-tap to actually perform what ordinarily would require a single-tap without “Explore by Touch”.

Controlling the Focus

Android tries its best to have intelligent focus management “out of the box”, without developer involvement. Many times, what it offers is sufficient for your needs. Other times, though, the decisions Android makes are inappropriate:

- Trying to navigate in a certain direction (e.g., right) moves focus to a widget that is not logically what should have the focus

- Focus has other side effects, like showing the soft keyboard on an EditText widget, that is not desirable

Hence, if you feel that you need to take more control over how focus management is handled, you have many means of doing so, covered in this section.

Establishing Focus

In order for a widget to get the focus, it has to be focusable.

You might think that the above sentence was just a chance for the author to be witty. It was... a bit. But there are actually two types of “focusable” when it comes to Android apps:

- Is it focusable when somebody is using a pointing device or the keyboard?
- Is it focusable in touch mode?

There are three major patterns for the default state of a widget:

1. Some are initially focusable in both cases (e.g., EditText)
2. Some are focusable in non-touch mode but are not focusable in touch mode (e.g., Button)
3. Some are not focusable in either mode (e.g., TextView)

So, when a Button is not focusable in touch mode, that means that while the button will take the focus when the user navigates to it (e.g., via keys), the button will *not* take the focus when the user simply taps on it.

You can control the focus semantics of a given widget in four ways:

- You can use `android:focusable` and `android:focusableInTouchMode` in a layout
- You can use `setFocusable()` and `setFocusableInTouchMode()` in Java

We will see examples of these shortly.

Requesting (or Abandoning) Focus

By default, the focus will be granted to the first focusable widget in the activity, starting from the upper left. Often times, this is a fine solution.

If you want to have some other widget get the focus (assuming that the widget is focusable, per the section above), you have two choices:

1. Call `requestFocus()` on the widget in question
2. You can give the widget's layout element a child element, named `<requestFocus />`, to stipulate that this widget should be the one to get the focus

Note that this is a child element, not an attribute, as you might ordinarily expect.

For example, let's look at the [Focus/Sampler](#) sample project, which we will use to illustrate various focus-related topics.

Our main activity, creatively named `MainActivity`, loads a layout named `request_focus.xml`, and demonstrates the `<requestFocus />` element:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/a_button"/>

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">

        <requestFocus/>
    </EditText>

</LinearLayout>
```

Here, we have three widgets in a horizontal `LinearLayout`: a `Button`, and two `EditText` widgets. The second `EditText` widget has the `<requestFocus />` child element, and so it gets the focus when we display our launcher activity:

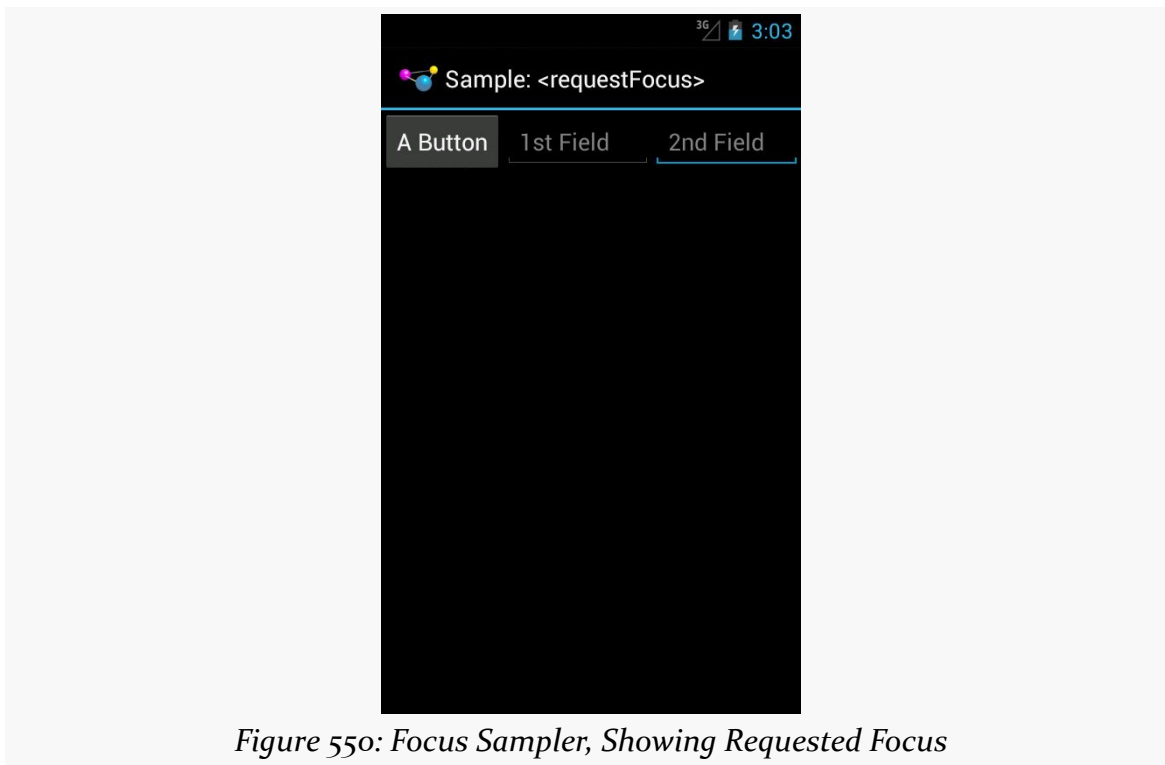

Figure 550: Focus Sampler, Showing Requested Focus

If we had skipped the `<requestFocus />` element, the focus would have wound up on the first `EditText`... assuming that we are working in touch mode. If the activity had been launched via the pointing device or keyboard, then the `Button` would have the focus, because the `Button` is focusable in non-touch mode by default.

Calling `requestFocus()` from Java code gets a bit trickier. There are a few flavors of the `requestFocus()` method on `View`, of which two will be the most popular:

- An ordinary zero-argument `requestFocus()`
- A one-argument `requestFocus()`, with the argument being the direction in which the focus should theoretically be coming from

You might look at the description of the second flavor and decide that the zero-argument `requestFocus()` looks a lot easier. And, sometimes it will work. However, sometimes it will not, as is the case with our second activity, `RequestFocusActivity`.

In this activity, our layout (focusable_button) is a bit different:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">
    </EditText>

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:focusableInTouchMode="true"
        android:text="@string/a_button"/>

</LinearLayout>
```

Here, we put the Button last instead of first. We have no `<requestFocus />` element anywhere, which would put the default focus on the first EditText widget. And, our Button has `android:focusableInTouchMode="true"`, so it will be focusable regardless of whether we are in touch mode or not.

In `onCreate()` of our activity, we use the one-parameter version of `requestFocus()` to give the Button the focus:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.focusable_button);
    initActionBar();

    button=findViewById(R.id.button1);
    button.requestFocus(View.FOCUS_RIGHT);
}
```

```
button.setOnClickListener(this);  
}
```

If there were only the one `EditText` before the `Button`, the zero-argument `requestFocus()` works. However, with a widget between the default focus and our `Button`, the zero-argument `requestFocus()` does not work, but using `requestFocus(View.FOCUS_RIGHT)` does. This tells Android that we want the focus, and it should be as if the user is moving to the right from where the focus currently lies.

All of our activities inherit from a `BaseActivity` that manages our action bar, with an overflow menu to get to the samples and the app icon to get to the original activity.

So, if you run the app and choose “Request Focus” from the overflow menu, you will see:

Figure 551: Focus Sampler, Showing Manually-Requested Focus

We also wire up the `Button` to the activity for click events, and in `onClick()`, we call `clearFocus()` to abandon the focus:

```
@Override
public void onClick(View v) {
    button.clearFocus();
}
```

What `clearFocus()` will do is return to the original default focus for this activity, in our case the first `EditText`:

Figure 552: Focus Sampler, After Clearing the Focus

Focus Ordering

Beyond manually placing the focus on a widget (or manually clearing that focus), you can also override the focus order that Android determines automatically. While Android's decisions usually are OK, they may not be optimal.

A widget can use `android:nextFocus...` attributes in the layout file to indicate the widget that should get control on a focus change in the direction indicated by the ... part. So, `android:nextFocusDown`, applied to Widget A, indicates which widget should receive the focus if, when the focus is on Widget A, the user “moves down” (e.g., presses a DOWN key, presses the down direction on a D-pad). The same logic holds true for the other three directions (`android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`).

For example, the `res/layout/table.xml` resource in the FocusSampler project is based on the `TableLayout` sample from early in this book, with a bit more focus control:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">

    <TableRow>

        <TextView android:text="@string/url"/>

        <EditText
            android:id="@+id/entry"
            android:layout_span="3"
            android:inputType="text"
            android:nextFocusRight="@+id/ok"/>
    </TableRow>

    <TableRow>

        <Button
            android:id="@+id/cancel"
            android:layout_column="2"
            android:text="@string/cancel"/>

        <Button
            android:id="@+id/ok"
            android:text="@string/ok"/>
    </TableRow>
</TableLayout>
```

In the original `TableLayout` sample, by default, pressing either `RIGHT` or `DOWN` while the `EditText` has the focus will move the focus to the “Cancel” button. This certainly works. However, it does mean that there is no single-key means of moving from the `EditText` to the “OK” button, and it would be nice to offer that, so those using the pointing device or keyboard can quickly move to either button.

This is a matter of overriding the default focus-change behavior of the `EditText` widget. In our case, we use `android:nextFocusRight="@+id/ok"` to indicate that the “OK” button should get the focus if the user presses `RIGHT` from the `EditText`. This gives `RIGHT` and `DOWN` different behavior, to reach both buttons.

Scrolling and Focusing Do Not Mix

Let's suppose that you have a UI design with a fixed bar of widgets at the top (e.g., action bar), a `ListView` dominating the activity, and a panel of widgets at the bottom (e.g., button panel, or a split action bar), such as this book's original action bar demo:

Figure 553: A Split Action Bar

This is a common UI pattern, much to the detriment of those using pointing devices or keyboards for navigation. In order to get to the bottom panel of widgets, they will have to scroll through the entire list first, because scrolling trumps focus changes. So while this is easy to navigate via a touchscreen, it is a major problem to navigate for those not using a touchscreen.

Similarly, if the user has scrolled down the list, and now wishes to get to the top action bar, the user would have to scroll all the way to the top of the list first.

Workarounds include:

- Overriding focus control such that left and right navigation from the list moves you to the action bar or button panel (e.g., left moves you to the action bar, right moves you to the button panel)
- In a television setup, having the “action bar” be vertical down the left, and the button panel be vertical down the right, so you automatically get the left/right navigation to move between these “zones”
- Eliminating the button panel, moving those items instead to the action bar, or perhaps an [action mode](#) (a.k.a., contextual action bar) if the buttons are only relevant if the user checks one or more items in the list
- Offer a hotkey, separate from navigation, that repositions the focus (e.g., CTRL-A to jump to the action bar), if you believe that users will read your documentation to discover this key combination

In the specific case of a split action bar, Android handles this for you: moving focus to the right from the top action bar moves you to the bottom action bar directly, whereas moving focus down from the top action bar moves you into your main content view (e.g., the `ListView` in the action bar sample image shown above).

Accessibility and Focus

People suffering from impaired vision, including the blind, have had to rely heavily on proper keyboard navigation for their use of Android apps, at least prior to Android 4.0 and “Explore by Touch”. These users need focus to be sensible, so that they can find their way through your app, with TalkBack supplying prompts for what has the focus. Having widgets that are unreachable in practice will eliminate features from your app for this audience, simply because they cannot get to them.

“Explore by Touch” provides accessibility assistance without reliance upon proper focus. However:

- “Explore by Touch” is new to Android 4.0, and many visually-impaired users will be using older devices, particularly through 2013
- “Explore by Touch” is less reliable than keyboard-based navigation, insofar as users have to remember specific screen locations (and get to them without seeing those locations), rather than simply memorizing certain key combinations
- “Explore by Touch”, by requiring additional taps (e.g., double-tap to tap a Button), may cause some challenges when the UI itself requires additional taps (e.g., a double-tap on a widget to perform an action — is this now a triple-tap in “Explore by Touch” mode?)

- “Explore by Touch” is mostly for the visually impaired, and does not help others that might benefit from key-based navigation (e.g., people with limited motor control)

So, even though “Explore by Touch” will help people use apps that cannot be navigated purely through key events, the better you can support keyboards, the better off your users will be.

Accessibility Beyond Focus

While getting focus management correct goes a long way towards making your application easier to use, it is not the only thing to consider for making your application truly accessible by all possible users. This section covers a number of other things that you should consider as part of your accessibility initiatives.

Content Descriptions

For TalkBack to work, it needs to have something useful to read aloud to the user. By default, for most widgets, all it can say is the type of widget that has the focus (e.g., “a checkbox”). That does not help the TalkBack-reliant user very much.

Please consider adding `android:contentDescription` attributes to most of your widgets, pointing to a string resource that briefly describes the widget (e.g., “the Enabled checkbox”). This will be used in place of the basic type of widget by TalkBack.

Classes that inherit from `TextView` will use the text caption of the widget by default, so your `Button` widgets may not need `android:contentDescription` if their captions will make sense to TalkBack users.

However, with an `EditText`, since the text will be what the user types in, the text is not indicative of the widget itself. Android will first use your `android:hint` value, if available, falling back to `android:contentDescription` if `android:hint` is not supplied.

Also, bear in mind that if the widget changes purpose, you need to change your `android:contentDescription` to match. For example, suppose you have a media player app with an `ImageButton` that you toggle between “play” and “pause” modes by changing its image. When you change the image, you also need to change the

`android:contentDescription` as well, lest sighted users think the button will now “pause” while blind users think that the button will now “play”.

Custom Widgets and Accessibility Events

The engine behind TalkBack is an accessibility service. Android ships with some, like TalkBack, and third parties can create other such services.

Stock Android widgets generate relevant accessibility events to feed data into these accessibility services. That is how `android:contentDescription` gets used, for example — on a focus change, stock Android widgets will announce the widget that just received the focus.

If you are creating custom widgets, you may need to raise your own accessibility events. This is particularly true for custom widgets that draw to the Canvas and process raw touch events (rather than custom widgets that merely aggregate existing widgets).

The Android developer documentation provides [instructions for when and how to supply these sorts of events](#).

Announcing Events

Sometimes, your app will change something about its visual state in ways that do not get picked up very well by any traditional accessibility events. For example, you might use `GestureDetector` to handle some defined library of gestures and change state in your app. Those state changes may have visual impacts, but `GestureDetector` will not know what those are and therefore cannot supply any sort of accessibility event about them.

To help with this, API Level 16 added `announceForAccessibility()` as a method on `View`. Just pass it a string and that will be sent out as an “announcement” style of `AccessibilityEvent`. Your code leveraging `GestureDetector`, for example, could use this to explain the results of having applied the gesture.

Font Selection and Size

For users with limited vision, being able to change the font size is a big benefit. Android 4.0 finally allows this, via the Settings app, so users can choose between

small, normal, large, and huge font sizes. Any place where text is rendered and is measured in sp will adapt.

The key, of course, is the sp part.

sp is perhaps the most confusing of the available dimension units in Android. px is obvious, and dp (or dip) is understandable once you recognize the impacts of screen density. Similarly, in, mm, and pt are fairly simple, at least once you remember that pt is 1/72nd of an inch.

If the user has the font scale set to “normal”, sp equates to dp, so a dimension of 30sp and 30dp will be the same size. However, values in dp do not change based on font scale; values in sp will increase or decrease in physical size based upon the user’s changes to the font scale.

We can see how this works in the [Accessibility/FontScale](#) sample project.

In our layout (res/layout/activity_main.xml), we have six pieces of text: two each (regular and bold) measured at 30px, 30dp, and 30sp:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/LinearLayout1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="10dp"
        android:text="@string/normal_30px"
        android:textSize="30px"
        tools:context=".MainActivity"/>

    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/bold_30px"
        android:textSize="30px"
        android:textStyle="bold"
        tools:context=".MainActivity"/>

    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="10dp"
        android:text="@string/normal_30dp"
```

```
        android:textSize="30dp"
        tools:context=".MainActivity"/>

        <TextView
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/bold_30dp"
            android:textSize="30dp"
            android:textStyle="bold"
            tools:context=".MainActivity"/>

        <TextView
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:layout_marginTop="10dp"
            android:text="@string/normal_30sp"
            android:textSize="30sp"
            tools:context=".MainActivity"/>

        <TextView
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/bold_30sp"
            android:textSize="30sp"
            android:textStyle="bold"
            tools:context=".MainActivity"/>
    </LinearLayout>
```

You will be able to see the differences between 30px and 30dp on any Android OS release, simply by running the app on devices with different densities. To see the changes between 30dp and 30sp, you will need to run the app on an Android 4.0+ device or emulator and change the font scale from the Settings app (typically in the Display section).

Here is what the text looks like with a normal font scale:

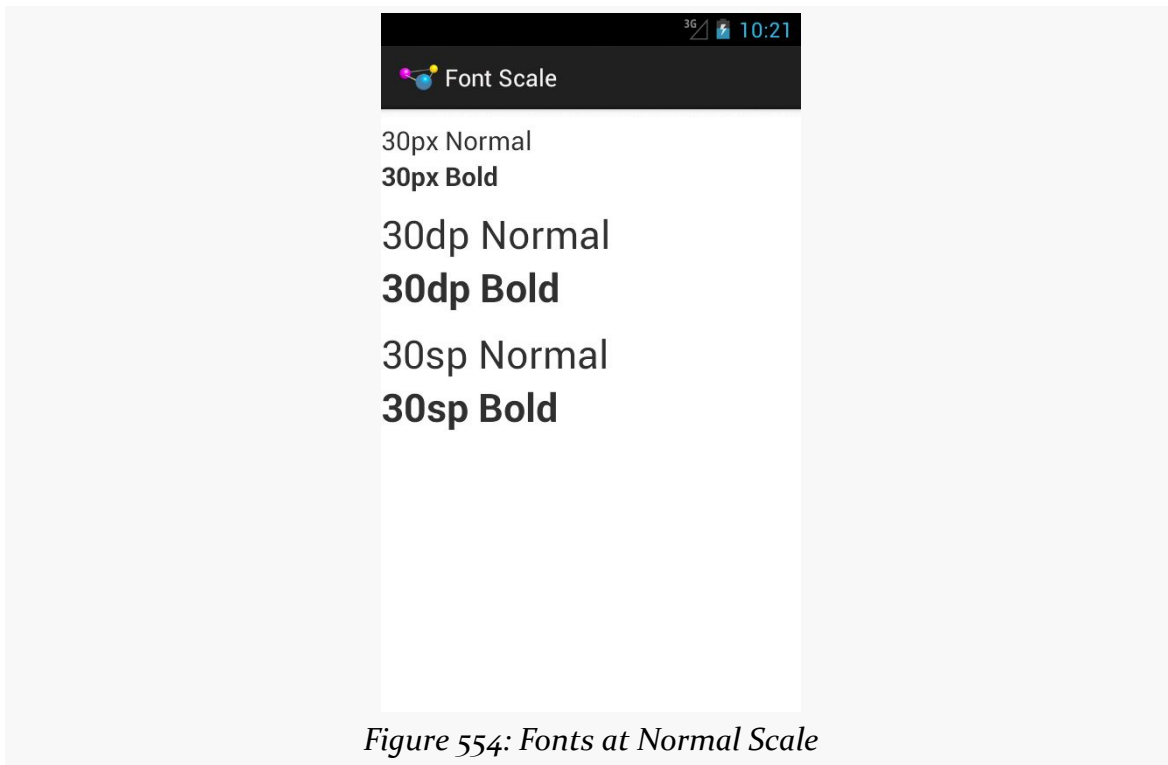

Figure 554: Fonts at Normal Scale

As you can see, 30dp and 30sp are equivalent.

If we raise the font scale to “large”, the 30sp text grows to match:

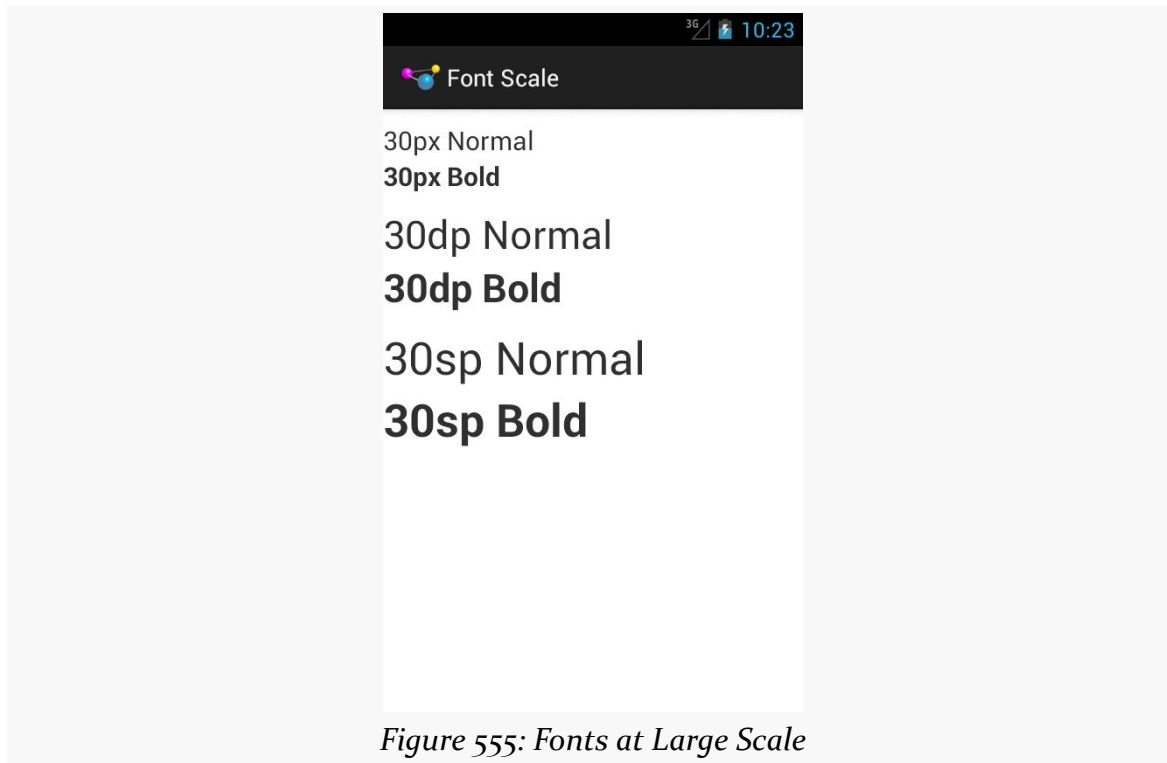

Figure 555: Fonts at Large Scale

Moving to “huge” scale increases the 30sp text size further:

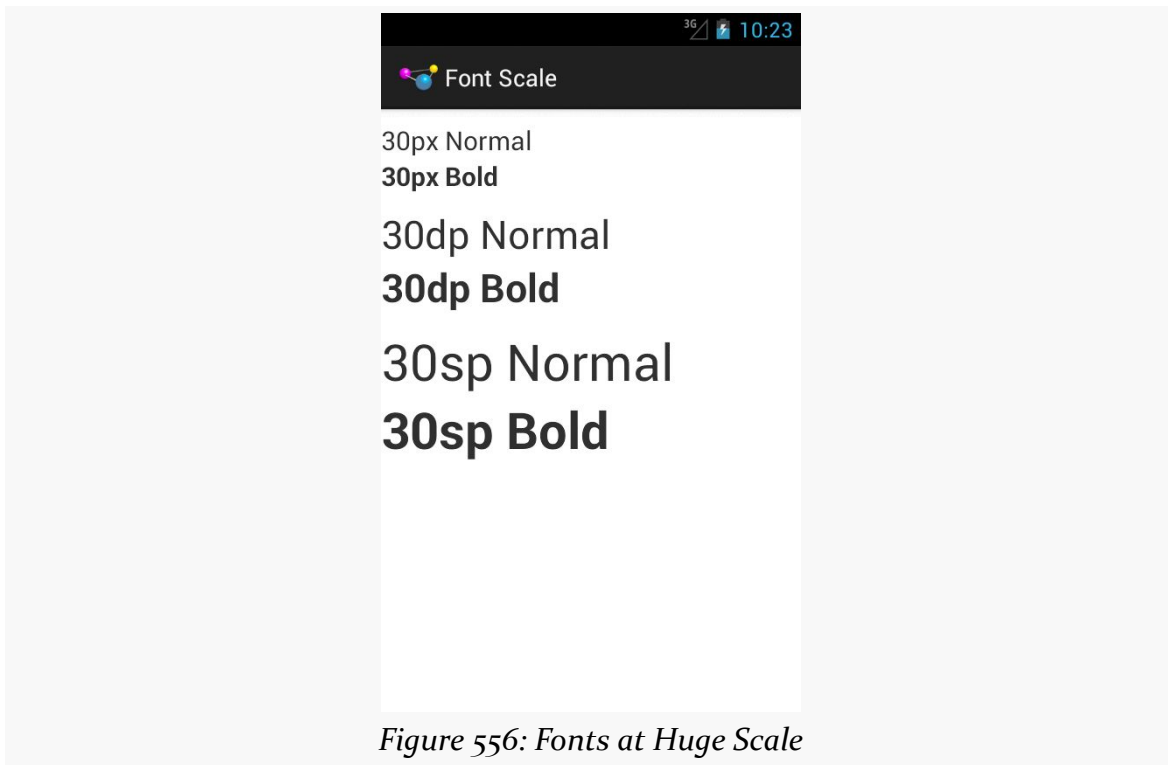

Figure 556: Fonts at Huge Scale

In the other direction, some users may elect to drop their font size to “small”, with a corresponding impact on the 30sp text:

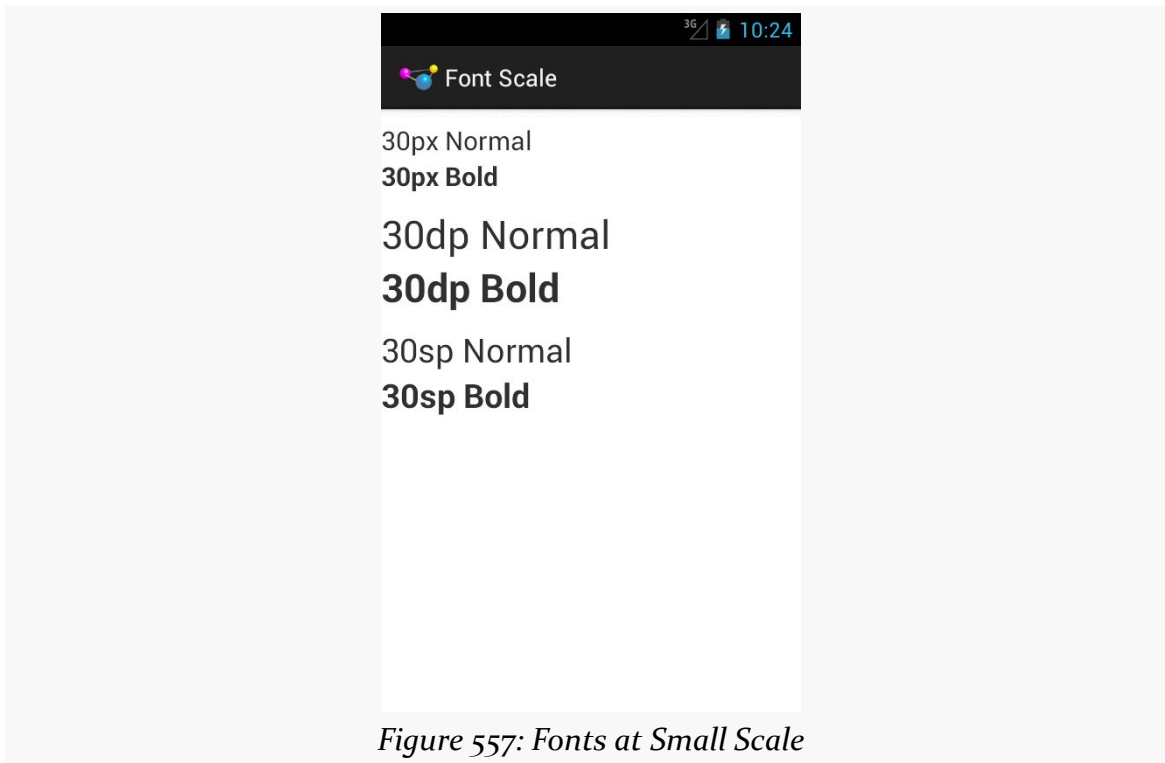

Figure 557: Fonts at Small Scale

As a developer, your initial reaction may be to run away from `sp`, because you do not control it. However, just as Web developers should deal with changing font scale in Web browsers, Android developers should deal with changing font scale in Android apps. Remember: the user is changing the font scale because the *user* feels that the revised scale is easier for them to use. Blocking such changes in your app, by avoiding `sp`, will not be met with love and adoration from your user base.

Also, bear in mind that changes to the font scale represent a configuration change. If your app is in memory at the time the user goes into Settings and changes the scale, if the user returns to your app, each activity that comes to the foreground will undergo the configuration change, just as if the user had rotated the screen or put the device into a car dock or something.

Widget Size

Users with ordinary sight already have trouble with tiny widgets, as they are difficult to tap upon.

Users trying to use the Explore by Touch facility added in Android 4.1 have it worse, as they cannot even see (or see well) the tiny target you are expecting them to tap

upon. They need to be able to reliably find your widget based on its relative position on the screen, and their ability to do so will be tied, in part, on widget size.

The [Android design guidelines recommend](#) 7–10mm per side minimum sizes for tappable widgets. In particular, they recommend 48dp per side, which results in a size of about 9mm per side.

You also need to consider how closely packed your widgets are. The closer the tap targets lie, the more likely it is that all users — whether using Explore by Touch or not — will accidentally tap on the wrong thing. Google recommends 8dp or more of margin between widgets. Also note that the key is *margins*, as while increasing padding might visually separate the widgets, the padding is included as part of the widget from the standpoint of touch events. While padding may help users with ordinary sight, margins provide similar help while also being of better benefit to those using Explore by Touch.

Gestures and Taps

If you employ gestures, be careful when employing the same gesture in different spots for different roles, particularly within the same activity.

For example, you might use a horizontal swipe to the right to switch pages in a `ViewPager` in some places and remove items from a `ListView` in others. While there may be visual cues to help explain this to users with ordinary sight, it may be far less obvious what is going on for TalkBack users. This is even more true if you are somehow combining these things (e.g., the `ListView` in question is in a page of the `ViewPager`).

Also, be a bit careful as you “go outside the box” for tap events. You might decide that a double-tap, or a two-finger tap, has special meaning on some widgets. Make sure that this still works when users use Explore by Touch, considering that the first tap will be “consumed” by Explore by Touch to announce the widget being tapped upon.

Enhanced Keyboard Support

All else being equal, users seeking accessibility assistance will tend to use keyboards when available. For users with limited (or no) sight, tactile keyboards are simply easier to use than touchscreens. For users with limited motor control, external devices that interface as keyboards may allow them to use devices that otherwise they could not.

Of course, plenty of users will use keyboards outside of accessibility as well. For example, devices like the ASUS Transformer series form perfectly good “netbook”-style devices when paired with their keyboards.

Hence, consider adding hotkey support, to assist in the navigation of your app. Some hotkeys may be automatically handled (e.g., Ctrl-C for copy in an `EditText`). However, in other cases you may wish to add those yourself (e.g., Ctrl-C for “copy” with respect to a checklist and its selected rows, in addition to a “copy” action mode item).

API Level 11 adds `KeyEvent` support for methods like `isCtrlPressed()` to detect meta keys used in combination with regular keys.

Audio and Haptics

Of course, another way to make your app more accessible is to provide alternative modes of input and output, beyond the visual.

Audio is popular in this regard:

- Using tones or clicks to reinforce input choices
- Integrating your own text-to-speech to augment TalkBack
- Integrating speech recognition for simple commands

However, bear in mind that deaf users will be unable to hear your audio. You are better served using both auditory and visual output, not just one or the other.

In some cases, haptics can be helpful for input feedback, by using the `Vibrator` system service to power the vibration motor. While most users will be able to feel vibrations, the limitation here is whether the device is capable of vibrating:

- Some tablets lack a vibration motor
- Television-based Android environment may or may not have some sort of vibration output (e.g., remote controls probably will not, but game controllers might)
- Devices not held in one’s hand, such as those in a dock, will make haptics less noticeable

So, audio and vibration can help augment visual input and output, though they should not be considered complete replacements except in rare occurrences.

Color and Color Blindness

[Approximately 8% of men \(and 0.5% of women\)](#) in the world are colorblind, meaning that they cannot distinguish certain close colors:

...It's not that colorblind people (in most cases) are incapable or perceiving "green," instead they merely distinguish fewer shades of green than you do. So where you see three similar shades of green, a colorblind user might only see one shade of green.

(from ["Tips for Designing for Colorblind Users"](#))

Hence, relying solely on colors to distinguish different items, particularly when required for user input, is not a wise move.

Make sure that there is something more to distinguish two pieces of your UI than purely a shift in color, such as:

- Labels or icons
- Textures (e.g., solid vs. striped)
- Borders (e.g., drop shadow)

Accessibility Beyond Impairment

Accessibility is often tied to impaired users: ones with limited (or no) sight, ones with limited (or no) hearing, ones with limited motor control, etc.

In reality, accessibility is for *situations* where users may have limitations. For example, a user who might not normally think of himself as "impaired" has limited sight, hearing, and motor control when those facilities are already in use, such as while driving.

Hence, offering features that help with accessibility can benefit *all* your users, not just ones you think of as "impaired". For example:

- Offer a UI mode with an eye towards use in low-visibility situations that can either be manually invoked (e.g., via a preference) or automatically invoked (e.g., via a car dock)
- Offer voice input (commands) and output (text-to-speech) — iOS's Siri is not just for the blind, after all

- Offer hotkeys, not only to help those requiring a keyboard as their primary mode of input (e.g., blind users minimizing touchscreen use), but to help those who opt into using it for input (e.g., using a keyboard with an Android tablet in lieu of a traditional notebook or netbook)

Miscellaneous UI Tricks

While well-written GUI frameworks are better organized than [XKCD's take on home organization](#), there are always a handful of tidbits that do, indeed, get categorized as “miscellaneous”.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having an appreciation for XKCD is welcome, but optional.

Full-Screen and Lights-Out Modes

Full-screen mode, in Android parlance, means removing any system-supplied “bars” from the screen: title bar, action bar, status bar, system bar, navigation bar, etc. You might use this for games, video players, digital book readers, or other places where the time spent in an activity is great enough to warrant removing some of the normal accouterments to free up space for whatever the activity itself is doing.

Lights-out mode, in Android parlance, is where you take the system bar or navigation bar and dim the widgets inside of them, such that the bar is still usable, but is less visually distracting. This is a new concept added in Android 3.0 and has no direct analogue in Android 1.x or 2.x.

Android 1.x/2.x

To have an activity be in full-screen mode, you have two choices:

1. Having the activity use a theme of `Theme.NoTitleBar.Fullscreen` (or some custom theme that inherits from `Theme.NoTitleBar.Fullscreen`)
2. Execute the following statements in `onCreate()` of your activity *before* calling `setContentView()`:

```
requestWindowFeature(Window.FEATURE_NO_TITLE);
getWindow().setFlags(WindowManager.LayoutParams.FLAG_FULLSCREEN,
    WindowManager.LayoutParams.FLAG_FULLSCREEN);
```

The first statement removes the title bar or action bar. The second statement indicates that you want the activity to run in full-screen mode, hiding the status bar.

Android 4.0+

Things got significantly more messy once we started adding in the system bar (and, later, the navigation bar as the replacement for the system bar). Since these bars provide the user access to HOME, BACK, etc., it is usually important for them to be available. Android's behavior, therefore, varies in how you ask for something to happen and what then happens, based upon whether the device is a phone or a tablet.

The [Activities/FullScreen](#) sample project tries to enumerate some of the possibilities. On an Android 4.0 device, we have three `RadioButtons`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <RadioButton
            android:id="@+id/normal"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="@string/display_normal"/>

        <RadioButton
            android:id="@+id/lowProfile"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_low_profile"/>
```

MISCELLANEOUS UI TRICKS

```
<RadioButton
    android:id="@+id/hideNav"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/display_hide_navigation"/>
</RadioGroup>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

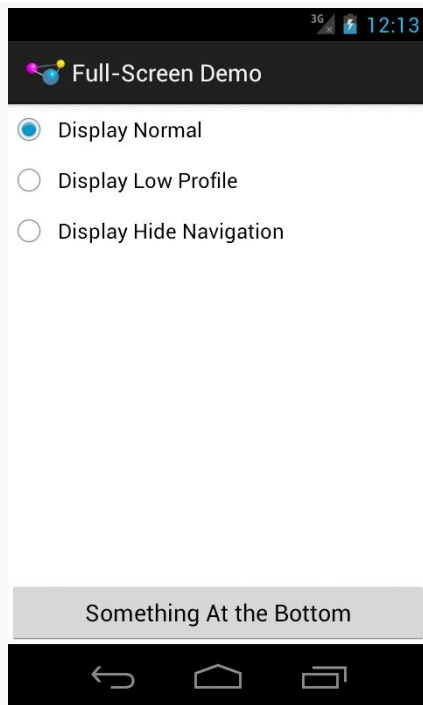

Figure 558: Sample UI, As Initially Launched on Android 4.0

...while on Android 4.1 or higher, we have another two possibilities:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
```

```
android:layout_height="wrap_content">

<RadioButton
    android:id="@+id/normal"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:checked="true"
    android:text="@string/display_normal"/>

<RadioButton
    android:id="@+id/lowProfile"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/display_low_profile"/>

<RadioButton
    android:id="@+id/hideNav"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/display_hide_navigation"/>

<RadioButton
    android:id="@+id/hideStatusBar"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/hide_status_bar"/>

<RadioButton
    android:id="@+id/fullScreen"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/display_full_screen"/>
</RadioGroup>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

MISCELLANEOUS UI TRICKS

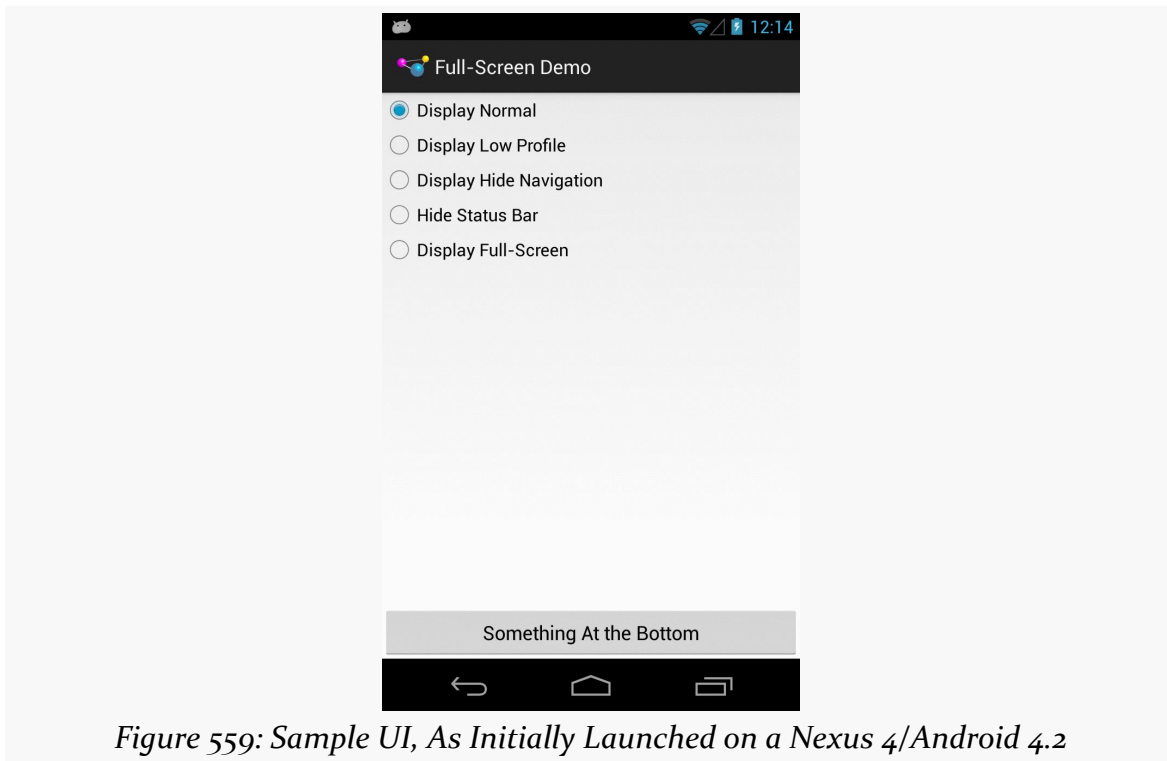

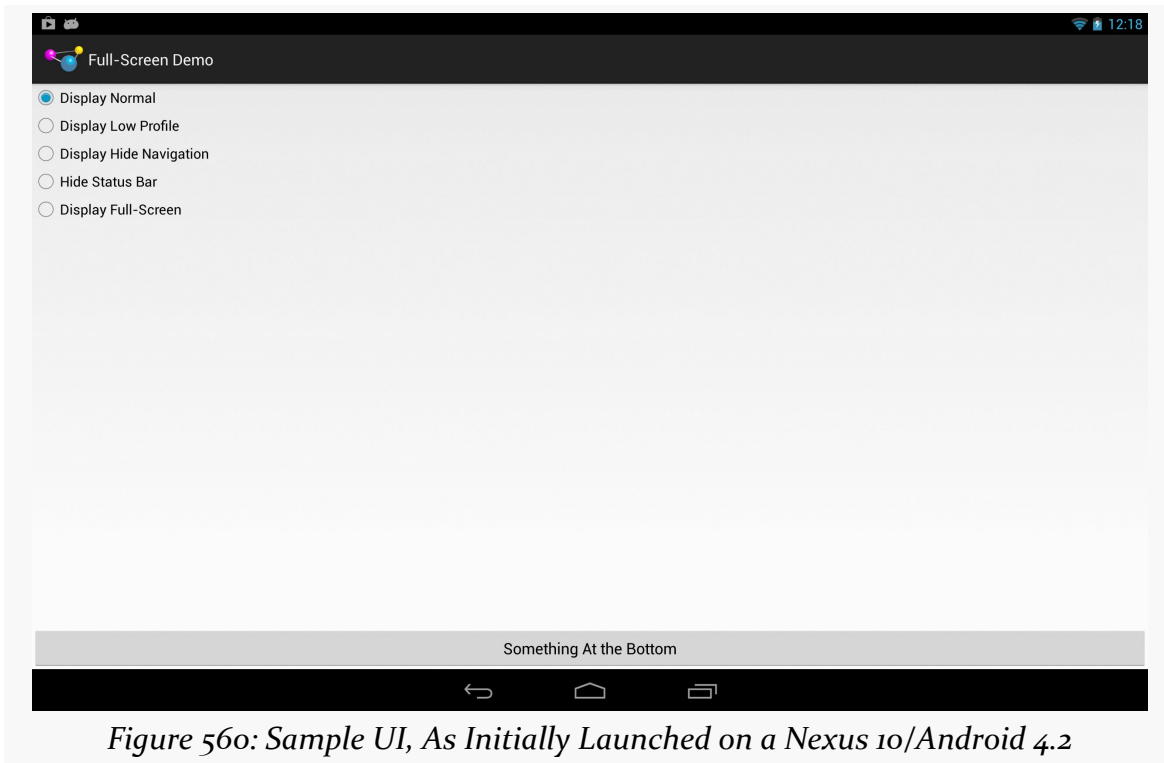

Figure 559: Sample UI, As Initially Launched on a Nexus 4/Android 4.2

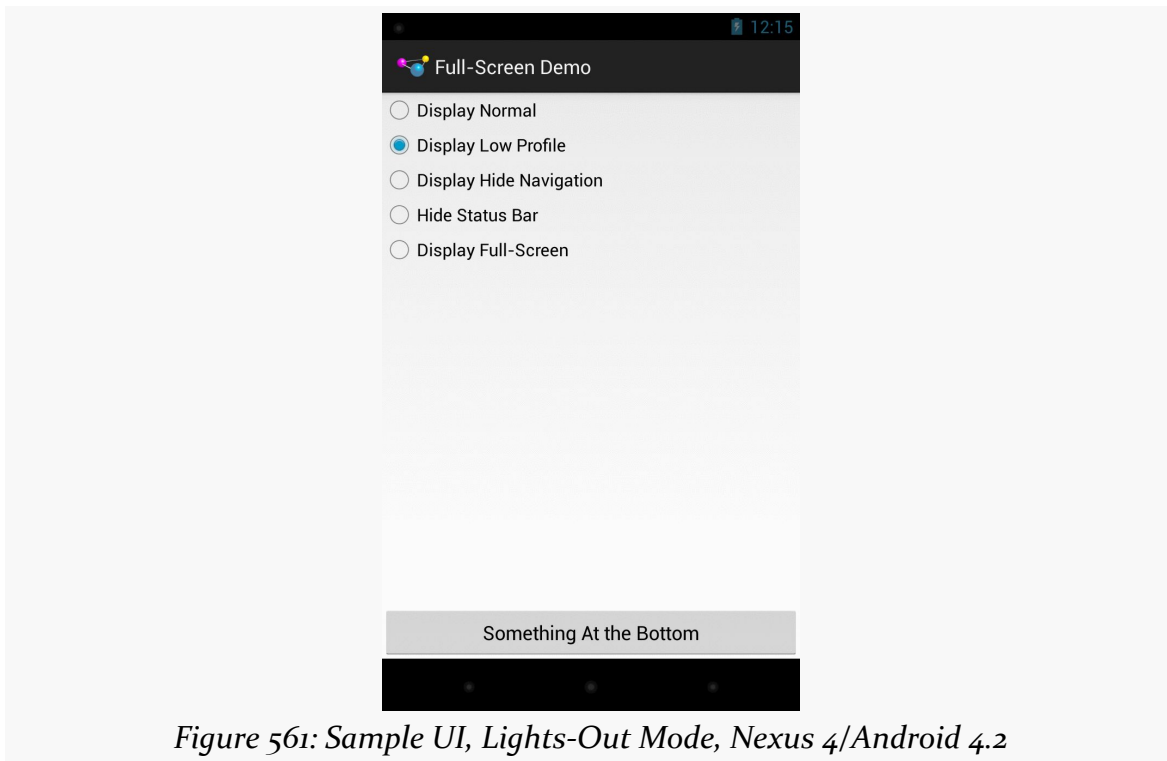

Controlling the full-screen and lights-out modes is managed via a call to `setSystemUiVisibility()`, a method on `View`. You pass in a value made up of an OR'd (`|`) set of flags indicating what you want the visibility to be, with the default being normal operation. Hence, in the screenshot above, you see a Nexus 4 in normal mode. Here is the same UI on a Nexus 10 in normal mode:

MISCELLANEOUS UI TRICKS

Lights-out, or low-profile mode, is achieved by calling `setSystemUiVisibility()` with the `View.SYSTEM_UI_FLAG_LOW_PROFILE` flag. This will dim the navigation or system bar, so the bar is there and the buttons are still active, but that they are less visually intrusive:

MISCELLANEOUS UI TRICKS

MISCELLANEOUS UI TRICKS

You can temporarily hide the navigation bar (or system bar) by passing `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION` to `setSystemUiVisibility()`. The bar will disappear, until the user touches the UI, in which case the bar reappears:

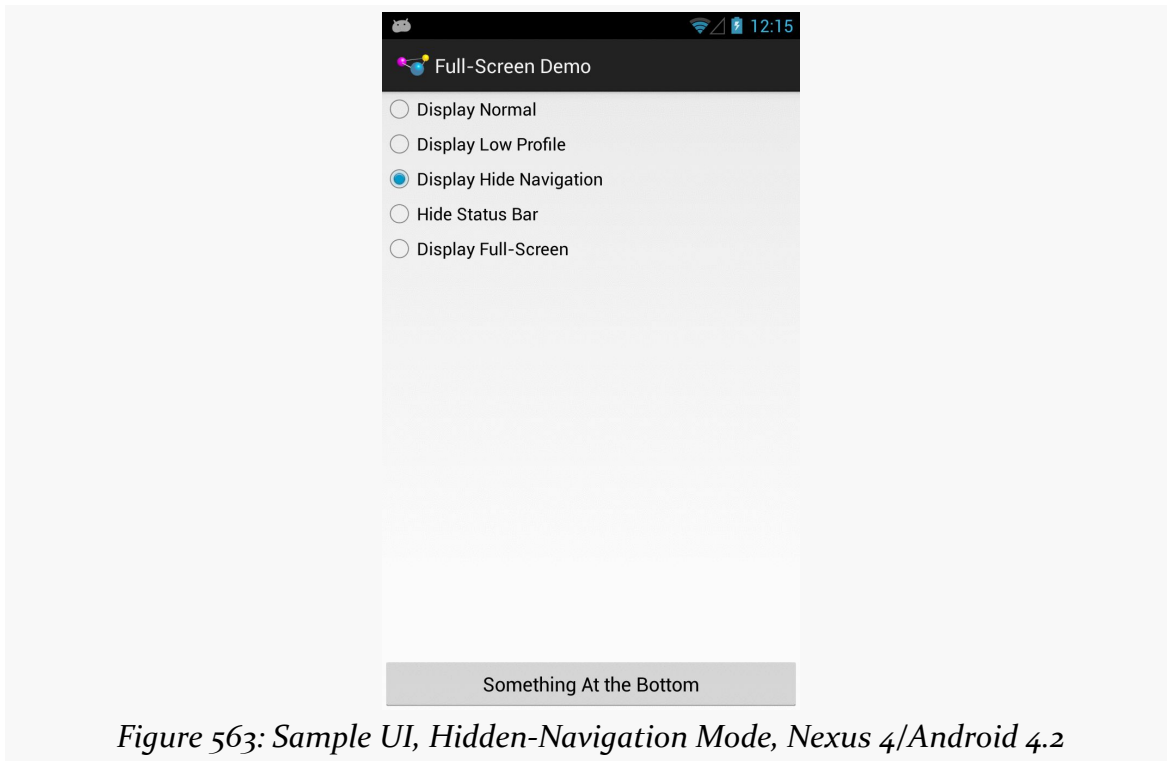

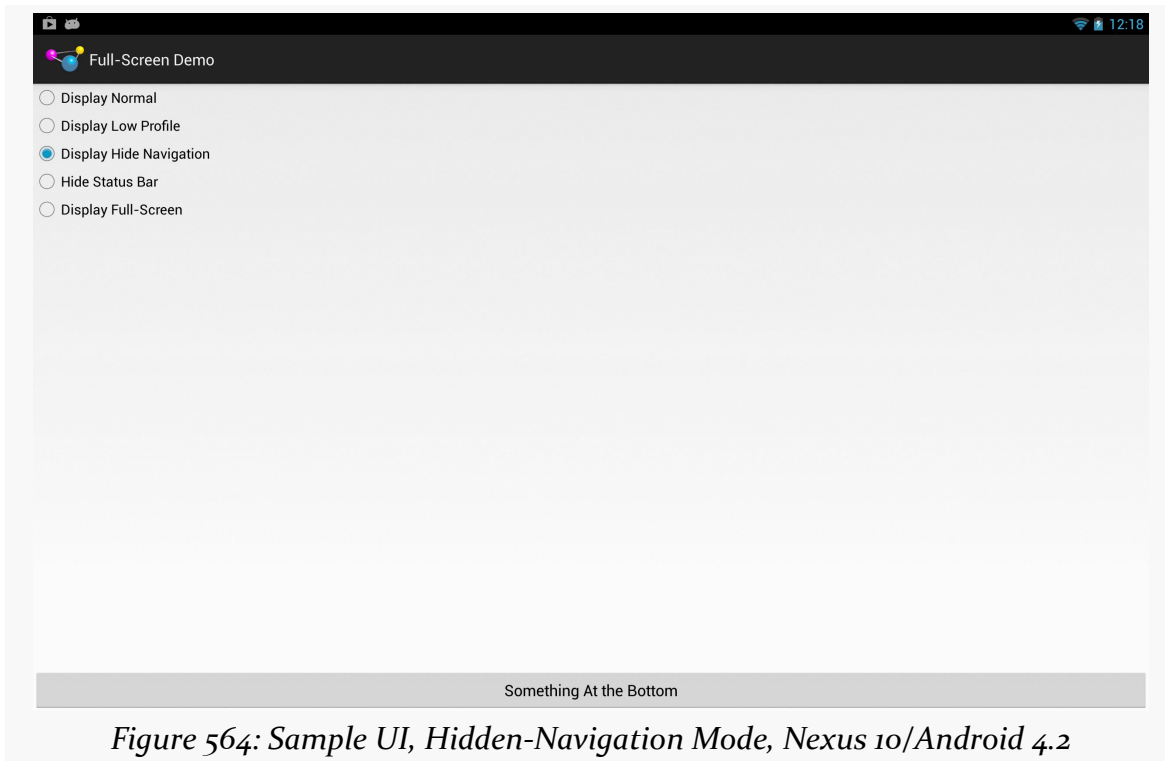

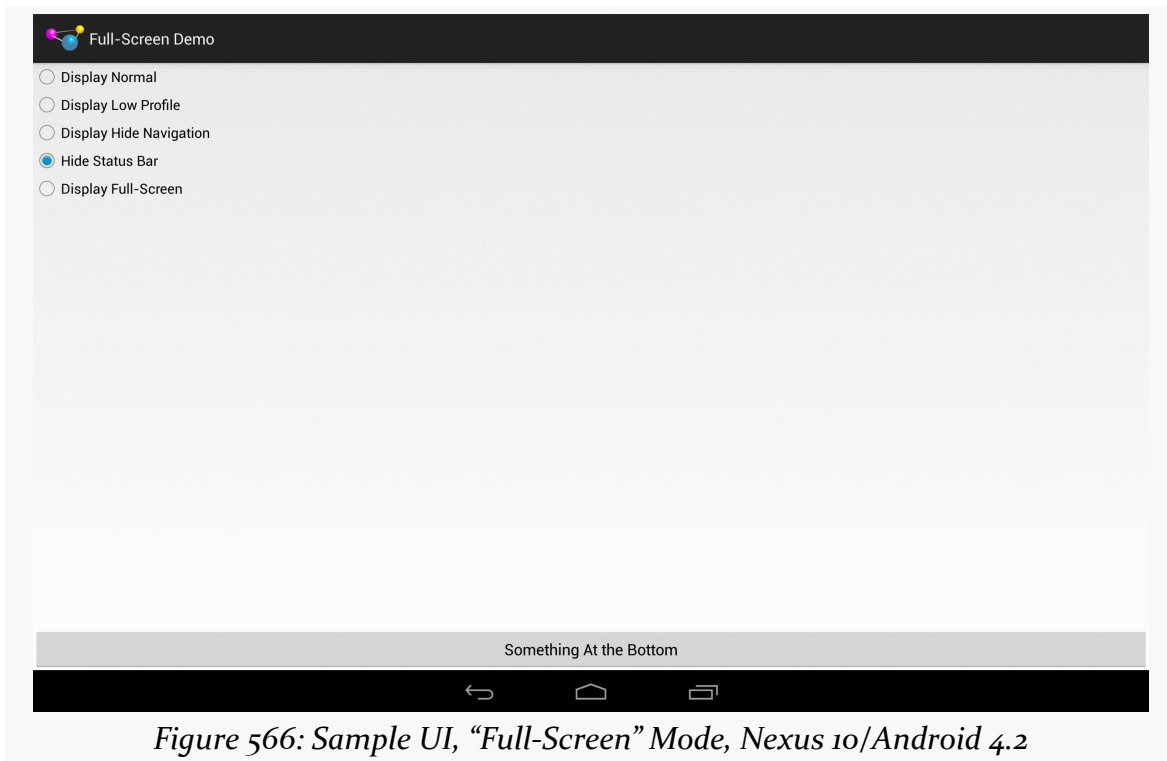

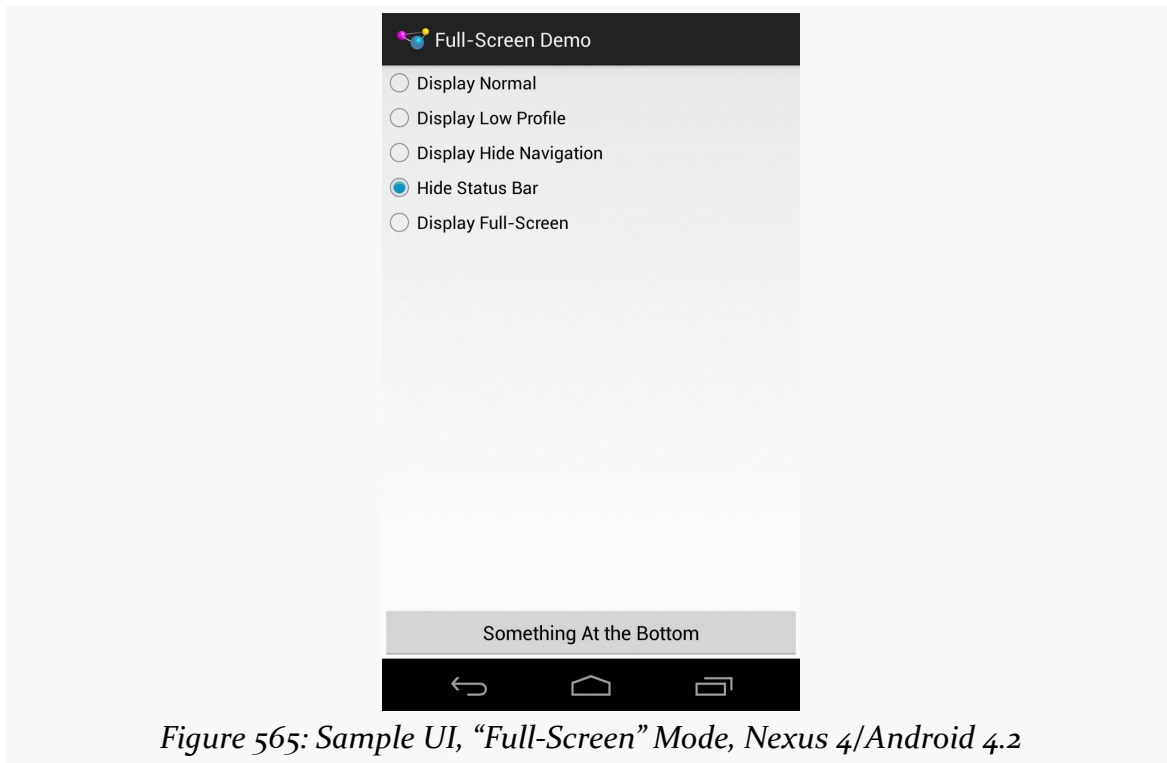

Figure 563: Sample UI, Hidden-Navigation Mode, Nexus 4/Android 4.2

MISCELLANEOUS UI TRICKS

Similarly, you can hide the status bar by passing `View.SYSTEM_UI_FLAG_FULLSCREEN` to `setSystemUiVisibility()`. However, despite this flag's name, it does not affect the navigation or system bar:

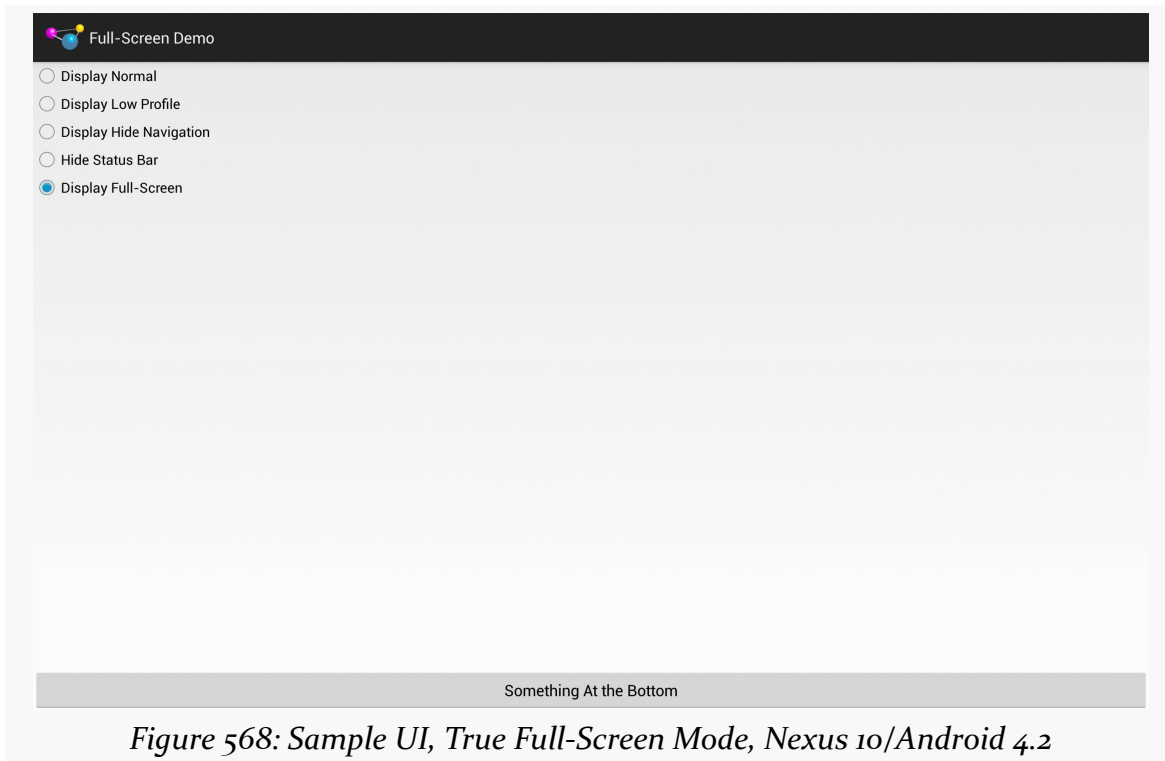

MISCELLANEOUS UI TRICKS

MISCELLANEOUS UI TRICKS

Hence, to hide both the status bar and the navigation or system bar, you need to pass both flags (`View.SYSTEM_UI_FLAG_FULLSCREEN` | `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION`):

Note that showing and hiding the ActionBar is also possible, via calls to `show()` and `hide()`, respectively.

Offering a Delayed Timeout

Android makes it easy for activities to keep the screen on while the activity is in the foreground, by means of `android:keepScreenOn` and `setKeepScreenOn()`.

However, these are very blunt instruments, and too many developers simply ask to keep the screen on constantly, even when that is not needed and can cause excessive battery drain. That is because it is very easy to *always* keep the screen on.

Say, for example, you are playing a game. Keeping the screen on while the game is being played is probably a good thing, particularly if the game does not require constant interaction with the screen. However, if you press the in-game pause button, the game might keep the screen on while the game is paused. This might lead you to press pause, put down your tablet (expecting it to fall asleep in a normal period of time), and then have the tablet keep going and going and going... until the battery runs dead.

Whether you use `setKeepScreenOn()` or directly use a `WakeLock`, it is useful to think of three tiers of user interaction.

The first tier is when your app is doing its “one big thing”: playing the game, playing the video, displaying the digital book, etc. If you expect that there will be periods of time when the user is actively engaged with your app, but is not interacting with the screen, keep the screen on.

The second tier is when your app is delivering something to the user that *probably* would get used without interaction in the short term, but not indefinitely. For example, a game might reasonably expect that 15 seconds could be too short to have the screen time out, but if the user has not done anything in 5–10 minutes, most likely they are not in front of the game. Similarly, a digital book reader should not try to keep the screen on for an hour without user interaction.

The third tier is when your app is doing anything other than the main content, where normal device behavior should resume. A video player might keep the screen on while the video is playing, but if the video ends, normal behavior should resume. After all, if the person who had been watching the video fell asleep, they will not be in position to press a power button.

The first and third tiers are fairly easy from a programming standpoint. Just `acquire()` and `release()` the `WakeLock`, or toggle `setKeepScreenOn()` between `true` and `false`.

The second tier — where you are willing to have a screen timeout, just not too quickly — requires you to add a bit more smarts to your app. A simple, low-overhead way of addressing this is to have a `postDelayed()` loop, to get a `Runnable` control every 5–10 seconds. Each time the user interacts with your app, update a `lastInteraction` timestamp. The `Runnable` compares `lastInteraction` with the current time, and if it exceeds some threshold, release the `WakeLock` or call `setKeepScreenOn(false)`. When the user interacts again, though, you will need to re-acquire the `WakeLock` or call `setKeepScreenOn(true)`. Basically, you have your own inactivity timing mechanism to control when you are inhibiting normal inactivity behavior or not.

To see the second tier in action, take a look at the [MiscUI/DelayedTimeout](#) sample project.

The UI is a simple button. We want to keep the screen awake while the user is using the button, but let it fall asleep after a period of inactivity that we control. To

MISCELLANEOUS UI TRICKS

accomplish this, we will use a `postDelayed()` loop, to get control every 15 seconds to see if there has been user activity:

```
package com.commonware.android.timeout;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;

public class MainActivity extends Activity implements Runnable {
    private static int TIMEOUT_POLL_PERIOD=15000; // 15 seconds
    private static int TIMEOUT_PERIOD=300000; // 5 minutes
    private View content=null;
    private long lastActivity=SystemClock uptimeMillis();

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        content=findViewById(android.R.id.content);
        content.setKeepScreenOn(true);
        run();
    }

    @Override
    public void onDestroy() {
        content.removeCallbacks(this);

        super.onDestroy();
    }

    @Override
    public void run() {
        if ((SystemClock.uptimeMillis() - lastActivity) > TIMEOUT_PERIOD) {
            content.setKeepScreenOn(false);
        }

        content.postDelayed(this, TIMEOUT_POLL_PERIOD);
    }

    public void onClick(View v) {
        lastActivity=SystemClock.uptimeMillis();
    }
}
```

In `onCreate()`, we call `setKeepScreenOn(true)` to keep the screen on, regardless of what the user's default timeout is. Then, we call the `run()` method from our `Runnable` interface (implemented on the activity itself). `run()` sees if 5 minutes has elapsed since the last bit of user activity (initially set to be the time the activity

launches). If 5 minutes has elapsed, we revert to normal screen-timeout behavior with `setKeepScreenOn(false)`. We also schedule ourselves, as a `Runnable`, to get control again in 15 seconds, to see if 5 minutes has elapsed since the last-seen activity. Our button's `onClick()` method simply updates the last-seen timestamp, and `onDestroy()` cleans up our `postDelayed()` loop by calling `removeCallbacks()` to stop invoking our `Runnable`.

The net is that the device's screen will remain on for 5 minutes since the last time the user taps the button, even if the user's default screen timeout is set to shorter than 5 minutes. Yet, at the same time, we do not keep the screen on *forever*, causing unnecessary battery drain.

Note that to test this, you will probably need to unplug your USB cable after installing the app on the device (since many developers have it set up to keep the screen on while plugged in). Also, you will need to set your device's screen timeout to be under 5 minutes, if it is not set that way already.

This is a primitive implementation, missing lots of stuff that you would want in production code (e.g., it never calls `setKeepScreenOn(true)` if we flipped it to `false` but *then* tap the button). And the complexity of determining if the user interacted with the screen will be tied to the complexity of your UI.

That being said, by having a more intelligent use of `WakeLock` and `setKeepScreenOn()`, you can deliver value to the user while not accidentally causing excessive battery drain. Users do not always remember to press the power button, so you need to make sure that just because the user made a mistake, that you do not make it worse.

Event Buses Alternatives

[Earlier in the book](#), we covered the concept of an event bus as a way of communicating between portions of our app, focusing on one event bus implementation: greenrobot's EventBus. Later, in the chapter on broadcast Intents, we [briefly covered LocalBroadcastManager](#).

However, those are not the only event buses available for Android, and others may fit your needs better. In this chapter, we will explore these and other event bus implementations, to compare and contrast.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapters on [basic event bus usage](#), [broadcast Intents](#), [AlarmManager and the scheduled service pattern](#), and [Notifications](#).

A Brief Note About the Sample Apps

The sample apps in this chapter are generally designed to run forever.

It is unlikely that you really want them to run forever, though. Hence, please uninstall each sample after experimenting with it, particularly if you are testing on hardware, such as your personal phone. Your battery will appreciate it.

Standard Intents as Event Bus

You can think of the standard Intent and <intent-filter> system as a three-channel event bus:

- One channel is used for starting activities
- One channel is used for starting or binding to services
- One channel is used for more ad-hoc “broadcast” events

The component starting an activity does not need to communicate directly with code for that activity — in fact, often times this is impossible, as they are separate apps running in separate processes. Instead, the component starting an activity sends an event indicating the particular operation to be performed (e.g., view this URL), and Android and the user determine which of candidate consumers is the one to process that event.

However, broadcast Intents are a closer analogue to a real “event bus”, in that an event produced by somebody can be consumed by zero, one, or several subscribed consumers, based upon the filtering provided by `<intent-filter>` elements in the manifest or `IntentFilter` objects for use with `registerReceiver()`.

In theory, you could use broadcast Intents as the backbone for a fairly flexible event bus within your app. In practice, this is not usually a good idea:

- Each broadcast involves inter-process communication (IPC), even if the event producer and consumer(s) are in the same process. This adds overhead.
- Because broadcasts are intrinsically IPC, you have to take security into account, to ensure only authorized producers can publish events that the consumers pick up.

LocalBroadcastManager as Event Bus

As was briefly noted [earlier in the book](#), the Android Support package offers a `LocalBroadcastManager`. This is designed to offer an event bus with a feel very similar to classic broadcast Intents, but local to your process. Not only does this avoid IPC overhead, but it improves security, as other apps have no means of spying on your internal communications.

`LocalBroadcastManager` is supplied by both the `android-support-v4.jar` and `android-support-v13.jar` libraries. Generally speaking, if your `android:minSdkVersion` is less than 13, you probably should choose `android-support-v4.jar`.

A Simple LocalBroadcastManager Sample

Let's see LocalBroadcastManager in action via the [Intents/Local](#) sample project.

Here, our LocalActivity sends a command to a NoticeService from onCreate():

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    notice=(TextView)findViewById(R.id.notice);
    startService(new Intent(this, NoticeService.class));
}
```

The NoticeService simply delays five seconds, then sends a local broadcast using LocalBroadcastManager:

```
package com.commonware.android.localcast;

import android.app.IntentService;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.LocalBroadcastManager;

public class NoticeService extends IntentService {
    public static final String BROADCAST=
        "com.commonware.android.localcast.NoticeService.BROADCAST";
    private static Intent broadcast=new Intent(BROADCAST);

    public NoticeService() {
        super("NoticeService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        SystemClock.sleep(5000);
        LocalBroadcastManager.getInstance(this).sendBroadcast(broadcast);
    }
}
```

Specifically, you get at your process' singleton instance of LocalBroadcastManager by calling getInstance() on the LocalBroadcastManager class.

Our LocalActivity registers for this local broadcast in onResume(), once again using getInstance() on LocalBroadcastManager:

```
@Override
public void onResume() {
```

EVENT BUSES ALTERNATIVES

```
super.onResume();

IntentFilter filter=new IntentFilter(NoticeService.BROADCAST);

LocalBroadcastManager.getInstance(this).registerReceiver(onNotice,
                                                         filter);
}
```

LocalActivity unregisters for this broadcast in onPause():

```
@Override
public void onPause() {
    super.onPause();

    LocalBroadcastManager.getInstance(this).unregisterReceiver(onNotice);
}
```

The BroadcastReceiver simply updates a TextView with the current date and time:

```
private BroadcastReceiver onNotice=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
        notice.setText(new Date().toString());
    }
};
```

If you start up this activity, you will see a “(waiting...)” bit of placeholder text for about five seconds, before having that be replaced by the current date and time.

The BroadcastReceiver, the IntentFilter, and the Intent being broadcast are the same as we would use with full broadcasts. It is merely how we are using them — via LocalBroadcastManager – that dictates they are local to our process versus the standard device-wide broadcasts.

A More Elaborate Sample

That sample is not terribly realistic, but it is simple.

A somewhat more realistic sample is the one using WakefulIntentService from [earlier in the book](#). However, that app was also fairly unrealistic, at least in terms of its output, as LogCat is not very useful to users. A more typical approach for a background service like this is to notify a foreground Activity, if there is one, about work that was accomplished, and otherwise display a Notification. We described that pattern in [the chapter on Notifications](#).

In the [EventBus/LocalBroadcastManager](#) sample project, we blend:

- Having a service wake up every so often to do some work
- Arranging to let the user know of background accomplishments via an Activity or a Notification
- Using LocalBroadcastManager to keep the communications in-process

The Activity

The EventDemoActivity that is our app's entry point is a bit similar to the one used in the WakefulIntentService demo, in that it calls `scheduleAlarms()` on `PollReceiver` to set up the `AlarmManager` schedule:

```
package com.commonware.android.eventbus.lbm;

import android.app.Activity;
import android.os.Bundle;

public class EventDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new EventLogFragment()).commit();

            PollReceiver.scheduleAlarms(this);
        }
    }
}
```

However, we also put an `EventLogFragment` on the screen, if it is not already there, via a `FragmentManager`. This is where we will display events coming from the service, while our activity is in the foreground. We will examine `EventLogFragment` and how it participates in the event bus shortly.

The PollReceiver

`PollReceiver` is unchanged from its `WakefulIntentService` demo original edition. This `BroadcastReceiver` will be used both for getting control at boot time (to reschedule the alarms, wiped on the reboot) and for sending the work to the `ScheduledService` for processing:

```
package com.commonware.android.eventbus.lbm;

import android.app.AlarmManager;
```

EVENT BUSES ALTERNATIVES

```
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=15000; // 15 seconds
    private static final int INITIAL_DELAY=1000; // 1 second

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
            PERIOD, pi);
    }
}
```

ScheduledService and Sending Events

Before, our ScheduledService just dumped a message to LogCat. This was crude but effective for what that demo required. Now, we want our service to let the UI layer know about some work that was accomplished, or to raise a Notification.

In this case, the “work” is generating a random number.

```
package com.commonware.android.eventbus.lbm;

import android.app.Notification;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.support.v4.app.NotificationCompat;
import android.support.v4.content.LocalBroadcastManager;
import java.util.Calendar;
```

EVENT BUSES ALTERNATIVES

```
import java.util.Random;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class ScheduledService extends WakefulIntentService {
    private static int NOTIFY_ID=1337;
    private Random rng=new Random();

    public ScheduledService() {
        super("ScheduledService");
    }

    @Override
    protected void doWakefulWork(Intent intent) {
        Intent event=new Intent(EventLogFragment.ACTION_EVENT);
        long now=Calendar.getInstance().getTimeInMillis();
        int random=rng.nextInt();

        event.putExtra(EventLogFragment.EXTRA_RANDOM, random);
        event.putExtra(EventLogFragment.EXTRA_TIME, now);

        if (!LocalBroadcastManager.getInstance(this).sendBroadcast(event)) {
            NotificationCompat.Builder b=new NotificationCompat.Builder(this);
            Intent ui=new Intent(this, EventDemoActivity.class);

            b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
                .setContentTitle(getString(R.string.notif_title))
                .setContentText(Integer.toHexString(random))
                .setSmallIcon(android.R.drawable.stat_notify_more)
                .setTicker(getString(R.string.notif_title))
                .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

            NotificationManager mgr=
                (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

            mgr.notify(NOTIFY_ID, b.build());
        }
    }
}
```

LocalBroadcastManager, as we have seen, uses the same Intent and IntentFilter and BroadcastReceiver structures as are used with regular broadcasts, just via a singleton message bus (LocalBroadcastManager.getInstance()) instead of the framework's IPC engine. Hence, we need an Intent that represents the message, so we create one, using an action string published by the EventLogFragment. We also attach two extras to this Intent, using keys published by EventLogFragment: the random number, plus the time of this event.

We then call sendBroadcast() on the singleton LocalBroadcastManager. This returns a boolean value, true indicating that one or more locally-registered receivers were delivered the Intent, false otherwise. Hence, if sendBroadcast() returns

true, we can assume that somebody in the UI layer picked up our message and is now responsible for displaying these results to the user.

Conversely, if `sendBroadcast()` returns false, we must assume that the UI layer did not receive the message, and so the service should inform the user directly, in this case via a Notification, showing the random number as the text in the notification drawer.

EventLogFragment and Receiving Events

EventLogFragment, therefore, is responsible for:

- Registering (and unregistering) to receive the broadcasts to be sent locally by the service
- Doing something with those events to inform the user about the all-important random numbers

In this case, we use a retained ListFragment with a ListView set into transcript mode, meaning that entries are added at the bottom, and older entries scroll off the top, like a chat transcript:

```
package com.commonware.android.eventbus.lbm;

import android.annotation.SuppressLint;
import android.app.ListFragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.Bundle;
import android.support.v4.content.LocalBroadcastManager;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Date;
import java.util.Locale;

public class EventLogFragment extends ListFragment {
    static final String EXTRA_RANDOM="r";
    static final String EXTRA_TIME="t";
    static final String ACTION_EVENT="e";
    private EventLogAdapter adapter=null;
```

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    setRetainInstance(true);
    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);

    if (adapter == null) {
        adapter=new EventLogAdapter();
    }

    setListAdapter(adapter);
}

@Override
public void onResume() {
    super.onResume();

    IntentFilter filter=new IntentFilter(ACTION_EVENT);

    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, filter);
}

@Override
public void onPause() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);

    super.onPause();
}

class EventLogAdapter extends ArrayAdapter<Intent> {
    DateFormat fmt=new SimpleDateFormat("HH:mm:ss", Locale.US);

    public EventLogAdapter() {
        super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<Intent>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
            (TextView)super.getView(position, convertView, parent);
        Intent event=getItem(position);
        Date date=new Date(event.getLongExtra(EXTRA_TIME, 0));

        row.setText(String.format("%s = %x", fmt.format(date),
            event.getIntExtra(EXTRA_RANDOM, -1)));

        return(row);
    }
}
```

EVENT BUSES ALTERNATIVES

```
}  
  
private BroadcastReceiver onEvent=new BroadcastReceiver() {  
    @Override  
    public void onReceive(Context context, Intent intent) {  
        adapter.add(intent);  
    }  
};  
}
```

The ListAdapter for the ListView is an EventLogAdapter, an ArrayAdapter for Intent objects, where in getView() we populate the list rows with the time and random value.

In onResume() and onPause(), we register for (and unregister from) the desired broadcast, pointing to an onEvent BroadcastReceiver that adds the incoming Intent to the EventLogAdapter. That, in turn, updates the ListView.

The result is that while the activity is in the foreground, the events will be displayed to the user directly:

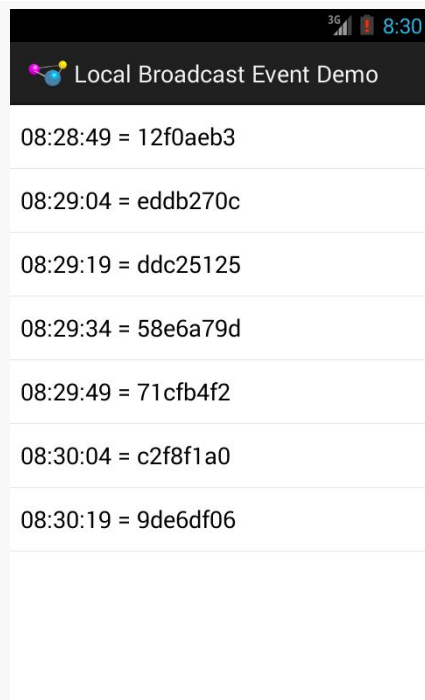

Figure 569: LocalBroadcastManager as Event Bus, Demo Activity

Whereas if events are processed while the activity is not in the foreground, a Notification will be shown with the last results:

Figure 570: LocalBroadcastManager as Event Bus, Demo Notification

Reference, Not Value

When you send a “real” broadcast Intent, your Intent is converted into a byte array (courtesy of the Parcelable interface) and transmitted to other processes. This occurs even if the recipient of the Intent is within your own process — that is what makes LocalBroadcastManager faster, as it avoids the inter-process communication.

However, since LocalBroadcastManager does not need to send your Intent between processes, that means it does not turn your Intent into a byte array. Instead, it just passes the Intent along to any registered BroadcastReceiver with a matching IntentFilter. In effect, while “real” broadcasts are pass-by-value, local broadcasts are pass-by-reference.

This can have subtle side effects.

For example, there are a few ways that you can put a collection into an Intent extra, such as `putStringArrayListExtra()`. This takes an `ArrayList` as a parameter. With

a real broadcast, once you send the broadcast, it does not matter what happens to the original `ArrayList` — the rest of the system is working off of a copy. With a local broadcast, though, the `Intent` holds onto the `ArrayList` you supplied via the setter. If you change that `ArrayList` elsewhere (e.g., clear it for reuse), the recipient of the `Intent` will see those changes.

Similarly, if you put a `Parcelable` object in an extra, the `Intent` holds onto the actual object while it is being broadcast locally, whereas a real broadcast would have resulted in a copy. If you change the object while the broadcast is in progress, the recipient of the broadcast will see those changes.

This can be a feature, not a bug, when used properly. But, regardless, it is a non-trivial difference, one that you will need to keep in mind.

Limitations of Local

While `LocalBroadcastManager` is certainly useful, it has some serious limitations.

The biggest is that it is purely local. While traditional broadcasts can either be internal (via `setPackage()`) or device-wide, `LocalBroadcastManager` only handles the local case. Hence, anything that might involve other processes, such as a `PendingIntent`, will not use `LocalBroadcastManager`. For example, you cannot register a receiver through `LocalBroadcastManager`, then use a `getBroadcast()` `PendingIntent` to try to reach that `BroadcastReceiver`. The `PendingIntent` will use the regular broadcast `Intent` mechanism, which the local-only receiver will not respond to.

Similarly, since a manifest-registered `BroadcastReceiver` is spawned via the operating system upon receipt of a matching true broadcast, you cannot use such receivers with `LocalBroadcastManager`. Only a `BroadcastReceiver` registered via `registerReceiver()` on the `LocalBroadcastManager` will use the `LocalBroadcastManager`. For example, you cannot implement the Activity-or-Notification pattern that we will see [later in this book](#) via `LocalBroadcastManager`.

Also, `LocalBroadcastManager` does not offer ordered or sticky broadcasts.

Square's Otto

`LocalBroadcastManager` has two major advantages:

1. It is part of the Android Support package, and therefore it is part of the officially-supported corner of the Android ecosystem
2. It works like traditional broadcasts, which will make it easier for some developers to “wrap their heads around” it

However, that same dependency on the Intent and IntentFilter structure adds bulk and limits flexibility. Hence, it is not surprising that there are alternative event buses to LocalBroadcastManager.

Java, outside of Android, has had a few event bus implementations. One of the more popular ones in recent years has been the event bus that is part of [Google’s Guava family of libraries](#). However, while a Java event bus perhaps can be used on Android, it may not be *optimal* for Android. Hence, a few projects have started with Guava’s event bus implementation and have extended it to be a bit more Android-aware, or perhaps even Android-centric.

[Square’s Otto](#) is one such event bus.

Basic Usage and Sample App

With LocalBroadcastManager, you work with a singleton instance, calling methods like registerReceiver() and sendBroadcast() upon it to subscribe to and raise events, respectively.

With Otto, you work with a singleton instance of a Bus, calling methods like register() and post() upon it to subscribe to and raise events, respectively.

Hence, at the core, Otto behaves much like LocalBroadcastManager. What differs is in the nature of the events and the subscribers.

With LocalBroadcastManager, events are Intents. With Otto, an event can be whatever data type you like. Hence, you can create your own . . . Event classes, holding whatever bits of data, in whatever data types suit you — you are not restricted to things that can go in an Intent extra. However, as has been noted on occasion, [“with great power comes great responsibility”](#), and so you will need to ensure that you use this carefully and do not wind up creating some sort of memory leak as a result. For example, do not pass something from an Activity to a Service via a custom event, where the Service will hold onto that information for a long time, if that “something” holds a reference back to the Activity.

With `LocalBroadcastManager`, subscribers are `BroadcastReceivers`, who use an `IntentFilter` to identify which events they are interested in. With `Otto`, subscribers are any class you want. A special `@Subscribe` annotation is used to both indicate what sorts of events the subscriber is interested in (based on the parameter to the annotated method) and what method should be invoked when a matching event is raised (the annotated method itself). Hence, not only do you use custom event classes to allow you to carry along custom data, but you use them as a filtering mechanism, much like you would use custom action strings with `LocalBroadcastManager`.

To see how this works, take a look at the [EventBus/Otto](#) sample project, which is a clone of the `EventBus/LocalBroadcastManager` demo, but one where we substitute in `Otto` as a replacement for `LocalBroadcastManager`. Our activity and `PollReceiver` are unchanged: they did not directly interact with `LocalBroadcastManager` and do not need to interact with `Otto`. The changes are isolated in our `ScheduledService` and `EventLogFragment`.

ScheduledService and Sending Events

First, we need a singleton `Otto Bus` instance, that serves the same basic role as does the singleton `LocalBroadcastManager` retrieved by `getInstance()`. However, `Otto` does not offer a similar `getInstance()` method. It is up to you to create and manage your own singleton. This gives you greater flexibility, such as having multiple independent buses for disparate event channels. However, it does mean that you need to put a `Bus` somewhere.

Fortunately, `Bus` does not need a `Context`, and so we can initialize a singleton as a static data member somewhere. Here, the “somewhere” is on `ScheduledService`:

```
static final Bus bus=new Bus(ThreadEnforcer.ANY);
```

The parameter to the `Bus` constructor is the threading rule to be enforced on this bus. If you attempt to use the `Bus` on a thread that is disallowed by the supplied `ThreadEnforcer`, you will get an `IllegalStateException` at runtime. `ThreadEnforcer.MAIN` ensures that you only use the `Bus` on Android’s main application thread. `ThreadEnforcer.ANY` allows the use of the `Bus` on any thread... though then you will need to do your own work to route control back to the main application thread, if needed.

Now, when it comes time for us to send a message, we can call `post()` on the `Bus`, supplying whatever sort of event object that we want:

```
@Override
protected void doWakefulWork(Intent intent) {
    bus.post(new RandomEvent(rng.nextInt()));
}
```

Here, we are posting an instance of a RandomEvent:

```
package com.commonware.android.eventbus.otto;

import java.util.Calendar;
import java.util.Date;

public class RandomEvent {
    Date when=Calendar.getInstance().getTime();
    int value;

    RandomEvent(int value) {
        this.value=value;
    }
}
```

EventLogFragment and Receiving Events

Over in our EventLogFragment, rather than register and unregister a BroadcastReceiver in onResume() and onPause(), we register and unregister the fragment itself with the singleton Bus:

```
@Override
public void onResume() {
    super.onResume();

    ScheduledService.bus.register(this);
}

@Override
public void onPause() {
    ScheduledService.bus.unregister(this);

    super.onPause();
}
```

Now, we can use the @Subscribe annotation to arrange to receive any event we want that is delivered via this Bus, based on event class. Since we want to receive RandomEvent messages, we merely need to have a public void method, taking a RandomEvent parameter, marked with the @Subscribe annotation, such as onRandomEvent():

```
@Subscribe
public void onRandomEvent(final RandomEvent event) {
```

```
if (getActivity() != null) {
    getActivity().runOnUiThread(new Runnable() {
        @Override
        public void run() {
            adapter.add(event);
        }
    });
}
```

Note that the method name can be anything we want, as it is the annotation, not the method name, that identifies this as being an event handling method.

In this method, we can do what we need to with our `RandomEvent`. In our case, `EventLogAdapter` has been modified to be an `ArrayAdapter` of `RandomEvent`, as opposed to being an `ArrayAdapter` of `Intent` as in the earlier sample. What we want to do is append the new `RandomEvent` to the end of the adapter.

However, while `LocalBroadcastManager` will only deliver events on the main application thread, Otto delivers events *on whatever thread they were sent upon*. In this case, we know that this will be a background thread, the one used by the `IntentService`. We cannot safely modify the `EventLogAdapter` on a background thread, as that will update the UI. So, we need to call `add()` on the adapter on the main application thread. Here, we use `runOnUiThread()` to pass a `Runnable` to the main application thread containing our `add()` call. However, it is possible that we do not have an activity right this moment, such as due to a configuration change. This demo simply drops those events; a production-grade app might wish to queue those within the fragment and apply them in some later lifecycle event (e.g., `onAttach()`, `onActivityCreated()`).

Handling the “Nobody’s Home” Scenario

What is missing, though, is the logic we used in `LocalBroadcastManager` to determine if somebody received our message, where we raised a `Notification` if that is not the case.

The solution for this with Otto is to have `ScheduledService` listen for `DeadEvent` events. A `DeadEvent` is delivered on the bus when an attempt to deliver some other event failed with no subscribers. The `DeadEvent` has an event field that contains the original event that failed to be delivered. If we can get the `DeadEvent`, we know the `RandomEvent` was not handled at the UI layer, and we can raise the `Notification`.

EVENT BUSES ALTERNATIVES

To do this, not only do we need to register `EventLogFragment` with the Bus, but we also need to register `ScheduledService` itself, so it can listen for a `DeadEvent`:

```
@Override
public void onCreate() {
    super.onCreate();

    bus.register(this);
}
```

```
@Override
public void onDestroy() {
    bus.unregister(this);

    super.onDestroy();
}
```

Then, our Notification logic can be moved into some method that has the `@Subscribe` annotation and a `DeadEvent` parameter:

```
@Subscribe
public void onDeadEvent(DeadEvent braiiiiiiinz) {
    RandomEvent original=(RandomEvent)braiiiiiiinz.event;
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
        .setTitle(getString(R.string.notif_title))
        .setContentText(Integer.toHexString(original.value))
        .setSmallIcon(android.R.drawable.stat_notify_more)
        .setTicker(getString(R.string.notif_title))
        .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
}
```

Event Producers

Standard broadcasts in Android can be broadcast in a “sticky” fashion. When an app registers for a sticky broadcast, not only does the app get any future matching broadcasts, but immediately it gets the last-broadcast Intent that matches.

`LocalBroadcastManager` does not offer a similar capability, and neither does Otto in the direct sense. However, Otto does have the concept of event producers, which can play a similar role.

You can annotate a method with `@Produce`, to indicate that it is an event producer. The method should take no parameters, but its return type should be one of your event classes (e.g., `RandomEvent`).

When an app calls `register()` on a `Bus`, Otto finds all of the `@Subscribe`-annotated methods and keeps track of them, for dispatching future events. However, in addition, Otto also checks to see if there is a matching event producer for the event type requested by the `@Subscribe` method. If there is a matching producer, the producer method is called, and that event is passed to the subscriber immediately, as part of the `register()` processing.

So, if we had a `@Produce` method in the sample app that returned a `RandomEvent`, the `onRandomEvent()` method would have been invoked immediately with the result of calling that `@Produce` method, in addition to being called with any future events raised by the app.

This is useful for cases where there may be interruptions in event processing. For example, in a configuration change, your activity and fragments are destroyed and recreated by default. But if you are posting events on a background thread, as we did in the sample, those events could occur while a configuration change is in process, and there may not be an available subscriber for the event right at that moment. The `@Produce` pattern would allow you to cache that result and give it to the new activity or fragment.

Revisiting greenrobot's EventBus

Of the three major in-process event bus implementations, [greenrobot's EventBus](#) is slightly less popular than `LocalBroadcastManager` and Otto.

`LocalBroadcastManager` is part of the Android SDK (albeit in the Android Support package), and so it will gain popularity from that status alone. Square has a vast range of libraries and has a following simply from all the work they have done, plus the work of individual Square engineers (e.g., Jake Wharton, author of `ActionBarSherlock`, `ViewPagerIndicator`, and many others).

This is not to say that greenrobot's `EventBus` is weaker than the alternatives. In fact, it may be the most powerful of the three. Like Otto, greenrobot's `EventBus` has Guava's `EventBus` in its heritage. Unlike Otto, greenrobot eschewed annotations, opting instead for a convention-based system utilizing method name patterns, to avoid the overhead of runtime annotations on Android prior to 4.0.

The [EventBus/GreenRobot](#) sample project is a clone of the EventBus/Otto project, replacing Otto with greenrobot's EventBus, that we will examine in this section.

Basic Usage and Sample App

As both Otto and greenrobot's EventBus have Guava's EventBus as antecedents, the flow of using both is similar, just with differing details.

ScheduledService

ScheduledService has a very similar feel to its Otto equivalent:

```
package com.commonware.android.eventbus.greenrobot;

import android.app.Notification;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.support.v4.app.NotificationCompat;
import java.util.Random;
import com.commonware.cwac.wakeful.WakefulIntentService;
import de.greenrobot.event.EventBus;
import de.greenrobot.event.NoSubscriberEvent;

public class ScheduledService extends WakefulIntentService {
    private static int NOTIFY_ID=1337;
    private Random rng=new Random();

    public ScheduledService() {
        super("ScheduledService");
    }

    @Override
    public void onCreate() {
        super.onCreate();

        EventBus.getDefault().register(this);
    }

    @Override
    protected void doWakefulWork(Intent intent) {
        EventBus.getDefault().post(new RandomEvent(rng.nextInt()));
    }

    @Override
    public void onDestroy() {
        EventBus.getDefault().unregister(this);

        super.onDestroy();
    }
}
```

```
public void onEvent(NoSubscriberEvent event) {
    RandomEvent randomEvent=(RandomEvent)event.originalEvent;
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
      .setTitle(getString(R.string.notif_title))
      .setContentType(Integer.toHexString(randomEvent.value))
      .setSmallIcon(android.R.drawable.stat_notify_more)
      .setTicker(getString(R.string.notif_title))
      .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
}
```

There are only two significant differences.

First, we use `EventBus.getDefault()` to get the stock `EventBus` singleton, rather than create our own instance as we did with `Otto`. We *could* create our own instance, though, as opposed to `LocalBroadcastManager`, which seems to prefer its own singleton.

Second, instead of having an `onDeadEvent()` @Subscribe method, we register our own interest in `EventBus` events, by calling `register()` on the `EventBus` instance in `onCreate()`.

The service itself then has an `onEvent()` method for our `NoSubscriberEvent`, where it raises the `Notification`.

When using greenrobot's `EventBus`, rather than using annotations to denote event-handling methods, we use a naming scheme: `onEvent()` (or variations on that theme, as will be seen shortly). Since Java allows method overloading with different parameter lists, this works just fine — we can have *N* event-handling methods in a class, with *N* different event types as the parameter. The greenrobot code simply finds all of the event-handling methods by name, rather than by annotation. This does limit the flexibility in choosing method names, though.

The `NoSubscriberEvent` fills the same basic role as the `DeadEvent` in `Otto` – it is raised when somebody else raises an event that nobody subscribed to. In our case, as with `Otto`'s `DeadEvent`, we are using `NoSubscriberEvent` to determine when the

RandomEvent is not picked up by the EventLogFragment, so we can raise the Notification.

EventLogFragment

The modified EventLogFragment also uses EventBus.getDefault() to register and unregister from the default bus instance. It too has a renamed event-handling method, now called onEventMainThread():

```
public void onEventMainThread(final RandomEvent event) {  
    adapter.add(event);  
}
```

The default behavior of threading with greenrobot's EventBus is to deliver the event on the same thread that posted the event, much like Otto. The onEvent() method used in ScheduledService, for example, accepts the event on the posting thread. However, there are other variations of the onEvent() method name that you can use, to signify that you want to have the event delivered on some other thread. onEventMainThread() indicates that we want to have the event delivered to the method on the main application thread, which is why the EventLogFragment can safely update the UI.

Hence, while the fragment is in the foreground, it will handle the RandomEvent; otherwise, the service will.

Other Notable Capabilities

In addition to the threading features, greenrobot's EventBus has a few other noteworthy bells and whistles:

- register() and unregister() optionally take an event class (e.g., RandomEvent.class) as a second parameter, allowing you to register and unregister from specific events, in addition to the default behavior of registering for all events for which you have handlers.
- postSticky() and registerSticky() allow you to have sticky events, much like sticky broadcasts with the classic broadcast Intent system.
- Ordered event processing as an option, akin to ordered broadcasts.
- Whereas Otto matches events only on the concrete base event class itself, greenrobot's EventBus also allows you to register event handlers for event class superclasses. For example, you could have a common AppEvent base class, with subclasses for specific scenarios, and have some object register

EVENT BUSES ALTERNATIVES

with an `onEvent(AppEvent)` method to find out about *all* of your events that inherit from `AppEvent`.

Trail: Home Screen Effects

Home Screen App Widgets

One of the oft-requested features added in Android 1.5 was the ability to add live elements to the home screen. Called “app widgets”, these can be added by users via a long-tap on the home screen and choosing an appropriate widget from the available roster. Android ships with a few app widgets, such as a music player, but developers can add their own — in this chapter, we will see how this is done.

For the purposes of this book, “app widgets” will refer to these items that go on the home screen. Other uses of the term “widget” will be reserved for the UI widgets, subclasses of View, usually found in the `android.widget` Java package.

In this chapter, we briefly touch on the [security](#) ramifications of app widgets, before continuing on to discuss how Android offers a [secure app widget](#) framework. We then go through all the steps of [creating a basic app widget](#). Next, we discuss how to deal with [multiple instances](#) of your app widget, the app widget [lifecycle](#), alternative models for [updating](#) app widgets, and how to offer [multiple layouts](#) for your app widget (perhaps based on device characteristics). We wrap with some notes about [hosting](#) your own app widgets in your own home screen implementation.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- [basic widgets](#)
- [broadcast Intents](#)
- [services](#)

East is East, and West is West...

Part of the reason it took as long as it did for app widgets to become available is security.

Android's security model is based heavily on Linux user, file, and process security. Each application is (normally) associated with a unique user ID. All of its files are owned by that user, and its process(es) run as that user. This prevents one application from modifying the files of another or otherwise injecting their own code into another running process.

In particular, the core Android team wanted to find a way that would allow app widgets to be displayed by the home screen application, yet have their content come from another application. It would be dangerous for the home screen to run arbitrary code itself or somehow allow its UI to be directly manipulated by another process.

The app widget architecture, therefore, is set up to keep the home screen application independent from any code that puts app widgets on that home screen, so bugs in one cannot harm the other.

The Big Picture for a Small App Widget

The way Android pulls off this bit of security is through the use of RemoteViews.

The application component that supplies the UI for an app widget is not an Activity, but rather a BroadcastReceiver (often in tandem with a Service). The BroadcastReceiver, in turn, does not inflate a normal View hierarchy, like an Activity would, but instead inflates a layout into a RemoteViews object.

RemoteViews encapsulates a limited edition of normal widgets, in such a fashion that the RemoteViews can be “easily” transported across process boundaries. You configure the RemoteViews via your BroadcastReceiver and make those RemoteViews available to Android. Android in turn delivers the RemoteViews to the app widget host (usually the home screen), which renders them to the screen itself.

This architectural choice has many impacts:

- You do not have access to the full range of widgets and containers. You can use `FrameLayout`, `LinearLayout`, and `RelativeLayout` for containers, and

AnalogClock, Button, Chronometer, ImageButton, ImageView, ProgressBar, and TextView for widgets. And, on API Level 11 and higher, you can use some AdapterView-based widgets, like ListView, as we will examine [in the next chapter](#). And, as of API Level 16 (Android 4.1), you can use [GridLayout...](#) but not its backport on earlier devices.

- The only user input you can get is clicks of the Button and ImageButton widgets. In particular, there is no EditText for text input.
- Because the app widgets are rendered in another process, you cannot simply register an OnClickListener to get button clicks; rather, you tell RemoteViews a PendingIntent to invoke when a given button is clicked.
- You do not hold onto the RemoteViews and reuse them yourself. Rather, the pattern appears to be that you create and send out a brand-new RemoteViews whenever you want to change the contents of the app widget. This, coupled with having to transport the RemoteViews across process boundaries, means that updating the app widget is rather expensive in terms of CPU time, memory, and battery life.
- Because the component handling the updates is a BroadcastReceiver, you have to be quick (lest you take too long and Android consider you to have timed out), you cannot use background threads, and your component itself is lost once the request has been completed. Hence, if your update might take a while, you will probably want to have the BroadcastReceiver start a Service and have the Service do the long-running task and eventual app widget update.

Crafting App Widgets

This will become somewhat easier to understand in the context of some sample code. In the [AppWidget/PairOfDice](#) project, you will find an app widget that displays a roll of a pair of dice. Clicking on the app widget re-rolls, in case you want a better result.

The Manifest

First, we need to register our BroadcastReceiver implementation in our AndroidManifest.xml file, along with a few extra features:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.dice"
    android:versionCode="1"
    android:versionName="1.0">
```

```
<uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

<supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

<uses-feature
    android:name="android.software.app_widgets"
    android:required="true"/>

<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
        android:name=".AppWidget"
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
        </intent-filter>

        <meta-data
            android:name="android.appwidget.provider"
            android:resource="@xml/widget_provider"/>
        </receiver>

    <activity
        android:name="PairOfDiceActivity"
        android:theme="@android:style/Theme.NoDisplay">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

Here, along with a do-nothing activity, we have a `<receiver>`. Of note:

1. Our `<receiver>` has `android:label` and `android:icon` attributes, which are not normally needed on `BroadcastReceiver` declarations. However, in this case, those are used for the entry that goes in the menu of available widgets to add to the home screen. Hence, you will probably want to supply values

for both of those, and use appropriate resources in case you want translations for other languages.

2. Our `<receiver>` has an `<intent-filter>` for the `android.appwidget.action.APPWIDGET_UPDATE` action. This means we will get control whenever Android wants us to update the content of our app widget. There may be other actions we want to monitor — more on this in a [later section](#).
3. Our `<receiver>` also has a `<meta-data>` element, indicating that its `android.appwidget.provider` details can be found in the `res/xml/widget_provider.xml` file. This metadata is described in the next section.

The uses-feature Element

If the central point of your application is to provide an app widget, you should strongly consider adding a `<uses-feature>` element to advertise this fact to markets like the Play Store:

```
<uses-feature android:name="android.software.app_widgets"
android:required="true" />
```

In principle, having this element means that markets should block the installation of your app on devices where there is no app-widget-capable home screen or other known places for supporting app widgets.

If, however, your app has an app widget, but it is an adjunct to other forms of UI (typically a launcher activity), then you may wish to leave off this `<uses-feature>` element, or set it to `android:required="false"`.

The Metadata

Next, we need to define the app widget provider metadata. This has to reside at the location indicated in the manifest — in this case, in `res/xml/widget_provider.xml`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
/>
```

Here, we provide four pieces of information:

1. The minimum width and height of the app widget (`android:minWidth` and `android:minHeight`). These are approximate — the app widget host (e.g., home screen) will tend to convert these values into “cells” based upon the overall layout of the UI where the app widgets will reside. However, they should be no smaller than the minimums cited here. Also, ideally, you use `dip` instead of `px` for the dimensions, so the number of cells will remain constant regardless of screen density.
2. The frequency in which Android should request an update of the widget’s contents (`android:updatePeriodMillis`). This is expressed in terms of milliseconds, so a value of 3600000 is a 60-minute update cycle. Note that the minimum value for this attribute is 30 minutes — values less than that will be “rounded up” to 30 minutes. Hence our 15-minute (900000 millisecond) request will actually result in an update every 30 minutes.
3. The initial layout to use for the app widget, for the time between when the user requests the app widget and when `onUpdate()` of our `AppWidgetProvider` gets control.

Note that the calculations for determining the number of cells for an app widget varies. The `dip` dimension value for an N -cell dimension was $(74 * N) - 2$ (e.g., a 2×3 cell app widget would request a width of 146dip and a height of 220dip). The value as of API Level 14 (a.k.a., Ice Cream Sandwich) is now $(70 * N) - 30$ (e.g., a 2×3 cell app widget would request a width of 110dip and a height of 180dip). To have your app widgets maintain a consistent number of cells, you will need two versions of your app widget metadata XML, one in `res/xml-v14/` (with the API Level 14 calculation) and one in `res/xml/` (for prior versions of Android).

The Layout

Eventually, you are going to need a layout that describes what the app widget looks like. You need to stick to the widget and container classes noted above; otherwise, this layout works like any other layout in your project.

For example, here is the layout for the `PairOfDice` app widget:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
```

```
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_5"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/right_die"
        android:layout_centerVertical="true"
        android:layout_alignParentRight="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginRight="7dip"
    />
</RelativeLayout>
```

All we have is a pair of `ImageView` widgets (one for each die), inside of a `RelativeLayout`. The `RelativeLayout` has a background, specified as a [nine-patch PNG file](#). This allows the `RelativeLayout` to have guaranteed contrast with whatever wallpaper is behind it, so the user can tell the actual app widget bounds.

The BroadcastReceiver

Next, we need a `BroadcastReceiver` that can get control when Android wants us to update our `RemoteViews` for our app widget. To simplify this, Android supplies an `AppWidgetProvider` class we can extend, instead of the normal `BroadcastReceiver`. This simply looks at the received `Intent` and calls out to an appropriate lifecycle method based on the requested action.

The one method that invariably needs to be implemented on the provider is `onUpdate()`. Other lifecycle methods may be of interest and are discussed [later](#) in this chapter.

For example, here is the implementation of the `AppWidgetProvider` for `PairOfDice`:

```
package com.commonware.android.appwidget.dice;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class AppWidget extends AppWidgetProvider {
    private static final int[] IMAGES={R.drawable.die_1,R.drawable.die_2,
```

HOME SCREEN APP WIDGETS

```

        R.drawable.die_3,R.drawable.die_4,
        R.drawable.die_5,R.drawable.die_6};

@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                    int[] appWidgetIds) {
    ComponentName me=new ComponentName(ctxt, AppWidget.class);

    mgr.updateAppWidget(me, buildUpdate(ctxt, appWidgetIds));
}

private RemoteViews buildUpdate(Context ctxt, int[] appWidgetIds) {
    RemoteViews updateViews=new RemoteViews(ctxt.getPackageName(),
                                            R.layout.widget);

    Intent i=new Intent(ctxt, AppWidget.class);

    i.setAction(AppWidgetManager.ACTION_APPWIDGET_UPDATE);
    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_IDS, appWidgetIds);

    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0 , i,
PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageViewResource(R.id.left_die,
                                    IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageViewResource(R.id.right_die,
                                    IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    return(updateViews);
}
}
```

To update the RemoteViews for our app widget, we need to build those RemoteViews (delegated to a `buildUpdate()` helper method) and tell an `AppWidgetManager` to update the widget via `updateAppWidget()`. In this case, we use a version of `updateAppWidget()` that takes a `ComponentName` as the identifier of the widget to be updated. Note that this means that we will update all instances of this app widget presently in use — the concept of multiple app widget instances is covered in greater detail [later](#) in this chapter.

Working with RemoteViews is a bit like trying to tie your shoes while wearing mittens — it may be possible, but it is a bit clumsy. In this case, rather than using methods like `findViewById()` and then calling methods on individual widgets, we need to call methods on RemoteViews itself, providing the identifier of the widget we wish to modify. This is so our requests for changes can be serialized for transport to

the home screen process. It does, however, mean that our view-updating code looks a fair bit different than it would if this were the main View of an activity or row of a ListView.

To create the RemoteViews, we use a constructor that takes our package name and the identifier of our layout. This gives us a RemoteViews that contains all of the widgets we declared in that layout, just as if we inflated the layout using a LayoutInflater. The difference, of course, is that we have a RemoteViews object, not a View, as the result.

We then use methods like:

1. `setImageViewResource()` to set the image for each of our ImageView widgets, in this case a randomly chosen die face (using graphics created from a set of SVG files from the [OpenClipArt site](#))
2. `setOnClickPendingIntent()` to provide a PendingIntent that should get fired off when a die, or the overall app widget background, is clicked

We then supply that RemoteViews to the AppWidgetManager, which pushes the RemoteViews structure to the home screen, which renders our new app widget UI.

The Result

If you compile and install all of this, you will have a new app widget entry available. How you add app widgets to the home screen varies based upon Android version and the home screen implementation, and there are too many possibilities to try to list here.

No matter how you add the Pair of Dice, the app widget will appear on the home screen:

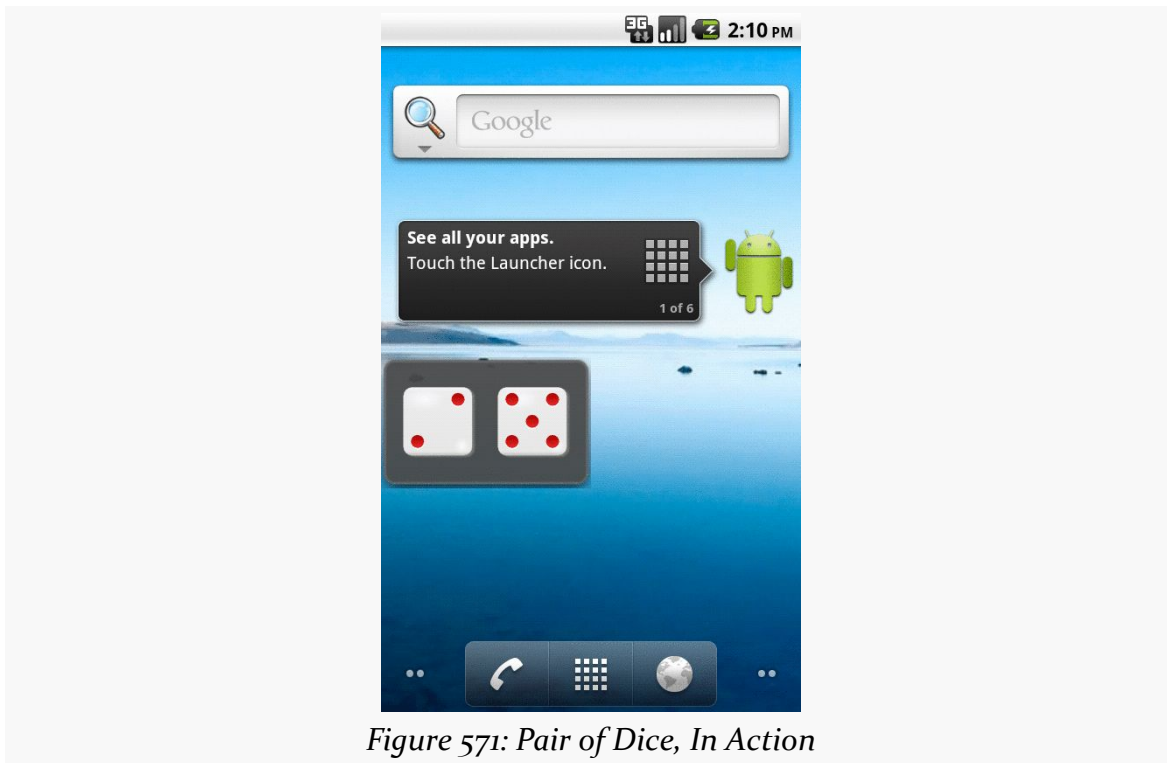

Figure 571: Pair of Dice, In Action

Another and Another

As indicated above, you can have multiple instances of the same app widget outstanding at any one time. For example, one might have multiple picture frames, or multiple “show-me-the-latest-RSS-entry” app widgets, one per feed. You will distinguish between these in your code via the identifier supplied in the relevant `AppWidgetProvider` callbacks (e.g., `onUpdate()`).

If you want to support separate app widget instances, you will need to store your state on a per-app-widget-identifier basis. You will also need to use an appropriate version of `updateAppWidget()` on `AppWidgetManager` when you update the app widgets, one that takes app widget identifiers as the first parameter, so you update the proper app widget instances.

Conversely, there is nothing requiring you to support multiple instances as independent entities. For example, if you add more than one `PairOfDice` app widget to your home screen, nothing blows up – they just show the same roll. That is because `PairOfDice` uses a version of `updateAppWidget()` that does not take any app widget IDs, and therefore updates all app widgets simultaneously.

App Widgets: Their Life and Times

There are three other lifecycle methods that `AppWidgetProvider` offers that you may be interested in:

1. `onEnabled()` will be called when the first widget instance is created for this particular widget provider, so if there is anything you need to do once for all supported widgets, you can implement that logic here
2. `onDeleted()` will be called when a widget instance is removed from the home screen, in case there is any data you need to clean up specific to that instance
3. `onDisabled()` will be called when the last widget instance for this provider is removed from the home screen, so you can clean up anything related to all such widgets

Note, however, that there is a bug in Android 1.5, where `onDeleted()` will not be properly called. You will need to implement `onReceive()` and watch for the `ACTION_APPWIDGET_DELETED` action in the received Intent and call `onDeleted()` yourself. This has since been fixed, and if you are not supporting Android 1.5, you will not need to worry about this problem.

Controlling Your (App Widget's) Destiny

As `PairOfDice` illustrates, you are not limited to updating your app widget only based on the timetable specified in your metadata. That timetable is useful if you can get by with a fixed schedule. However, there are cases in which that will not work very well:

1. If you want the user to be able to configure the polling period (the metadata is baked into your APK and therefore cannot be modified at runtime)
2. If you want the app widget to be updated based on external factors, such as a change in location

The recipe shown in `PairOfDice` will let you use `AlarmManager` (described in [another chapter](#)) or proximity alerts or whatever to trigger updates. All you need to do is:

1. Arrange for something to broadcast an Intent that will be picked up by the `BroadcastReceiver` you are using for your app widget provider
2. Have the provider process that Intent directly or pass it along to a `Service` (such as an `IntentService`)

Also, note that the `updatePeriodMillis` setting not only tells the app widget to update every so often, it will even *wake up the phone* if it is asleep so the widget can perform its update. On the plus side, this means you can easily keep your widgets up to date regardless of the state of the device. On the minus side, this will tend to drain the battery, particularly if the period is too fast. If you want to avoid this wakeup behavior, set `updatePeriodMillis` to 0 and use `AlarmManager` to control the timing and behavior of your widget updates.

Note that if there are multiple instances of your app widget on the user's home screen, they will all update approximately simultaneously if you are using `updatePeriodMillis`. If you elect to set up your own update schedule, you can control which app widgets get updated when, if you choose.

Change Your Look

If you have been doing most of your development via the Android emulator, you are used to all “devices” having a common look and feel, in terms of the home screen, lock screen, and so forth. This is the so-called “Google Experience” look, and many actual Android devices have it.

However, some devices have their own presentation layers. HTC has “Sense”, seen on the HTC Hero and HTC Tattoo, among other devices. Motorola has MOTOBUR, seen on the Motorola CLIQ and DEXT. Other device manufacturers, like Sony Ericsson, Samsung, and LG, have followed suit, as will others in the future. These presentation layers replace the home screen and lock screen, among other things. Moreover, they usually come with their own suite of app widgets with their own look and feel. Your app widget may look fine on a Google Experience home screen, but the look might clash when viewed on a Sense or MOTOBUR device.

Fortunately, there are ways around this. You can set your app widget's look on the fly at runtime, to choose the layout that will look the best on that particular device.

The first step is to create an app widget layout that is initially invisible (`res/layout/invisible.xml`):

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:visibility="invisible">
```

```
>  
</RelativeLayout>
```

This layout is then the one you would reference from your app widget metadata, to be used when the app widget is first created:

```
<appwidget-provider  
  xmlns:android="http://schemas.android.com/apk/res/android"  
  android:minWidth="292dip"  
  android:minHeight="72dip"  
  android:updatePeriodMillis="900000"  
  android:configure="com.commonware.android.appwidget.TWPrefs"  
  android:initialLayout="@layout/invisible"  
>
```

This ensures that when your app widget is initially added, you do not get the “Problem loading widget” placeholder, yet you also do not choose one layout versus another — it is simply invisible for a brief moment.

Then, in your `AppWidgetProvider` (or attached `IntentService`), you can make the choice of what layout to inflate as part of your `RemoteViews`. Rather than using the invisible one, you can choose one based on the device or other characteristics. The biggest challenge is that there is no good way to determine what presentation layer, if any, is in use on a device. For the time being, you will need to use the various fields in the `android.os.Build` class to “sniff” on the device model and make a decision that way.

One Size May Not Fit All

It may be that you want to offer multiple app widget sizes to your users. Some might only want a small app widget. Some might really like what you have to offer and want to give you more home screen space to work in.

Android 1.x/2.x

The good news: this is easy to do.

The bad news: it requires you, in effect, to have one app widget per size.

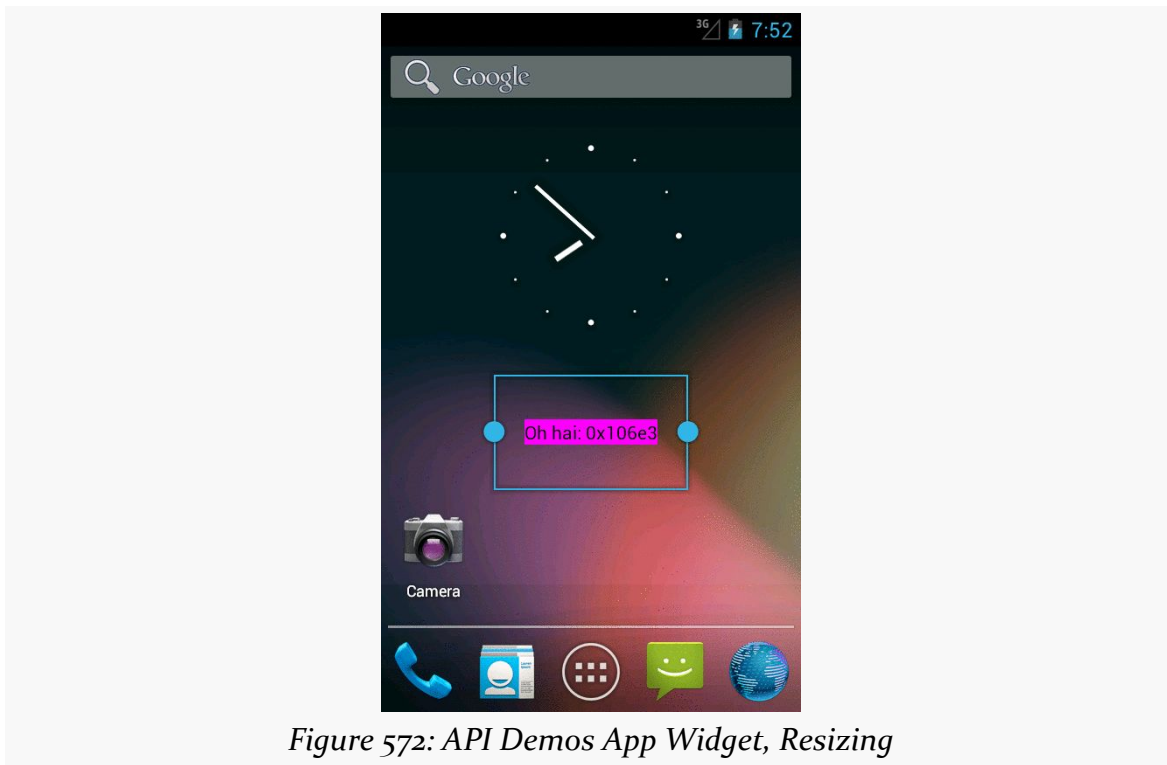

The size of an app widget is determined by the app widget metadata XML file. That XML file is tied to a `<receiver>` element in the manifest representing one app widget. Hence, to have multiple sizes, you need multiple metadata files and multiple `<receiver>` elements.

HOME SCREEN APP WIDGETS

This also means your app widgets will show up multiple times in the app widget selection list, when the user goes to add an app widget to their home screen. Hence, supporting many sizes will become annoying to the user, if they perceive you are “spamming” the app widget list. Try to keep the number of app widget sizes to a reasonable number (say, one or two sizes).

Android 3.0+

As of API Level 11, it is possible to have a resizable app widget. To do this, you can have an `android:resizeMode` attribute in your widget metadata, with a value of `horizontal`, `vertical`, or `both` (e.g., `horizontal|vertical`). When the user long-taps on an existing widget, they should see handles to allow the widget to be resized:

You can also have `android:minResizeWidth` and `android:minResizeHeight` attributes, measured in dp, that indicate the approximate smallest size that your app widget can support. These values will be interpreted in terms of “cells”, as with the `android:minWidth` and `android:minHeight` attributes, and so the dp values you supply will not be used precisely.

However, for Android 3.x and 4.0 (API Level 11–15), your code would not be informed about being resized. You had to simply ensure that your layout would intelligently use any extra space automatically. Hence, resizing tended to be used primarily with adapter-driven app widgets, as will be discussed [in the next chapter](#).

Starting with API Level 16, though, you can find out when the user resizes your app widget, so you can perhaps use a different layout for a different size, or otherwise adapt to the available space. Finding out about resize events takes a bit more work, as is illustrated in the [AppWidget/Resize](#) sample project.

This app widget project is similar to PairOfDice, described earlier in this chapter. However, our layout skips the dice, replacing them with a TextView widget in the RelativeLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    android:orientation="horizontal">

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textAppearance="?android:attr/textAppearanceMedium">

    </TextView>
</RelativeLayout>
```

Our widget_provider.xml resource stipulates our desired android:resizeMode and minimum resize dimensions:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="180dip"
    android:minHeight="110dip"
    android:minResizeWidth="110dip"
    android:minResizeHeight="40dip"
    android:initialLayout="@layout/widget"
    android:resizeMode="horizontal|vertical"
/>
```

Finding out about app widget resizing is a different event than finding out about app widget updates. Hence, we need to add a new <action> element to the

HOME SCREEN APP WIDGETS

<intent-filter> of our <receiver> in the manifest, indicating that we want APPWIDGET_OPTIONS_CHANGED as well as ACTION_UPDATE:

```
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
        android:name="AppWidget"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
            <action
                android:name="android.appwidget.action.APPWIDGET_OPTIONS_CHANGED"/>
        </intent-filter>
    </receiver>
</application>
```

Then, our app widget implementation can override an onAppWidgetOptionsChanged() method:

```
@Override
public void onAppWidgetOptionsChanged(Context ctxt,
    AppWidgetManager mgr,
    int appWidgetId,
    Bundle newOptions) {
    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), R.layout.widget);
    String msg=
        String.format(Locale.getDefault(),
            "[%d-%d] x [%d-%d]",
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT));
    updateViews.setTextViewText(R.id.size, msg);
    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

You will notice that we skip onUpdate(). We will be called with onAppWidgetOptionsChanged() when the app widget is added and resized. Hence, in the case of this app widget, we can define what the app widget looks like from onAppWidgetOptionsChanged(), eschewing onUpdate(). That being said, more typical app widgets will wind up implementing both methods, especially if they are

supporting lower API levels than 16, where `onAppWidgetOptionsChanged()` will not be called.

Also remember that your process may well be terminated in between calls to app widget lifecycle methods like `onUpdate()` and `onAppWidgetOptionsChanged()`. Hence, if there is data from one method that you want in the other, be sure to persist that data somewhere.

In the `AppWidget` implementation of `onAppWidgetOptionsChanged()`, we can find out about our new app widget size by means of the `Bundle` supplied to our method. What we *cannot* find out is our exact size. Rather, we are provided minimum and maximum dimensions of our app widget via four values in the `Bundle`:

- `AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT`

In our case, we grab these `int` values and pour them into a `String` template, using that to fill in the `TextView` of the app widget's contents.

When our app widget is initially launched, we show our initial size ranges:

HOME SCREEN APP WIDGETS

Figure 573: Resize Widget, As Initially Added

When the user resizes our app widget, we show the new size ranges:

HOME SCREEN APP WIDGETS

Figure 574: Resize Widget, During Resize Operation

However, not all home screen implementations will necessarily send the `APPWIDGET_OPTIONS_CHANGED` when an app widget is added to the home screen, only when the user resizes it later. For example, while the emulator's home screen for Android 4.1 broadcasts `APPWIDGET_OPTIONS_CHANGED`, it does not for 4.2 or 4.3. Hence, you may want to also examine the size information in `onUpdate()` as well, so that you react to the initial size as well as any future sizes. One way to do this is to simply iterate over the supplied app widget IDs and invoke your own `onAppWidgetOptionsChanged()` method:

```
// based on http://stackoverflow.com/a/18552461/115145

@Override
public void onUpdate(Context context,
    AppWidgetManager appWidgetManager,
    int[] appWidgetIds) {
    super.onUpdate(context, appWidgetManager, appWidgetIds);

    for (int appWidgetId : appWidgetIds) {
        Bundle options=appWidgetManager.getAppWidgetOptions(appWidgetId);

        onAppWidgetOptionsChanged(context, appWidgetManager, appWidgetId,
            options);
    }
}
```

```
}  
}
```

Lockscreen Widgets

Android's lockscreen (a.k.a., the keyguard) has long been unmodifiable by developers. This led to a number of developers creating so-called “replacement lockscreens”, which generally reduce device security, as they can be readily bypassed. However, with API Level 17 (Android 4.2), developers now can create app widgets that the user can deploy to the lockscreen, helping to eliminate the need for “replacement lockscreens”.

Declaring that an app widget supports being on the lockscreen instead of (or in addition to) the home screen is very easy. All you must do is add an `android:widgetCategory` attribute to your app widget metadata resource. That attribute should have a value of either `keyguard` (for the lockscreen), `home_screen`, or both (e.g., `keyguard|home_screen`), depending upon where you want the app widget to be eligible. By default, if this attribute is missing, Android assumes a default value of `home_screen`.

Users cannot resize the lockscreen widgets at this time. However, you still will want to specify an `android:resizeMode` attribute in your app widget metadata, as whether or not you include vertical resizing will affect the height of your app widget. Lockscreen widgets without `vertical` will have a fixed small height on tablets, while lockscreen widgets with `vertical` will fill the available height. Lockscreen widgets on phones will always be small (to fit above the PIN/password entry area), and lockscreen widgets on all devices will stretch to fill available space horizontally.

You can also specify a different starting layout to use when your app is added to the lockscreen, as opposed to being added to the home screen. To do this, just add an `android:initialKeyguardLayout` attribute to your app widget metadata, pointing to the lockscreen-specific layout to use.

To see this in action, take a look at the [AppWidget/TwoOrThreeDice](#) sample project. This is a revised clone of the `PairOfDice` sample, allowing the dice to be added to the lockscreen, and showing three dice on the lockscreen instead of the two on the home screen.

Our app widget metadata now contains the lockscreen-related attributes: `android:widgetCategory` and `android:initialKeyguardLayout`:

HOME SCREEN APP WIDGETS

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
    android:initialKeyguardLayout="@layout/lockscreen"
    android:widgetCategory="keyguard|home_screen"
/>
```

Our lockscreen layout simply adds a third die, `middle_die`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_3"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/middle_die"
        android:layout_centerInParent="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
        android:layout_marginRight="7dip"
    />
    <ImageView android:id="@+id/right_die"
        android:layout_centerVertical="true"
        android:layout_alignParentRight="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginRight="7dip"
    />
</RelativeLayout>
```

However, by specifying a different layout for the lockscreen widget, we have a problem. We need to know, in our Java code, what layout to use for the RemoteViews and how many dice need to be updated. And, ideally, we would handle this in a backwards-compatible fashion, so our app widget will have its original functionality on older Android devices. Plus, supporting the lockscreen makes it that much more likely that the user will have more than one instance of our app widget (e.g., one on

HOME SCREEN APP WIDGETS

the lockscreen and one on the homescreen), so we should do a better job than PairOfDice did about handling multiple app widget instances.

To deal with the latter point, our new onUpdate() method iterates over each of the app widget IDs supplied to it and calls a private updateWidget() method for each, so we can better support multiple instances:

```
@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
    int[] appWidgetIds) {
    for (int appWidgetId : appWidgetIds) {
        updateWidget(ctxt, mgr, appWidgetId);
    }
}
```

The updateWidget() method is a bit more complicated than the PairOfDice equivalent code:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void updateWidget(Context ctxt, AppWidgetManager mgr,
    int appWidgetId) {
    int layout=R.layout.widget;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        int category=
            mgr.getAppWidgetOptions(appWidgetId)
                .getInt(AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY,
                    -1);

        layout=
            (category == AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD)
                ? R.layout.lockscreen : R.layout.widget;
    }

    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), layout);
    Intent i=new Intent(ctxt, AppWidget.class);

    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);

    PendingIntent pi=
        PendingIntent.getBroadcast(ctxt, appWidgetId, i,
            PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageViewResource(R.id.left_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageViewResource(R.id.right_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);
}
```

```
if (layout == R.layout.lockscreen) {
    updateViews.setImageResource(R.id.middle_die,
                                  IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickListener(R.id.middle_die, pi);
}

mgr.updateAppWidget(appWidgetId, updateViews);
}
```

First, we need to choose which layout we are working with. We assume that we are to use the original `R.layout.widget` resource by default. But, if we are on API Level 17 or higher, we can call `getAppWidgetOptions()` on the `AppWidgetManager`, to get the `Bundle` of options — the same options that we could be delivered in `onAppWidgetOptionsUpdate()` as described [in the previous section](#). One value that will be in this `Bundle` is `AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY`, which will be an `int` with a value of `AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD` if our app widget is on the lockscreen. In that case, we switch to using `R.layout.lockscreen`. In addition, we know then we need to update the `middle_die` when we are updating the other dice.

There is also a subtle change in our `getBroadcast()` call to `PendingIntent`: we pass in the app widget ID as the second parameter, whereas in `PairOfDice` we passed 0. `PendingIntent` objects are cached in our process, and by default we will get the same `PendingIntent` when we call `getBroadcast()` for the same `Intent`. However, in our case, we may *want* two or more different `PendingIntent` objects for the same `Intent`, with differing extras (`EXTRA_APPWIDGET_ID`). Since extras are not considered when evaluating equivalence of `Intent` objects, just having different extras is insufficient to get different `PendingIntent` objects for those `Intent` objects. The second parameter to `getBroadcast()` (and `getActivity()` and `getService()`) on `PendingIntent` is a unique identifier, to differentiate between two otherwise equivalent `Intent` objects, forcing `PendingIntent` to give us distinct `PendingIntent` objects. This way, we can support two or more app widget instances, each having their own `PendingIntent` objects for their click events.

On an Android 4.2 lockscreen, you should be able to swipe to one side (e.g., a bezel swipe from left to right), to expose an option to add an app widget:

Tapping the “+” indicator (and, if needed, entering your device PIN or password), brings up an app widget chooser:

HOME SCREEN APP WIDGETS

Figure 576: Lockscreen Widget Selection List, On a 4.2 Emulator

Choosing TwoOrThreeDice will then add the app widget to the lockscreen, with three dice, not two:

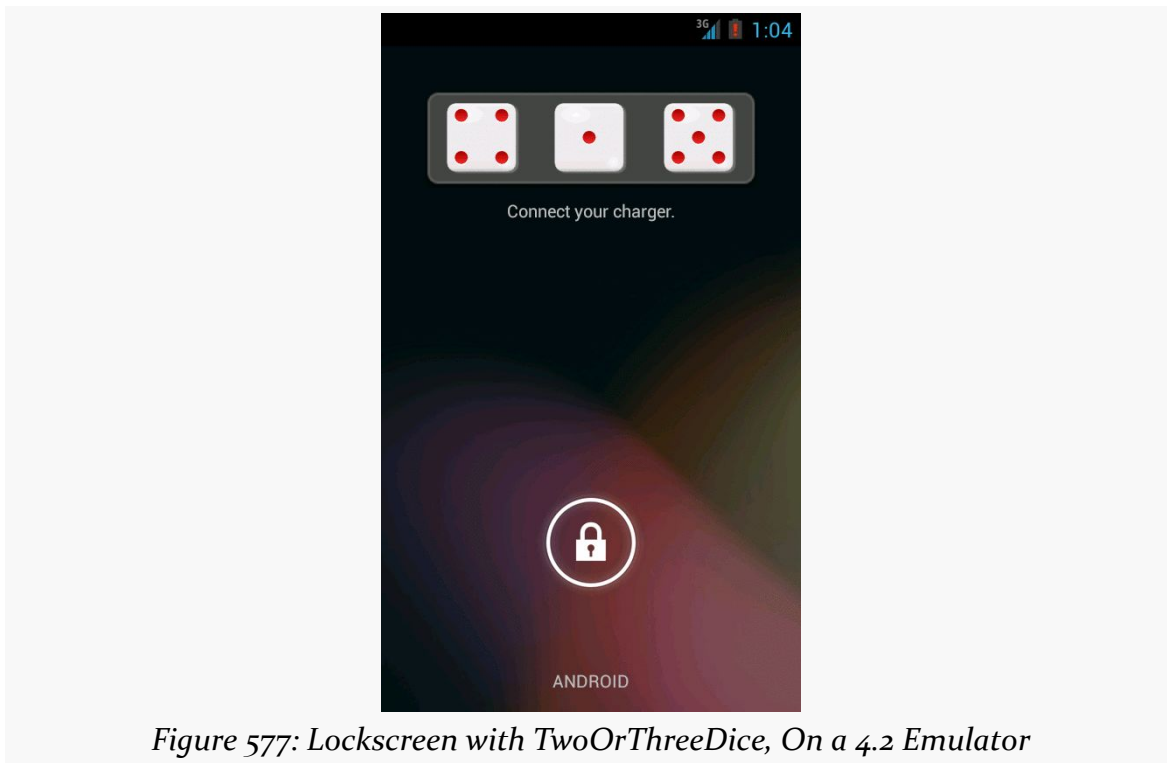

Figure 577: Lockscreen with TwoOrThreeDice, On a 4.2 Emulator

Preview Images

App widgets can now have preview images attached. Preview images are drawable resources representing a preview of what the app widget might look like on the screen. On tablets, this will be used as part of an app widget gallery, replacing the simple context menu presentation you see on Android 1.x and 2.x phones:

HOME SCREEN APP WIDGETS

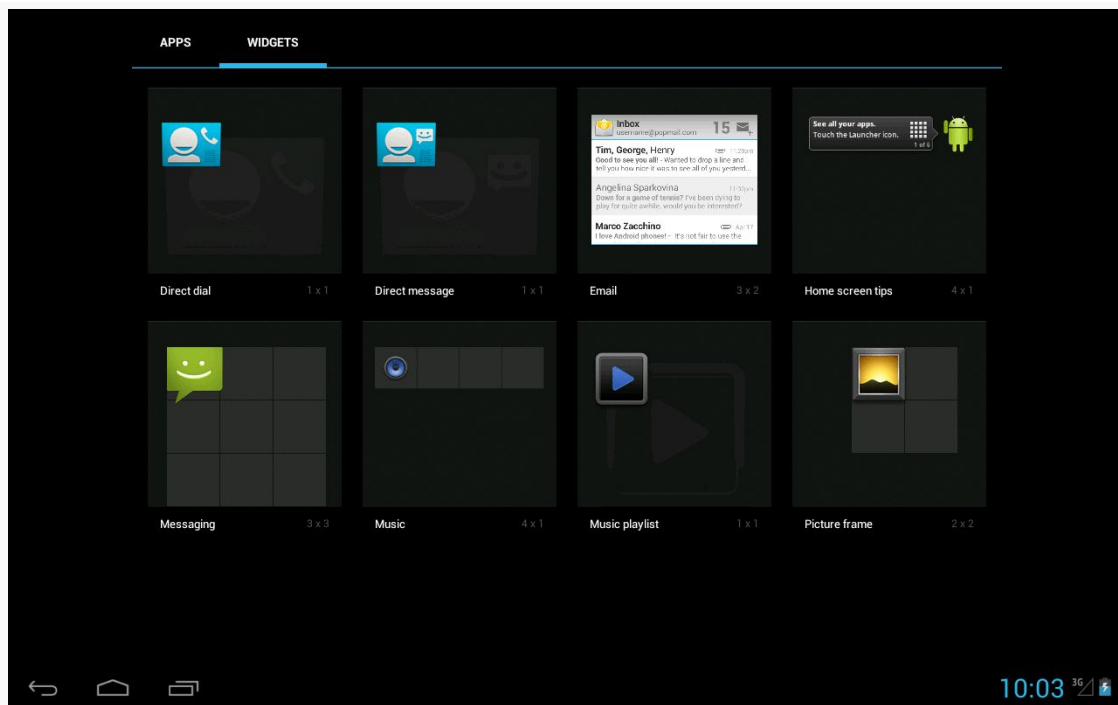

Figure 578: The XOOM tablet's app widget gallery

To create the preview image itself, the Android 3.0 emulator contains a Widget Preview application that lets you run an app widget in its own container, outside of the home screen:

Figure 579: The Widget Preview application, showing a preview of the Analog Clock app widget

From here, you can take a snapshot and save it to external storage, copy it to your project's `res/drawable-nodpi/` directory (indicating that there is no intrinsic density assumed for this image), and reference it in your app widget metadata via an `android:previewImage` attribute. We will see an example of such an attribute in [the chapter on advanced app widgets](#).

Being a Good Host

In addition to creating your own app widgets, it is possible to host app widgets. This is mostly aimed for those creating alternative home screen applications, so they can take advantage of the same app widget framework and all the app widgets being built for it.

This is not very well documented at this juncture, but it apparently involves the `AppWidgetHost` and `AppWidgetHostView` classes. The latter is a `View` and so should be able to reside in an app widget host's UI like any other ordinary widget.

Adapter-Based App Widgets

API Level 11 introduced a few new capabilities for app widgets, to make them more interactive and more powerful than before. The documentation lags a bit, though, so determining how to use these features takes a bit of exploring. Fortunately for you, the author did some of that exploring on your behalf, to save you some trouble.

Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#) and all of its prerequisites.

AdapterViews for App Widgets

In addition to the classic widgets available for use in app widgets and RemoteViews, five more were added for API Level 11:

1. GridView
2. ListView
3. StackView
4. ViewFlipper
5. AdapterViewFlipper

Three of these (GridView, ListView, ViewFlipper) are widgets that existed in Android since the outset. StackView is a new widget to provide a “stack of cards” UI:

Figure 580: The Google Books app widget, showing a StackView

AdapterViewFlipper works like a ViewFlipper, allowing you to toggle between various children with only one visible at a time. However, whereas with ViewFlipper all children are fully-instantiated View objects held by the ViewFlipper parent, AdapterViewFlipper uses the Adapter model, so only a small number of actual View objects are held in memory, no matter how many potential children there are.

With the exception of ViewFlipper, the other four all require the use of an Adapter. This might seem odd, as there is no way to provide an Adapter to a RemoteViews. That is true, but Android 3.0 added new ways for Adapter-like communication between the app widget host (e.g., home screen) and your application. We will take an in-depth look at that in [an upcoming section](#).

Building Adapter-Based App Widgets

In an activity, if you put a ListView or GridView into your layout, you will also need to hand it an Adapter, providing the actual row or cell View objects that make up the contents of those selection widgets.

In an app widget, this becomes a bit more complicated. The host of the app widget does not have any Adapter class of yours. Hence, just as we have to send the contents of the app widget's UI via a RemoteViews, we will need to provide the rows or cells via RemoteViews as well. Android, starting with API Level 11, has a RemoteViewsService and RemoteViewsFactory that you can use for this purpose.

Let's take a look, in the form of the [AppWidget/LoremWidget](#) sample project, which will put a ListView of 25 Latin words into an app widget.

The AppWidgetProvider

At its core, our AppWidgetProvider (named WidgetProvider, in a stunning display of creativity) still needs to create and configure a RemoteViews object with the app widget UI, then use `updateAppWidget()` to push that RemoteViews to the host via the AppWidgetManager. However, for an app widget that involves an AdapterView, like ListView, there are two more key steps:

- You have to tell the RemoteViews the identity of a RemoteViewsService that will help fill the role that the Adapter would in an activity
- You have to provide the RemoteViews with a “template” PendingIntent to be used when the user taps on a row or cell in the AdapterView, to replace the `onListItemClick()` or similar method you might have used in an activity

For example, here is WidgetProvider for our nonsense-word app widget:

```
package com.commonware.android.appwidget.lorem;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import android.widget.RemoteViews;

public class WidgetProvider extends AppWidgetProvider {
    public static String EXTRA_WORD=
        "com.commonware.android.appwidget.lorem.WORD";

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager appWidgetManager,
        int[] appWidgetIds) {
        for (int i=0; i<appWidgetIds.length; i++) {
            Intent svcIntent=new Intent(ctxt, WidgetService.class);

            svcIntent.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetIds[i]);
            svcIntent.setData(Uri.parse(svcIntent.toUri(Intent.URI_INTENT_SCHEME)));

            RemoteViews widget=new RemoteViews(ctxt.getPackageName(),
                R.layout.widget);

            widget.setRemoteAdapter(R.id.words, svcIntent);

            Intent clickIntent=new Intent(ctxt, LoremActivity.class);
```

ADAPTER-BASED APP WIDGETS

```
        PendingIntent clickPI=PendingIntent
            .getActivity(ctxt, 0,
                        clickIntent,
                        PendingIntent.FLAG_UPDATE_CURRENT);

        widget.setPendingIntentTemplate(R.id.words, clickPI);

        appWidgetManager.updateAppWidget(appWidgetIds[i], widget);
    }

    super.onUpdate(ctxt, appWidgetManager, appWidgetIds);
}
```

The call to `setRemoteAdapter()` is where we point the `RemoteViews` to our `RemoteViewsService` for our `AdapterView` widget. The main rules for the `Intent` used to identify the `RemoteViewsService` are:

1. The service must be identified by its data (`Uri`), so even if you create the `Intent` via the `Context-and-Class` constructor, you will need to convert that into a `Uri` via `toUri(Intent.URI_INTENT_SCHEME)` and set that as the `Uri` for the `Intent`. Why? While your application has access to your `RemoteViewsService` Class object, the app widget host will not, and so we need something that will work across process boundaries. You could elect to add your own `<intent-filter>` to the `RemoteViewsService` and use an `Intent` based on that, but that would make your service more publicly visible than you might want.
2. Any extras that you package on the `Intent` — such as the app widget ID in this case — will be on the `Intent` that is delivered to the `RemoteViewsService` when it is invoked by the app widget host.

Note that there are two flavors of `setRemoteAdapter()`. An older deprecated one takes the app widget ID as the first parameter. The current one does not. The current one, though, is only available on API Level 14 and higher.

The call to `setPendingIntentTemplate()` is where we provide a `PendingIntent` that will be used as the template for all row or cell clicks. As we will see in a bit, the underlying `Intent` in the `PendingIntent` will have more data added to it by our `RemoteViewsFactory`.

In all other respects, our `WidgetProvider` is unremarkable compared to other app widgets. It will need to be registered in the manifest as a `<receiver>`, as with any other app widget.

The RemoteViewsService

Android supplies a `RemoteViewsService` class that you will need to extend, and this class is the one you must register with the `RemoteViews` for an `AdapterView` widget. For example, here is `WidgetService` (once again, a highly creative name) from the `LoremWidget` project:

```
package com.commonware.android.appwidget.lorem;

import android.content.Intent;
import android.widget.RemoteViewsService;

public class WidgetService extends RemoteViewsService {
    @Override
    public RemoteViewsFactory onGetViewFactory(Intent intent) {
        return(new LoremViewsFactory(this.getApplicationContext(),
                                     intent));
    }
}
```

As you can see, this service is practically trivial. You have to override one method, `onGetViewFactory()`, which will return the `RemoteViewsFactory` to use for supplying rows or cells for the `AdapterView`. You are passed in an `Intent`, the one used in the `setRemoteAdapter()` call. Hence, if you have more than one `AdapterView` widget in your app widget, you could elect to have two `RemoteViewsService` implementations, or one that discriminates between the two widgets via something in the `Intent` (e.g., custom action string). In our case, we only have one `AdapterView`, so we create an instance of a `LoremViewFactory` and return it. Google demonstrates using `getApplicationContext()` here to supply the `Context` object to `RemoteViewsFactory`, instead of using the `Service` as a `Context` — it is unclear at this time why this is.

Another thing different about the `RemoteViewsService` is how it is registered in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.lorem"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="19"/>

    <uses-feature
        android:name="android.software.app_widgets"
```

```
        android:required="true"/>

<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name="LoremActivity"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.NoDisplay">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>

    <receiver
        android:name="WidgetProvider"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
        </intent-filter>

        <meta-data
            android:name="android.appwidget.provider"
            android:resource="@xml/widget_provider"/>
    </receiver>

    <service
        android:name="WidgetService"
        android:permission="android.permission.BIND_REMOTEVIEWS"/>
</application>

</manifest>
```

Note the use of `android:permission`, specifying that whoever sends an Intent to `WidgetService` must hold the `BIND_REMOTEVIEWS` permission. This can only be held by the operating system. This is a security measure, so arbitrary applications cannot find out about your service and attempt to spoof being the OS and cause you to supply them with `RemoteViews` for the rows, as this might leak private data.

The RemoteViewsFactory

A `RemoteViewsFactory` interface implementation looks and feels a lot like an `Adapter`. In fact, one could imagine that the Android developer community might create `CursorRemoteViewsFactory` and `ArrayRemoteViewsFactory` and such to further simplify writing these classes.

ADAPTER-BASED APP WIDGETS

For example, here is LoremViewsFactory, the one used by the LoremWidget project:

```
package com.commonware.android.appwidget.lorem;

import android.appwidget.AppWidgetManager;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.widget.RemoteViews;
import android.widget.RemoteViewsService;

public class LoremViewsFactory implements
    RemoteViewsService.RemoteViewsFactory {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private Context ctxt=null;
    private int appWidgetId;

    public LoremViewsFactory(Context ctxt, Intent intent) {
        this.ctxt=ctxt;
        appWidgetId=
            intent.getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                AppWidgetManager.INVALID_APPWIDGET_ID);
    }

    @Override
    public void onCreate() {
        // no-op
    }

    @Override
    public void onDestroy() {
        // no-op
    }

    @Override
    public int getCount() {
        return(items.length);
    }

    @Override
    public RemoteViews getViewAt(int position) {
        RemoteViews row=
            new RemoteViews(ctxt.getPackageName(), R.layout.row);

        row.setTextViewText(android.R.id.text1, items[position]);

        Intent i=new Intent();
        Bundle extras=new Bundle();

        extras.putString(WidgetProvider.EXTRA_WORD, items[position]);
    }
}
```

ADAPTER-BASED APP WIDGETS

```
extras.putInt(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);
i.putExtras(extras);
row.setOnClickListener(android.R.id.text1, i);

return(row);
}

@Override
public RemoteViews getLoadingView() {
    return(null);
}

@Override
public int getViewTypeCount() {
    return(1);
}

@Override
public long getItemId(int position) {
    return(position);
}

@Override
public boolean hasStableIds() {
    return(true);
}

@Override
public void onDataChange() {
    // no-op
}
}
```

You need to implement a handful of methods that have the same roles in a `RemoteViewsFactory` as they do in an `Adapter`, including:

1. `getCount()`
2. `getViewTypeCount()`
3. `getItemId()`
4. `hasStableIds()`

In addition, you have `onCreate()` and `onDestroy()` methods that you must implement, even if they do nothing, to satisfy the interface.

You will need to implement `getLoadingView()`, which will return a `RemoteViews` to use as a placeholder while the app widget host is getting the real contents for the app widget. If you return `null`, Android will use a default placeholder.

The bulk of your work will go in `getViewAt()`. This serves the same role as `getView()` does for an Adapter, in that it returns the row or cell View for a given position in your data set. However:

1. You have to return a RemoteViews, instead of a View, just as you have to use RemoteViews for the main content of the app widget in your AppWidgetProvider
2. There is no recycling, so you do not get a View (or RemoteViews) back to somehow repopulate, meaning you will create a new RemoteViews every time

The impact of the latter is that you do not want to put large data sets into an app widget, as scrolling may get sluggish, just as you do not want to implement an Adapter without recycling unused View objects.

In LoremViewsFactory, the `getViewAt()` implementation creates a RemoteViews for a custom row layout, cribbed from one in the Android SDK:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2006 The Android Open Source Project

    Licensed under the Apache License, Version 2.0 (the "License");
    you may not use this file except in compliance with the License.

        http://www.apache.org/licenses/LICENSE-2.0

    Unless required by applicable law or agreed to in writing, software
    distributed under the License is distributed on an "AS IS" BASIS,
    WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    See the License for the specific language governing permissions and
    limitations under the License.
-->

<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/text1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"
    android:gravity="center_vertical"
    android:paddingLeft="6dip"
    android:minHeight="?android:attr/listPreferredItemHeight"
/>
```

Then, `getViewAt()` pours in a word from the static String array of Latin words into that RemoteViews for the TextView inside it. It also creates an Intent and puts the Latin word in as an EXTRA_WORD extra, then provides that Intent to `setOnClickFillInIntent()`. In addition, it adds the app widget instance ID as an

extra, reusing the framework's own `AppWidgetManager.EXTRA_APPWIDGET_ID` as the key. The contents of the “fill-in” Intent are merged into the “template” `PendingIntent` from `setPendingIntentTemplate()`, and the resulting `PendingIntent` is what is invoked when the user taps on an item in the `AdapterView`. The fully-configured `RemoteViews` is then returned.

The Rest of the Story

The app widget metadata needs no changes related to Adapter-based app widget contents. However, `LoremWidget` does add the `android:previewImage` attribute:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="146dip"
    android:minHeight="146dip"
    android:updatePeriodMillis="0"
    android:initialLayout="@layout/widget"
    android:autoAdvanceViewId="@+id/words"
    android:previewImage="@drawable/preview"
    android:resizeMode="vertical"
/>
```

This points to the `res/drawable-nodpi/preview.png` file that represents a “widgetshot” of the app widget in isolation, obtained from the Widget Preview application:

Figure 581: The preview of LoremWidget

Also, the metadata specifies `android:resizeMode="vertical"`. This attribute is new to Android 3.1, and allows the app widget to be resized by the user (in this case, only in the vertical direction, to show more rows). Older versions of Android will ignore this attribute, and the app widget will remain in your requested size. You can use

vertical, horizontal, or both (via the pipe operator) as values for `android:resizeMode`.

When the user taps on an item in the list, our `PendingIntent` is set to bring up `LoremActivity`. This activity has `android:theme="@android:style/Theme.NoDisplay"` set in the manifest, meaning that it will not have its own user interface. Rather, it will extract our `EXTRA_WORD` — and the app widget ID — out of the `Intent` used to launch the activity and displays them in a `Toast` before finishing:

```
package com.commonware.android.appwidget.lorem;

import android.app.Activity;
import android.appwidget.AppWidgetManager;
import android.os.Bundle;
import android.widget.Toast;

public class LoremActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        String word=getIntent().getStringExtra(WidgetProvider.EXTRA_WORD);

        if (word == null) {
            word="We did not get a word!";
        }

        Toast.makeText(this,
                      String.format("#%d: %s",
getIntent().getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
AppWidgetManager.INVALID_APPWIDGET_ID),
                      word), Toast.LENGTH_LONG).show();

        finish();
    }
}
```

The Results

When you compile and install the application, nothing new shows up in the home screen launcher, because we have no activity defined to respond to `ACTION_MAIN` and `CATEGORY_HOME`. This would be unusual for an application distributed through the Play Store, as users often get confused if they install something and then do not know how to start it. However, for the purposes of this example, we should be fine, as readers of programming books never get confused about such things.

ADAPTER-BASED APP WIDGETS

However, if you bring up the app widget gallery (e.g., long-tap on the home screen of a Motorola XOOM), you will see LoremWidget there, complete with preview image. You can drag it into one of the home screen panes and position it. When done, the app widget appears as expected:

Figure 582: A XOOM home screen, showing the LoremWidget on the left

The ListView is live and can be scrolled. Tapping an entry brings up the corresponding Toast:

Figure 583: A XOOM home screen, showing the LoremWidget on the left

The above image illustrates that a Toast is not a great UI choice on a tablet, given the relative size of the Toast compared to the screen. Users will be far more likely to miss the Toast than ever before.

If the user long-taps on the app widget, they will be able to reposition it. On Android 3.1 and beyond, when they lift their finger after the long-tap, the app widget will show resize handles on the sides designated by your `android:resizeMode` attribute:

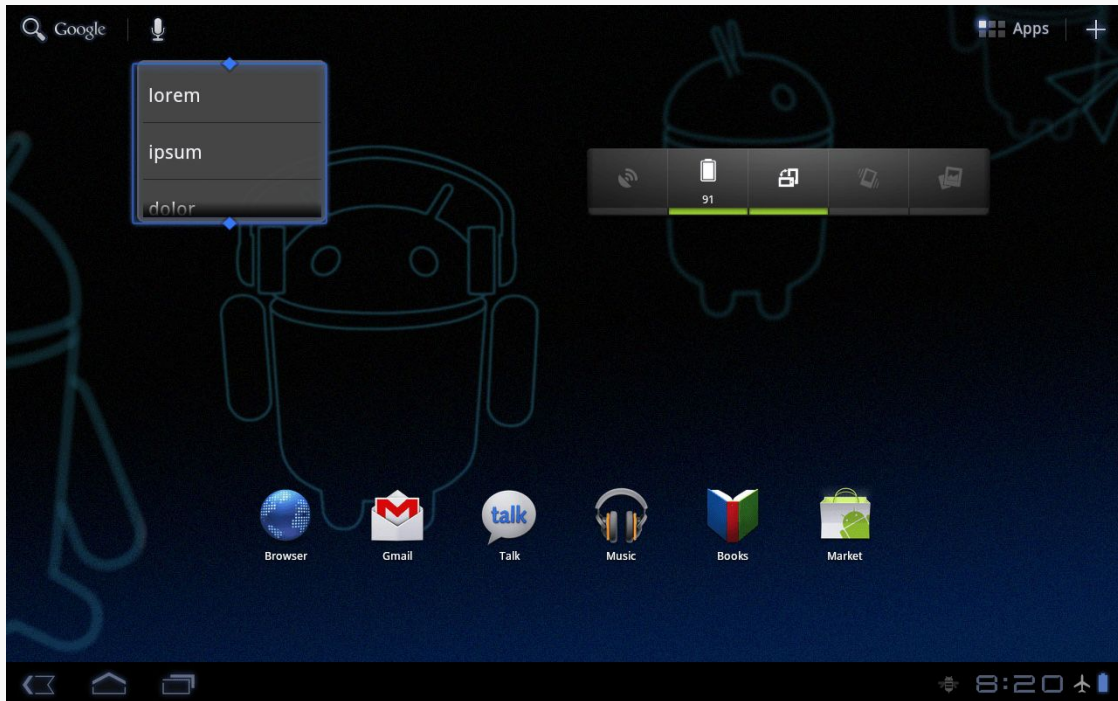

Figure 584: A phone home screen, showing the LoremWidget on the left, with resize handles

The user can then drag those handles to expand or shrink the app widget in the specified dimensions:

ADAPTER-BASED APP WIDGETS

Trail: Data Storage and Retrieval

Content Provider Theory

Android publishes data to you via an abstraction known as a “content provider”. Access to contacts and the call log, for example, are given to you via a set of content providers. In a few places, Android expects you to supply a content provider, such as for integrating your own search suggestions with the Android Quick Search Box. And, content providers are one way for you to supply data to third party applications, or to consume information from third party applications. As such, content providers have the potential to be something you would encounter frequently, even if in practice they do not seem used much.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [working with local databases](#).

Using a Content Provider

Any `Uri` in Android that begins with the `content://` scheme represents a resource served up by a content provider. Content providers offer data encapsulation using `Uri` instances as handles – you neither know nor care where the data represented by the `Uri` comes from, so long as it is available to you when needed. The data could be stored in a SQLite database, or in flat files, or retrieved off a device, or be stored on some far-off server accessed over the Internet.

Given a `Uri`, you may be able to perform basic CRUD (create, read, update, delete) operations using a content provider. `Uri` instances can represent either collections or individual pieces of content. Given a collection `Uri`, you may be able to create new pieces of content via insert operations. Given an instance `Uri`, you may be able to

read data represented by the `Uri`, update that data, or delete the instance outright. Or, given a `Uri`, you may be able to open up a handle to what amounts to a file, that you can read and, possibly, write to.

These are all phrased as “may” because the content provider system is a facade. The actual implementation of a content provider dictates what you can and cannot do, and not all content providers will support all capabilities.

Pieces of Me

The simplified model of the construction of a content `Uri` is the scheme, the namespace of data, and, optionally, the instance identifier, all separated by slashes in URL-style notation. The scheme of a content `Uri` is always `content://`.

So, a content `Uri` of `content://constants/5` represents the constants instance with an identifier of 5.

The combination of the scheme and the namespace is known as the “base `Uri`” of a content provider, or a set of data supported by a content provider. In the example above, `content://constants` is the base `Uri` for a content provider that serves up information about “constants” (in this case, physical constants).

The base `Uri` can be more complicated. For example, if the base `Uri` for contacts were `content://contacts/people`, the contacts content provider may serve up other data using other base `Uri` values.

The base `Uri` represents a collection of instances. The base `Uri` combined with an instance identifier (e.g., 5) represents a single instance.

Most of the Android APIs expect these to be `Uri` objects, though in common discussion, it is simpler to think of them as strings. The `Uri.parse()` static method creates a `Uri` out of the string representation.

Getting a Handle

So, where do these `Uri` instances come from?

The most popular starting point, if you know the type of data you want to work with, is to get the base `Uri` from the content provider itself in code. For example, `CONTENT_URI` is the base `Uri` for contacts represented as people — this maps to `content://contacts/people`. If you just need the collection, this `Uri` works as-is; if

you need an instance and know its identifier, you can call `addId()` on the `Uri` to inject it, so you have a `Uri` for the instance.

You might also get `Uri` instances handed to you from other sources, such as getting `Uri` handles for contacts via sub-activities responding to `ACTION_PICK` intents. In this case, the `Uri` is truly an opaque handle... unless you decide to pick it apart using the various getters on the `Uri` class.

You can also hard-wire literal `String` objects (e.g., `"content://contacts/people"`) and convert them into `Uri` instances via `Uri.parse()`. This is not an ideal solution, as the base `Uri` values could conceivably change over time. For example, the contacts content provider's base `Uri` is no longer `content://contacts/people` due to an overhaul of that subsystem. However, when you integrate with content providers from third parties, most likely you will not have a choice but to “hard-wire” in the content `Uri` based on a string.

The Database-Style API

Of the two flavors of API that a content provider may support, the database-style API is more prevalent. Using a `ContentResolver`, you can perform standard “CRUD” operations (create, read, update, delete) using what looks like a SQL interface.

Makin’ Queries

Given a base `Uri`, you can run a query to return data out of the content provider related to that `Uri`. This has much of the feel of SQL: you specify the “columns” to return, the constraints to determine which “rows” to return, a sort order, etc. The difference is that this request is being made of a content provider, not directly of some database (e.g., `SQLite`).

You have two main options for running a query:

1. Use the `query()` method on `ContentResolver` from some sort of background thread
2. Use a `CursorLoader`, as is discussed [in an upcoming chapter](#)

The standard `query()` method on `ContentResolver` takes five parameters:

- The base `Uri` of the content provider to query, or the instance `Uri` of a specific object to query

- An array of properties (think “columns”) from that content provider that you want returned by the query
- A constraint statement, functioning like a SQL WHERE clause
- An optional set of parameters to bind into the constraint clause, replacing any ? that appear there
- An optional sort statement, functioning like a SQL ORDER BY clause

This method returns a `Cursor` object, which you can use to retrieve the data returned by the query.

This will hopefully make more sense given an example. This chapter shows some sample bits of code from the [ContentProvider/ConstantsPlus](#) sample project. This is the same basic application as was first shown back in the [chapter on database access](#), but rewritten to pull the database logic into a content provider, which is then used by the activity.

The activity starts off, in `onCreate()`, by executing a `LoadCursorTask`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    new LoadCursorTask().execute();
}
```

In `doInBackground()`, `LoadCursorTask` calls a `doQuery()` method on the activity, which in turn uses a `ContentResolver` to query our `ContentProvider`:

```
private Cursor doQuery() {
    return(getContentResolver().query(Provider.Constants.CONTENT_URI,
                                     PROJECTION, null, null, null));
}
```

In the call to `query()`, we provide:

1. The `Uri` passed into the activity by the caller (`CONTENT_URI`), in this case representing the collection of physical constants managed by the content provider
2. A list of properties to retrieve
3. Three `null` values, indicating that we do not need a constraint clause (the `Uri` represents the instance we need), nor parameters for the constraint, nor a sort order (we should only get one entry back)

The biggest “magic” here is the list of properties. The lineup of what properties are possible for a given content provider should be provided by the documentation (or source code) for the content provider itself. In this case, we define logical values on the Provider content provider implementation class that represent the various properties (namely, the unique identifier, the display name or title, and the value of the constant).

Adapting to the Circumstances

Now that we have a Cursor via `query()`, we have access to the query results and can do whatever we want with them. You might, for example, manually extract data from the Cursor to populate widgets or other objects.

However, if the goal of the query was to return a list from which the user should choose an item, you probably should consider using `SimpleCursorAdapter`. This class bridges between the Cursor and a selection widget, such as a `ListView` or `Spinner`. Pour the Cursor into a `SimpleCursorAdapter`, hand the adapter off to the widget, and you are set — your widget will show the available options.

After executing the `query()` and getting the Cursor, the `LoadCursorTask` in `ConstantsBrowser`, in its `onPostExecute()` method, creates a `SimpleCursorAdapter` with the following parameters:

1. The activity (or other Context) creating the adapter; in this case, the `ConstantsBrowser` itself
2. The identifier for a layout to be used for rendering the list entries (`R.layout.row`)
3. The cursor (`constantsCursor`)
4. The properties to pull out of the cursor and use for configuring the list entry View instances (`TITLE` and `VALUE`)
5. The corresponding identifiers of `TextView` widgets in the list entry layout that those properties should go into (`R.id.title` and `R.id.value`)

```
new SimpleCursorAdapter(this,
    R.layout.row, constantsCursor,
    new String[] {Provider.Constants.TITLE,
        Provider.Constants.VALUE},
    new int[] {R.id.title, R.id.value});
```

If you need more control over the views than you can reasonably achieve with the stock view construction logic, subclass `SimpleCursorAdapter` and override

`getView()` to create your own widgets to go into the list, as demonstrated earlier in this book.

The complexity regarding which `SimpleCursorAdapter` constructor to use is because Google deprecated the old constructor in API Level 11, replacing it with a new constructor... that just takes a flag as an additional parameter. Normally, that flag is 0. But, since the new constructor does not exist on API Level 10 and below, we create the `SimpleCursorAdapter` using the proper constructor based on API level.

And, of course, you can manually manipulate the `Cursor` (e.g., `moveToFirst()`, `getString()`), just like you can with a database `Cursor`.

Give and Take

Of course, content providers would be astonishingly weak if you couldn't add or remove data from them, and were instead limited to only update what is there. Fortunately, content providers offer these abilities as well.

To insert data into a content provider, you have two options available on the `ContentProvider` interface (available through `getContentResolver()` to your activity):

- Use `insert()` with a collection `Uri` and a `ContentValues` structure describing the initial set of data to put in the row
- Use `bulkInsert()` with a collection `Uri` and an array of `ContentValues` structures to populate several rows at once

The `insert()` method returns a `Uri` for you to use for future operations on that new object. The `bulkInsert()` method returns the number of created rows; you would need to do a query to get back at the data you just inserted.

For example, if the user chooses our “Add” overflow item, we pop up a dialog to collect a new constant:

```
private void add() {
    View addView=getLayoutInflater().inflate(R.layout.add_edit, null);
    AlertDialog.Builder builder=new AlertDialog.Builder(this);

    builder.setTitle(R.string.add_title).setView(addView)
        .setPositiveButton(R.string.ok, this)
        .setNegativeButton(R.string.cancel, null).show();
}
```

CONTENT PROVIDER THEORY

Then, if the user taps the “OK” button in the dialog, our `onClick()` listener is called, where we collect the entered values from the user, pour them into a `ContentValues` structure, and pass that to an `InsertTask`:

```
@Override
public void onClick(DialogInterface dialog, int which) {
    ContentValues values=new ContentValues(2);
    AlertDialog dlg=(AlertDialog)dialog;
    EditText title=(EditText)dlg.findViewById(R.id.title);
    EditText value=(EditText)dlg.findViewById(R.id.value);

    values.put(DatabaseHelper.TITLE, title.getText().toString());
    values.put(DatabaseHelper.VALUE, value.getText().toString());

    new InsertTask().execute(values);
}
```

`InsertTask`, in its `doInBackground()` method, calls `insert()` on a `ContentResolver` to insert this row:

```
@Override
protected Void doInBackground(ContentValues... values) {
    getContentResolver().insert(Provider.Constants.CONTENT_URI, values[0]);

    constantsCursor=doQuery();
    constantsCursor.getCount();

    return(null);
}
```

Notice that we also call `doQuery()` again. That is because our `Cursor` is now out of date, and we need to obtain a fresh `Cursor` with fresh results. We also call `getCount()` on the `Cursor` — both in `InsertTask` and in `LoadCursorTask` — just to be sure that the `Cursor` has loaded all of its data, while we are safely on the background thread.

The `onPostExecute()` implementation in `InsertTask` uses `changeCursor()` on `CursorAdapter()` to swap in our new `Cursor` for any old one:

```
@Override
public void onPostExecute(Void arg0) {
    ((CursorAdapter)getListAdapter()).changeCursor(constantsCursor);
}
```

To delete one or more rows from the content provider, use the `delete()` method on `ContentResolver`. This works akin to a SQL `DELETE` statement and takes three parameters:

- A `Uri` representing the collection (or instance) from which you wish to delete rows
- A constraint statement, functioning like a SQL `WHERE` clause, to determine which rows should be deleted
- An optional set of parameters to bind into the constraint clause, replacing any `?` that appear there

The File System-Style API

Sometimes, what you are trying to retrieve does not look like a set of rows and columns, but rather looks like a file. For example, the `MediaStore` content provider manages the index of all music, video, and image files available on external storage, and you can use `MediaStore` to open up any such file you find.

Some content providers, like `MediaStore`, support both the database-style and file system-style APIs — you query to find media that matches your criteria, then can open some file that matches. Other content providers might only support the file system-style API.

Given a `Uri` that represents some file managed by the content provider, you can use `openInputStream()` and `openOutputStream()` on a `ContentResolver` to access an `InputStream` or `OutputStream`, respectively. Note, though, that not all content providers may support both modes. For example, a content provider that serves files stored inside the application (e.g., assets in the APK file), you will not be able to get an `OutputStream` to modify the content.

Building Content Providers

Building a content provider is probably a very tedious task. There are many requirements of a content provider, in terms of methods to implement and public data members to supply. And, until you try using it, you have no great way of telling if you did any of it correctly (versus, say, building an activity and getting validation errors from the resource compiler).

That being said, building a content provider is of huge importance if your application wishes to make data available to other applications. If your application is keeping its data solely to itself, you may be able to avoid creating a content provider, just accessing the data directly from your activities. But, if you want your data to possibly be used by others — for example, you are building a feed reader and you

want other programs to be able to access the feeds you are downloading and caching — then a content provider is right for you.

First, Some Dissection

The content `Uri` is the linchpin behind accessing data inside a content provider. When using a content provider, all you really need to know is the provider's base `Uri`; from there you can run queries as needed, or construct a `Uri` to a specific instance if you know the instance identifier.

When building a content provider, though, you need to know a bit more about the innards of the content `Uri`.

A content `Uri` has two to four pieces, depending on situation:

1. It always has a scheme (`content://`), indicating it is a content `Uri` instead of a `Uri` to a Web resource (`http://`).
2. It always has an authority, which is the first path segment after the scheme. The authority is a unique string identifying the content provider that handles the content associated with this `Uri`.
3. It may have a data type path, which is the list of path segments after the authority and before the instance identifier (if any). The data type path can be empty, if the content provider only handles one type of content. It can be a single path segment (`foo`) or a chain of path segments (`foo/bar/goo`) as needed to handle whatever data access scenarios the content provider requires.
4. It may have an instance identifier, which is an integer identifying a specific piece of content. A content `Uri` without an instance identifier refers to the collection of content represented by the authority (and, where provided, the data path).

For example, a content `Uri` could be as simple as `content://sekrits`, which would refer to the collection of content held by whatever content provider was tied to the `sekrits` authority (e.g., `SecretsProvider`). Or, it could be as complex as `content://sekrits/card/pin/17`, which would refer to a piece of content (identified as 17) managed by the `sekrits` content provider that is of the data type `card/pin`.

Next, Some Typing

Next, you need to come up with some MIME types corresponding with the content your content provider will provide.

Android uses both the content `Uri` and the MIME type as ways to identify content on the device. A collection content `Uri` — or, more accurately, the combination of authority and data type path — should map to a pair of MIME types. One MIME type will represent the collection; the other will represent an instance. These map to the `Uri` patterns above for no-identifier and identifier, respectively. As you saw earlier in this book, you can fill in a MIME type into an `Intent` to route the `Intent` to the proper activity (e.g., `ACTION_PICK` on a collection MIME type to call up a selection activity to pick an instance out of that collection).

The collection MIME type should be of the form `vnd.X.cursor.dir/Y`, where `X` is the name of your firm, organization, or project, and `Y` is a dot-delimited type name. So, for example, you might use `vnd.tlagency.cursor.dir/sekrits.card.pin` as the MIME type for your collection of secrets.

The instance MIME type should be of the form `vnd.X.cursor.item/Y`, usually for the same values of `X` and `Y` as you used for the collection MIME type (though that is not strictly required).

Implementing the Database-Style API

Just as an activity and a receiver are both Java classes, so is a content provider. So, the big step in creating a content provider is crafting its Java class, with a base class of `ContentProvider`.

In your subclass of `ContentProvider`, you are responsible for implementing five methods that, when combined, perform the services that a content provider is supposed to offer to activities wishing to create, read, update, or delete content via the database-style API.

Implement `onCreate()`

As with an activity, the main entry point to a content provider is `onCreate()`. Here, you can do whatever initialization you want. In particular, here is where you should lazy-initialize your data store. For example, if you plan on storing your data in such-and-so directory on an SD card, with an XML file serving as a “table of contents”, you

should check and see if that directory and XML file are there and, if not, create them so the rest of your content provider knows they are out there and available for use.

Similarly, if you have rewritten your content provider sufficiently to cause the data store to shift structure, you should check to see what structure you have now and adjust it if what you have is out of date.

Implement query()

As one might expect, the `query()` method is where your content provider gets details on a query some activity wants to perform. It is up to you to actually process said query.

The query method gets, as parameters:

1. A `Uri` representing the collection or instance being queried
2. A `String` array representing the list of properties that should be returned
3. A `String` representing what amounts to a SQL `WHERE` clause, constraining which instances should be considered for the query results
4. A `String` array representing values to “pour into” the `WHERE` clause, replacing any `?` found there
5. A `String` representing what amounts to a SQL `ORDER BY` clause

You are responsible for interpreting these parameters however they make sense and returning a `Cursor` that can be used to iterate over and access the data.

As you can imagine, these parameters are aimed towards people using a `SQLite` database for storage. You are welcome to ignore some of these parameters (e.g., you elect not to try to roll your own SQL `WHERE` clause parser), but you need to document that fact so activities only attempt to query you by instance `Uri` and not by using parameters that you elect to ignore.

Implement insert()

Your `insert()` method will receive a `Uri` representing the collection and a `ContentValues` structure with the initial data for the new instance. You are responsible for creating the new instance, filling in the supplied data, and returning a `Uri` to the new instance.

Implement `update()`

Your `update()` method gets the `Uri` of the instance or collection to change, a `ContentValues` structure with the new values to apply, a `String` for a SQL `WHERE` clause, and a `String` array with parameters to use to replace `?` found in the `WHERE` clause. Your responsibility is to identify the instance(s) to be modified (based on the `Uri` and `WHERE` clause), then replace those instances' current property values with the ones supplied.

This will be annoying, unless you are using `SQLite` for storage. Then, you can pretty much pass all the parameters you received to the `update()` call to the database, though the `update()` call will vary slightly depending on whether you are updating one instance or several.

Implement `delete()`

As with `update()`, `delete()` receives a `Uri` representing the instance or collection to work with and a `WHERE` clause and parameters. If the activity is deleting a single instance, the `Uri` should represent that instance and the `WHERE` clause may be null. But, the activity might be requesting to delete an open-ended set of instances, using the `WHERE` clause to constrain which ones to delete.

As with `update()`, though, this is simple if you are using `SQLite` for database storage (sense a theme?). You can let it handle the idiosyncrasies of parsing and applying the `WHERE` clause — all you have to do is call `delete()` on the database.

Implement `getType()`

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

Update the Manifest

The glue tying the content provider implementation to the rest of your application resides in your `AndroidManifest.xml` file. Simply add a `<provider>` element as a child of the `<application>` element, such as:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

The `android:name` property is the name of the content provider class, with a leading dot to indicate it is in the stock namespace for this application's classes (just like you use with activities).

The `android:authorities` property should be a semicolon-delimited list of the authority values supported by the content provider. Recall, from earlier in this chapter, that each content Uri is made up of a scheme, authority, data type path, and instance identifier. Each authority from each `CONTENT_URI` value should be included in the `android:authorities` list.

Now, when Android encounters a content Uri, it can sift through the providers registered through manifests to find a matching authority. That tells Android which

application and class implements the content provider, and from there Android can bridge between the calling activity and the content provider being called.

Add Notify-On-Change Support

A feature that your content provider can offer to its clients is notify-on-change support. This means that your content provider will let clients know if the data for a given content `Uri` changes.

For example, suppose you have created a content provider that retrieves RSS and Atom feeds from the Internet based on the user's feed subscriptions (via OPML, perhaps). The content provider offers read-only access to the contents of the feeds, with an eye towards several applications on the phone using those feeds versus everyone implementing their own feed poll-fetch-and-cache system. You have also implemented a service that will get updates to those feeds asynchronously, updating the underlying data store. Your content provider could alert applications using the feeds that such-and-so feed was updated, so applications using that specific feed can refresh and get the latest data.

On the content provider side, to do this, call `notifyChange()` on your `ContentResolver` instance (available in your content provider via `getContext().getContentResolver()`). This takes two parameters: the `Uri` of the piece of content that changed and the `ContentObserver` that initiated the change. In many cases, the latter will be `null`; a non-`null` value simply means that the observer that initiated the change will not be notified of its own changes.

On the content consumer side, an activity can call `registerContentObserver()` on its `ContentResolver` (via `getContentResolver()`). This ties a `ContentObserver` instance to a supplied `Uri` — the observer will be notified whenever `notifyChange()` is called for that specific `Uri`. When the consumer is done with the `Uri`, `unregisterContentObserver()` releases the connection.

Implementing the File System-Style API

If you want consumers of your `ContentProvider` to be able to call `openInputStream()` or `openOutputStream()` on a `Uri`, you will need to implement the `openFile()` method. This method is optional — if you are not supporting `openInputStream()` or `openOutputStream()`, you do not need to implement `openFile()` at all.

The `openFile()` method returns a curious object called a `ParcelFileDescriptor`. Given that, the `ContentResolver` can obtain the `InputStream` or `OutputStream` that was requested. There are various static methods on `ParcelFileDescriptor` to create instances of it, such as an `open()` method that takes a `File` object as the first parameter. Note that this works for both files on external storage and files within your own project's app-local file storage (e.g., `getFilesDir()`).

Note that you are welcome to also implement `onCreate()`, if you wish to do some initialization when the content provider starts up. Also, you will have to provide `do-nothing` implementations of `query()`, `insert()`, `update()`, and `delete()`, as those methods are mandatory in `ContentProvider` subclasses, even if you do not plan to support them.

Issues with Content Providers

Content providers are not without their issues.

The biggest complaint seems to be the lack of an `onDestroy()` companion to the `onCreate()` method you can implement. Hence, if you open a database in `onCreate()`, you close it... never. Sometimes, you can alleviate this by initializing things on demand and releasing them immediately, such as opening a database as part of `insert()` and closing it within the same method. This does not always work, however — for example, you cannot close the database you query in `query()`, since the `Cursor` you return would become invalid.

The fact that `ContentProvider` is effectively a facade means that a consumer of a `ContentProvider` has no idea what to expect. It is up to documentation to explain what `Uri` values can be used, what columns can be returned, what query syntax is supported, and so on. And, the fact that it is a facade means that much of the richness of the `SQLite` interface is lost, such as `GROUP BY`. To top it off, the API supported by `ContentProvider` is rather limited — if what you want to share does not look like a database and does not look like a file, it may be difficult to force it into the `ContentProvider` API.

However, perhaps the biggest problem is that, by default, content providers are exported, meaning they can be accessed by other processes (third party applications or the Android OS). Sometimes this is desired. Sometimes, it is not. You need to set `android:exported` to be `false` on your manifest entry for the content provider if you want to keep the provider private to your application. This is the inverse of all other components, which are private by default, unless they have an `<intent-filter>`.

CONTENT PROVIDER THEORY

Note that API Level 17 changes the default — if your `android:targetSdkVersion` is set to 17 or higher, `android:exported` is false by default, not true as before.

Content Provider Implementation Patterns

[The previous chapter](#) focused on the concepts, classes, and methods behind content providers. This chapter more closely examines some implementations of content providers, organized into simple patterns.

Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#), along with [the chapter on permissions](#).

The Single-Table Database-Backed Content Provider

The simplest database-backed content provider is one that only attempts to expose a single table's worth of data to consumers. The `CallLog` content provider works this way, for example.

Step #1: Create a Provider Class

We start off with a custom subclass of `ContentProvider`, named, cunningly enough, `Provider`. Here we need the database-style API methods: `query()`, `insert()`, `update()`, `delete()`, and `getType()`.

onCreate()

Here is the onCreate() method for Provider, from the [ContentProvider/ConstantsPlus](#) sample application:

```
@Override
public boolean onCreate() {
    db=new DatabaseHelper(getContext());

    return((db == null) ? false : true);
}
```

While that does not seem all that special, the “magic” is in the private DatabaseHelper object, a fairly conventional SQLiteOpenHelper implementation:

```
package com.commonware.android.constants;

import android.content.ContentValues;
import android.content.Context;
import android.database.Cursor;
import android.database.sqlite.SQLiteOpenHelper;
import android.database.sqlite.SQLiteDatabase;
import android.hardware.SensorManager;

class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    static final String TITLE="title";
    static final String VALUE="value";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        Cursor c=db.rawQuery("SELECT name FROM sqlite_master WHERE type='table' AND name='constants'", null);

        try {
            if (c.getCount()==0) {
                db.execSQL("CREATE TABLE constants (_id INTEGER PRIMARY KEY AUTOINCREMENT, title TEXT, value REAL);");

                ContentValues cv=new ContentValues();

                cv.put(Provider.Constants.TITLE, "Gravity, Death Star I");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
                db.insert("constants", Provider.Constants.TITLE, cv);

                cv.put(Provider.Constants.TITLE, "Gravity, Earth");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_EARTH);
            }
        } catch (Exception e) {
            // ignore
        }
    }
}
```

CONTENT PROVIDER IMPLEMENTATION PATTERNS

```
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Jupiter");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_JUPITER);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mars");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MARS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mercury");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MERCURY);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Moon");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MOON);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Neptune");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_NEPTUNE);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Pluto");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_PLUTO);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Saturn");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SATURN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Sun");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SUN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, The Island");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_THE_ISLAND);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Uranus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_URANUS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Venus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_VENUS);
db.insert("constants", Provider.Constants.TITLE, cv);
}
}
finally {
    c.close();
}
}

@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
```

```
        android.util.Log.w("Constants", "Upgrading database, which will destroy all  
old data");  
        db.execSQL("DROP TABLE IF EXISTS constants");  
        onCreate(db);  
    }  
}
```

Note that we are creating the DatabaseHelper in onCreate() and are never closing it. That is because there is no onDestroy() (or equivalent) method in a ContentProvider. While we might be tempted to open and close the database on every operation, that will not work, as we cannot close the database and still hand back a live Cursor from the database. Hence, we leave it open and assume that SQLite's transactional nature will ensure that our database is not corrupted when Android shuts down the ContentProvider.

query()

For SQLite-backed storage providers like this one, the query() method implementation should be largely boilerplate. Use a SQLiteQueryBuilder to convert the various parameters into a single SQL statement, then use query() on the builder to actually invoke the query and give you a Cursor back. The Cursor is what your query() method then returns.

For example, here is query() from Provider:

```
@Override  
public Cursor query(Uri url, String[] projection, String selection,  
                   String[] selectionArgs, String sort) {  
    SQLiteQueryBuilder qb=new SQLiteQueryBuilder();  
  
    qb.setTables(TABLE);  
  
    String orderBy;  
  
    if (TextUtils.isEmpty(sort)) {  
        orderBy=Constants.DEFAULT_SORT_ORDER;  
    }  
    else {  
        orderBy=sort;  
    }  
  
    Cursor c=  
        qb.query(db.getReadableDatabase(), projection, selection,  
                selectionArgs, null, null, orderBy);  
  
    c.setNotificationUri(getContext().getContentResolver(), url);  
}
```

```
    return(c);  
}
```

We create a `SQLiteQueryBuilder` and pour the query details into the builder, notably the name of the table that we query against and the sort order (substituting in a default sort if the caller did not request one). When done, we use the `query()` method on the builder to get a `Cursor` for the results. We also tell the resulting `Cursor` what `Uri` was used to create it, for use with the content observer system.

The `query()` implementation, like many of the other methods on `Provider`, delegates much of the `Provider`-specific information to private methods, such as:

1. the name of the table (`getTableName()`)
2. the default sort order (`getDefaultSortOrder()`)

insert()

Since this is a `SQLite`-backed content provider, once again, the implementation is mostly boilerplate: validate that all required values were supplied by the activity, merge your own notion of default values with the supplied data, and call `insert()` on the database to actually create the instance.

For example, here is `insert()` from `Provider`:

```
@Override  
public Uri insert(Uri url, ContentValues initialValues) {  
    long rowID=  
        db.getWritableDatabase().insert(TABLE, Constants.TITLE,  
                                         initialValues);  
  
    if (rowID > 0) {  
        Uri uri=  
            ContentUris.withAppendedId(Provider.Constants.CONTENT_URI,  
                                       rowID);  
        getContext().getContentResolver().notifyChange(uri, null);  
  
        return(uri);  
    }  
  
    throw new SQLException("Failed to insert row into " + url);  
}
```

The pattern is the same as before: use the provider particulars plus the data to be inserted to actually do the insertion.

update()

Here is update() from Provider:

```
@Override
public int update(Uri url, ContentValues values, String where,
                  String[] whereArgs) {
    int count=
        db.getWritableDatabase()
            .update(TABLE, values, where, whereArgs);

    getContext().getContentResolver().notifyChange(url, null);

    return(count);
}
```

In this case, updates are always applied across the entire collection, though we could have a smarter implementation that supported updating a single instance via an instance Uri.

delete()

Similarly, here is delete() from Provider:

```
@Override
public int delete(Uri url, String where, String[] whereArgs) {
    int count=db.getWritableDatabase().delete(TABLE, where, whereArgs);

    getContext().getContentResolver().notifyChange(url, null);

    return(count);
}
```

This is almost a clone of the update() implementation described above.

getType()

The last method you need to implement is getType(). This takes a Uri and returns the MIME type associated with that Uri. The Uri could be a collection or an instance Uri; you need to determine which was provided and return the corresponding MIME type.

For example, here is getType() from Provider:

```
@Override
public String getType(Uri url) {
```

```
if (isCollectionUri(url)) {  
    return("vnd.commonware.cursor.dir/constant");  
}  
  
return("vnd.commonware.cursor.item/constant");  
}
```

Step #2: Supply a Uri

You may wish to add a public static member... somewhere, containing the Uri for each collection your content provider supports, for use by your own application code. Typically, this is a public static final Uri put on the content provider class itself:

```
public static final Uri CONTENT_URI=  
    Uri.parse("content://com.commonware.android.constants.Provider/  
constants");
```

You may wish to use the same namespace for the content Uri that you use for your Java classes, to reduce the chance of collision with others.

Bear in mind that if you intend for third parties to access your content provider, they will not have access to this public static data member, as your class is not in their project. Hence, you will need to publish the string representation of this Uri that they can hard-wire into their application.

Step #3: Declare the “Columns”

Remember those “columns” you referenced when you were using a content provider, [in the previous chapter](#)? Well, you may wish to publish public static values for those too for your own content provider.

Specifically, you may want a public static class implementing BaseColumns that contains your available column names, such as this example from Provider:

```
public static final class Constants implements BaseColumns {  
    public static final Uri CONTENT_URI=  
        Uri.parse("content://com.commonware.android.constants.Provider/  
constants");  
    public static final String DEFAULT_SORT_ORDER="title";  
    public static final String TITLE="title";  
    public static final String VALUE="value";  
}
```

Since we are using SQLite as a data store, the values for the column name constants should be the corresponding column names in the table, so you can just pass the projection (array of columns) to SQLite on a query(), or pass the ContentValues on an insert() or update().

Note that nothing in here stipulates the types of the properties. They could be strings, integers, or whatever. The biggest limitation is what a Cursor can provide access to via its property getters. The fact that there is nothing in code that enforces type safety means you should document the property types well, so people attempting to use your content provider know what they can expect.

Step #4: Update the Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
</application>
</manifest>
```

The Local-File Content Provider

Implementing a content provider that supports serving up files based on `Uri` values is similar, and generally simpler, than creating a content provider for the database-style API. In this section, we will examine the [ContentProvider/Files](#) sample project. This project demonstrates a common use of the filesystem-style API: serving files from internal storage to third-party applications (who, by default, cannot read your internally-stored files).

Note that this sample project will only work on devices that have an application capable of viewing PDF files accessed via `content://Uri` values.

The FileProvider Class

Our `ContentProvider` is named `FileProvider`. However, most of the logic is contained in an `AbstractFileProvider` that will be used for a handful of sample apps in this chapter. We will look at both of those classes, focusing first on the `FileProvider`.

onCreate()

We have an `onCreate()` method. In many cases, this would not be needed for this sort of provider. After all, there is no database to open. In this case, we use `onCreate()` to copy the file(s) out of assets into the app-local file store. In principle, this would allow our application code to modify these files as the user uses the app (versus the unmodifiable editions in assets/).

```
@Override
public boolean onCreate() {
    File f=new File(getContext().getFilesDir(), "test.pdf");

    if (!f.exists()) {
        AssetManager assets=getContext().getResources().getAssets();

        try {
            copy(assets.open("test.pdf"), f);
        }
        catch (IOException e) {
            Log.e("FileProvider", "Exception copying from assets", e);
        }
    }
}
```

```
        return(false);
    }
}

return(true);
}
```

This uses a static `copy()` method, inherited from `AbstractFileProvider`, that can copy an `InputStream` from an asset to a local `File`. We will take a peek at this later in this chapter.

openFile()

We need to implement `openFile()`, to return a `ParcelFileDescriptor` corresponding to the supplied `Uri`:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws
FileNotFoundException {
    File f=new File(getContext().getFilesDir(), uri.getPath());

    if (f.exists()) {
        return(ParcelFileDescriptor.open(f, parseMode(mode)));
    }

    throw new FileNotFoundException(uri.getPath());
}
```

We are passed in a *nix-style string mode, which will be a value like `r` for read access, `wt` for write access (and truncate the file), etc. In API Level 19+, `ParcelFileDescriptor` has a convenience method for converting such modes into the equivalent `ParcelFileDescriptor` flag values. For older devices, you can simply use the `parseMode()` code that Google added:

```
// following is from ParcelFileDescriptor source code
// Copyright (C) 2006 The Android Open Source Project
// (even though this method was added much after 2006...)

private static int parseMode(String mode) {
    final int modeBits;
    if ("r".equals(mode)) {
        modeBits=ParcelFileDescriptor.MODE_READ_ONLY;
    }
    else if ("w".equals(mode) || "wt".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    }
}
```

```
}
else if ("wa".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_WRITE_ONLY
        | ParcelFileDescriptor.MODE_CREATE
        | ParcelFileDescriptor.MODE_APPEND;
}
else if ("rw".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_READ_WRITE
        | ParcelFileDescriptor.MODE_CREATE;
}
else if ("rwt".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_READ_WRITE
        | ParcelFileDescriptor.MODE_CREATE
        | ParcelFileDescriptor.MODE_TRUNCATE;
}
else {
    throw new IllegalArgumentException("Bad mode '" + mode + "'");
}
return modeBits;
}
```

Our `openFile()` method then uses `parseMode()` in the call to the static `open()` method on `ParcelFileDescriptor`, which opens the file (with the desired access mode) and gives us our `ParcelFileDescriptor` back that we can return. If the file is not found, we can throw a `FileNotFoundException` to indicate that.

getDataLength()

`AbstractFileProvider` gives us a callback — `getDataLength()` — where we can indicate how big a file is, given its `Uri`. That information will be made available to clients consuming this stream. The default will be to indicate that the file size is unknown... and that usually works. However, if it is easy for you to determine the file size, do so, and it will increase the compatibility of your app with possible consumers.

In this case, determining the size of a local file is easy:

```
protected long getDataLength(Uri uri) {
    File f=new File(getContext().getFilesDir(), uri.getPath());

    return(f.length());
}
```

The AbstractFileProvider Class

AbstractFileProvider is designed to handle a lot of common boilerplate for streaming providers like the one provided in this sample.

getType()

Just as our database-style ContentProvider needed to implement getType() to provide a MIME type given a Uri, so too do our streaming providers. The difference is that a streaming provider usually wants to use “real” MIME types, values that third-party apps are likely to recognize. For example, a PDF file should use a MIME type of application/pdf, as that is what PDF viewing apps will expect.

Android has some convenience code for determining a likely MIME type. You can use MimeTypeMap to convert a file extension to a MIME type, or you can use guessContentTypeFromName() onURLConnection to get a MIME type for a URL. Both use the same underlying database — the difference is mostly a matter of whether you have a bare file extension already or not. So, the default implementation of getType() in AbstractFileProvider uses guessContentTypeFromName():

```
@Override
public String getType(Uri uri) {
    return(URLConnection.guessContentTypeFromName(uri.toString()));
}
```

If you know that *your* MIME type is unlikely to be recognized by Android (e.g., you invented your own), a subclass of AbstractFileProvider could handle those cases, chaining to the superclass for other Uri values.

insert(), update(), and delete()

ContentProvider itself is abstract, requiring us to implement a variety of methods to satisfy the compiler. Three of them — insert(), update(), and delete() — have no role in a pure-streaming ContentProvider, so AbstractFileProvider has stub implementations:

```
@Override
public Uri insert(Uri uri, ContentValues initialValues) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int update(Uri uri, ContentValues values, String where,
```

```
        String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int delete(Uri uri, String where, String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}
```

A `ContentProvider` that supports *both* the database-style and streaming APIs will need real implementations of those methods for the database operations, perhaps throwing an `Exception` for requests to insert, update, or delete a `Uri` that represents a stream.

`query()` and `getFileName()`

We also need to implement `query()`. You can get by with having this be a stub similar to `insert()` and `kin`. However, for better compatibility, you should have a more robust `query()` implementation, as it will be used by `ContentResolver` to retrieve two pieces of metadata about a `Uri`:

- What is a valid filename to use to represent this `Uri`, should we need a human-readable name? After all, a `ContentProvider Uri` does not have to represent a human-readable path, and so the last segment of that `Uri` could be a cryptic string of hex digits or something, not a filename.
- What is the length of the data that should be delivered by the stream?

`query()` will be called with a projection that contains either `OpenableColumns.DISPLAY_NAME`, `OpenableColumns.SIZE`, or both. A streaming `ContentProvider` ideally supports returning a `Cursor` with this data. The `AbstractFileProvider` implementation of `query()` handles this for us:

```
private final static String[] OPENABLE_PROJECTION= {
    OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE };

@Override
public Cursor query(Uri uri, String[] projection, String selection,
    String[] selectionArgs, String sortOrder) {
    if (projection == null) {
        projection=OPENABLE_PROJECTION;
    }

    final MatrixCursor cursor=new MatrixCursor(projection, 1);
    MatrixCursor.RowBuilder b=cursor.newRow();
```

```
for (String col : projection) {
    if (OpenableColumns.DISPLAY_NAME.equals(col)) {
        b.add(getFileName(uri));
    }
    else if (OpenableColumns.SIZE.equals(col)) {
        b.add(getDataLength(uri));
    }
    else { // unknown, so just add null
        b.add(null);
    }
}

return(cursor);
}
```

If the supplied projection is null, we assume that the caller wants the standard `OpenableColumns`; otherwise, we will use the supplied projection.

Our return value will be a `MatrixCursor`. This amounts to a `Cursor` interface on a two-dimensional array, where you build up the rows in that array via a `MatrixCursor.RowBuilder`. In our case, there will only be one such row, for the relevant values for the file to be streamed in support of the requested `Uri`.

We iterate over the columns in the projection, calling out to `getFileName()` and `getDataLength()` methods for `OpenableColumns.DISPLAY_NAME` and `OpenableColumns.SIZE` respectively (and using null as the result for anything else). The default implementations of those methods return the last path segment of the `Uri` and `AssetFileDescriptor.UNKNOWN_LENGTH`, respectively:

```
protected String getFileName(Uri uri) {
    return(uri.getLastPathSegment());
}

protected long getDataLength(Uri uri) {
    return(AssetFileDescriptor.UNKNOWN_LENGTH);
}
```

Subclasses can override those as needed, as we saw with `getDataLength()` in the concrete `FileProvider` class.

copy()

`AbstractFileProvider` also has a convenience `copy()` static method that copies an `InputStream` to a `File`, used from the `FileProvider.onCreate()` method:

```
static protected void copy(InputStream in, File dst)
    throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) >= 0) {
        out.write(buf, 0, len);
    }

    in.close();
    out.close();
}
}
```

The Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element, as with any other content provider:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.cp.files"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="FilesCPDemo"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>

        <provider
            android:name=".FileProvider"
```

```
        android:authorities="com.commonware.android.cp.files"
        android:exported="true"/>
    </application>
</manifest>
```

Note, however, that we have `android:exported="true"` set in our `<provider>` element. This means that this content provider can be accessed from third-party apps or other external processes (e.g., the media framework for playing back videos).

Using this Provider

The activity is fairly trivial, simply creating an `ACTION_VIEW` Intent on our PDF file and starting up an activity for it, then finishing itself:

```
package com.commonware.android.cp.files;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        startActivity(new Intent(Intent.ACTION_VIEW,
                                Uri.parse(FileProvider.CONTENT_URI
                                    + "test.pdf")));
        finish();
    }
}
```

Here, we use a `CONTENT_URI` published by `FileProvider` as the basis for identifying the file:

```
public static final Uri CONTENT_URI=
    Uri.parse("content://com.commonware.android.cp.files/");
```

The Protected Provider

The problem with the preceding example is that any app on the device, if it knows the right `Uri` to ask for, will be able to access the file. This may be desired, but often times it will not be. Instead, you may want to specifically indicate which apps, at specific points in time, can view the file.

Particularly if your objective is to start a third-party app to work with that file, setting up this sort of security is not that difficult. To see how that works, we will walk through the [ContentProvider/GrantUriPermissions](#) sample project. This is a clone of the ContentProvider/Files project with this extra security added on.

The way the defense works is by using [Android's permission system](#). We will mark the ContentProvider as being not exported, then selectively grant that access to a specific Uri to the app that we want to view our file.

Step #1: Mark the Provider as Not Exported

Putting `android:exported="false"` on the `<provider>` element indicates that no app has the ability to make requests of your ContentProvider, except for specific cases where you authorize it:

```
<provider
  android:name="FileProvider"
  android:authorities="com.commonware.android.cp.files"
  android:exported="false"
  android:grantUriPermissions="false"
  tools:ignore="ExportedContentProvider">
  <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

With no other changes, if we tried to use the app, the third-party PDF viewer would crash when trying to read our PDF file from the Uri.

Step #2: Grant Access to the Uri

To allow third parties to get access only when we specify, we need to make a few more changes.

This `<provider>` element also has `android:grantUriPermissions="false"`. That is the default value for this attribute, shown here purely for illustration purposes. It also has a `<grant-uri-permissions>` child element, listing the local path (within the ContentProvider) to our PDF file.

The `<grant-uri-permissions>` element (or elements, plural) allow us to override the permission requirement for certain pieces of content, granting access to that content on a per-request basis. There are three possibilities:

1. If `android:grantUriPermissions` is true, then we will be able to grant access to any content within our provider

2. If `android:grantUriPermissions` is false, but we have `<grant-uri-permissions>` sub-elements, we can only grant access to the content identified by the `Uri` paths specified in those sub-elements
3. If `android:grantUriPermissions` is false, and we have no `<grant-uri-permissions>` sub-elements (the default case), we cannot grant access to any content within our provider

In this case, we specify that we will only grant access to `/test.pdf`. Since that is the only content in this provider, we could have the same net effect by setting `android:grantUriPermissions` to true.

Then, when we create an `Intent` used to interact with another component, we can include a flag indicating what permission we wish to grant:

```
package com.commonware.android.cp.perms;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        Intent i=new Intent(Intent.ACTION_VIEW, Uri.parse(FileProvider.CONTENT_URI +
"test.pdf"));

        i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
        startActivity(i);
        finish();
    }
}
```

In this revised version of our activity, we add `FLAG_GRANT_READ_URI_PERMISSION` to the `Intent` used with `startActivity()`. This will grant the activity that responds to our `Intent` read access to the specific `Uri` in the `Intent`, overriding the exported status. That is why, when you run this app on a device, the PDF viewer will still be able to view the file.

There is also `FLAG_GRANT_WRITE_URI_PERMISSION` for granting write access, not needed here, as our provider only supports read access.

While this is most commonly used with `startActivity()` (e.g., allowing a mail program limited access to your attachments provider), this can also be used with

`startService()`, `bindService()`, and the various flavors of sending broadcasts (e.g., `sendBroadcast()`).

The Stream Provider

Sometimes, we want a provider that looks like the local-file provider from the preceding section... but we do not have a file. Instead, we have data in some other form, such as a byte array, or a `String`, or an `InputStream`. Writing that material to a file may be problematic, or even counterproductive.

For example, imagine an app that stores data on the user's behalf in an encrypted fashion. One such file is a PDF, that the user would like to view. There are PDF viewers that can view files served via `content://Uri` values, as the previous section demonstrated... but that assumes an unencrypted file. While we could decrypt the file, writing the decrypted results to another file, and serve the decrypted data to the PDF viewer, now we have a persistent decrypted version of the data. That opens a window of time when the data might be accessed by people with nefarious intent, which is something we are trying to avoid by using the encrypted store in the first place. Rather, it would be nice if we could decrypt the data *on the fly* and give that decrypted result to the PDF viewer. Of course, there are security risks intrinsic to that too — after all, we do not know what the PDF viewer might do with the unencrypted data — but it is at least an improvement.

The good news is that Android does support streaming options for `openFile()`-style `ContentProvider` implementations. However, as one might expect, they are not the simplest things to implement.

In this section, we will examine the [ContentProvider/Pipe](#) sample project. This is a near clone of the `ContentProvider/Files` sample from the preceding section. However, rather than simply handing the file to Android to serve as content, we will stream it in ourselves. In principle, as part of this streaming, we could be decrypting it from an encrypted state. Since this sample shares much code with the previous sample, we will focus solely on the changes here.

Note that this sample was inspired by the sample found at <https://github.com/nandeeshwar/Pfd-Create-Pipe>.

The Pipes

Starting with API Level 9, it is possible to create a pipe between two processes, from the Android SDK, via `ParcelFileDescriptor`. In the previous section, we saw how `ParcelFileDescriptor` could be used to open a local file and make that available to other processes — the `createPipe()` method gives us a pipe.

The “pipe” returned by `createPipe()` is a two-element array of `ParcelFileDescriptor` objects. The first element in the array represents the “read” end of the pipe. In our case, that is the end that should be used by a PDF viewer to read in the file contents. The second element of the array represents the “write” end of the pipe, which we will use to supply the file’s contents to the “read” end (and to the PDF viewer by extension).

The Revised `openFile()`

With that in mind, here is our revised `openFile()` method:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws
FileNotFoundException {
    ParcelFileDescriptor[] pipe=null;

    try {
        pipe=ParcelFileDescriptor.createPipe();
        AssetManager assets=getContext().getResources().getAssets();

        new TransferThread(assets.open(uri.getLastPathSegment()),
            new AutoCloseOutputStream(pipe[1])).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
        throw new FileNotFoundException("Could not open pipe for: "
            + uri.toString());
    }

    return(pipe[0]);
}
```

We create our pipe via `createPipe()`, then get an `InputStream` on our PDF file stored as an asset — unlike the `ContentProvider/Files` sample, we do not need to copy the asset to a local file now. We then kick off a background thread, implemented in an inner class named `TransferThread`, to actually copy the data from the asset to the write end of the pipe.

Rather than supply `TransferThread` with a `ParcelFileDescriptor` for the write end of the pipe, we supply an `OutputStream`. Specifically, we pass in a `ParcelFileDescriptor.AutoCloseOutputStream`. This is an `OutputStream` that knows to close the `ParcelFileDescriptor` when we close the stream. Otherwise, it behaves like a fairly typical `OutputStream`.

The Transfer

`TransferThread` is a fairly conventional copy-data-from-stream-to-stream implementation:

```
static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
    public void run() {
        byte[] buf=new byte[1024];
        int len;

        try {
            while ((len=in.read(buf)) >= 0) {
                out.write(buf, 0, len);
            }

            in.close();
            out.flush();
            out.close();
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                "Exception transferring file", e);
        }
    }
}
```

Here, we read in data in 1KB blocks from the `InputStream` (our asset) and write the data to our `OutputStream` (obtained from the `ParcelFileDescriptor`).

The Results

Our activity logic has not substantially changed. We still create an `ACTION_VIEW` Intent on the `content://Uri` from our provider, pointing to our `test.pdf` asset.

Any PDF viewer capable of handling `content:// Uri` values will use a `ContentResolver` to open an `InputStream` for our `Uri`. In the `ContentProvider/Files` sample, that `InputStream` would receive the contents of the file directly from Android. In this new sample, that `InputStream` is reading in bytes off of our pipe, until such time as it has read in all the streamed data and we have closed the `OutputStream`.

Not every possible consumer of a `Uri` will be able to work with our stream, though. For example, `MediaPlayer` expects to be able to determine, up front, how big the file is, and while that works for file-backed `ParcelFileDescriptors`, it does not work for those representing a pipe. Hence, `MediaPlayer` will crash when trying to use a `Uri` to a pipe-based stream, which is certainly unfortunate.

The author would like to thank Reuben Scratton for his assistance in [tracking down this MediaPlayer limitation](#).

FileProvider

The Android Support package now contains its own implementation of a `FileProvider` that greatly simplifies serving files from internal or external storage to another app.

Here, we will see Google's `FileProvider` in action via the [ContentProvider/V4FileProvider](#) sample project. This is a near clone of the `ContentProvider/Pipe` sample from the preceding section, just without our own `ContentProvider` implementation, serving a file from internal storage.

The Rationale

The [documentation for FileProvider](#) states:

Apps should generally avoid sending raw filesystem paths across process boundaries, since the receiving app may not have the same access as the sender. Instead, apps should send `Uri` backed by a provider like `FileProvider`.

This is not just an issue for passing files from internal storage to other apps. On Android 4.2+ tablets, it could even be an issue for external storage, as each user account gets its own portion of external storage. There may be scenarios in which your app (associated with one user) winds up needing to pass the contents of a file on external storage to another app (associated with another user). Regular filesystem

paths will not work in this case, as one user account cannot directly access another user account's files, even on external storage.

The Sources of Files

Google's `FileProvider` offers automatic serving of files from three root points:

- `getFilesDir()` (i.e., the standard portion of internal storage for your app)
- `getCacheDir()` (i.e., internal storage, but files that the OS can purge if needed to free up disk space)
- `Environment.getExternalStorageDirectory()` (i.e., the root of external storage)

For each of these, you will be able to specify a specific subdirectory's worth of files that should be served, if you do not want the entire directory's contents published via `FileProvider`. You will also be able to specify an alias, which serves as the first path segment (after the authority in the `content://Uri`) — `FileProvider` maps that path segment to a specific location of files to serve.

The Manifest Entry

The information about what files to serve comes in the form of an XML resource file. You can name the file whatever you like, but its content needs to be a root `<paths>` element, with a series of children for the different directories you wish to serve. Those directories will be denoted via child elements with specific names:

- `<files-path>` for `getFilesDir()`
- `<cache-path>` for `getCacheDir()`
- `<external-path>` for `Environment.getExternalStorageDirectory()`

For example, our sample project has a `res/xml/provider_paths.xml` file with the following contents:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
  <files-path name="stuff" />
</paths>
```

Here, we are saying that we want to serve the contents of `getFilesDir()`, using a virtual root path of `stuff`. With an authority of `com.commonware.android.cp.v4file`, this means that a `Uri` of

CONTENT PROVIDER IMPLEMENTATION PATTERNS

`content://com.commonware.android.cp.v4file/stuff/test.pdf` would serve up a `test.pdf` file in the `getFilesDir()` directory.

The optional `path` attribute of the `<files-path>`, etc. elements indicates a particular subdirectory, relative to the element-specific root, that should be used as the source of files. So, for example, had the `provider_paths.xml` file looked like:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
  <files-path name="stuff" path="help/" />
</paths>
```

...then `content://com.commonware.android.cp.v4file/stuff/test.pdf` would map to `help/test.pdf` inside of `getFilesDir()`.

You then point to this XML resource from a `<meta-data>` element in the `<provider>` element in the manifest, teaching `FileProvider` what to serve. For example, our `<provider>` element in this sample app is:

```
        android:resource="@xml/provider_paths"/>
    </provider>
</application>
</manifest>
```

Here, our `android:name` points to Google's `FileProvider` (or, more accurately, `android.support.v4.content.FileProvider`), not some class of our own. We still provide the `android:authorities` value, along with any permission rules that we want. Beyond that, we have a `<meta-data>` element, with an `android:name` of `android.support.FILE_PROVIDER_PATHS`, that points to our XML resource with the path information.

You will also notice that our `android:exported` attribute is set to `false`. As it turns out, `FLAG_GRANT_READ_URI_PERMISSION` trumps the exported status of a provider. If you pass a `Uri` to an activity using `FLAG_GRANT_READ_URI_PERMISSION`, the activity will be able to read the contents of that `Uri`, even if the provider itself is not exported.

The Usage

At this point, the `FileProvider` is ready for use, insofar as we can specify `Uri` values like `content://com.commonware.android.cp.v4file/stuff/test.pdf` and get

results. Of course, we actually need to have files in our internal storage, and we need to use such a `Uri`.

Hence, our activity combines the unpack-the-file-from-assets logic from our own providers in earlier samples, plus starts up a PDF viewer on our designated `test.pdf` file:

```
package com.commonware.android.cp.v4file;

import android.app.Activity;
import android.content.Intent;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.support.v4.content.FileProvider;
import android.util.Log;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class FilesCPDemo extends Activity {
    private static final String AUTHORITY="com.commonware.android.cp.v4file";

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        File f=new File(getFilesDir(), "test.pdf");

        if (!f.exists()) {
            AssetManager assets=getResources().getAssets();

            try {
                copy(assets.open("test.pdf"), f);
            }
            catch (IOException e) {
                Log.e("FileProvider", "Exception copying from assets", e);
            }
        }

        Intent i=
            new Intent(Intent.ACTION_VIEW,
                FileProvider.getUriForFile(this, AUTHORITY, f));

        i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
        startActivity(i);
        finish();
    }

    static private void copy(InputStream in, File dst) throws IOException {
        FileOutputStream out=new FileOutputStream(dst);
        byte[] buf=new byte[1024];
    }
}
```

```
int len;

while ((len=in.read(buf)) > 0) {
    out.write(buf, 0, len);
}

in.close();
out.close();
}
```

FileProvider offers a handy `getUriForFile()` static helper method that will return a `Uri` for a given file, incorporating our specified content provider authority.

The result of running this activity is the same as the other file-serving provider samples from this chapter: a PDF viewer (if one is available) will display the `test.pdf` file.

StreamProvider

FileProvider is rather nice: you can serve up typical file-based content without having to roll your own implementation of `ContentProvider` and `openFile()`. However, it only supports a few sources of data: `getFilesDir()`, `getCacheDir()`, and `Environment.getExternalStoragePublicDirectory()`.

The author of this book has written `StreamProvider`, a fork of `FileProvider` that adds support for serving content from assets, raw resources, `getExternalFilesDir()`, and `getExternalCacheDir()`. `StreamProvider` can be found in [the CWAC-Provider project](#).

Once you have added the CWAC-Provider dependency to your project (e.g., added the JAR to `libs/`), you use it much the same as you would use `FileProvider`:

- Define an XML metadata file with a `<paths>` root element, containing one or more elements describing what you want the provider to serve
- Add `com.commonware.cwac.provider.StreamProvider` as a `<provider>` to your manifest, under your own `android:authority`, with a `<meta-data>` element (with a name of `com.commonware.cwac.provider.STREAM_PROVIDER_PATHS`), pointing to that XML metadata
- Use `FLAG_GRANT_READ_URI_PERMISSION` and `FLAG_GRANT_WRITE_URI_PERMISSION` in `Intent` objects you use to have third

CONTENT PROVIDER IMPLEMENTATION PATTERNS

parties use the files the `StreamProvider` serves, to allow those apps selective, temporary access to the file

The XML metadata can have:

- `<external-files-path>` for serving files from `getExternalFilesDir(null)`
- `<external-cache-path>` for serving files from `getExternalCacheDir()`
- `<raw-resource>` for serving a particular raw resource, where the path is the name of the raw resource (without file extension)
- `<asset>` for serving files from `assets/`

These are in addition to the `<files-path>`, `<external-path>`, and `<cache-path>` supported by `FileProvider`.

Hence, `StreamProvider` is especially useful when you want to package some content — such as a PDF file for online help — that you want to serve from your app. Just drop the file in `assets/` in your project, set up `StreamProvider` to serve up assets, and use an appropriate Intent with `startActivity()` to view that file.

The Loader Framework

One perpetual problem in Android development is getting work to run outside the main application thread. Every millisecond we spend on the main application thread is a millisecond that our UI is frozen and unresponsive. Disk I/O, in particular, is a common source of such slowdowns, particularly since this is one place where the emulator typically out-performs actual devices. While disk operations rarely get to the level of causing an “application not responding” (ANR) dialog to appear, they can make a UI “janky”.

Android 3.0 introduced a new framework to help deal with loading bulk data off of disk, called “loaders”. The hope is that developers can use loaders to move database queries and similar operations into the background and off the main application thread. That being said, loaders themselves have issues, not the least of which is the fact that it is new to Android 3.0 and therefore presents some surmountable challenges for use in older Android devices.

This chapter will outline the programming pattern loaders are designed to solve, how to use loaders (both built-in and third-party ones) in your activities, and how to create your own loaders for scenarios not already covered.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

Cursors: Issues with Management

Android has had the concept of “managed cursors” since Android 1.0, and perhaps before that. A managed Cursor is one that an Activity... well... manages. More specifically:

1. When the activity is stopped, the managed Cursor is deactivated, freeing up all of the memory associated with the result set, and thereby reducing the activity’s heap footprint while it is not in the foreground
2. When the activity is restarted, the managed Cursor is requeried, to bring back the deactivated data, along the way incorporating any changes in that data that may have occurred while the activity was off-screen
3. When the activity is destroyed, the managed Cursor is closed.

This is a delightful set of functionality. Cursor objects obtained from a ContentProvider via `managedQuery()` are automatically managed; a Cursor from SQLiteDatabase can be managed by `startManagingCursor()`.

The problem is that the `requeried()` operation that is performed when the activity is restarted is executed on the main application thread. Many times, this is not a huge deal. However, given the nature of on-device flash and the Linux filesystem that many Android devices use (YAFFS2), it is entirely possible that what ordinarily is quick sometimes will not be. Also, you might be testing with small data sets, and your users might be working with bigger ones. As a result, the `requeried()` may slow down your UI in ways that the user will notice.

Introducing the Loader Framework

The Loader framework was designed to solve three issues with the old managed Cursor implementation:

- Arranging for a `requeried()` (or the equivalent) to be performed on a background thread)
- Arranging for the original query that populated the data in the first place to also be performed on a background thread, which the managed Cursor solution did not address at all
- Supporting loading things other than a Cursor, in case you have data from other sources (e.g., XML files, JSON files, Web service calls) that might be able to take advantage of the same capabilities as you can get from a Cursor via the loaders

There are three major pieces to the Loader framework: `LoaderManager`, `LoaderCallbacks`, and the Loader itself.

LoaderManager

`LoaderManager` is your gateway to the Loader framework. You obtain one by calling `getLoaderManager()` (or `getSupportLoaderManager()`, as is described [later in this chapter](#)). Via the `LoaderManager` you can initialize a Loader, restart that Loader (e.g., if you have a different query to use for loading the data), etc.

LoaderCallbacks

Much of your interaction with the Loader, though, comes from your `LoaderCallbacks` object, such as your activity if that is where you elect to implement the `LoaderCallbacks` interface. Here, you will implement three “lifecycle” methods for consuming a Loader:

1. `onCreateLoader()` is called when your activity requests that a `LoaderManager` initialize a Loader. Here, you will create the instance of the Loader itself, teaching it whatever it needs to know to go load your data
2. `onLoadFinished()` is called when the Loader has actually loaded the data — you can take those results and pour them into your UI, such as calling `swapCursor()` on a `CursorAdapter` to supply the fresh Cursor’s worth of data
3. `onLoaderReset()` is called when you should stop using the data supplied to you in the last `onLoadFinished()` call (e.g., the Cursor is going to be closed), so you can arrange to make that happen (e.g., call `swapCursor(null)` on a `CursorAdapter`)

When you implement the `LoaderCallbacks` interface, you will need to provide the data type of whatever it is that your Loader is loading (e.g., `LoaderCallbacks<Cursor>`). If you have several loaders returning different data types, you may wish to consider implementing `LoaderCallbacks` on multiple objects (e.g., instances of anonymous inner classes), so you can take advantage of the type safety offered by Java generics, rather than implementing `LoaderCallbacks<Object>` or something to that effect.

Loader

Then, of course, there is Loader itself.

Consumers of the Loader framework will use some concrete implementation of the abstract Loader class in their LoaderCallbacks onCreateLoader() method. API Level 11 introduced only one concrete implementation: CursorLoader, designed to perform queries on a ContentProvider, and described in [a later section](#).

Honeycomb... Or Not

Loader and its related classes were introduced in Android 3.0 (API Level 11). If your application is only going to be deployed on such devices, you can use loaders “naturally” via the standard implementation.

If, however, you are interested in using loaders but also want to support pre-Honeycomb devices, the Android Support package offers its own implementation of Loader and the other classes. However, to use it, you will need to work within four constraints:

- You will need to add the Android Support package’s JAR to your project (e.g., copy the JAR into your `libs/` directory and add it to your build path)
- You will need to inherit from `FragmentActivity`, not the OS base `Activity` class or other refinements (e.g., `MapActivity`), or from other classes that inherit from `FragmentActivity` (e.g., `SherlockFragmentActivity`).
- You will need to import the `support.v4` versions of various classes (e.g., `android.support.v4.app.LoaderManager` instead of `android.app.LoaderManager`)
- You will need to get your `LoaderManager` by calling `getSupportLoaderManager()`, instead of `getLoaderManager()`, on your `FragmentActivity`

These limitations are the same ones that you will encounter when using fragments on older devices. Hence, while loaders and fragments are not really related, you may find yourself adopting both of them at the same time, as part of incorporating the Android Support package into your project.

Using CursorLoader

Let’s start off by examining the simplest case: using a `CursorLoader` to asynchronously populate and update a `Cursor` retrieved from a `ContentProvider`. This is illustrated in the [Loaders/ConstantsLoader](#) sample project, which is the same show-the-list-of-gravity-constants sample application that [we examined previously](#), updated to use the Loader framework. Note that this project does not

THE LOADER FRAMEWORK

use the Android Support package and therefore only supports API Level 11 and higher.

In `onCreate()`, rather than executing a `managedQuery()` to retrieve our constants, we ask our `LoaderManager` to initialize a loader, after setting up our `SimpleCursorAdapter` on a null `Cursor`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=new SimpleCursorAdapter(this,
                                    R.layout.row, null,
                                    new String[] {Provider.Constants.TITLE,
                                                    Provider.Constants.VALUE},
                                    new int[] {R.id.title, R.id.value});

    setListAdapter(adapter);
    registerForContextMenu(getListView());
    getLoaderManager().initLoader(0, null, this);
}
```

Using a null `Cursor` means we will have an empty list at the outset, a problem we will rectify shortly.

The `initLoader()` call on `LoaderManager` (retrieved via `getLoaderManager()`) takes three parameters:

- A locally-unique identifier for this loader
- An optional `Bundle` of data to supply to the loader
- A `LoaderCallbacks` implementation to use for the results from this loader (here set to be the activity itself, as it implements the `LoaderManager.LoaderCallbacks<Cursor>` interface)

The first time you call this for a given identifier, your `onCreateLoader()` method of the `LoaderCallbacks` will be called. Here, you need to initialize the `Loader` to use for this identifier. You are passed the identifier plus the `Bundle` (if any was supplied). In our case, we want to use a `CursorLoader`:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, Provider.Constants.CONTENT_URI,
                            PROJECTION, null, null, null));
}
```

`CursorLoader` takes a `Context` plus all of the parameters you would ordinarily use with `managedQuery()`, such as the content provider `Uri`. Hence, converting existing

code to use `CursorLoader` means converting your `managedQuery()` call into an invocation of the `CursorLoader` constructor inside of your `onCreateLoader()` method.

At this point, the `CursorLoader` will query the content provider, but do so on a background thread, so the main application thread is not tied up. When the `Cursor` has been retrieved, it is supplied to your `onLoadFinished()` method of your `LoaderCallbacks`:

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {  
    adapter.swapCursor(cursor);  
}
```

Here, we call the new `swapCursor()` available on `CursorAdapter`, to replace the original `null` `Cursor` with the newly-loaded `Cursor`.

Your `onLoadFinished()` method will also be called whenever the data represented by your `Uri` changes. That is because the `CursorLoader` is registering a `ContentObserver`, so it will find out about data changes and will automatically requery the `Cursor` and supply you with the updated data.

Eventually, `onLoaderReset()` will be called. You are passed a `Cursor` object that you were supplied previously in `onLoadFinished()`. You need to make sure that you are no longer using that `Cursor` at this point — in our case, we swap `null` back into our `CursorAdapter`:

```
public void onLoaderReset(Loader<Cursor> loader) {  
    adapter.swapCursor(null);  
}
```

And that's pretty much it, at least for using `CursorLoader`. Of course, you need a content provider to make this work, and creating a content provider involves a bit of work.

What Else Is Missing?

The `Loader` framework does an excellent job of handling queries in the background. What it does not do is help us with anything else that is supposed to be in the background, such as inserts, updates, deletes, or creating/upgrading the database. It is all too easy to put those on the main application thread and therefore possibly encounter issues. Moreover, since the thread(s) used by the `Loader` framework are an

implementation detail, we cannot use those threads ourselves necessarily for the other CRUD operations.

Issues, Issues, Issues

Unfortunately, not all is rosy with the Loader framework.

There appears to be a bug in the Android Support package's implementation of the framework. If you use a Loader from a fragment that has `setRetainInstance()` set to true, you will not be able to use the Loader again after a configuration change, such as a screen rotation. This bug is not seen with the native API Level 11+ implementation of the framework.

Loaders Beyond Cursors

Loaders are not limited to loading something represented by a Cursor. You can load any sort of content that might take longer to load than you would want to spend on the main application thread. While the only concrete Loader implementation supplied by Android at this time loads a Cursor from a ContentProvider, you can create your own non-Cursor Loader implementation or employ one written by a third party.

What Happens When...?

Here are some other common development scenarios and how the Loader framework addresses them.

... the Data Behind the Loader Changes?

According to [the Loader documentation](#), “They monitor the source of their data and deliver new results when the content changes”.

The documentation is incorrect.

A Loader *can* “monitor the source of their data and deliver new results when the content changes”. There is nothing in the framework that requires this behavior. Moreover, there are some cases where it is clearly a bad idea to do this — imagine a Loader loading data off of the Internet, needing to constantly poll some server to look for changes.

The documentation for a Loader implementation should tell you the rules. Android's built-in `CursorLoader` does deliver new results, by means of a behind-the-scenes `ContentObserver`. `SQLiteCursorLoader` does not deliver new results at this time. `SharedPreferencesLoader` hands you a `SharedPreferences` object, which intrinsically is aware of any changes, and so `SharedPreferencesLoader` does nothing special here.

... the Configuration Changes?

The managed Cursor system that the Loader framework replaces would automatically requery() any managed Cursor objects when an activity was restarted. This would update the Cursor in place with fresh data after a configuration change. Of course, it would do that on the main application thread, which was not ideal.

Your Loader objects are retained across the configuration change automatically. Barring bugs in a specific Loader implementation, your Loader should then hand the new activity instance the data that was retrieved on behalf of the old activity instance (e.g., the Cursor).

Hence, you do not have to do anything special for configuration changes.

... the Activity is Destroyed?

Another thing the managed Cursor system gave you was the automatic closing of your Cursor when the activity was destroyed. The Loader framework does this as well, by triggering a reset of the Loader, which obligates the Loader to release any loaded data.

... the Activity is Stopped?

The final major feature of the managed Cursor system was that it would deactivate() a managed Cursor when the activity was stopped. This would release all of the heap space held by that Cursor while it was not on the screen. Since the Cursor was refreshed as part of restarting the activity, this usually worked fairly well and would help minimize pressure on the heap.

Alas, this does not appear to be supported by the Loader framework. The Loader is reset when an activity is destroyed, not stopped. Hence, the Loader data will continue to tie up heap space even while the activity is not in the foreground.

THE LOADER FRAMEWORK

For many activities, this should not pose a problem, as the heap space consumed by their Cursor objects is modest. If you have an activity with a massive Cursor, though, you may wish to consider what steps you can take on your own, outside of the Loader framework, to help with this.

The ContactsContract Provider

One of the more popular stores of data on your average Android device is the contact list. This is particularly true with Android 2.0 and newer versions, which track contacts across multiple different “accounts”, or sources of contacts. Some may come from your Google account, while others might come from Exchange or other services.

This chapter will walk you through some of the basics for accessing the contacts on the device. Along the way, we will revisit and expand upon our knowledge of using a `ContentProvider`.

First, we will review the [contacts APIs](#), past and present. We will then demonstrate how you can connect to the contacts engine to let users [pick and view contacts](#)... all without your application needing to know much of how contacts work. We will then show how you can [query](#) the contacts provider to obtain contacts and some of their details, like email addresses and phone numbers. We wrap by showing how you can invoke a built-in activity to let the user [add a new contact](#), possibly including some data supplied by your application.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

Introducing You to Your Contacts

Android makes contacts available to you via a complex `ContentProvider` framework, so you can access many facets of a contact's data — not just their name, but addresses, phone numbers, groups, etc. Working with the contacts `ContentProvider` set is simple... only if you have an established pattern to work with. Otherwise, it may prove somewhat daunting.

Organizational Structure

The contacts `ContentProvider` framework can be found as the set of `ContactsContract` classes and interfaces in the `android.provider` package. Unfortunately, there is a dizzying array of inner classes to `ContactsContract`.

Contacts can be broken down into two types: raw and aggregate. Raw contacts come from a sync provider or are hand-entered by a user. Aggregate contacts represent the sum of information about an individual culled from various raw contacts. For example, if your Exchange sync provider has a contact with an email address of `jdoe@foo.com`, and your Facebook sync provider has a contact with an email address of `jdoe@foo.com`, Android may recognize that those two raw contacts represent the same person and therefore combine those in the aggregate contact for the user. The classes relating to raw contacts usually have `Raw` somewhere in their name, and these normally would be used only by custom sync providers.

The `ContactsContract.Contacts` and `ContactsContract.Data` classes represent the “entry points” for the `ContentProvider`, allowing you to query and obtain information on a wide range of different pieces of information. What is retrievable from these can be found in the various `ContactsContract.CommonDataKinds` series of classes. We will see examples of these operations later in this chapter.

A Look Back at Android 1.6

Prior to Android 2.0, Android had no contact synchronization built in. As a result, all contacts were in one large pool, whether they were hand-entered by users or were added via third-party applications. The API used for this is the `Contacts ContentProvider`.

In principle, the `Contacts ContentProvider` should still work, as it is merely deprecated in Android 2.0.1, not removed. In practice, it has one big limitation: it

will only report contacts added directly to the device (as opposed to ones synchronized from Microsoft Exchange, Facebook, or other sources).

Pick a Peck of Pickled People

Let's start by finding a contact. After all, that's what the contacts system is for.

Contacts, like anything stored in a `ContentProvider`, is identified by a `Uri`. Hence, we need a `Uri` we can use in the short term, perhaps to read some data, or perhaps just to open up the contact detail activity for the user.

We could ask for a raw contact, or we could ask for an aggregate contact. Since most consumers of the contacts `ContentProvider` will want the aggregate contact, we will use that.

For example, take a look at the [Contacts/Pick](#) sample project, as this shows how to pick a contact from a collection of contacts, then display the contact detail activity. This application gives you a really big "Gimme!" button, which when clicked will launch the contact-selection logic:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/pick"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="Gimme a contact!"
    android:layout_weight="1"
/>
```

Our first step is to determine the `Uri` to use to reference the collection of contacts we want to pick from. In the long term, there should be just one answer for aggregate contacts:

`android.provider.ContactsContract.Contacts.People.CONTENT_URI`. However, that only works for Android 2.0 (SDK level 5) and higher. On older versions of Android, we need to stick with the original `android.provider.Contacts.CONTENT_URI`. To accomplish this, we will use a pinch of reflection to determine our `Uri` via a static initializer when our activity starts:

```
private static Uri CONTENT_URI=null;

static {
    int sdk=new Integer(Build.VERSION.SDK).intValue();

    if (sdk>=5) {
```

THE CONTACTS CONTRACT PROVIDER

```
try {
    Class<?>
clazz=Class.forName("android.provider.ContactsContract$Contacts");

    CONTENT_URI=(Uri)clazz.getField("CONTENT_URI").get(clazz);
}
catch (Throwable t) {
    Log.e("PickDemo", "Exception when determining CONTENT_URI", t);
}
}
else {
    CONTENT_URI=Contacts.People.CONTENT_URI;
}
}
```

Then, you need to create an Intent for the ACTION_PICK on the chosen Uri, then start another activity (via startActivityForResult()) to allow the user to pick a piece of content of the specified type:

```
Intent i=new Intent(Intent.ACTION_PICK, CONTENT_URI);

startActivityForResult(i, PICK_REQUEST);
```

When that spawned activity completes with RESULT_OK, the ACTION_VIEW is invoked on the resulting contact Uri, as obtained from the Intent returned by the pick activity:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==PICK_REQUEST) {
        if (resultCode==RESULT_OK) {
            startActivity(new Intent(Intent.ACTION_VIEW,
                                    data.getData()));
        }
    }
}
```

The result: the user chooses a collection, picks a piece of content, and views it.

Figure 586: The PickDemo sample application, as initially launched

Figure 587: The same application, after clicking the “Gimme!” button, showing the list of available people

Figure 588: A view of a contact, launched by PickDemo after choosing one of the people from the pick list

Note that the `Uri` we get from picking the contact is valid in the short term, but should not be held onto in a persistent fashion (e.g., put in a database). If you need to try to store a reference to a contact for the long term, you will need to get a “lookup `Uri`” on it, to help deal with the fact that the aggregate contact may shift over time as raw contact information for that person comes and goes.

Spin Through Your Contacts

The preceding example allows you to work with contacts, yet not actually have any contact data other than a transient `Uri`. All else being equal, it is best to use the contacts system this way, as it means you do not need any extra permissions that might raise privacy issues.

Of course, all else is rarely equal.

Your alternative, therefore, is to execute queries against the contacts `ContentProvider` to get actual contact detail data back, such as names, phone numbers, and email addresses. The [Contacts/Spinners](#) sample application will demonstrate this technique.

Contact Permissions

Since contacts are privileged data, you need certain permissions to work with them. Specifically, you need the `READ_CONTACTS` permission to query and examine the `ContactsContract` content and `WRITE_CONTACTS` to add, modify, or remove contacts from the system. This only holds true if your code will have access to personally-identifying information, which is why the `Pick` sample above — which just has an opaque `Uri` — does not need any permission.

For example, here is the manifest for the `Contacts/Spinners` sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
    android:versionName="1.0"
    package="com.commonware.android.contacts.spinners"
    xmlns:android="http://schemas.android.com/apk/res/android">

    <uses-permission android:name="android.permission.READ_CONTACTS" />
    <uses-sdk android:minSdkVersion="3"
        android:targetSdkVersion="6" />
    <supports-screens android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false" />
    <application android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity android:label="@string/app_name"
            android:name=".ContactSpinners">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Pre-Joined Data

While the database underlying the `ContactsContract` content provider is private, one can imagine that it has several tables: one for people, one for their phone numbers, one for their email addresses, etc. These are tied together by typical database relations, most likely 1:N, so the phone number and email address tables would have a foreign key pointing back to the table containing information about people.

To simplify accessing all of this through the content provider interface, Android pre-joins queries against some of the tables. For example, you can query for phone

numbers and get the contact name and other data along with the number — you do not have to do this join operation yourself.

The Sample Activity

The ContactSpinners activity is simply a ListActivity, though it sports a Spinner to go along with the obligatory ListView:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Spinner android:id="@+id/spinner"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:drawSelectorOnTop="true"
    />
    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
    />
</LinearLayout>
```

The activity itself sets up a listener on the Spinner and toggles the list of information shown in the ListView when the Spinner value changes:

```
package com.commonware.android.contacts.spinners;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.ListAdapter;
import android.widget.Spinner;

public class ContactSpinners extends ListActivity
    implements AdapterView.OnItemClickListener {
    private static String[] options={"Contact Names",
                                    "Contact Names & Numbers",
                                    "Contact Names & Email Addresses"};

    private ListAdapter[] listAdapters=new ListAdapter[3];

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
```

```
setContentView(R.layout.main);

initListAdapters();

Spinner spin=(Spinner)findViewById(R.id.spinner);
spin.setOnItemSelectedListener(this);

ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
                                                android.R.layout.simple_spinner_item,
                                                options);

aa.setDropDownViewResource(
    android.R.layout.simple_spinner_dropdown_item);
spin.setAdapter(aa);
}

public void onItemSelected(AdapterView<?> parent,
                           View v, int position, long id) {
    setListAdapter(listAdapters[position]);
}

public void onNothingSelected(AdapterView<?> parent) {
    // ignore
}

private void initListAdapters() {
    listAdapters[0]=ContactsAdapterBridge.INSTANCE.buildNameAdapter(this);
    listAdapters[1]=ContactsAdapterBridge.INSTANCE.buildPhonesAdapter(this);
    listAdapters[2]=ContactsAdapterBridge.INSTANCE.buildEmailAdapter(this);
}
}
```

When the activity is first opened, it sets up three Adapter objects, one for each of three perspectives on the contacts data. The Spinner simply resets the list to use the Adapter associated with the Spinner value selected.

Dealing with API Versions

Of course, once again, we have to ponder different API levels.

Querying ContactsContract and querying Contacts is similar, yet different, both in terms of the Uri each uses for the query and in terms of the available column names for the resulting projection.

Rather than using reflection, this time we ruthlessly exploit a feature of the VM: classes are only loaded when first referenced. Hence, we can have a class that refers to new APIs (ContactsContract) on a device that lacks those APIs, so long as we do not reference that class.

THE CONTACTS CONTRACT PROVIDER

To accomplish this, we define an abstract base class, `ContactsAdapterBridge`, that will have a singleton instance capable of running our queries and building a `ListAdapter` for each. Then, we create two concrete subclasses, one for the old API:

```
package com.commonware.android.contacts.spinners;

import android.app.Activity;
import android.database.Cursor;
import android.provider.Contacts;
import android.widget.ListAdapter;
import android.widget.SimpleCursorAdapter;

class OldContactsAdapterBridge extends ContactsAdapterBridge {
    ListAdapter buildNameAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts.People._ID,
                                           Contacts.PeopleColumns.NAME
                                           };
        Cursor c=a.managedQuery(Contacts.People.CONTENT_URI,
                                PROJECTION, null, null,
                                Contacts.People.DEFAULT_SORT_ORDER);

        return(new SimpleCursorAdapter( a,
                                        android.R.layout.simple_list_item_1,
                                        c,
                                        new String[] {
                                            Contacts.PeopleColumns.NAME
                                        },
                                        new int[] {
                                            android.R.id.text1
                                        }));
    }

    ListAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts.Phones._ID,
                                           Contacts.Phones.NAME,
                                           Contacts.Phones.NUMBER
                                           };
        Cursor c=a.managedQuery(Contacts.Phones.CONTENT_URI,
                                PROJECTION, null, null,
                                Contacts.Phones.DEFAULT_SORT_ORDER);

        return(new SimpleCursorAdapter( a,
                                        android.R.layout.simple_list_item_2,
                                        c,
                                        new String[] {
                                            Contacts.Phones.NAME,
                                            Contacts.Phones.NUMBER
                                        },
                                        new int[] {
                                            android.R.id.text1,
                                            android.R.id.text2
                                        }));
    }
}
```

THE CONTACTS CONTRACT PROVIDER

```
ListAdapter buildEmailAdapter(Activity a) {
    String[] PROJECTION=new String[] { Contacts.ContactMethods._ID,
                                       Contacts.ContactMethods.DATA,
                                       Contacts.PeopleColumns.NAME
                                       };
    Cursor c=a.managedQuery(Contacts.ContactMethods.CONTENT_EMAIL_URI,
                           PROJECTION, null, null,
                           Contacts.ContactMethods.DEFAULT_SORT_ORDER);

    return(new SimpleCursorAdapter( a,
                                    android.R.layout.simple_list_item_2,
                                    c,
                                    new String[] {
                                        Contacts.PeopleColumns.NAME,
                                        Contacts.ContactMethods.DATA
                                    },
                                    new int[] {
                                        android.R.id.text1,
                                        android.R.id.text2
                                    }));
}
```

... and one for the new API:

```
package com.commonware.android.contacts.spinners;

import android.app.Activity;
import android.database.Cursor;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.CommonDataKinds.Email;
import android.provider.ContactsContract.CommonDataKinds.Phone;
import android.widget.ListAdapter;
import android.widget.SimpleCursorAdapter;

class NewContactsAdapterBridge extends ContactsAdapterBridge {
    ListAdapter buildNameAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts._ID,
                                           Contacts.DISPLAY_NAME,
                                           };
        Cursor c=a.managedQuery(Contacts.CONTENT_URI,
                               PROJECTION, null, null, null);

        return(new SimpleCursorAdapter( a,
                                        android.R.layout.simple_list_item_1,
                                        c,
                                        new String[] {
                                            Contacts.DISPLAY_NAME
                                        },
                                        new int[] {
                                            android.R.id.text1
                                        }));
    }
}
```

```
}

ListAdapter buildPhonesAdapter(Activity a) {
    String[] PROJECTION=new String[] { Contacts._ID,
                                       Contacts.DISPLAY_NAME,
                                       Phone.NUMBER
                                       };
    Cursor c=a.managedQuery(Phone.CONTENT_URI,
                           PROJECTION, null, null, null);

    return(new SimpleCursorAdapter( a,
                                    android.R.layout.simple_list_item_2,
                                    c,
                                    new String[] {
                                        Contacts.DISPLAY_NAME,
                                        Phone.NUMBER
                                    },
                                    new int[] {
                                        android.R.id.text1,
                                        android.R.id.text2
                                    }));
}

ListAdapter buildEmailAdapter(Activity a) {
    String[] PROJECTION=new String[] { Contacts._ID,
                                       Contacts.DISPLAY_NAME,
                                       Email.DATA
                                       };
    Cursor c=a.managedQuery(Email.CONTENT_URI,
                           PROJECTION, null, null, null);

    return(new SimpleCursorAdapter( a,
                                    android.R.layout.simple_list_item_2,
                                    c,
                                    new String[] {
                                        Contacts.DISPLAY_NAME,
                                        Email.DATA
                                    },
                                    new int[] {
                                        android.R.id.text1,
                                        android.R.id.text2
                                    }));
}
}
```

Our ContactsAdapterBridge class then uses the SDK level to determine which of those two classes to use as the singleton:

```
package com.commonware.android.contacts.spinners;

import android.app.Activity;
import android.os.Build;
import android.widget.ListAdapter;
```

```
abstract class ContactsAdapterBridge {
    abstract ListAdapter buildNameAdapter(Activity a);
    abstract ListAdapter buildPhonesAdapter(Activity a);
    abstract ListAdapter buildEmailAdapter(Activity a);

    public static final ContactsAdapterBridge INSTANCE=buildBridge();

    private static ContactsAdapterBridge buildBridge() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<5) {
            return(new OldContactsAdapterBridge());
        }

        return(new NewContactsAdapterBridge());
    }
}
```

Accessing Contact Information

The first Adapter shows the names of all of the contacts. Since all the information we seek is in the contact itself, we can use the CONTENT_URI provider, retrieve all of the contacts in the default sort order, and pour them into a SimpleCursorAdapter set up to show each person on its own row:

Assuming you have some contacts in the database, they will appear when you first open the ContactSpinners activity, since that is the default perspective:

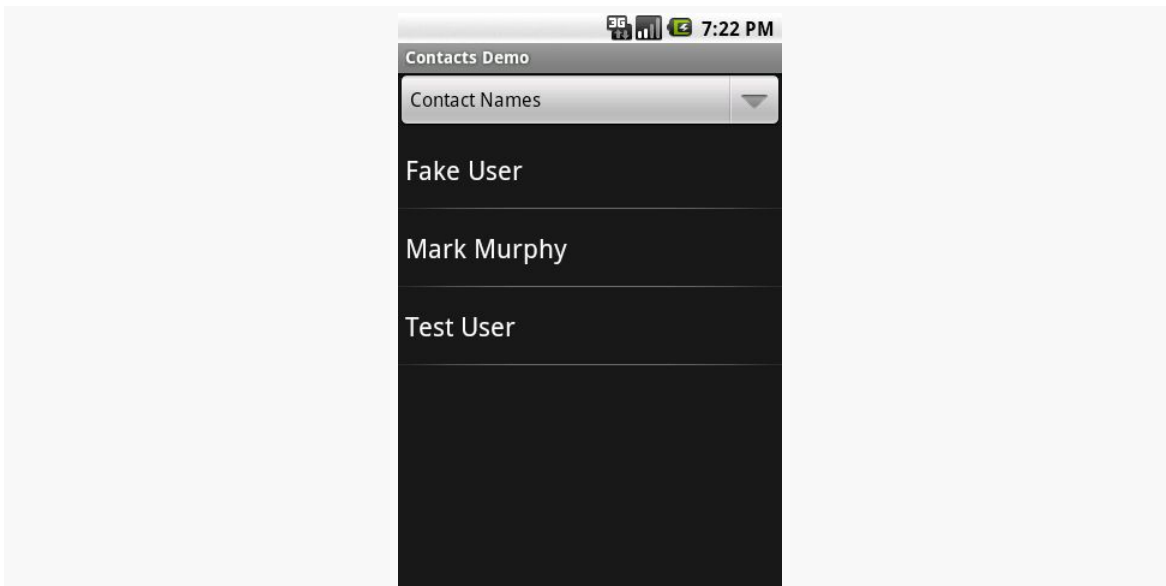

Figure 589: The ContactsDemo sample application, showing all contacts

Figure 590: The ContactsDemo sample application, showing all contacts that have phone numbers

Similarly, to get a list of all the email addresses, we can use the `CONTENT_URI` content provider. Again, the results are displayed via a two-line `SimpleCursorAdapter`:

Figure 591: The ContactsDemo sample application, showing all contacts with email addresses

Makin' Contacts

Let's now take a peek at the reverse direction: adding contacts to the system. This was never particularly easy and now is... well, different.

First, we need to distinguish between sync providers and other apps. Sync providers are the guts underpinning the accounts system in Android, bridging some existing source of contact data to the Android device. Hence, you can have sync providers for Exchange, Facebook, and so forth. These will need to create raw contacts for newly-added contacts to their backing stores that are being sync'd to the device for the first time. Creating sync providers is outside of the scope of this book for now.

It is possible for other applications to create contacts. These, by definition, will be phone-only contacts, lacking any associated account, no different than if the user added the contact directly. The recommended approach to doing this is to collect the data you want, then spawn an activity to let the user add the contact — this avoids your application needing the `WRITE_CONTACTS` permission and all the privacy/data integrity issues that creates. In this case, we will stick with the new `ContactsContract` content provider, to simplify our code, at the expense of requiring Android 2.0 or newer.

To that end, take a look at the [Contacts/Inserter](#) sample project. It defines a simple activity with a two-field UI, with one field apiece for the person's first name and phone number:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="First name:"
        />
        <EditText android:id="@+id/name"
        />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Phone:"
        />
        <EditText android:id="@+id/phone"
            android:inputType="phone"
        />
    </TableRow>
    <Button android:id="@+id/insert" android:text="Insert!" />
</TableLayout>
```

The trivial UI also sports a button to add the contact:

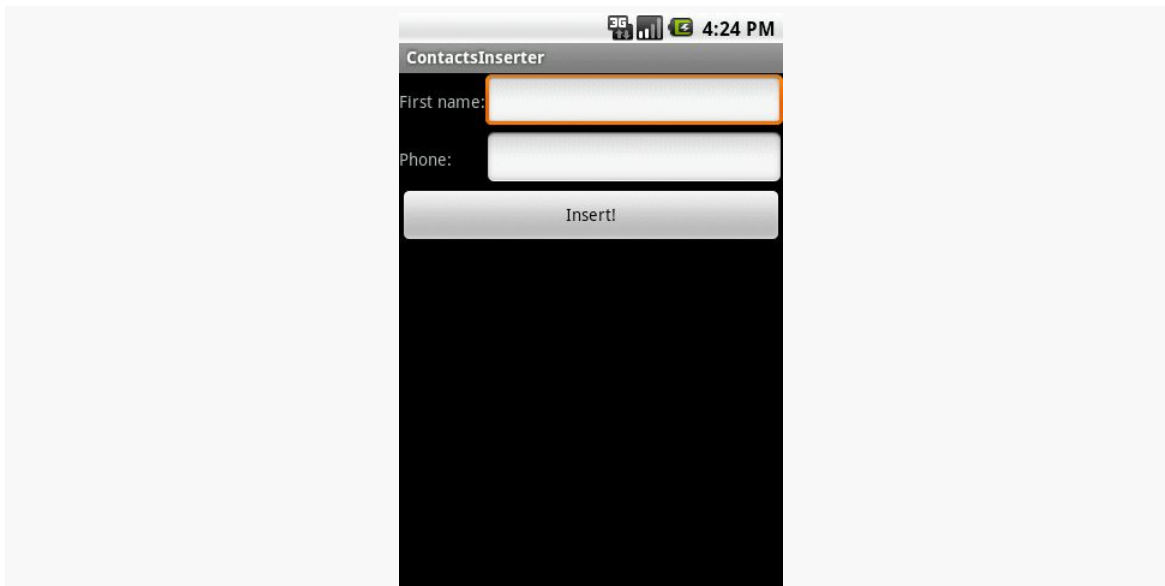

Figure 592: The ContactInserter sample application

When the user clicks the button, the activity gets the data and creates an Intent to be used to launch the add-a-contact activity. This uses the `ACTION_INSERT_OR_EDIT` action and a couple of extras from the `ContactsContract.Intents.Insert` class:

```
package com.commonware.android.inserter;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.Intents.Insert;
import android.view.View;
import android.widget.Button;
import android.widget.EditText;

public class ContactsInserter extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        Button btn=(Button)findViewById(R.id.insert);

        btn.setOnClickListener(onInsert);
    }

    View.OnClickListener onInsert=new View.OnClickListener() {
        public void onClick(View v) {
            EditText fld=(EditText)findViewById(R.id.name);
```

THE CONTACTS CONTRACT PROVIDER

```
String name=fld.getText().toString();

fld=(EditText)findViewById(R.id.phone);

String phone=fld.getText().toString();
Intent i=new Intent(Intent.ACTION_INSERT_OR_EDIT);

i.setType(Contacts.CONTENT_ITEM_TYPE);
i.putExtra(Insert.NAME, name);
i.putExtra(Insert.PHONE, phone);
startActivity(i);
    }
};
}
```

We also need to set the MIME type on the Intent via setType(), to be CONTENT_ITEM_TYPE, so Android knows what sort of data we want to actually insert. Then, we call startActivity() on the resulting Intent. That brings up an add-or-edit activity:

... where if the user chooses “Create new contact”, they are taken to the ordinary add-a-contact activity, with our data pre-filled in:

Figure 594: The edit-contact form, showing the data from the ContactInserter activity

Note that the user could choose an existing contact, rather than creating a new contact. If they choose an existing contact, the first name of that contact will be overwritten with the data supplied by the ContactsInserter activity, and a new phone number will be added from those Intent extras.

The CalendarContract Provider

The Android Open Source Project (AOSP) has had a Calendar application from its earliest days. This application originally was designed to sync with Google Calendar, later extended to other sync sources, such as Microsoft's Exchange. However, this application was not part of the Android SDK, so there was no way to access it from your Android application.

At least, no officially documented and supported way.

Many developers poked through the AOSP source code and found that the Calendar application had a `ContentProvider`. Moreover, this `ContentProvider` was exported (by default). So many developers used undocumented and unsupported means for accessing calendar information. This occasionally broke, as Google modified the Calendar app and changed these pseudo-external interfaces.

Android 4.0 added official SDK support for interacting with the Calendar application via its `ContentProvider`. As part of the SDK, these new interfaces should be fairly stable — if nothing else, they should be supported indefinitely, even if new and improved interfaces are added sometime in the future. So, if you want to tie into the user's calendars, you can. Bear in mind, though, that the new `CalendarContract` `ContentProvider` is not identical to the older undocumented providers, so if you are aiming to support pre-4.0 devices, you have some more work to do.

Of course, similar to the `ContactsContract` `ContentProvider`, the `CalendarContract` `ContentProvider` is severely lacking in documentation, and anything not documented is subject to change.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

You Can't Be a Faker

While the Android 4.0 emulator has the `CalendarContract` `ContentProvider`, it will do you little good. While you can define a Google account on the emulator, the emulator lacks any ability to sync content with that account. Hence, you cannot see any events for your calendars in the Calendar app, and you cannot access any calendar data via `CalendarContract`.

Hence, at present, in order to test your use of `CalendarContract`, you will need to have hardware that runs Android 4.0 (or higher), with one or more accounts set up that have calendar data.

Do You Have Room on Your Calendar?

As a `ContentProvider`, `CalendarContract` is not significantly different from any other such provider that Android supplies or that you write yourself, in that there are `Uri` values representing collections of data, upon which you can query, insert, update, and delete as needed.

The Collections

The two main collections of data that you are likely to be interested in are `CalendarContract.Calendars` (the collection of all defined calendars) and `CalendarContract.Events` (the collection of all defined events across all calendars). Each of those has a `CONTENT_URI` static data member that you would use with `ContentResolver` or a `CursorLoader` to perform operations on those collections. An entry in `CalendarContract.Events` points back to its corresponding calendar via a `CALENDAR_ID` column that you can query upon; the remaining columns on `CalendarContract.Events` have names apparently designed to match with the [iCalendar specification](#) (e.g., `DTSTART` and `DTEND` for the start and end times of the event).

Three other collections may be of interest:

1. `CalendarContract.Instances` has one entry per occurrence of an event, so recurring events get multiple rows
2. `CalendarContract.Attendees` has information about each attendee of an event
3. `CalendarContract.Reminders` has information about each reminder scheduled for an event (e.g., when to remind the user), for those events with associated reminders

Each of those ties back to its associated `CalendarContract.Events` row via an `EVENT_ID` column.

Calendar Permissions

There are two permissions for working with `CalendarContract`: `READ_CALENDAR` and `WRITE_CALENDAR`. As you might expect, querying `CalendarContract` requires the `READ_CALENDAR` permission; modifying `CalendarContract` data requires the `WRITE_CALENDAR` permission.

These permissions have existed since Android's earliest days, even in the SDK, as a side effect of the "meat cleaver" approach the core Android team employed to create the initial SDK. Hence, you can request these permissions in the manifest with any Android build target, without compiler errors. Of course, actually referring to `CalendarContract` will require a build target of API Level 14 or higher.

Querying for Events

For example, let's populate a `ListView` with the roster of all events the user has across all calendars, using a `CursorLoader`, showing the name of each event, the event's start date, and the event's end date. You can find this in the [Calendar/Query](#) sample project in the book's source code.

Our manifest has the `READ_CALENDARS` permission, as you would expect:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.cal.query"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk android:minSdkVersion="14"/>
```

```
<uses-permission android:name="android.permission.READ_CALENDAR"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name=".CalendarQueryActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

We will use a simple ListActivity and so therefore do not need an activity layout. Our row layout (res/layout/row.xml) has three TextView widgets for the three pieces of data that we want to display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/linearlayout1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="4dip"
        android:layout_marginRight="4dip"
        android:layout_weight="1"
        android:ellipsize="end"
        android:textSize="20sp"/>

    <LinearLayout
        android:id="@+id/linearlayout2"
        android:layout_width="wrap_content"
        android:layout_height="match_parent"
        android:layout_marginRight="4dip"
        android:orientation="vertical">

        <TextView
            android:id="@+id/dtstart"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="top"
            android:textSize="10sp"/>

        <TextView
```

THE CALENDARCONTRACT PROVIDER

```
        android:id="@+id/dtend"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom"
        android:textSize="10sp"/>
    </LinearLayout>
</LinearLayout>
```

In our activity (CalendarQueryActivity), in onCreate(), we set up a SimpleCursorAdapter on a null Cursor at the outset and define the activity as being the adapter's ViewBinder:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=
        new SimpleCursorAdapter(this, R.layout.row, null, ROW_COLUMNS,
                                ROW_IDS);
    adapter.setViewBinder(this);
    setListAdapter(adapter);

    getLoaderManager().initLoader(0, null, this);
}
```

A ViewBinder is a way to tailor how Cursor data is poured into row widgets, without subclassing the SimpleCursorAdapter. Implementing the SimpleCursorAdapter.ViewBinder interface requires us to implement a setViewValue() method, which will be called when the adapter wishes to pour data from one column of a Cursor into one widget. We will examine this method shortly.

The SimpleCursorAdapter will pour data from the ROW_COLUMNS in our Cursor into the ROW_IDS widgets in our row layout:

```
private static final String[] ROW_COLUMNS=
    new String[] { CalendarContract.Events.TITLE,
                  CalendarContract.Events.DTSTART,
                  CalendarContract.Events.DTEND };
private static final int[] ROW_IDS=
    new int[] { R.id.title, R.id.dtstart, R.id.dtend };
```

Our onCreate() also initializes the Loader framework, triggering a call to onCreateLoader(), where we create and return a CursorLoader:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, CalendarContract.Events.CONTENT_URI,
                            PROJECTION, null, null,
```

THE CALENDARCONTRACT PROVIDER

```
        CalendarContract.Events.DTSTART));  
    }
```

We query on `CalendarContract.Events.CONTENT_URI`, asking for a certain set of columns indicated by our `PROJECTION` static data member:

```
private static final String[] PROJECTION=  
    new String[] { CalendarContract.Events._ID,  
        CalendarContract.Events.TITLE,  
        CalendarContract.Events.DTSTART,  
        CalendarContract.Events.DTEND };
```

The `ROW_COLUMNS` we map are a subset of the `PROJECTION`, skipping the `_ID` column that `SimpleCursorAdapter` needs but will not be displayed. Our query is also set up to sort by the start date (`CalendarContract.Events.DTSTART`).

When the query is complete, we pop it into the adapter in `onLoadFinished()` and remove it in `onLoaderReset()`:

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {  
    adapter.swapCursor(cursor);  
}  
  
public void onLoaderReset(Loader<Cursor> loader) {  
    adapter.swapCursor(null);  
}
```

Our `setViewValue()` implementation then converts the `DTSTART` and `DTEND` values into formatted strings by way of `DateUtils` and the `formatDateTime()` method:

```
@Override  
public boolean setViewValue(View view, Cursor cursor, int columnIndex) {  
    long time=0;  
    String formattedTime=null;  
  
    switch (columnIndex) {  
        case 2:  
        case 3:  
            time=cursor.getLong(columnIndex);  
            formattedTime=  
                DateUtils.formatDateTime(this, time,  
                    DateUtils.FORMAT_ABBREV_RELATIVE);  
            ((TextView)view).setText(formattedTime);  
            break;  
  
        default:  
            return(false);  
    }  
}
```

```
        return(true);  
    }  
}
```

The `setViewValue()` method should return `true` for any columns it handles and `false` for columns it does not — skipped columns are handled by `SimpleCursorAdapter` itself.

If you run this on a device with available calendar data, you will get a list of those events:

Figure 595: The Calendar Query sample application, with some events redacted

Penciling In an Event

What is rarely documented in the Android SDK is what activities might exist that support the MIME types of a given `ContentProvider`. In part, that is because device manufacturers have the right to remove or replace many of the built-in applications.

The Calendar application is considered by Google to be a “core” application. Quoting the Android 2.3 version of the [Compatibility Definition Document](#) (CDD):

The Android upstream project defines a number of core applications, such as a phone dialer, calendar, contacts book, music player, and so on. Device implementers MAY replace these applications with alternative versions. However, any such alternative versions MUST honor the same Intent patterns provided by the upstream project. For example, if a device contains an alternative music player, it must still honor the Intent pattern issued by third-party applications to pick a song.

Hence, in theory, so long as the CDD does not change and device manufacturers correctly honor it, those Intent patterns described by the Calendar application's manifest should be available across Android 4.0 devices. The Calendar application appears to support ACTION_INSERT and ACTION_EDIT for both the collection MIME type (`vnd.android.cursor.dir/event`) and the instance MIME type (`vnd.android.cursor.item/event`). Notably, there is no support for ACTION_PICK to pick a calendar or event, the way you can use ACTION_PICK to pick a contact.

The MediaStore Provider

Playing back media is a popular pastime on Android devices, one in which your app may want to participate. The easiest way for you to find out what media is available for you to display, edit, or otherwise work with is via the MediaStore content provider. MediaStore is part of the Android framework and allows you to query for images, audio files, and video files that are indexed on the device.

This chapter will review the general workings of MediaStore, plus work through an example of getting video files — and their thumbnails — from MediaStore.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

It is also a pretty good idea to have read the chapters on media recording and playback that might be of relevance, depending on what you intend to do with the MediaStore:

- [Audio Playback](#)
- [Audio Recording](#)
- [Video Playback](#)
- [Using the Camera via 3rd-Party Apps](#)
- [Working Directly with the Camera](#)

You might also wish to consider skimming through [the chapter on files](#) again, as it will be cross-referenced in several places in this chapter.

What Is the MediaStore?

[The documentation for MediaStore](#) describes it this way:

The Media provider contains meta data for all available media on both internal and external storage devices.

This definition... leaves a bit to be desired.

From our standpoint as Android developers, the MediaStore is a `ContentProvider`, supplied by Android. We can use it much like we use other system-supplied providers, like `ContactsContract` and `CalendarContract`. In this case, the primary role of MediaStore is for us to find media, just as the primary role of `ContactsContract` is for us to find contacts.

The “meta data” reference in the documentation refers to the fact that MediaStore itself does not store the media, even though that’s what the name MediaStore would suggest. `MediaMetadataStore` would be a more accurate description. We can learn *about* available media — names, durations, etc. — and we can get a `Uri` from MediaStore pointing to the media, but the media itself lives as a file somewhere else.

Indexed Media

MediaStore has media as a primary focus. Here, “media” refers to:

- Images (typically photos)
- Audio (music, podcasts, etc.)
- Video (whether recorded by the device, downloaded from somewhere, etc.)

MediaStore has intrinsic knowledge of these, particularly for the file formats and codecs that Android supports. As a result, the index maintained by MediaStore will contain some metadata in common for all file types, such as:

- title
- MIME type
- dates (when the file was added, when the file was modified)

...and other metadata that will be unique to one or two of the major types, such as:

- duration for audio and video (but not images)

- height and width for images and video (but not audio)
- geotagging for images and video (but not audio)

Indexed Non-Media

As was mentioned in passing in [the chapter on files](#), Android uses MTP for Android 4.0+ as the USB protocol for sharing files with a desktop or notebook computer.

To power this, Android does not go straight to the filesystem, but rather works with MediaStore. MediaStore maintains an index of *all* files, not just “media”. Whatever shows up in MediaStore is what shows up to the user in their Windows drive letter, OS X mounted volume, etc.

You too can query MediaStore for non-media files. Android will try to maintain a MIME type — probably based on file extensions — and so you can find all indexed PDF files, for example, by querying MediaStore.

MediaStore and “Other” External Storage

In [the chapter on files](#), we covered the difference between internal storage and external storage. Primarily, MediaStore maintains an index of external storage.

However, many Android devices today have multiple locations that could be considered “external storage”. While the vast majority of Android devices have “external storage” as a portion of on-board flash memory, Android device manufacturers are welcome to add other options, such as:

- card slots (typically microSD)
- USB host ports (capable of mounting thumb drives and the like)

From the standpoint of the Android SDK, such secondary storage locations are off-limits, in that there is nothing in the Android SDK to tell us if there are any such locations, where they are located (in terms of File objects to their roots), whether they can be read from, or whether they can be written to. You will find various blog posts and Stack Overflow answers where developers have attempted to catalog all of the possibilities, using a mix of low-level Linux information and manufacturer-based heuristics, but these techniques will be generally unreliable across thousands of device models.

However, many manufacturers who have added such secondary storage options will arrange to have that storage be indexed and be part of MediaStore. So, if the user slides in a microSD card containing audio files, on many devices, when you query MediaStore for available audio files, you will find those on the microSD card in addition to those on “traditional” external storage. From the user’s standpoint, in terms of consuming media, this is sufficient.

How Does My Content Get Indexed?

As was noted back in [the chapter on files](#), if you write files to external storage, you will want to use `MediaScannerConnection` to ensure that those files get indexed. In that chapter, the focus was on ensuring that your files would be visible to attached desktops/notebooks via MTP. However, what *really* happens is that `MediaScannerConnection` updates MediaStore, which in turn drives the MTP-served content.

Even if you fail to index content manually, at some point, Android is likely to pick up the files. For example, Android will scan external storage after a reboot. However, using `MediaScannerConnection` to “tap Android on the shoulder” and have it index your file means that it will show up in MediaStore more quickly. This is very important for multimedia assets — if you downloaded some media, you want that to be indexed as soon as possible, so the user can turn around and consume that media, whether through your app or another one on the user’s device.

How Do I Retrieve Video from the MediaStore?

Video players will need to find out what videos are available on the device, eligible for playback. They may wish to retrieve other details, such as the video title, duration, and so forth. And, of course, they will need something that they can use to actually play back the video itself.

In this section, we will work through the [Media/VideoList](#) sample project. This project has a `VideosFragment` that will show the roster of available videos; tapping on a video in the list will launch the user’s video player to watch that video.

Requesting Permission

Starting on API Level 19 devices, you need to hold the `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE` permissions to be able to work with the MediaStore.

Hence, the VideoList sample app has the READ_EXTERNAL_STORAGE permission in its manifest, as it has no need to write to external storage:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.video.list"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"
        android:xlargeScreens="true" />

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="17" />

    <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

    <application
        android:allowBackup="false"
        android:hardwareAccelerated="true"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />

                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Querying for Video

VideosFragment uses [the Loader framework](#), since MediaStore is a ContentProvider and Loader is a convenient way to asynchronously load content from a ContentProvider. VideosFragment implements the LoaderManager.LoaderCallbacks interface and, in onActivityCreated(), calls getLoaderManager().initLoader() to initialize its Loader.

That triggers a call to onCreateLoader(), where VideosFragment creates a CursorLoader to query the MediaStore for videos:

THE MEDIASTORE PROVIDER

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(
        getActivity(),
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}
```

The Uri for video content from MediaStore is MediaStore.Video.Media.EXTERNAL_CONTENT_URI. Passing in null for the list of columns to return will return all available columns — not the most efficient approach, but it is convenient. The sort order of MediaStore.Video.Media.TITLE has the results sorted by the TITLE column, so the videos are returned alphabetically.

Back up in onActivityCreated(), we initialized a SimpleCursorAdapter to handle our results, passing in the TITLE and _ID columns into our custom row layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>

</LinearLayout>
```

onActivityCreated() also attaches a custom ViewBinder, ThumbnailBinder, that we will cover in the next section, before eventually attaching the initially-empty SimpleCursorAdapter to the ListView of our ListFragment:

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    String[] from=
        { MediaStore.Video.Media.TITLE, MediaStore.Video.Media._ID };
}
```

THE MEDIASTORE PROVIDER

```
int[] to= { android.R.id.text1, R.id.thumbnail };
SimpleCursorAdapter adapter=
    new SimpleCursorAdapter(getActivity(), R.layout.row, null,
                           from, to, 0);

adapter.setViewBinder(this);
setListAdapter(adapter);

getLoaderManager().initLoader(0, null, this);
}
```

The rest of our `LoaderManager.LoaderCallbacks` methods are fairly conventional, using `swapCursor()` to load in the results of the query (or `null` if the loader is reset):

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((CursorAdapter)getListAdapter()).swapCursor(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((CursorAdapter)getListAdapter()).swapCursor(null);
}
```

Showing the Thumbnails

If you have used a video player on Android, most have an activity (or fragment) akin to the one we are implementing in this section. And, most of those will show thumbnail images of the videos in question.

However, retrieving and showing those thumbnails is a bit complicated, because Android may need to *generate* the thumbnail, if there is not already a thumbnail for the video, or if its cache of thumbnails was cleared. Generating a thumbnail takes time, time that we do not want to spend on the main application thread.

So we need to load this image asynchronously. Picasso reportedly supports this, but at the time of this writing, [it remains undocumented](#) and hence may not be reliable.

Instead, this sample app will use another popular image loading library: [the Universal Image Loader \(UIL\)](#).

Preparing the ImageLoader

UIL works off of an ImageLoader to handle the asynchronous loading of images for some scope, such as for a fragment. Hence, our fragment holds an ImageLoader instance, which we configure in `onAttach()`, as we need an Activity to set up the loader:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    ImageLoaderConfiguration ilConfig=
        new ImageLoaderConfiguration.Builder(getActivity()).build();

    imageLoader=ImageLoader.getInstance();
    imageLoader.init(ilConfig);
}
```

UIL supports many configuration options for the ImageLoader, all of which we are ignoring here, settling for the defaults.

Attaching the ViewBinder

Next, the thumbnail will need to be displayed using some sort of `ImageView`. Since `SimpleCursorAdapter` cannot populate an `ImageView` directly, we need some other way to fill in the `ImageView`. To handle this, we create an implementation of a `ViewBinder`, named `ThumbnailBinder` — that is what we attached to our `SimpleCursorAdapter` via `setViewBinder()` back in `onActivityCreated()`.

A `ViewBinder` is a way to tailor how `Cursor` data is poured into row widgets, without subclassing the `SimpleCursorAdapter`. Implementing the `SimpleCursorAdapter.ViewBinder` interface requires us to implement a `setViewValue()` method, which will be called when the adapter wishes to pour data from one column of a `Cursor` into one widget:

```
@Override
public boolean setViewValue(View v, Cursor c, int column) {
    if (column == c.getColumnIndex(MediaStore.Video.Media._ID)) {
        Uri video=
ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            c.getInt(column));
        DisplayImageOptions opts=new DisplayImageOptions.Builder()
            .showImageOnLoading(R.drawable.ic_media_video_poster)
            .build();
```

```
        imageLoader.displayImage(video.toString(), (ImageView)v, opts);  
        return(true);  
    }  
  
    return(false);  
}
```

If our `ViewBinder` is being asked to bind the video ID column (`MediaStore.Video.Media._ID`), we first construct the `Uri` to the video using `ContentUris.withAppendedId()`. Then, we create a `UIL`-supplied `DisplayImageOptions` object, where we can provide details for how to handle the image load. In this case, we supply a drawable resource to use as a placeholder image while the thumbnail is being loaded. Finally, we tell the `imageLoader` we set up in `onAttach()` to display the image. `UIL` recognizes the `Uri` structure for a video from `MediaStore` and uses utility methods like `getThumbnail()` on `MediaStore.Video.Thumbnails` to actually retrieve the thumbnail.

The net result is that when we populate our `ListView` with our `ViewBinder`-enhanced `SimpleCursorAdapter`, the `ListView` rows will initially have the placeholder image, replaced by the actual video thumbnails as they get loaded.

Playing the Selection

`VideosFragment` extends a version of `ContractListFragment`, as was used in the `EU4You` samples [earlier in this book](#). The activity that hosts this fragment is obligated to implement the `VideosFragment.Contract` interface, which in turn requires an `onVideoSelected()` method.

In `onListItemClick()` of `VideosFragment`, the fragment calls `onVideoSelected()` on the `Contract`, supplying:

- the `String` representation of the `Uri` that points to the video itself, pulled from the `MediaStore.Video.Media.DATA` column of the `Cursor` we loaded from the `MediaStore`
- the `MIME` type of that video, pulled from the `MediaStore.Video.Media.MIME_TYPE` column of that same `Cursor`

```
public void onActivityCreated(Bundle state) {  
    super.onActivityCreated(state);  
  
    String[] from=  
        { MediaStore.Video.Media.TITLE, MediaStore.Video.Media._ID };  
    int[] to= { android.R.id.text1, R.id.thumbnail };  
}
```

THE MEDIASTORE PROVIDER

```
SimpleCursorAdapter adapter=  
    new SimpleCursorAdapter(getActivity(), R.layout.row, null,  
                             from, to, 0);  
  
adapter.setViewBinder(this);
```

The main activity — surprisingly named MainActivity — loads up a VideosFragment as a static fragment via the res/layout/main.xml resource:

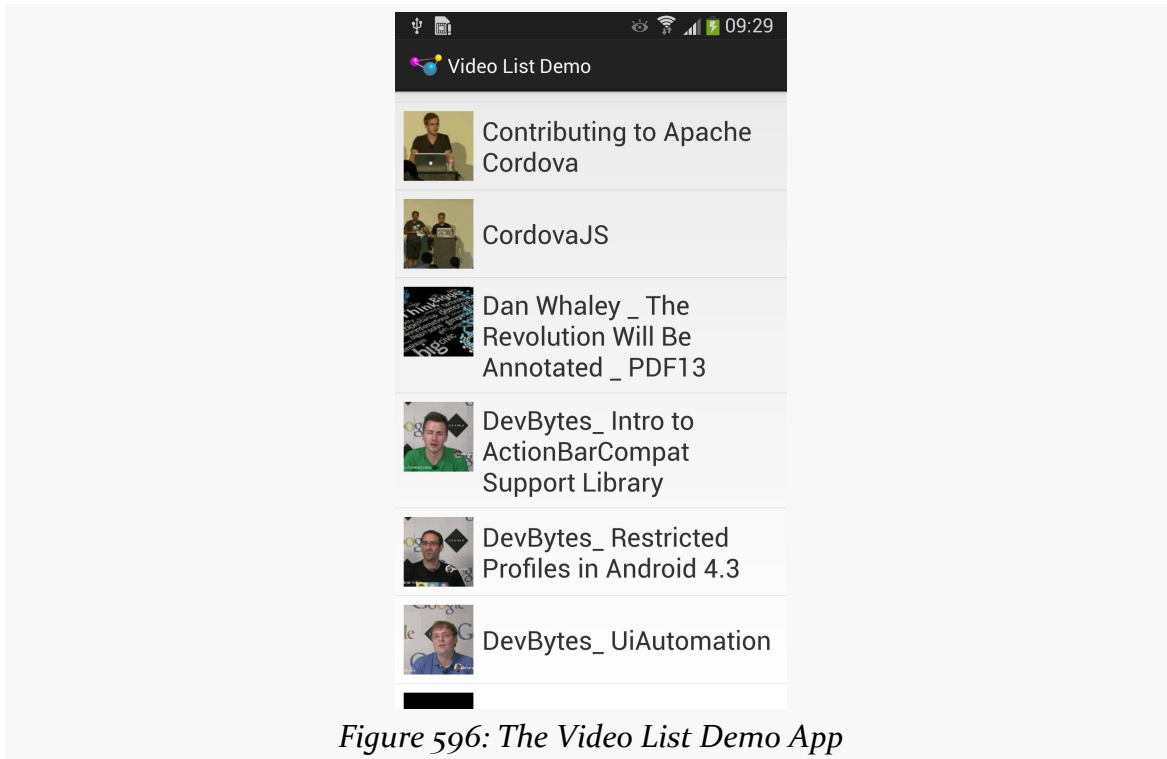

```
<?xml version="1.0" encoding="utf-8"?>  
<fragment xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/videos"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:name="com.commonware.android.video.list.VideosFragment"  
>
```

MainActivity implements VideosFragment.Contract and therefore has an onVideoSelected() method. It simply constructs an Intent to view the video and starts an activity with it:

```
package com.commonware.android.video.list;  
  
import android.app.Activity;  
import android.content.Intent;  
import android.net.Uri;  
import android.os.Bundle;  
import java.io.File;  
  
public class MainActivity extends Activity implements  
    VideosFragment.Contract {  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.main);  
    }  
  
    @Override  
    public void onVideoSelected(String uri, String mimeType) {  
        Uri video=Uri.fromFile(new File(uri));  
        Intent i=new Intent(Intent.ACTION_VIEW);  
  
        i.setDataAndType(video, mimeType);  
        startActivity(i);  
    }  
}
```

The Results

Running this on a device with videos available should show the list of those videos, complete with title and thumbnail:

Tapping on any entry in the list should bring up a video player on your device, assuming that one or more such players (that are capable of supporting `content://Uri` values) are installed.

Consuming Documents

Android has long offered the ability for an app to pick some file or stream from another app and consume it. However, the original options were designed around an app loading content from another app. Even though our *code* would be requesting content based on abstractions like MIME types, the *implementation* and user experience would be based on the traditional “pick an app to fulfill this request” chooser.

Google, given its clear interest in cross-cutting storage engines like Google Drive, wanted something better. In Android 4.4, they added the Storage Access Framework (SAF) to provide a better user experience, with only modest changes to client code.

In this chapter, we will examine what it takes to consume documents published via the SAF.

Prerequisites

This chapter assumes that you have read [the chapter on ContentProvider patterns](#) or have equivalent experience with consuming streams published by a ContentProvider.

The Storage Access... What?

Let’s think about photos for a minute.

A person might have photos managed as:

- on-device photos, mediated by an app like a gallery

- photos stored online in a photo-specific service, like Instagram
- photos stored online in a generic file-storage service, like Google Drive or Dropbox

Now, let's suppose that person is in an app that allows the user to pick a photo, such as to attach to an email.

The classic Android solution would be for the user to have to first choose the app to use to find the photo (e.g., Gallery, Instagram, Google Drive, Dropbox), then find the photo using that app. Then, if all goes well, the original app would receive a `Uri` to that photo and be able to make use of it.

However, this flow has three main problems:

1. From the user's standpoint, they need to know where they have the photo before they can go looking for it. Given the prominence of generic file-storage services, the user might not remember where the photo is stored, but might remember enough details about the photo (e.g., timeframe when taken, tags that might have been attached to the photo) to find it... but the user has to sequentially search each possible photo-storing app until the right one is found.
2. From the client app developer's standpoint, too many apps screw up handling the classic `ACTION_PICK` and `ACTION_GET_CONTENT` activities, failing to return a result in all cases. Users then are as likely to blame the client app for the mistake as they are to blame the photo-storing app, or Android itself.
3. None of this was designed with online file-sharing services in mind. What happens if an app knows about a possible file, but the file is not available on the device right now, because it has not been downloaded from the online service?

The Storage Access Framework is designed to address these issues. It provides its own “picker” UI to allow users to find a file of interest that matches the MIME type that the client app wants. File providers simply publish details about their available files — including those that may not be on the device but could be retrieved if needed. The picker UI allows for easy browsing and searching across all possible file providers, to streamline the process for the user. And, since Android is the one providing the picker, the picker should more reliably give a result to the client app based upon the user's selection (if any).

The Storage Access Framework Participants

Providers are specialized `ContentProvider` implementations, usually extending `DocumentsProvider`, that can tell Android about the documents that are published by an app. This includes providing any sort of organizational structure (directory tree, tag cloud, etc.)

The **clients** are apps that wish to consume (or create) documents managed by providers. Clients will indicate what sort of document they want, in the form of a MIME type, where applicable.

The **picker** is the system UI that allows the user to pick a document (or documents) from among the documents published by all providers that meet the criteria established by a client requesting access to the document(s).

Picking How to Pick (a Peck of Pickled Pepper Photos)

`ACTION_PICK` would seem to be the Intent action to use to pick something. It works, but it is designed for the case where you know the specific collection of “somethings” you want to pick from. Use this, for example, to pick a contact specifically out of `ContactsContract`.

In cases where you know the MIME type you want, but you do not particularly know or care about the exact source of the file, use `ACTION_GET_CONTENT` on API Level 18 and below for everything.

For MIME types that clearly represent a document, file, or other sort of stream, use `ACTION_OPEN_DOCUMENT` (and the SAF) on API Level 19+. The SAF picker will incorporate both full-fledged SAF-compliant providers’ documents along with apps that only support `ACTION_GET_CONTENT`. However, since `ACTION_OPEN_DOCUMENT` is only available on API Level 19+ devices, if you are supporting older devices, you will need to check `Build.VERSION.SDK_INT` and choose an Intent action accordingly.

For MIME types that represent entries in a database (e.g., a calendar entry), use `ACTION_GET_CONTENT`, even on API Level 19+. Google also recommends using `ACTION_GET_CONTENT` on API Level 19+ “if you want your app to simply read/import data”, though it is unclear why they make this recommendation or why the user experience should differ based upon how the bytes would be used.

Opening a Document

Technically, we do not “open” a document using `ACTION_OPEN_DOCUMENT`. Instead, we are requesting a `Uri` pointing to some document that the user chooses.

To do that, create an `Intent` with:

- `ACTION_OPEN_DOCUMENT` as the action
- `CATEGORY_OPENABLE` as the category
- your desired MIME type

Then, use that `Intent` with `startActivityForResult()`.

For example, the [Documents/Consumer](#) sample application contains a `ConsumerFragment` that adds an “Open” item to the action bar overflow. Clicking on “Open” triggers a call to the `open()` method on the fragment. And, for API Level 19+ devices, that will in turn request to “open” a document:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i=new Intent().setType("image/*");

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        startActivityForResult(i.setAction(Intent.ACTION_OPEN_DOCUMENT)
                                .addCategory(Intent.CATEGORY_OPENABLE),
                                REQUEST_OPEN);
    }
    else {
        startActivityForResult(i.setAction(Intent.ACTION_GET_CONTENT),
                                REQUEST_GET);
    }
}
```

This `open()` method also gracefully degrades for older devices, falling back to `ACTION_GET_CONTENT`. In both cases, we are trying to allow the user to pick some image (MIME type of `image/*`). The two `startActivityForResult()` calls use different request IDs (`REQUEST_OPEN` versus `REQUEST_GET`), so that we can distinguish the sort of result that we get in `onActivityResult()`:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
                             Intent resultData) {
    if (resultCode == Activity.RESULT_OK) {
        Uri uri=null;
```

```
if (resultData != null) {
    uri=resultData.getData();
    logToTranscript(uri.toString());

    if (requestCode == REQUEST_OPEN) {
        Cursor c=
            getActivity().getContentResolver().query(uri, null, null,
                                                    null, null);

        if (c != null && c.moveToFirst()) {
            int displayNameColumn=
                c.getColumnIndex(OpenableColumns.DISPLAY_NAME);

            if (displayNameColumn >= 0) {
                logToTranscript("Display name: "
                    + c.getString(displayNameColumn));
            }

            int sizeColumn=c.getColumnIndex(OpenableColumns.SIZE);

            if (sizeColumn < 0 || c.isNull(sizeColumn)) {
                logToTranscript("Size not available");
            }
            else {
                logToTranscript(String.format("Size: %d",
                    c.getInt(sizeColumn)));
            }
        }
        else {
            logToTranscript("...no metadata available?");
        }
    }
}
```

Both ACTION_GET_CONTENT and ACTION_OPEN_DOCUMENT should supply a Uri in the result Intent that points to the document the user chose, if the user actually chose one and we got RESULT_OK as the result code. This sample logs that Uri value to a “transcript” (TextView inside of a ScrollView) to show what we get back.

If the result is from an ACTION_OPEN_DOCUMENT request (REQUEST_OPEN request code), we can try to get some metadata about the document. The provider should support a query on the returned Uri that will give us the display name (OpenableColumns.DISPLAY_NAME) and possibly the size of the file (OpenableColumns.SIZE). So, we use a ContentResolver to run this query, and if we get results back, we try to read out these two values and record them to the transcript as well. Note, though, that:

CONSUMING DOCUMENTS

- There is no guarantee that either column will be in the result set, or that the result set will have any rows
- The size might not be known, particularly if the file is not presently resident on the device (e.g., it is being downloaded now, given that the user chose the file), and so we need to call `isNull()` on the `Cursor` to see if we actually have a `SIZE` value before trying to get it as an integer

The user is presented with the system's picker, to choose an image, complete with a navigation drawer to get to various spots within the picker:

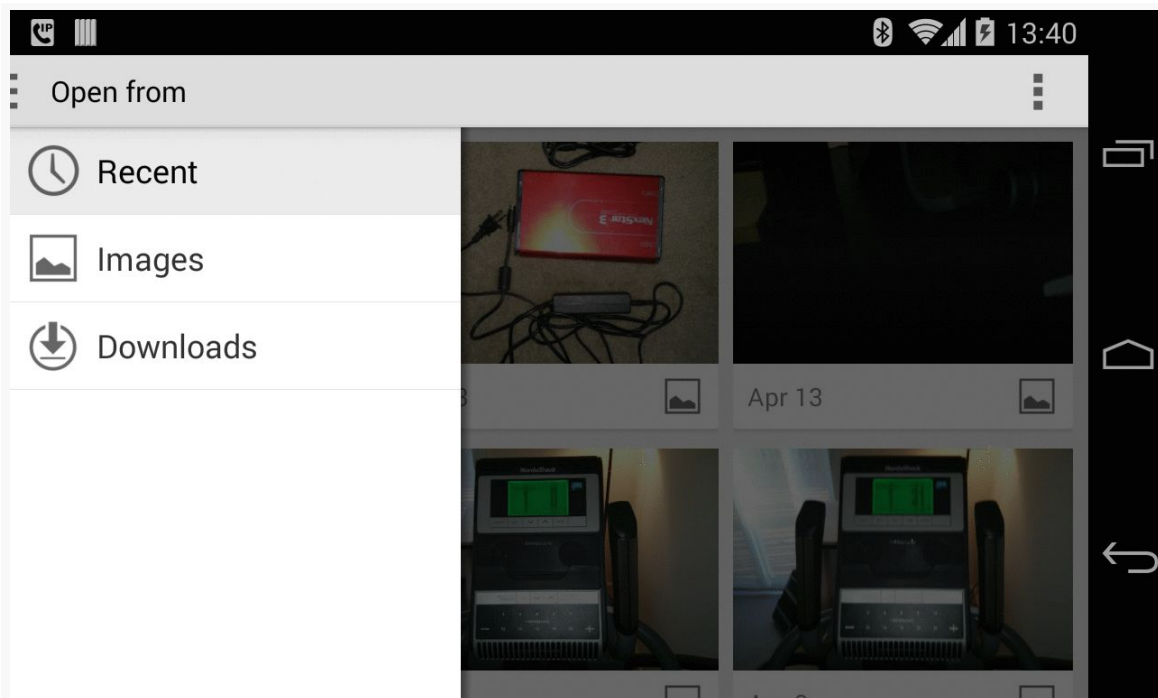

Figure 597: Storage Access Framework Picker, Showing Images

When the user taps on an image, the results wind up in our transcript UI:

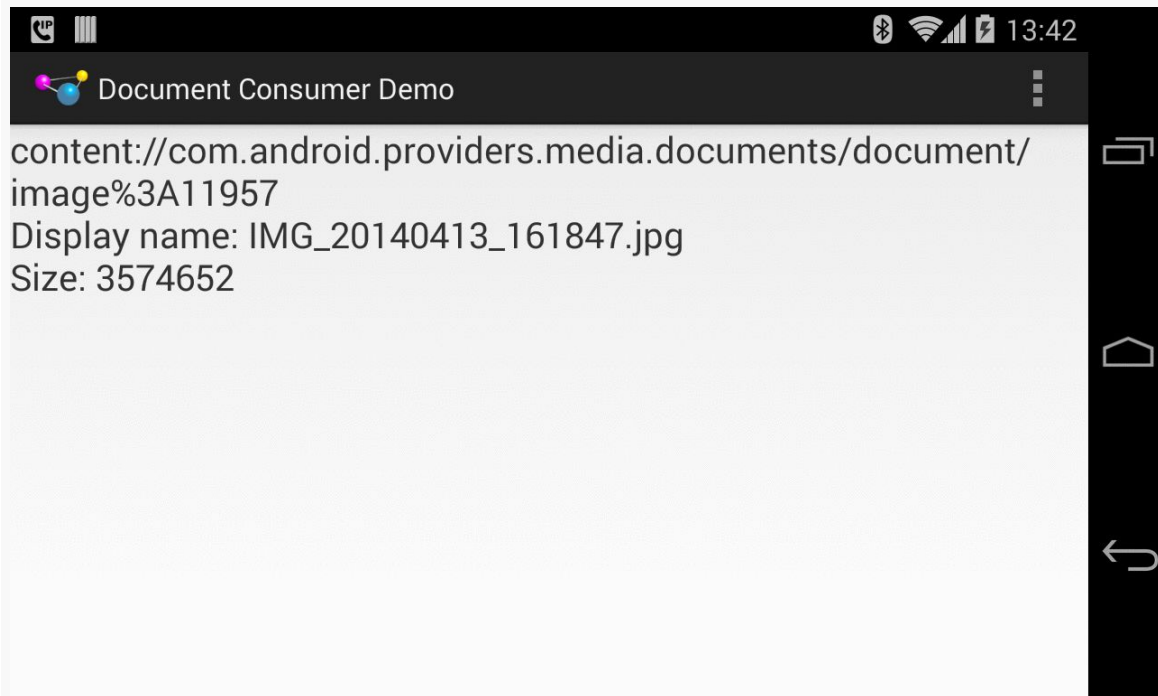

Figure 598: Uri, Display Name, and Size of Chosen File

Note that the default behavior of `ACTION_OPEN_DOCUMENT` is to let the user choose a single file. If your Intent includes `EXTRA_ALLOW_MULTIPLE`, set to true, then the user can choose multiple documents. Rather than getting their `Uri` values via `getData()` on the result Intent, you will need to call `getClipData()` on the Intent and iterate over the “clipboard entries”.

The `Uri` itself can then be used to get an `InputStream` or `OutputStream` for the contents, using `openInputStream()` and `openOutputStream()` on `ContentResolver`, respectively. Note, though, that you cannot pass the `Uri` to other applications, as they may not have rights to work with that document the way that you do.

The Rest of the CRUD

`ACTION_OPEN_DOCUMENT` will give you a `Uri` for a document that you can open for reading — the “R” in “CRUD”.

However, the other CRUD operations are also entirely possible.

Create

`ACTION_CREATE_DOCUMENT` will give you a `Uri` for a document that you can open for writing, as it is your document.

To do this, construct an `Intent` with:

- an action of `ACTION_CREATE_DOCUMENT`
- a category of `CATEGORY_OPENABLE`
- the MIME type of the content you wish to write
- an extra, named `EXTRA_TITLE`, containing your desired filename

Then, invoke `startActivityForResult()` on that `Intent`, and use the `Uri` supplied in the result `Intent` delivered to `onActivityResult()`.

Update

The `Uri` returned from an `ACTION_OPEN_DOCUMENT` request may be writable. If it is, you can use `openOutputStream()` on a `ContentResolver` to write to that document. You can determine if a document is writable by examining the `COLUMN_FLAGS` value returned from a `query()` on the `Uri` — if it includes `FLAG_SUPPORTS_WRITE`, you can write to the document.

Delete

Similarly, if the `COLUMN_FLAGS` value includes `FLAG_SUPPORTS_DELETE`, you can delete the document by calling the static `deleteDocument()` method on the `DocumentsContract` class, supplying a `ContentResolver` plus the `Uri` of the document to be deleted.

Pondering Persistent Permissions

By default, you will have the rights to read (and optionally write) to the document represented by the `Uri` until the device is rebooted. That may be sufficient for your needs.

If, however, you need the rights to survive a reboot, you can call `takePersistableUriPermission()` on a `ContentResolver`, indicating the `Uri` of the document and the permissions (`FLAG_GRANT_READ_URI_PERMISSION` and/or

CONSUMING DOCUMENTS

FLAG_GRANT_WRITE_URI_PERMISSION) that you want persisted. Those rights will then survive a reboot. However:

- They will not survive the document being deleted, so just because you have a saved Uri, do not assume that the Uri will still be valid
- You can revoke those rights by calling `releasePersistableUriPermission()` later on

In addition, you can call `getPersistedUriPermissions()` to find out what persisted permissions your app has. This returns a List of `UriPermission` objects, where each one of those represents a Uri, what persisted permissions (read or write) you have, and when the permissions were persisted.

Providing Documents

The Storage Access Framework gives developers access to ACTION_OPEN_DOCUMENT and related Intent actions to perform operations on a document provider.

However, what if you want to *be* a document provider?

To do that, you will need to create a subclass of DocumentsProvider, override some abstract methods, and perhaps put up with some really obtuse error messages.

This chapter will help you in setting up your DocumentsProvider. With luck, you will escape without encountering errors.

Prerequisites

This chapter assumes that you have read [the preceding chapter on consuming documents](#), along with its prerequisites.

Have Your Content, and Provide it Too

Most apps will not need to implement a document provider. They might not even consume documents, let alone provide them to other apps.

However, if your app has document-style content, and that content is of a MIME type that could reasonably be manipulated by other apps, you should consider implementing a document provider to allow the user to manipulate that content using those other apps.

Historically, developers had two main approaches for content:

1. Store it on internal storage
2. Store it on external storage

The internal storage route would be for content that would not normally be user-accessible, while external storage would be for user-accessible content.

In either of those cases, you will want to consider creating a document provider. In the case of internal storage, the user has no way to get to that content except through your app, and so if your app does not offer some capabilities that other apps do for that content, you limit your user by not having a document provider. In the case of external storage, while users in theory could use a file manager or something to try to get other apps to recognize the content, it will be easier for users if you provide a document provider to proactively publish this content to consuming apps.

However, bear in mind that your app does not have to store its content in either of these places. It could store the content in *somebody else's* document provider, using the mechanisms discussed in [the preceding chapter on consuming documents](#). In this case, you would not need to publish a document provider yourself, as the content is available through the same provider that your code is using.

It may also be the case that while your app is the one directly storing the content on internal or external storage, that content would not reasonably be used by other apps. Perhaps it is in some non-standard format that other apps are unlikely to support. Perhaps the files are not to be used by other apps for security reasons. In these cases, skipping the document provider is reasonable, though not exactly ideal from the user's standpoint. In particular, it restricts them from using those files with apps that can work with any file, such as attaching them to email messages.

So, for example:

- If you are implementing a camera app, and you are not storing the photos in the standard `DIRECTORY_DCIM` location for photos, but you are storing the photos yourself in files consider implementing a document provider so users can get at the photos you are taking. But, if you are implementing a camera app, you might elect to allow the user to indicate some place in somebody else's document provider where you could save the photo on their behalf.
- If you are implementing some sort of network-synced file service (e.g., DropBox, Bittorrent Sync), or some sort of on-device version control system, consider implementing a document provider so users can manipulate the documents that you are managing on their behalf.

Key Provider Concepts

Creating a document provider is significantly more complex than is creating a document consumer. To help make sense of what is required, here are some key terms that you will need to understand.

Roots

A document provider can publish one or more “roots”. Basically, a “root” points to a tree of documents. Many providers will have just one root, but it is entirely possible for your provider to have more than one.

Documents

Documents, in turn, represent what in filesystem terms would be considered files and directories. A document can either have children (e.g., a directory) or it can have content (e.g., a file), but not both.

A root *also* is a document — here, “root” refers to the root of a tree of documents.

Root and Document IDs

Each root has an ID unique to your app to identify that root as being distinct from any other root. This is a string.

Each document — files and directories alike — will have a string document ID to uniquely identify that document within its root. If you have some natural identifier (e.g., a primary key in some table), feel free to use it. Otherwise, you might consider your document ID to be some path to get to the document.

And, since a root is also a document, a root will have both a root ID and a document ID.

These document IDs need to be durable. Clients, or the Storage Access Framework itself, may wind up caching these IDs. Hence, pick something that not only uniquely identifies this document, but will *continue* to uniquely identify the document even after the document has been modified.

Pieces of a Provider

The [Documents/Provider](#) sample application implements a document provider, one that serves documents baked into the app itself in `assets/`. Of course, this is a rather artificial scenario — usually, a document provider will be working with a read/write data store, like internal storage.

The Activity

A document provider app probably needs a real UI. Perhaps that UI is for broader functionality that the app provides on top of serving documents. Perhaps that UI is merely to configure the document store, such as providing account credentials for the online storage service that the document provider exposes on Android.

If nothing else, you will need a do-nothing activity for the user to run, to ensure that your app is moved out of the stopped state.

In the sample app, this is handled by `MainActivity`, which uses `Theme.NoDisplay` to eschew a UI and just shows a `Toast` to indicate that the provider is now activated:

```
package com.commonware.android.documents.provider;

import android.app.Activity;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class MainActivity extends Activity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

The API Level Resources

The document provider itself comes courtesy of a subclass of `DocumentsProvider`. However, the `DocumentsProvider` class only exists on API Level 19 and higher — our

subclass is useless on older devices. To ensure that our provider is only used on API Level 19 and higher, we should only enable it on API Level 19+ devices.

To that end, in `res/values/bools.xml`, we have a boolean resource named `min19`, set to false:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">false</bool>
</resources>
```

In `res/values-v19/bools.xml`, we redefine that boolean resource to be true:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">true</bool>
</resources>
```

Hence, when we refer to the `min19` boolean resource, we will get true or false depending upon whether we are on API Level 19 or not.

The Manifest

Since `DocumentsProvider` is a subclass of `ContentProvider`, we will need a `<provider>` element in the manifest pointing to our subclass of `DocumentsProvider`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.documents.provider"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="19"
        android:targetSdkVersion="19"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/AppTheme">
        <activity
            android:name="MainActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
        </intent-filter>
    </activity>
    <provider
        android:name=".DemoDocumentsProvider"
        android:authorities="com.commonware.android.documents.provider"
        android:grantUriPermissions="true"
        android:exported="true"
        android:permission="android.permission.MANAGE_DOCUMENTS"
        android:enabled="@bool/min19">
        <intent-filter>
            <action android:name="android.content.action.DOCUMENTS_PROVIDER"
        />
        </intent-filter>
    </provider>
</application>
</manifest>
```

That element:

- Uses our @bool/min19 resource from above to indicate that this component should only be enabled on API Level 19 and higher
- Is exported, but requires that applications looking to talk to our provider hold the `MANAGE_DOCUMENTS` permission, which can only be held by the firmware (or apps signed with the firmware's signing key)
- Sets the `android:grantUriPermissions` attribute to `true`, as that will be used by `DocumentsProvider` to allow third-party apps limited, conditional access to our documents
- Has your standard `android:name` and `android:authorities` attributes, as with any other `<provider>`

In addition, the `<provider>` has a nested `<intent-filter>` element. This may seem odd, as this used to be impossible, and it is not intuitively obvious what it would mean for a `ContentProvider` to have an `IntentFilter`. It also is [not documented as being allowed on <provider>](#), so we have no official explanation of what this means. Most likely, the magic `android.content.action.DOCUMENTS_PROVIDER` filter is being used simply as a marker, to indicate to Android that this particular `<provider>` is part of the Storage Access Framework and implements a `DocumentsProvider`.

The DocumentsProvider

The real business logic of publishing documents comes from your subclass of `DocumentsProvider`. As this class is new to API Level 19, your build target (e.g., `compileSdkVersion` in `build.gradle`) needs to be 19 or higher.

PROVIDING DOCUMENTS

A minimal DocumentsProvider implementation will typically need five methods, outlined below.

onCreate()

As with any ContentProvider, your DocumentsProvider can override onCreate() to perform initialization work. Technically, this is not required, but the odds are very good that you will have *something* that you need to initialize.

In the case of our sample DocumentsProvider — named DemoDocumentsProvider — onCreate() simply obtains access to an AssetManager instance that can be used for serving documents:

```
private AssetManager assets;

@Override
public boolean onCreate() {
    assets=getContext().getAssets();

    return(true);
}
```

queryRoots()

Your queryRoots() method needs to return information about the root(s) that your provider will provide.

However, rather than returning this in the form of some clean object model (e.g., a List of Document.Root objects or some such), the return value is a Cursor. While in principle this Cursor could come from a database, in many cases it will be a MatrixCursor, which is a Cursor interface over a two-dimensional array representing the rows and columns.

From here, you should return all *presently valid* roots. The “presently valid” part is because a root might exist but not be usable at the present time. For example, suppose that you are writing a DocumentsProvider that provides a document interface to an Internet-hosted storage service. In this case, you may need the user to authenticate in order to allow access to those files, such as to pass that authentication data along to the Web service to be able to retrieve directory and file data. If the user is not presently logged in, though, not only can you not talk to the Web service right now, but you do not have the ability to force the user to authenticate right now. Instead, you will have to cull the root(s) governed by those

PROVIDING DOCUMENTS

authentication credentials. This may mean that the Cursor you return has no rows, as you simply do not have anything that can be published right now.

The Cursor that you return will have one row per presently valid root. The columns will be ones defined on the DocumentsContract.Root class. Your queryRoots() method is passed a String array representing the columns requested by the Storage Access Framework. As your app may not support all of those columns, you will need to determine the intersection between the requested columns and the ones you support.

The sample app defines a SUPPORTED_ROOT_PROJECTION static data member to list the DocumentsContract.Root columns that are supported in general:

```
private static final String[] SUPPORTED_ROOT_PROJECTION=new String[] {
    Root.COLUMN_ROOT_ID, Root.COLUMN_FLAGS, Root.COLUMN_TITLE,
    Root.COLUMN_DOCUMENT_ID, Root.COLUMN_ICON };
```

And the demo provider has a private netProjection() utility method that computes the intersection between the requested columns and the supported ones:

```
private static String[] netProjection(String[] requested, String[] supported) {
    if (requested==null) {
        return(supported);
    }

    ArrayList<String> result=new ArrayList<String>();

    for (String request : requested) {
        for (String support : supported) {
            if (request.equals(support)) {
                result.add(request);
                break;
            }
        }
    }

    return(result.toArray(new String[0]));
}
```

That net projection is used in the MatrixCursor constructor, to teach it the available columns, as part of the queryRoots() implementation:

```
@Override
public Cursor queryRoots(String[] projection)
    throws FileNotFoundException {
    String[] netProjection=
        netProjection(projection, SUPPORTED_ROOT_PROJECTION);
    MatrixCursor result=new MatrixCursor(netProjection);
}
```

PROVIDING DOCUMENTS

```
MatrixCursor.RowBuilder row=result.newRow();

row.add(Root.COLUMN_ROOT_ID, ROOT_ID);
row.add(Root.COLUMN_ICON, R.drawable.ic_launcher);
row.add(Root.COLUMN_FLAGS, Root.FLAG_LOCAL_ONLY);
row.add(Root.COLUMN_TITLE, getContext().getString(R.string.root));
row.add(Root.COLUMN_DOCUMENT_ID, ROOT_DOCUMENT_ID);

return(result);
}
```

queryRoots() then adds a row to the MatrixCursor, through a MatrixCursor.RowBuilder, containing five columns:

1. DocumentsContract.Root.COLUMN_ROOT_ID is the root ID for this root, as described [earlier in this chapter](#).
2. DocumentsContract.Root.COLUMN_ICON, which is a reference to a drawable resource that may be used in Storage Access Framework UI to help visually represent this root. In principle, this could be anything; in practice, you will probably choose your launcher icon, as it is the icon that the user will recognize.
3. DocumentsContract.Root.COLUMN_FLAGS, indicating which optional capabilities this root supports. In this case, the only flag we are setting is FLAG_LOCAL_ONLY, indicating that network I/O is not required to browse the contents of the provider. Our sample app indicates that it is local-only, as its documents are all packaged in assets/. A provider backed by a Web service, though, would not include this flag, so the Storage Access Framework knows that calls to some of the other methods (e.g., queryChildDocuments()) may take a significant amount of time.
4. DocumentsContract.Root.COLUMN_TITLE, which is a string identifying this root. The title and icon will tend to be included in Storage Access Framework-supplied UIs. In this case, with only a single root, the title is hard-coded to be a string resource. In other cases, this might be some other human-grokkable display name (e.g., the name of some storage service account).
5. DocumentsContract.Root.COLUMN_DOCUMENT_ID, which returns the document ID representing the document tree for this root.

In this case, the document IDs for this DocumentsProvider are the relative paths within assets/ of the files, starting from a root docs/ directory. So, while the root ID could be anything, the root document ID should be consistent with the other document ID values. In this case, the sample app uses:

PROVIDING DOCUMENTS

```
private static final String ROOT_ID="thisIsMyBoomstick";
private static final String ROOT_DOCUMENT_ID="docs";
```

queryChildDocuments()

As noted previously, some documents will represent a directory, while others will represent files. For those that represent a directory, `queryChildDocuments()` will need to return the document information for the contents of the directory.

`queryChildDocuments()` is passed:

- the document ID of the directory
- the columns, defined on the `DocumentsContract.Document` class, that the Storage Access Framework wants
- the sort order, expressed as a SQL-style `ORDER BY` clause (minus the actual `ORDER BY` part), that you might use to help control the order in which to return the child documents (or ignore if you wish)

As with `queryRoots()`, we need to come up with the intersection of the columns that the requester asks for and the columns that we support. There is a static string array named `SUPPORTED_DOCUMENT_PROJECTION` that represents the columns that we support:

```
private static final String[] SUPPORTED_DOCUMENT_PROJECTION=
    new String[] { Document.COLUMN_DOCUMENT_ID, Document.COLUMN_SIZE,
        Document.COLUMN_MIME_TYPE, Document.COLUMN_DISPLAY_NAME,
        Document.COLUMN_FLAGS};
```

The `queryChildDocuments()` method then uses the same `netProjection()` helper method that `queryRoots()` did to determine the intersection:

```
@Override
public Cursor queryChildDocuments(String parentDocId,
    String[] projection,
    String sortOrder)
    throws FileNotFoundException {
    String[] netProjection=
        netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
    MatrixCursor result=new MatrixCursor(netProjection);

    try {
        String[] children=assets.list(parentDocId);

        for (String child : children) {
            addDocumentRow(result, child,
                parentDocId + File.separator + child);
        }
    }
}
```

```
    }  
  }  
  catch (IOException e) {  
    Log.e(getClass().getSimpleName(),  
        "Exception reading asset dir", e);  
  }  
  
  return(result);  
}
```

As with `queryRoots()`, the return value of `queryChildDocuments()` is a `Cursor` representing the documents contained in this directory. Once again, we use a `MatrixCursor` to build up an in-memory `Cursor`, this time for all files within the `assets/` directory denoted by `parentDocId`, using the `list()` method on `AssetManager` to find out what those files are.

The logic to populate the `MatrixCursor` is delegated to an `addDocumentRow()` private method, as we will be using it elsewhere in this `DocumentsProvider` implementation. `addDocumentRow()` creates a `MatrixCursor.RowBuilder` and fills in the supported columns:

```
private void addDocumentRow(MatrixCursor result, String child,  
    String assetPath) throws IOException {  
  MatrixCursor.RowBuilder row=result.newRow();  
  
  row.add(Document.COLUMN_DOCUMENT_ID, assetPath);  
  
  if (isDirectory(assetPath)) {  
    row.add(Document.COLUMN_MIME_TYPE, Document.MIME_TYPE_DIR);  
  }  
  else {  
    String ext=MimeTypeMap.getFileExtensionFromUrl(assetPath);  
  
    row.add(Document.COLUMN_MIME_TYPE,  
        MimeTypeMap.getSingleton().getMimeTypeFromExtension(ext));  
    row.add(Document.COLUMN_SIZE, getAssetLength(assetPath));  
  }  
  
  row.add(Document.COLUMN_DISPLAY_NAME, child);  
  row.add(Document.COLUMN_FLAGS, 0);  
}
```

Of note:

- the document ID of the child is simply its relative path within `assets/`
- the MIME type is a special one if the child document represents a directory, or else is looked up using `MimeTypeMap` if the child document represents a file

PROVIDING DOCUMENTS

- the “display name” could be something special (e.g., the <title> of a Web page), but in this case is just the filename

To determine if an asset path represents a directory, the `isDirectory()` utility method just sees if `list()` returns a non-empty list:

```
private boolean isDirectory(String assetPath) throws IOException {
    return(assets.list(assetPath).length>=1);
}
```

To find the size of a document — to fill in the `COLUMN_SIZE` column in the output — we can ask the `AssetManager` for a `FileDescriptor` on the asset, then obtain the length from that descriptor, as seen in the `getAssetLength()` utility method:

```
private long getAssetLength(String assetPath) throws IOException {
    return(assets.openFd(assetPath).getLength());
}
```

The net result is that, given the name of a directory in `assets/`, we return a `Cursor` with one row per child of that directory, with columns indicating details of that child.

queryDocument()

`queryDocument()` is similar to `queryChildDocuments()`. Both return a `Cursor` with the same sorts of columns as output. The difference: `queryDocument()` provides you with the document ID of a file, and you return details of that file. By contrast, `queryChildDocuments()` gives you the document ID of a directory, and you return the details of all documents within that directory.

This is why `addDocumentRow()` was implemented as a separate method, as we need the same business logic (populate a `MatrixCursor` row based on an asset path) from `queryDocument()`:

```
@Override
public Cursor queryDocument(String documentId, String[] projection)
    throws FileNotFoundException {
    String[] netProjection=
        netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
    MatrixCursor result=new MatrixCursor(netProjection);

    try {
        addDocumentRow(result, Uri.parse(documentId).getLastPathSegment(),
            documentId);
    }
}
```

PROVIDING DOCUMENTS

```
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception reading asset dir", e);
}

return(result);
}
```

In this case, the only thing different is that we need to get the bare filename, for use in the `DISPLAY_NAME` field. Here, we cheat a bit and use `getLastPathSegment()` on `Uri` to obtain the filename.

openDocument()

The `openDocument()` method behaves much like the `openFile()` method of a classic streaming `ContentProvider`: given a path, you return a `ParcelFileDescriptor` representing the file contents. For documents that are true files on the filesystem, you can use the static `open()` method on `ParcelFileDescriptor`. For documents that are not files on the filesystem — such as documents that are assets in the APK — you will need to set up a `ParcelFileDescriptor` pipe and stream the content that way.

That is what `DemoDocumentsProvider` does, using logic copied from the book's streaming `ContentProvider` samples:

```
@Override
public ParcelFileDescriptor openDocument(String documentId,
                                         String mode,
                                         CancellationSignal signal)
    throws FileNotFoundException {
    ParcelFileDescriptor[] pipe=null;

    try {
        pipe=ParcelFileDescriptor.createPipe();
        AssetManager assets=getContext().getResources().getAssets();

        new TransferThread(assets.open(documentId),
            new ParcelFileDescriptor.AutoCloseOutputStream(pipe[1])).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
        throw new FileNotFoundException("Could not open pipe for: "
            + documentId);
    }

    return(pipe[0]);
}
```

`openDocument()` is passed three parameters:

PROVIDING DOCUMENTS

1. The document ID of the document to stream back
2. A file mode (r, w, or wt) indicating what sort of operations the client wants to perform on the stream
3. A CancellationSignal that we can use to find out that our streaming is being interrupted

In this case:

- openDocument() ignores the mode, because it did not return FLAG_SUPPORTS_WRITE in either queryChildDocuments() or queryDocument() to indicate that writing is an option, so the mode should always be r
- openDocument() ignores the CancellationSignal, though in reality it should pay attention to it when streaming back the content and stop streaming when requested

The TransferThread that does the actual streaming is, once again, the same as the one used earlier in this book for a streaming ContentProvider:

```
static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
    public void run() {
        byte[] buf=new byte[8192];
        int len;

        try {
            while ((len=in.read(buf)) >= 0) {
                out.write(buf, 0, len);
            }

            in.close();
            out.flush();
            out.close();
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                "Exception transferring file", e);
        }
    }
}
```

The Results

If you have both this sample app and the one from [the previous chapter](#), then run the one from the previous chapter to bring up the Storage Access Framework UI, you will see our provider among the list of available providers:

Figure 599: Storage Access Framework Picker, Showing Custom Provider

The provider's `assets/docs/` directory contains three files, one just off the root and two in a `bar/` subdirectory:

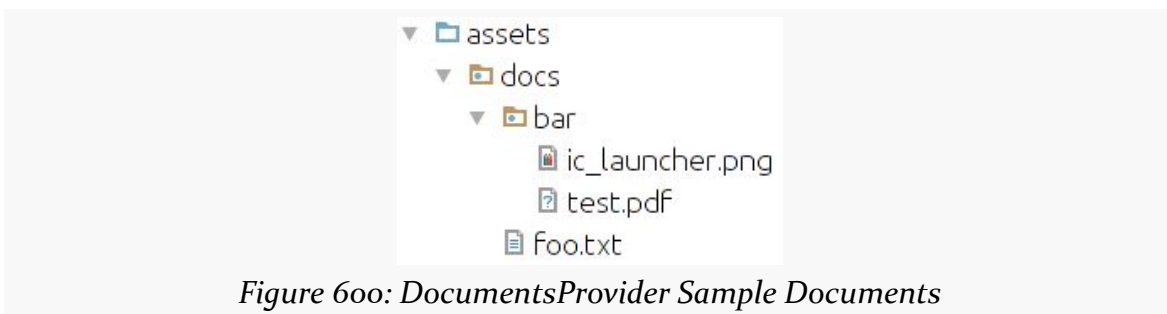

Figure 600: DocumentsProvider Sample Documents

Hence, tapping on our provider in the Storage Access Framework picker brings up the contents of the root document:

PROVIDING DOCUMENTS

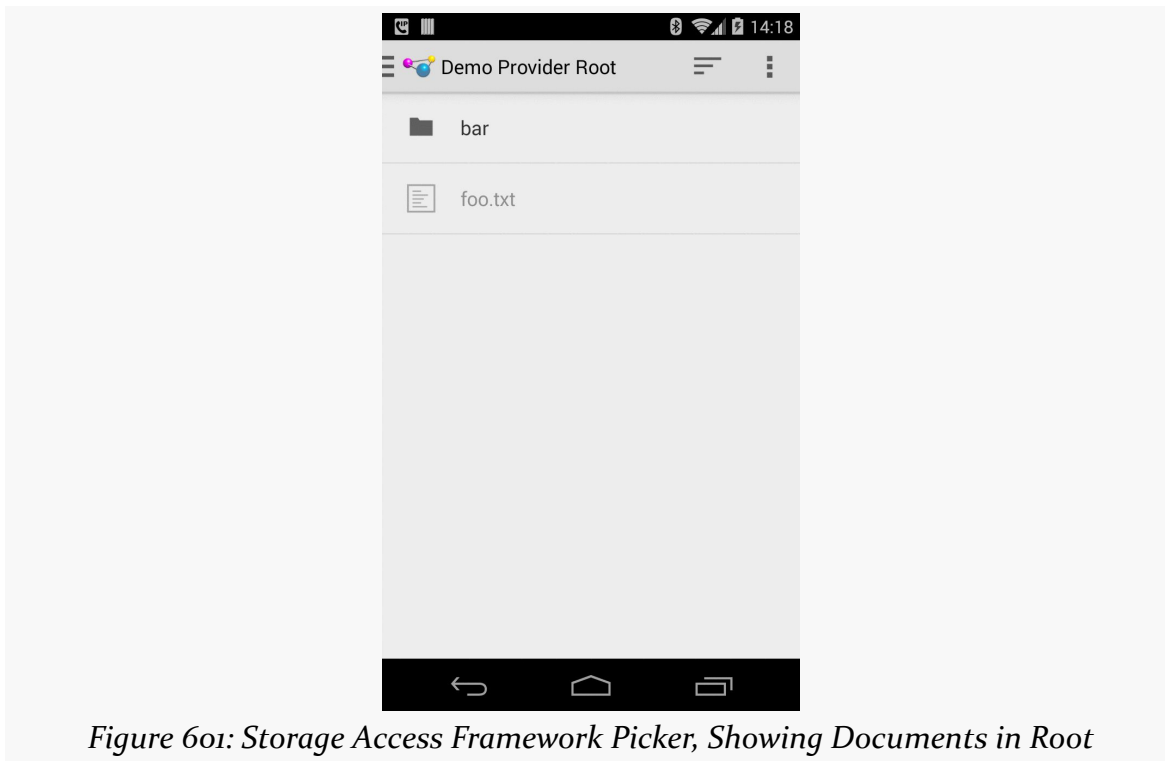

Figure 601: Storage Access Framework Picker, Showing Documents in Root

Tapping on the bar / directory brings up its contents in turn:

PROVIDING DOCUMENTS

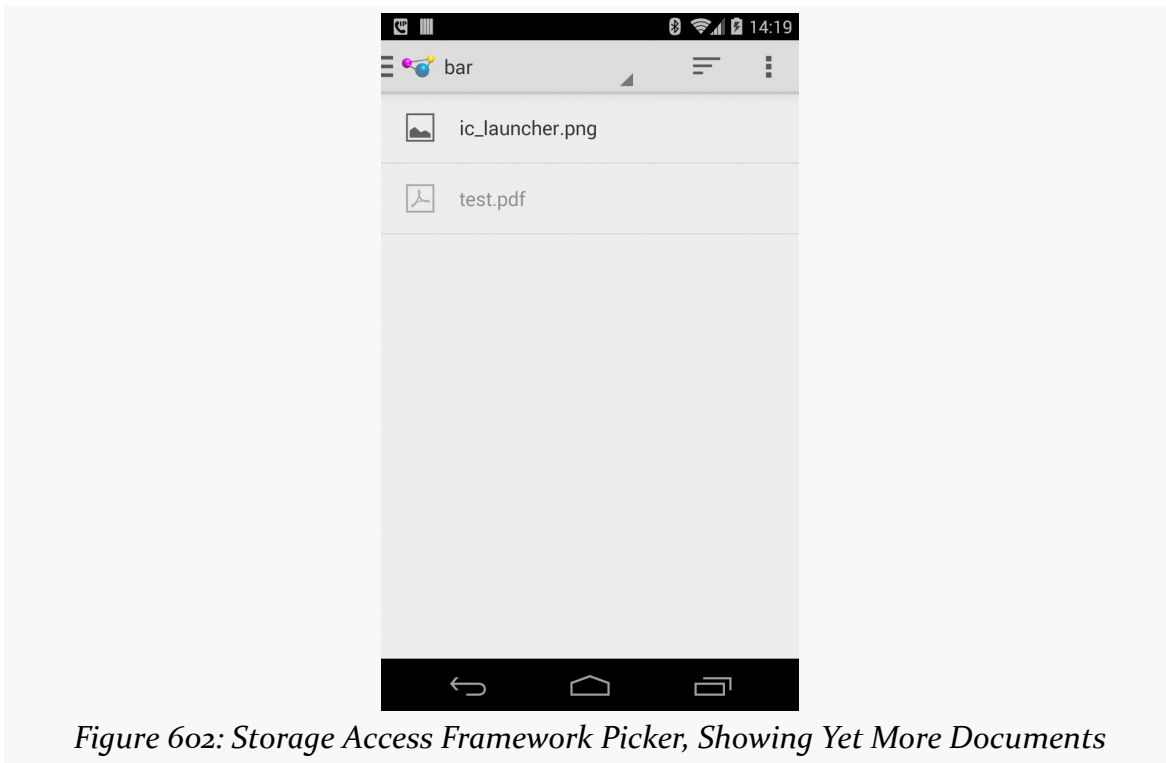

Figure 602: Storage Access Framework Picker, Showing Yet More Documents

Tapping on one of the files brings up the details for that file:

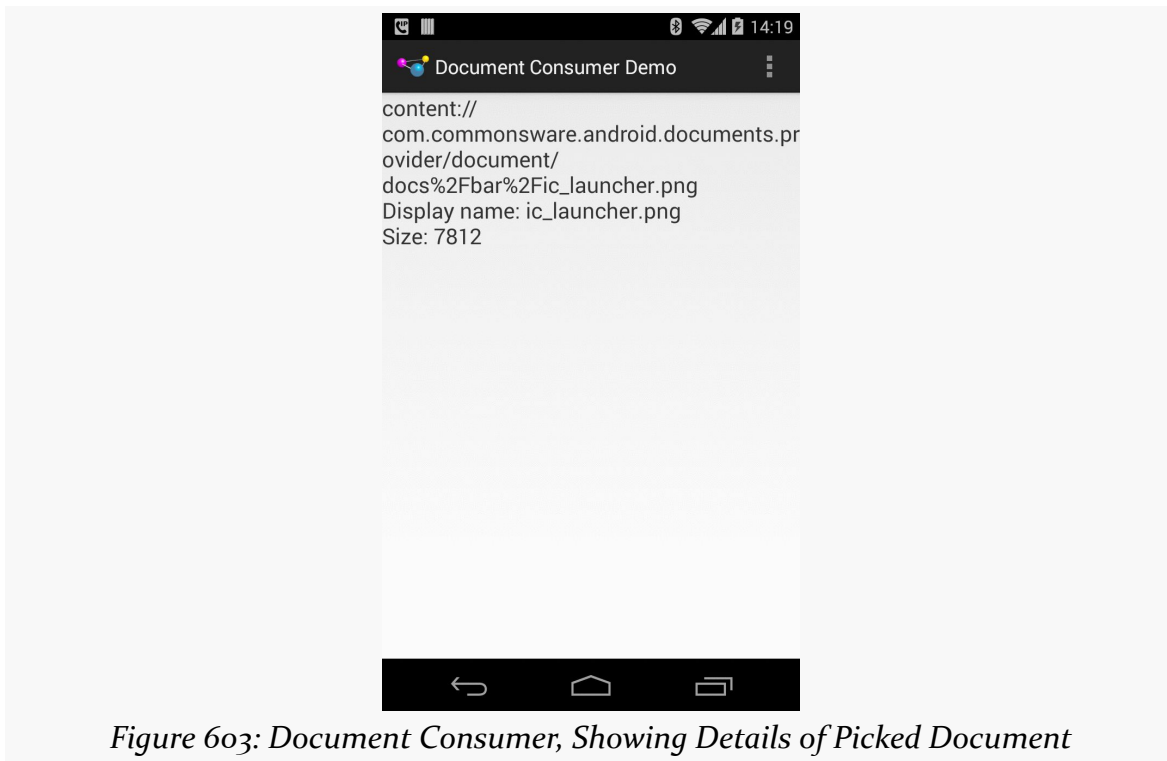

Figure 603: Document Consumer, Showing Details of Picked Document

Optional Provider Capabilities

A `DocumentsProvider` can do a fair bit more than what the above sample app demonstrates. While the sample will suffice for the basics, it is reasonably likely that a production-grade `DocumentsProvider` will need to implement and provide some other optional capabilities, such as those described in this section.

Other CRUD Operations

CRUD — Create, Read, Update, and Delete — is a standard shorthand for the basic operations one can perform on data. The sample app handles the “Read” portion of CRUD, but a `DocumentsProvider` can support all of them if desired.

Create

It may be that your `DocumentsProvider` is only going to serve up documents that were created in your app, or were created outside of the Android device (e.g., on a Web app). If, however, you want consumers of your provider to be able to use

PROVIDING DOCUMENTS

`ACTION_CREATE_DOCUMENT` to create new documents in your provider, you will need to do a few things.

First, in the `COLUMN_FLAGS` for the relevant root(s) returned by `queryRoots()`, you will need to include `FLAG_SUPPORTS_CREATE`, defined on `DocumentsContract.Root`. This indicates that at least one directory within that root supports creating new documents. Without this flag, your root(s) will be shown for `ACTION_OPEN_DOCUMENT` requests but not `ACTION_CREATE_DOCUMENT` requests.

Next, in one or more directories returned as part of `queryDocument()` and `queryChildDocuments()` calls, in the `COLUMN_FLAGS` column, you will need to include `FLAG_DIR_SUPPORTS_CREATE`, defined on `DocumentsContract.Documents`. This indicates that this document is a directory that supports creating new documents inside of it. Otherwise, a directory will be assumed to not support creating new documents. Note that this flag is only used for documents representing directories, not documents representing files.

Finally, you will need to implement `createDocument()` in your `DocumentsProvider`. This will be called if a consumer app used `ACTION_CREATE_DOCUMENT` and the user chose your provider and one of your directories for the new document. You are passed in:

- the document ID of the directory
- the MIME type of the new file
- a suggested display name to use for the new file, though you can modify this if needed

Your job, in `createDocument()`, is to create the document and return the document ID for the newly-created document. For example, if your documents are held in internal storage, you might create a new file for the document itself plus a database row in some documents table to hold the MIME type and display name.

Update

For something like files, an “update” is replacing the current contents with something new. In the case of a streaming protocol like `DocumentsProvider`, this implies that your provider can support output as well as input.

This too requires a few changes to your provider.

PROVIDING DOCUMENTS

First, for the file(s) that can be updated, in the results for `queryDocument()` and `queryChildDocuments()`, you will need to include `FLAG_SUPPORTS_WRITE` in `COLUMN_FLAGS`, to indicate that writing to this file should work.

Then, you will need to pay attention to the mode passed into `openDocument()`. If the mode is `w` or `wt`, you would need to arrange to support writing the file, where your background thread reads from an `InputStream` on the pipe and writes the data to wherever your data is being stored.

Delete

For any documents that the consumer can delete, include `FLAG_SUPPORTS_DELETE` in `COLUMN_FLAGS` in the results for `queryDocument()` and `queryChildDocuments()`.

You will also need to implement `deleteDocument()` in your `DocumentsProvider`. You are supplied the document ID to delete, and your job is to delete it.

If the document represents a directory, you may also need to delete all of its children. That really depends on how you are leveraging the “directory” construct in `DocumentsProvider`:

- If the “directory” is like a filesystem directory, where children have only one parent, you will want to delete the children when you delete the parent
- If the “directory” is more like a category, such as a tag, where children could have multiple parents, you will need to decide how to handle the children that would be orphaned by your deleting the last parent (delete the children? move them to some other default parent? something else?)

Change Notification

If the data served by your provider changes, it is incumbent upon you to let possible consumers know about the change. For example, if you elect to delete children when you delete their parent, you should let consumers know that those children were deleted. This is not necessary for direct operations performed by consumers (e.g., writing to a document), but is necessary for anything else.

To do that, you call `notifyChange()` on a `ContentResolver`, just as you would for changes to the data in a `ContentProvider`. However, `notifyChange()` takes a `Uri` as a parameter, to indicate the scope of the change. There are static utility methods on `DocumentsContract` that will return a `Uri` that you can use. Notably:

- `buildDocumentUri()`, given your authority and a document ID, provides a `Uri` that points to that document
- `buildChildDocumentsUri()`, given your authority and a document ID, provides a `Uri` that represents the collection of children of that document

So, for example, if by deleting a parent you also delete the children, you would use `buildChildDocumentsUri()` with `notifyChange()` to ensure that consumers know that those children were modified. The Storage Access Framework will use methods like `queryChildDocuments()` to determine that the children were deleted in this case.

Thumbnails

By default, the Storage Access Framework will use stock icons for directories and files. You can supply your own thumbnails instead, though, if you want. To do this:

- Include `FLAG_SUPPORTS_THUMBNAIL` in the `COLUMN_FLAGS` for the affected document(s) in `queryDocument()` and `queryChildDocuments()`
- Implement `openDocumentThumbnail()` in your `DocumentsProvider`

`openDocumentThumbnail()` is provided the document ID of the document whose thumbnail is required, along with a `Point` object providing a requested size. While your thumbnail does not have to exactly match that size — for example, the aspect ratio that is requested may not match the thumbnail — it should be close.

However, the return value for `openDocumentThumbnail()` is an `AssetFileDescriptor`, which is a wrapper around a `ParcelFileDescriptor`. If your image exists as a file that happens to be the right size, return it by using the static `open()` method on `ParcelFileDescriptor` is fairly straightforward. If, however, you need to scale your source image to fit the desired size, implementing this via a pipe will be moderately tedious.

Recent Documents

If your app has its own concept of recent documents, you can expose that roster to the Storage Access Framework, which can incorporate it as part of its UI. To do this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_RECENTS` in the `COLUMN_FLAGS` value for the root(s) that support recent documents
- Implement `queryRecentDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you

PROVIDING DOCUMENTS

need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the recent documents for that root

The two constraints upon the returned `Cursor` are:

- It should be sorted descending based on last-modified date (e.g., the `COLUMN_LAST_MODIFIED` column in your rows)
- It should be capped at 64 rows, though it can be less if desired

Note that you can, if you wish, have the `Cursor` return rows reflecting both files and directories — you are not limited to one or the other.

Search

If your provider has its own search capability, you can expose that to the Storage Access Framework, which in turn can make it available to users looking for a certain document. To support this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_SEARCH` in the `COLUMN_FLAGS` value for the root(s) that support searching
- Implement `querySearchDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the results of a search

`querySearchDocuments()` is passed a `String` representing the search expression entered by the user. It is up to you to decide what that expression means. It is also up to you to determine where you are searching for that expression (filenames? file contents?).

Note that the `Cursor` you return should only contain documents that reflect files, not documents that point to directories.

Other Flags

There are a few other flags that are available to you on `DocumentsContract.Document` that you can use in `COLUMN_FLAGS` for `Cursor` results representing a document or collection of documents, such as the results of `queryDocument()` and `queryChildDocuments()`:

PROVIDING DOCUMENTS

- If the document represents a directory, and you are supporting thumbnails, and you would like the contents of this directory to be represented in a thumbnail grid as opposed to a list, include `FLAG_DIR_PREFERS_GRID`
- If the document represents a directory, and you feel that users will be better served showing the documents in descending order based upon `COLUMN_LAST_MODIFIED`, rather than alphabetical by display name, include `FLAG_DIR_PREFERS_LAST_MODIFIED`

Encrypted Storage

SQLite databases, by default, are stored on internal storage, accessible only to the app that creates them.

At least, that is the theory.

In practice, it is conceivable that others could get at an app's SQLite database, and that those "others" may not have the user's best interests at heart. Hence, if you are storing data in SQLite that should remain confidential despite extreme measures to steal the data, you may wish to consider encrypting the database.

Perhaps the simplest way to encrypt a SQLite database is to use [SQLCipher](#). SQLCipher is a SQLite extension that encrypts and decrypts database pages as they are written and read. However, SQLite extensions need to be compiled into SQLite, and the stock Android SQLite does not have the SQLCipher extension.

[SQLCipher for Android](#), therefore, comes in the form of a replacement implementation of SQLite that you add as an NDK library to your project. It also ships with replacement editions of the `android.database.sqlite.*` classes that use the SQLCipher library instead of the built-in SQLite. This way, your app can be largely oblivious to the actual database implementation, particularly if it is hidden behind a `ContentProvider` or similar abstraction layer.

SQLCipher for Android is a joint initiative of [Zetetic](#) (the creators of SQLCipher) and [the Guardian Project](#) (home of many privacy-enhancing projects for Android). SQLCipher for Android is open source, under the Apache License 2.0.

Many developers of enterprise-grade apps for Android (e.g., Salesforce.com, JPMorgan Chase) use SQLCipher for securing their apps.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

Scenarios for Encryption

So, why might you want to encrypt a database?

Some developers probably are thinking that this is a way of protecting the app's content against "those pesky rooted device users". In practice, this is unlikely to help. As with most encryption mechanisms, SQLCipher uses an encryption key. If the app has the key, such as being hard-coded into the app itself, anyone can get the key by reverse-engineering the app.

Rather, encrypted databases are to help the user defend their data against other people seeing it when they should not. The classic example is somebody leaving their phone in the back of a taxi — if that device winds up in the hands of some group with the skills to root the device, they can get at any unencrypted content they want. While some users will handle this via the whole-disk encryption available since Android 3.0, others might not.

If the database is going anywhere other than internal storage, there is all the more reason to consider encrypting it, as then it may not even require a rooted device to access the database. Scenarios here include:

1. Databases stored on external storage
2. Databases backed up using external storage, BackupManager, or another Internet-based solution
3. Databases explicitly being shared among a user's devices, or between a user's device and a desktop (note that SQLCipher works on many operating systems, including desktops and iOS)

Obtaining SQLCipher

SQLCipher for Android is available from [its GitHub repository](#). The [downloads area](#) contains ZIP archives of what you need. As of September 2014, the current shipping version was 3.1.0.

NOTE: If you have been using SQLCipher prior to version 2.2.1, please upgrade to 3.0.x! Some modifications were made in July 2013 “to address a compatibility issue with an upcoming Android OS release” (presumably Android 4.4). You can read more [in the SQLCipher project’s blog post about the upgrade](#).

NOTE #2: If you have been using SQLCipher prior to version 3.0.x, and you have deployed your app in production, you will have some additional work to do to upgrade your database to the new file format. This is covered [later in this chapter](#).

Attaching SQLCipher To Your Project

The way you get SQLCipher for Android set up for your project depends upon your IDE.

Android Studio

Someday, hopefully we will be able to get SQLCipher for Android via an artifact in a repository.

In the short term, though, you have to go through a manual setup, based in part on one of the NDK recipes mentioned in [the chapter on the NDK](#):

- Copy the contents of the `assets/` directory from the ZIP file into your project’s `assets/` directory in the `main/` source set (e.g., `app/src/main/assets/` from a typical project root directory)
- Copy the JARs from the ZIP file’s `libs/` directories into a top-level `libs/` directory, as a peer to `app/` or other modules in the project
- Copy the `armeabi/`, `armeabi-v7a/`, and `x86/` directories from the ZIP file’s `libs/` directories into a `jniLibs/` directory in your `main/` source set
- In your `build.gradle`, have the following line in your top-level dependencies closure:

```
compile fileTree(dir: 'libs', include: '*.jar')
```

That tells Gradle for Android to pull in your JARs, and the `jniLibs/` directory tells Gradle for Android to package those pre-build NDK libraries with your app as well.

The [Database/ConstantsSecure-AndroidStudio](#) and [Database/SQLCipherPassphrase-AndroidStudio](#) sample projects demonstrate this setup.

Eclipse

Given an existing Android project, to use SQLCipher for Android, you need to extract the contents of the ZIP archive's `libs/` directory and put them in your own project's `libs/` directory (creating the latter if needed). The ZIP archive's `libs/` directory contains a few JARs, plus a set of NDK-compiled C/C++ libraries for SQLite with the SQLCipher extension.

You will also need to copy the contents of the ZIP archive's `assets/` folder into your project's `assets/` folder (creating the latter if needed).

Using SQLCipher

If you have existing code that uses classic Android SQLite, you will need to change your import statements to pick up the SQLCipher for Android equivalents of the classes. For example, you obtain `SQLiteDatabase` now from `net.sqlcipher.database.sqlcipher`, not `android.database.sqlite`. Similarly, you obtain `SQLException` from `net.sqlcipher.database` instead of `android.database`. Unfortunately, there is no complete list of which classes need this conversion — `Cursor`, for example, does not. Try converting everything from `android.database` and `android.database.sqlite`, and leave alone those that do not exist in the SQLCipher for Android equivalent packages.

Before starting to use SQLCipher for Android, you need to call `SQLiteDatabase.loadLibs()`, supplying a suitable `Context` object as a parameter. This initializes the necessary libraries. If you are using a `ContentProvider`, just call this in `onCreate()` before actually using anything else with your database. If you are not using a `ContentProvider`, you probably will want to create a custom subclass of `Application` and make this call from that class' `onCreate()`, and reference your custom `Application` class in the `android:name` attribute of the `<application>` element in your manifest. Either of these approaches will help ensure that the libraries are ready before you try doing anything with the database.

Finally, when calling `getReadableDatabase()` or `getWritableDatabase()` on `SQLiteDatabase`, you need to supply the encryption key to use. This may be somewhat tricky with a `ContentProvider`, as there is not an obvious way for you to get the key to the provider in advance of accessing the database. On older versions of Android, you will probably wind up using a static data member — before trying to first use the database, get the encryption key (e.g., based on a password typed by the user), put it in a static data member, and have your `ContentProvider` read the value from there.

However, starting with API Level 11, there is another approach for interacting with a `ContentProvider` beyond the scope of the traditional `query()`, `insert()`, etc. methods, by means of the `call()` method. That is the approach taken in the [Database/ConstantsSecure](#) sample app (and the [Database/ConstantsSecure-AndroidStudio](#) equivalent for Android Studio), yet another variation of the `ConstantsBrowser`, but where the information is stored in a `SQLCipher` for Android database, to keep our precious gravitational constants away from those who might abuse them.

Our revised `Provider` class switches its imports to the ones needed by `SQLCipher` for Android:

```
import net.sqlcipher.SQLException;
import net.sqlcipher.database.SQLiteDatabase;
import net.sqlcipher.database.SQLiteQueryBuilder;
```

In `onCreate()`, it initializes the libraries before creating our `DatabaseHelper` (our `SQLiteOpenHelper` implementation):

```
@Override
public boolean onCreate() {
    SQLiteDatabase.loadLibs(getContext());
    dbHelper=(new DatabaseHelper(getContext()));

    return((dbHelper == null) ? false : true);
}
```

That `DatabaseHelper` is unchanged from previous editions, other than altering the imports to use `SQLCipher` for Android equivalents. However, in order to really use this `DatabaseHelper`, we will need the user's passphrase, which is set via the `call()` mechanism.

A client can call `call()` on a `ContentProvider` by means of a `ContentResolver`. `call()` takes the `Uri` of the `ContentProvider`, the name of the “method” to call, and

ENCRYPTED STORAGE

an optional String argument and Bundle for additional parameters. For example, our ConstantsBrowser activity now uses call() to call a “method” on the Provider, supplying the encryption key (here hard-coded for simplicity):

```
getContentResolver().call(Provider.Constants.CONTENT_URI,  
    Provider.SET_KEY_METHOD, "sekrit", null);
```

That call() routes to a call() implementation on the ContentProvider, which is supplied all of the parameters except the Uri. It is up to the ContentProvider to examine the “method” name and handle it accordingly, optionally returning a Bundle of return values. In the case of our Provider class, if the call is for setting the encryption key, and the supplied key is not null, we use it to access our SQLiteDatabase:

```
@Override  
public Bundle call(String method, String arg, Bundle extras) {  
    if (SET_KEY_METHOD.equals(method) && arg != null) {  
        db=dbHelper.getWritableDatabase(arg);  
    }  
  
    return(null);  
}
```

This way, we supply the passphrase to the ContentProvider before trying to use the database, while also avoiding a static data member. The downside of this approach, or pretty much anything involving SQLCipher for Android, is that we have to be very careful to ensure that we are routing the user through the login process before trying to use the database, no matter how they enter our app (launcher icon, recent tasks, app widget tap, started by a third-party app, etc.). While in this case, our hard-coded passphrase avoids this complexity, it results in extremely weak security, as anyone could decompile the app, find the passphrase, and decrypt the database. We will touch on keys and passwords more [later in this chapter](#).

Note that we do not hold onto the passphrase, only the opened database. This is for added security, so somebody with a debugger cannot attach to our process and inspect the ContentProvider to find the passphrase. Of course, in this particular implementation, they could just as easily find where we hard-coded it.

The implementation of methods like query() then use the already-opened SQLiteDatabase:

```
@Override  
public Cursor query(Uri url, String[] projection, String selection,  
    String[] selectionArgs, String sort) {
```

```
SQLiteQueryBuilder qb=new SQLiteQueryBuilder();

qb.setTables(TABLE);

String orderBy;

if (TextUtils.isEmpty(sort)) {
    orderBy=Constants.DEFAULT_SORT_ORDER;
}
else {
    orderBy=sort;
}

Cursor c=
    qb.query(db, projection, selection, selectionArgs, null, null,
            orderBy);

c.setNotificationUri(getContext().getContentResolver(), url);

return(c);
}
```

Nothing else in the ConstantsBrowser activity needs to change, because the ContentProvider facade hides the rest of the implementation details.

SQLCipher Limitations

Alas, SQLCipher for Android is not perfect.

It will add a few MB to the size of your APK file per CPU architecture. For most modern Android devices, this extra size will not be a huge issue, though it will be an impediment for older devices with less internal storage, or for apps that are getting close to the size limits imposed by the Play Store or other distribution mechanisms. The chapter on the NDK contains [a section about a technology called libhoudini](#) that can help reduce this bloat, albeit with a significant performance penalty.

However, the size is mostly from code, and that may cause a problem for Eclipse users. Eclipse may crash with its own OutOfMemoryError during the final build process. To address that, find your eclipse.ini file (location varies by OS and installation method) and increase the -Xmx value shown on one of the lines (e.g., change it to -Xmx512m).

Other code that expects to be using native SQLite databases will require alteration to work with SQLCipher for Android databases. For example, the SQLiteAssetHelper described [elsewhere in this book](#) would need to be ported to use

the SQLCipher for Android implementations of SQLiteOpenHelper, SQLiteDatabase, etc. This is not too difficult for an open source component like SQLiteAssetHelper.

Passwords and Sessions

Given an encrypted database, there are several ways that an attacker can try to access the data, including:

1. Use a brute-force attack via the app itself
2. Use a brute-force attack on the database directly, by copying it to some other machine
3. Obtain the password by the strategic deployment of [a \\$5 wrench](#)

The classic way to prevent the first approach is by having business logic that prevents lots of failed login attempts in a short period of time. This can be built into your login dialog (or the equivalent), tracking the number and times of failed logins and introducing delays, forced app exits, or something to add time and hassle for trying lots of passwords.

Since manually trying passwords is nasty, brutish, and long, many attackers would automate the process by copying the SQLCipher database to another machine (e.g., desktop) and running a brute-force attack on it directly. SQLCipher for Android has many built-in protections to help defend against this. So long as you are using a sufficiently long and complex encryption key, you should be fairly well-protected against such attacks.

Defending against wrenches is decidedly more difficult and is beyond the scope of this book.

About Those Passphrases...

Having a solid encryption algorithm, like the AES-256 used by default with SQLCipher for Android, is only half the battle. The other half is in using a high-quality passphrase, one that is unlikely to be guessed by anyone looking to break the encryption.

Upgrading to Encryption

Suppose you have an app already out on the market, and you decide that you want to add the option for encryption. It is fairly likely that the user will be miffed if they lose all their data in the process of switching to an encrypted database. Therefore, you will want to try to retain their data.

SQLCipher for Android does not support in-place encryption of database. However, it *does* support working with unencrypted databases and encrypted databases simultaneously, giving you the option of migration.

The approach boils down to:

- Open the unencrypted database in SQLCipher for Android, using an empty passphrase
- Use the ATTACH statement to open the encrypted database inside the same SQLCipher for Android session
- Use a supplied `sqlcipher_export()` function to migrate most of the data
- Copy the Android database schema version between the databases
- DETACH the encrypted database
- Close the unencrypted database (and, presumably, delete it)
- Use the encrypted database from this point forward

Since both database files will exist at one time, you will find it simplest to use separate names for them (e.g., `stuff.db` and `stuff-encrypted.db`).

To see how this works, take a look at the [Database/SQLCipherPassphrase](#) sample app (and the [Database/SQLCipherPassphrase-AndroidStudio](#) equivalent for Android Studio), which is a variation of the original, non-ContentProvider “constants” sample app, this time using SQLCipher for Android and supporting an upgrade from a non-encrypted database to an encrypted one.

The bulk of the logic for handling the encryption upgrade is in a static `encrypt()` method on our DatabaseHelper:

```
static void encrypt(Context ctxt) {
    SQLiteDatabase.loadLibs(ctxt);

    File dbFile=ctxt.getDatabasePath(DATABASE_NAME);
    File legacyFile=ctxt.getDatabasePath(LEGACY_DATABASE_NAME);

    if (!dbFile.exists() && legacyFile.exists()) {
        SQLiteDatabase db=
```

ENCRYPTED STORAGE

```
        SQLiteDatabase.openOrCreateDatabase(legacyFile, "", null);

        db.rawQuerySQL(String.format("ATTACH DATABASE '%s' AS encrypted KEY '%s';",
                                     dbFile.getAbsolutePath(), PASSPHRASE));
        db.rawQuerySQL("SELECT sqlcipher_export('encrypted')");
        db.rawQuerySQL("DETACH DATABASE encrypted;");

        int version=db.getVersion();

        db.close();

        db=SQLiteDatabase.openOrCreateDatabase(dbFile, PASSPHRASE, null);
        db.setVersion(version);
        db.close();

        legacyFile.delete();
    }
}
```

First, we initialize SQLCipher for Android by calling `loadLibs()` on the SQLCipher version of `SQLiteDatabase`. We could do this someplace else, but for this sample, this is as good a spot as any.

We then create `File` objects pointing at the locations of the old, unencrypted database (with a name represented by a `LEGACY_DATABASE_NAME` static data member) and the new encrypted database (`DATABASE_NAME`). To get the `File` locations of those databases, we use `getDatabasePath()`, a method on `Context`, which returns the correct location for a database file given its name.

If the encrypted database exists, there is nothing that we need to do. Similarly, if it does not exist but the unencrypted database *also* does not exist, there is nothing that we *can* do. In either of those cases, we skip over the rest of the logic. In the first case, we already did the conversion (presumably); in the latter case, this is a new installation, and our `SQLiteOpenHelper` `onCreate()` logic will handle that. But, in the case where we do not have the encrypted database but do have the unencrypted one, we can create the encrypted database from the unencrypted data, which is what the bulk of the `encrypt()` method does.

To that, we:

- Use `openOrCreateDatabase()` to open the already-existing unencrypted database file *in SQLCipher for Android*, using "" as the passphrase.
- Use a `rawExecSQL()` method available on the SQLCipher for Android version of `SQLiteDatabase` to ATTACH the encrypted database, given its path, to our database session, using the supplied passphrase. This means that we can

access the tables from both databases simultaneously, though we need to prefix all references to the attached database via its handle, encrypted.

- Use `rawExecSQL()` to execute `SELECT sqlcipher_export('encrypted')`, which copies most of our data from the unencrypted database (the database we have open) into the encrypted database (the one we attached). The big thing that `sqlcipher_export()` does *not* copy is the schema version number that Android maintains.
- Use `rawExecSQL()` to DETACH the attached encrypted database, as we no longer need it.
- Call `getVersion()` on the `SQLiteDatabase` representing the unencrypted database, to retrieve the schema version number that Android maintains.
- Close the unencrypted database and open the encrypted one using `openOrCreateDatabase()`.
- Use `setVersion()` on `SQLiteDatabase` to set the schema version of the encrypted database to the value we had from the unencrypted database.
- Close the encrypted database and delete the unencrypted database file. Note that on API Level 16+, we could use the `deleteDatabase()` method on `SQLiteDatabase` to cleanly delete everything associated with SQLite.

The combination of doing all of that migrates our data from an unencrypted database to an encrypted one.

Then, we simply need to call `encrypt()` before we try loading our constants, from `doInBackground()` of our `LoadCursorTask`:

```
@Override
protected Void doInBackground(Void... params) {
    DatabaseHelper.encrypt(ctxt);
    constantsCursor=doQuery();
    constantsCursor.getCount();

    return(null);
}
```

To test this upgrade logic, you will need to:

- Run [the original unencrypted version of this sample](#), found in the [Database/Constants](#) sample application
- Add a new constant using the unencrypted version of the app
- Run the encrypted version of the sample from this section, which shares the same package name as the original and therefore will replace it on your emulator

You will see your added constant appear along with all of the standard ones, yet if you examine `/data/data/com.commonware.android.constants/databases` on your ARM emulator via DDMS, you will see that your database is now named `constants-crypt.db` instead of `constants.db`, as we have replaced the unencrypted database with an encrypted one.

Changing Encryption Passphrases

Another thing the user might wish to do is change their passphrase. Perhaps they fear that their existing passphrase has been compromised (e.g., a narrow escape from a \$5 wrench). Perhaps they rotate their passphrases as a matter of course. Perhaps they simply keep typing in their current one incorrectly and want to switch to one they think they can enter more accurately.

SQLCipher for Android supports a `rekey PRAGMA` that can accomplish this. Given an open encrypted database `db` — opened using the old passphrase — you can change the password to a `newPassword` string variable via:

```
db.execSQL(String.format("PRAGMA rekey = '%s'", newPassword));
```

Note that this may take some time, as SQLCipher for Android needs to re-encrypt the entire database.

Dealing with the Version 3.0.x Upgrade

If you are starting with SQLCipher for Android with the 3.0.x release, all is good.

If you have been using SQLCipher for Android from previous releases, but you are still in development mode, all is still good, so long as you can wipe out your old databases.

If you have apps in production using SQLCipher for Android from previous releases, you will have a small headache: the database structure has changed. SQLCipher for Android provides us with a `PRAGMA cipher_migrate` that we can run to upgrade the database in place to the new structure, once we have opened the database with our passphrase. However:

1. There is no great built-in place to put the code for calling this pragma
2. You do not want to blindly call this pragma every time you open the database, as it results in extra processing time

SQLCipher for Android, in an attempt to help with this, offers a modified version of methods like `openOrCreateDatabase()` on `SQLiteDatabase`, ones that take a `SQLiteDatabaseHook` implementation as the last parameter. This interface requires two methods:

1. `preKey()`, called after the database is opened but before the passphrase is applied
2. `postKey()`, called after the database is opened and after the passphrase is applied, but before anything else is done (e.g., standard `SQLiteOpenHelper` schema version checking)

Both methods are passed the `SQLiteDatabase` as a parameter, for you to do with as needed. So, for example, you could have a `postKey()` implementation that does the `postKey()` call only if needed:

```
public class SQLCipherV3Hook implements SQLiteDatabaseHook {
    private static final String PREFS=
        "net.sqlcipher.database.SQLCipherV3Helper";

    public static void resetMigrationFlag(Context ctxt, String dbPath) {
        SharedPreferences prefs=
            ctxt.getSharedPreferences(PREFS, Context.MODE_PRIVATE);
        prefs.edit().putBoolean(dbPath, false).commit();
    }

    @Override
    public void preKey(SQLiteDatabase database) {
        // no-op
    }

    @Override
    public void postKey(SQLiteDatabase database) {
        SharedPreferences prefs=
            getContext().getSharedPreferences(PREFS, Context.MODE_PRIVATE);
        boolean isMigrated=prefs.getBoolean(database.getPath(), false);

        if (!isMigrated) {
            database.rawQuery("PRAGMA cipher_migrate;");
            prefs.edit().putBoolean(database.getPath(), true).commit();
        }
    }
}
```

You can also pass a `SQLiteDatabaseHook` implementation into the `SQLiteOpenHelper` constructor as the fifth parameter, which will be used when `SQLiteOpenHelper` works with the underlying `SQLiteDatabase`.

Multi-Factor Authentication

Another way to effectively boost the strength of your security is to implement your own multi-factor authentication. In this case, the passphrase is not obtained solely through the user typing in the whole thing, but instead is synthesized from two or more sources. So, in addition to some `EditText` widget for entering in a portion of the passphrase, the rest could come from things like:

- A value written to an NFC tag that the user must tap
- A value encoded in a QR code that the user must scan
- A value obtained by some Bluetooth-connected device via a custom protocol

You, in code, would concatenate the pieces together, possibly using delimiters that cannot be typed in (e.g., ASCII characters below 32) to denote the sources of each segment of the passphrase. The result would be the actual passphrase you would use with `SQLCipher` for Android.

The objective is to make it easier for users to have more complex passphrases, while not having to type in something complex every time. Tapping an NFC tag is much faster than tapping out a passphrase on a typical phone keyboard, for example. Also, the “something you know and something you have” benefit of multi-factor authentication can help with defending against \$5 wrench attacks: if the NFC tag was destroyed, and the user never knew the portion of the passphrase stored on it, the user cannot divulge it.

Of course, this adds risks, such as the NFC tag being destroyed accidentally (e.g., “my dog ate it”). This can be mitigated in some cases by some “admin” being able to reset the password or supply a new NFC tag. In that case, getting the credentials requires *two* kidnappings and *two* \$5 wrenches (or the serial application of a single \$5 wrench, if budgets preclude buying two such wrenches), adding to the degree of difficulty for breaking the encryption by that means.

Detecting Failed Logins

If you try to decrypt a database using the incorrect passphrase — whether an attempt by outsiders to use the app, or the user “fat-fingering” the passphrase and making a typo — you will get an exception:

```
11-19 09:17:22.700: E/SQLiteOpenHelper(1634):  
net.sqlcipher.database.SQLiteException: file is encrypted or is not a  
database
```

Alas, this is not a specific exception, making it a bit difficult to detect failed passphrases specifically. Your options are:

- Assume that your testing is sound and that exceptions when opening a database represent invalid passphrases, or
- Use a generic error message that hints at an invalid passphrase but leaves open the possibility of something else being wrong, or
- Read into the exception's message looking for "file is encrypted or is not a database", though this is fragile in the face of changes to SQLCipher for Android

SQLCipher for Android and Performance

Some developers worry about the overhead that encryption will place on the database I/O, and therefore worry that SQLCipher for Android will make their app unacceptably slow.

The impact of SQLCipher is not that bad, particularly for hardware with faster CPUs. Encryption is CPU-intensive, so faster CPUs reduce the overhead of the encryption. Also, since the disk I/O is comparable between SQLite and SQLCipher, the fact that flash memory is slow will mean that disk I/O, not decryption speed, will be the primary determinant of the speed of your queries. Similarly, disk I/O will count for more than CPU speed for the encryption needed for INSERT/UPDATE/DELETE operations.

For example, porting [one relatively crude benchmark](#) to use SQLCipher for Android showed no statistically significant performance difference from the SQLite edition on a Nexus 5 running Android 4.4.2.

To the extent that encryption adds overhead, it will tend to magnify existing problems. For example, anything that involves a "table scan" (i.e., a non-indexed lookup of database contents) will need more pages to be decrypted and, therefore, more decryption time. If your database I/O is well-tuned for SQLite, such as adding appropriate indexes, then your SQLCipher for Android overhead should be nominal.

Of course, the worse the CPU, the worse the story, and so older/cheaper devices may fare worse with SQLCipher for Android by comparison.

Encrypted Preferences

There are effectively three forms of data storage in Android:

- SQLite databases
- SharedPreferences
- Arbitrary files, in whatever format you want

You can encrypt SQLite via SQLCipher for Android, as seen in this chapter. You can encrypt arbitrary files as part of your data format, such as via `javax.crypto`.

What is not supported, out of the box, is a way to encrypt SharedPreferences.

There are two approaches for encrypting the contents of SharedPreferences:

1. Encrypt the container in which the SharedPreferences are stored
2. Encrypt each preference value as you store it in the SharedPreferences, and decrypt it when you read the value back out

Encryption via Custom SharedPreferences

SharedPreferences is an interface. Hence, you can create other implementations of that interface that store their data in something other than unencrypted XML files.

CWSharedPreferences is one such implementation. You can find it in the [cwac-prefs project on GitHub](#).

CWSharedPreferences handles the SharedPreferences and SharedPreferences.Editor interfaces, along with the in-memory representations of the preferences. It then delegates the work of *storing* the preferences to a strategy object, implementing a strategy interface (CWSharedPreferences.StorageStrategy). Two such strategy implementations are supplied in the project: one using ordinary SQLite, and one using SQLCipher for Android.

The basic recipe for using CWSharedPreferences is:

- Create the strategy object, such as

```
new SQLCipherStrategy(getContext(), NAME, "atestpassword", LoadPolicy.SYNC)
```

(here, NAME is the name of the set of preferences, "atestpassword" is your passphrase, and LoadPolicy.SYNC indicates that the preferences should be loaded from disk immediately, not on a background thread)

- Create a CSharedPreferences that employs your chosen strategy:

```
new CSharedPreferences(yourStrategyObjectGoesHere);
```

- Use the CSharedPreferences as you would any other SharedPreferences implementation
- Call close() on the strategy object, to release any resources that it might hold (e.g., open database connection)

Encryption via Custom Preference UI and Accessors

The big drawback to the custom SharedPreferences is the fact that you cannot get the PreferenceScreen system to work with it. The preference UI is hard-wired to use the stock implementation of SharedPreferences and does not appear to support any way to substitute in some other implementation.

Hence, another approach is to keep things in standard SharedPreferences' XML files, but encrypt text values on a preference-by-preference basis. Since the data type needs to remain the same, most likely you would restrict this to encrypting strings (e.g., EditTextPreference, ListPreference) rather than numbers, booleans, etc.

To do this, you would need to:

- Implement static methods somewhere for your encryption and decryption algorithms
- Subclass the Preference classes of interest and override methods that would deal with the raw preference data, like onDialogClosed(), to encrypt the values you persist and decrypt the values you read in, using the static methods mentioned above
- Use your extended Preference classes in your preference XML as needed
- Use those static methods as part of reading (or writing) the preference values directly via SharedPreferences

The downsides to this approach include:

- Only certain preferences are encrypted, rather than all of them

- You lose some of the low-level encryption power of SQLCipher for Android, such as automatic hashing of passphrases, which you would have to handle yourself
- There may not be a library that supplies these extended Preference classes, forcing you to roll your own

IOCipher

SQLCipher for Android is also used as the backing store for [IOCipher](#). IOCipher is a virtual file system (VFS) for Android, allowing you to write code that looks and works like it uses normal file I/O, yet all of the files are actually saved as BLOBs in a SQLCipher for Android database. The result is a fully-encrypted VFS, inheriting all of SQLCipher's security features, such as default AES-256 encryption. This may be easier for you to use than encrypting and decrypting files individually via `javax.crypto`, for example.

IOCipher is considered to be in pre-alpha state as of November 2012.

Packaging and Distributing Data

Sometimes, you not only want to ship your code and simple resources with your app, but you also want to ship other types of data, such as an initial database that your app will use when first run. This chapter will examine the means by which you can do those sorts of things.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

Packing a Database To Go

Android's support for databases is focused on databases you create and populate entirely at runtime. Even if you want some initial data in the database, the expectation is that you would add that via Java code, such as the series of `insert()` calls we made in the `DatabaseHelper` of the various flavors of the `ConstantsBrowser` sample application.

However, that is tedious and slow for larger initial data sets, even if you make careful use of transactions to minimize the disk I/O.

What would be nice is to be able to ship a pre-populated database with your app. While Android does not offer built-in support for this, there are a few ways you can accomplish it yourself. One of the easiest, though, is to use existing third-party code

that supports this pattern, such as Jeff Gilfelt's `SQLiteAssetHelper`, available via [a GitHub repository](#).

Eclipse users can download a JAR. Android Studio users can add a compile statement to the dependencies closure in `build.gradle` to pull in `com.readystatesoftware.sqliteasset:sqliteassethelper:...` (for some version indicated by ...) from `mavenCentral()`.

`SQLiteAssetHelper` replaces your existing `SQLiteOpenHelper` subclass with one that handles database creation and upgrading for you. Rather than you writing a lot of SQL code for each of those, you provide a pre-populated SQLite database (for creation) and a series of SQL scripts (for upgrades). `SQLiteAssetHelper` then does the work to set up your pre-populated database when the database is first accessed and running your SQL scripts as needed to handle schema changes. And, `SQLiteAssetHelper` is open source, licensed under the same Apache License 2.0 that is used for Android proper.

To examine `SQLiteAssetHelper` in action, let's look at the [Database/ConstantsAssets](#) sample project. This is yet another rendition of the same app as the other flavors of `ConstantsBrowser`, but one where we use a pre-populated database.

Create and Pack the Database

Whereas normally you create your SQLite database at runtime from Java code in your app, you now create your SQLite database using whatever tools you like, at development time. Whether you use the command-line `sqlite3` utility, the SQLite Manager extension for Firefox, or anything else, is up to you. You will need to set up all of your tables, indexes, and so forth.

Then, you need to:

1. Create an `assets/databases/` directory in your project
2. Copy your database into this directory (or put it there in the first place, if you prefer)

If your `minSdkVersion` is less than 11, you will instead need to have a ZIP or GZIP archive containing the database. The archive should have the same name as the database file, just with the `.zip` or `.gz` extension. The reason for the ZIP compression comes from an Android 1.x/2.x limitation – assets that are compressed by the Android build tools have a file-size limitation (around 1MB). Hence, you need

to store larger files in a file format that will not be compressed by the Android build tools, and those tools will not try to compress a .zip file.

In the ConstantsAssets project, you will see an assets/databases/constants.db file, containing a copy of the SQLite database with our constants table and pre-populated values.

Unpack the Database, With a Little Help(er)

Your compressed database will ship with your APK. To get it into its regular position on internal storage, you use SQLiteAssetHelper. Simply create a subclass of SQLiteAssetHelper and override its constructor, supplying the same values as you would for a SQLiteOpenHelper subclass, notably the database name and schema revision number. Note that the database name that you use must match the filename of the compressed database, minus the .zip extension.

So, for example, our new DatabaseHelper looks like this:

```
package com.commonware.android.dbasset;

import android.content.Context;
import com.readystatesoftware.sqliteasset.SQLiteAssetHelper;

class DatabaseHelper extends SQLiteAssetHelper {
    static final String TITLE="title";
    static final String VALUE="value";
    static final String TABLE="constants";
    private static final String DATABASE_NAME="constants.db";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }
}
```

SQLiteAssetHelper will then copy your database out of assets and set it up for conventional use, as soon as you call getReadableDatabase() or getWritableDatabase() on an instance of your SQLiteAssetHelper subclass.

Upgrading Sans Java

Traditionally, with SQLiteOpenHelper, to handle a revision in your schema, you override onUpgrade() and do the upgrade work in there. With SQLiteAssetHelper, there is a built-in onUpgrade() method that uses SQL scripts in your APK to do the upgrade work instead.

These scripts will also reside in your `assets/databases/` directory of your project. The name of the file will be `$NAME_upgrade_$FROM-$TO.sql`, where you replace `$NAME` with the name of your database (e.g., `constants.db`), `$FROM` with the old schema version number (e.g., 1) and `$TO` with the new schema version number (e.g., 2). Hence, you wind up with files like `assets/databases/constants.db_upgrade_1-2.sql`. This should contain the SQL statements necessary to upgrade your schema between the versions.

`SQLiteAssetHelper` will chain these together as needed. Hence, to upgrade from schema version 1 to 3, you could either have a single dedicated 1->3 script, or a 1->2 script and a 2->3 script.

Limitations

The biggest limitation comes with disk space. Since APK files are read-only at runtime, you cannot delete the copy of the database held as an asset in your APK file once `SQLiteAssetHelper` has unpacked it. This means that the space taken up by your ZIP file will be taken up indefinitely. Note, though, that you could use this to your advantage, offering the user a “start over from scratch” option that deletes their existing database, so `SQLiteAssetHelper` will unpack a fresh original copy on the next run. Or, you could implement a `SQLiteDownloadHelper` that follows the `SQLiteAssetHelper` approach but obtains its database from the Internet instead of from assets.

In principle, SQLite could change their file format. If that ever happens, you will need to make sure that you create a SQLite database in the file format that can be used by Android, more so than what can be used by the latest SQLite standalone tools.

Advanced Database Techniques

This chapter offers tips and techniques for working with SQLite beyond what the previous chapters in the book have covered.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the ones on [databases](#) and [Internet access](#).

Also, please read [the chapter on advanced action bar techniques](#), particularly [the section on SearchView](#), as that is used in one of the sample apps.

Full-Text Indexing

Standard SQL databases are great for ordinary queries. In particular, when it comes to text, SQL databases are great for finding rows where a certain column value matches a particular string. They are usually pretty good about finding when a column value matches a particular string prefix, if there is an index on that column. Things start to break down when you want to search for an occurrence of a string in a column, as this usually requires a “table scan” (i.e., iteratively examining each row to see if this matches). And getting more complex than that is often impossible, or at least rather difficult.

SQLite, in its stock form, inherits all those capabilities and limitations. However, SQLite also offers full-text indexing, where we can search our database much like how we use a search engine (e.g., “find all rows where this column has both foo and bar in it somewhere”). While a full-text index takes up additional disk space, the speed of the full-text searching is quite impressive.

For example, if you are reading this book using the Android APK edition (instead of the PDF, EPUB, or Kindle/MOBI editions), tap on the SearchView action bar item and search for FTS4. You will get a list of matches back almost instantaneously, despite the fact that you are searching a multi-megabyte book. That is because this book ships a SQLite-powered full-text index of the book's contents, specifically to power your use of SearchView.

In this section, we will review how you can add full-text indexing to your SQLite database and how you can let the user take advantage of that index using a SearchView.

First, a Word About SQLite Versions

SQLite has evolved since Android's initial production release in 2008.

In many cases, Android does not incorporate updates to third-party code, for backwards-compatibility reasons (e.g., Apache's HttpClient). In the case of SQLite, newer Android versions do take on newer versions of SQLite... but the exact version of SQLite that a given version of Android uses is undocumented. Worse, some device manufacturers replace the stock SQLite for a version of Android with a different one.

[This Stack Overflow answer](#) contains a mapping of Android OS releases to SQLite versions, including various “anomalies” where manufacturers have elected to ship something else.

In many cases, the SQLite version does not matter. Core SQLite capabilities will have existed since the earliest days of Android. However, full-text indexing did not exist in the first SQLite used by Android, meaning that you will have to pay attention to your `minSdkVersion` and aim high enough that devices should support the full-text indexing option you choose.

Note that you could use an external SQLite implementation, one that gives you a newer SQLite engine than what might be on the device. For example, [SQLCipher for Android](#) ships its own copy of SQLite (with the SQLCipher extensions compiled in), one that is often newer than the one that is baked into the firmware of any given device.

FTS3 and FTS4

There are two full-text indexing options available in SQLite: FTS3 and FTS4. FTS4 can be much faster on certain queries, though overall the speed of the two implementations should be similar. FTS4 has two key limitations:

1. It may take a bit more disk space for its indexes.
2. It was added to SQLite 3.7.4, which was only introduced into standard Android in API Level 11.

The sample app for this section will demonstrate FTS4, as that is available on most Android devices.

Note that the Android developer documentation does not cover FTS3 or FTS4 full-text indexing. The details for the SQL syntax to support these options can be found in [the SQLite documentation](#).

Creating a Full-Text Indexed Table

A full-text indexed table, using FTS3 or FTS4, uses SQLite's `CREATE VIRTUAL TABLE` syntax. This indicates that you are opting into some special table-storage behavior, rather than the stock stuff.

In the [Database/FTS](#) sample project, the `onCreate()` method of our `SQLiteOpenHelper` subclass (`DatabaseHelper`) creates such a virtual table, using FTS4 for full-text indexing:

```
@Override
public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE VIRTUAL TABLE questions USING fts4("
        + "_id INTEGER PRIMARY KEY, title TEXT, "
        + "link TEXT, profileImage TEXT, creationDate INTEGER, "
        + "order=DESC);");
}
```

There are a few differences here from a typical `CREATE TABLE` statement, beyond the introduction of the `VIRTUAL` keyword:

- The `USING fts4` indicates that the virtual table is employing the FTS4 full-text indexing engine. To use FTS3, just replace `fts4` with `fts3`.
- You can have key-value pairs in the column list, separated by equals signs, to provide options for configuring the virtual table. In this case, it will provide

options for configuring the FTS4 indexing behavior. In this case, we are providing `order=DESC`, to indicate that the full-text index should be optimized for returning items in descending order. Note that these options only exist for FTS4, not FTS3. The full roster of available options is covered in [the SQLite documentation](#).

This gives us a table that supports normal table operations but also has a full-text index for its columns. However, there are some limitations, notably that these tables ignore constraints. So, for example, the `PRIMARY KEY` constraint applied to the `_id` column is ignored.

Populating a Full-Text Indexed Table

Adding content to an FTS3 or FTS4 table uses the same `INSERT` statements that you might use for a regular table. For example, the `DatabaseHelper` in the sample app has an `insertQuestions()` method that deletes all existing rows in the questions table, then inserts a bunch of rows based on a supplied `List` of `Item` objects:

```
void insertQuestions(Context app, List<Item> items) {
    SQLiteDatabase db=getDb(app);

    db.beginTransaction();

    db.delete("questions", null, null);

    try {
        for (Item item : items) {
            Object[] args={ item.id, item.title, item.link,
                            item.owner.profileImage, item.creationDate};

            db.execSQL("INSERT INTO questions (_id, title, "
                        +"link, profileImage, creationDate) "
                        +"VALUES (?, ?, ?, ?, ?)",
                        args);
        }

        db.setTransactionSuccessful();
    }
    finally {
        db.endTransaction();
    }
}
```

If those `Item` objects look familiar, that is because this app is a modified version of the Stack Overflow questions apps profiled in [the chapter on Internet access](#).

The reason why we are deleting everything before inserting is just to keep the sample simple. The database table will hold all of the questions pulled from the Stack Exchange API. Each time we run the app, we get the latest questions from that API. The vision was to use INSERT OR REPLACE or INSERT OR IGNORE statements to be able to merge content into the table. However, FTS3 and FTS4 tables ignore all constraints, as noted above, which prevents the conflict resolution options (e.g., OR REPLACE) from working. Hence, rather than manually sifting through to find if there is an existing row or not for a given ID value, this sample simply gets rid of all existing rows. A production-grade app would likely apply a more sophisticated algorithm.

Querying a Full-Text Indexed Table

While you can query a full-text indexed table using normal SELECT statements, usually the point is to apply the MATCH operator, as is seen in the loadQuestions() method from DatabaseHelper:

```
Cursor loadQuestions(Context app, String match) {
    SQLiteDatabase db=getDb(app);

    if (TextUtils.isEmpty(match)) {
        return(db.rawQuery("SELECT * FROM questions ORDER BY creationDate DESC",
                           null));
    }

    String[] args={ match };

    return(db.rawQuery("SELECT * FROM questions WHERE title "
                       +"MATCH ? ORDER BY creationDate DESC", args));
}
```

The MATCH operator supports a wide range of query structures, including:

- Keyword matches (e.g., Android)
- Prefix matches (e.g., SQL*)
- Phrase matches (e.g., "open source")
- NEAR, AND, OR, and NOT operators (e.g., sqlite AND database)

The result is the same sort of Cursor that you would get from a regular SELECT statement against a non-full-text-indexed table.

Some Notes About the Rest of the Sample App

As noted previously, this sample app is a revised version of the Stack Overflow questions list from [the chapter on Internet access](#). It is specifically derived from [the Picasso version of the sample](#). However, this version is designed to allow the user to full-text search the downloaded question data (e.g., title), above and beyond just seeing the list of latest questions.

This, in turn, requires a few more changes than those outlined so far. The following sections outline some of the highlights.

Adding a ModelFragment

The original sample had a very simple data model: a list of questions retrieved via Retrofit. Hence, the sample did not include much in the way of model management.

The FTS sample needs a database, which implies more local disk I/O that we are responsible for, which in turn leads us in the direction of implementing a model fragment (ModelFragment), much as the tutorials and a few other samples do:

```
package com.commonware.android.fts;

import android.app.Activity;
import android.app.Fragment;
import android.content.Context;
import android.database.Cursor;
import android.os.Bundle;
import android.util.Log;
import de.greenrobot.event.EventBus;
import retrofit.RestAdapter;

public class ModelFragment extends Fragment {
    private Context app=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        setRetainInstance(true);
    }

    @Override
    public void onAttach(Activity host) {
        super.onAttach(host);

        EventBus.getDefault().register(this);
    }
}
```

```
if (app==null) {
    app=host.getApplicationContext();
    new FetchQuestionsThread().start();
}

@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
}

public void onEventBackgroundThread(SearchRequestedEvent event) {
    try {
        Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app,
event.match);

        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception searching database", e);
    }
}

class FetchQuestionsThread extends Thread {
    @Override
    public void run() {
        RestAdapter restAdapter=
            new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
                .build();
        StackOverflowInterface so=
            restAdapter.create(StackOverflowInterface.class);

        SOQuestions questions=so.questions("android");

        try {
            DatabaseHelper
                .getInstance(app)
                .insertQuestions(app, questions.items);
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception populating database", e);
        }

        try {
            Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, null);

            EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
```

```
        "Exception populating database", e);
    }
}
}
```

In `onCreate()`, we mark this fragment as retained, as that is key to the model fragment pattern, so the fragment retains the model data across configuration changes.

In `onAttach()`, we register for the greenrobot EventBus, plus kick off a `FetchQuestionsThread` if we have not done so already (i.e., this is the first `onAttach()` call we have received). `onDetach()` unregisters us from the event bus.

`FetchQuestionsThread`, in turn, uses Retrofit to download the questions from Stack Overflow, then uses `DatabaseHelper` to insert the questions into the FTS-enabled database table, then uses the `DatabaseHelper` again to retrieve all existing questions in the form of a Cursor, which it wraps in a `ModelLoadedEvent` and posts to the EventBus. This time, though, it posts it as a sticky event.

That sticky event is consumed by a revised version of the `QuestionsFragment`, in its `onEventMainThread()` method:

```
public void onEventMainThread(ModelLoadedEvent event) {
    ((SimpleCursorAdapter)getListAdapter()).changeCursor(event.model);

    if (sv!=null) {
        sv.setEnabled(true);
    }
}
```

But because this is a sticky event, we will get this event both when it is raised (because the data is loaded) and any time thereafter when the fragment registers with the EventBus. This allows `QuestionsFragment` to *not* be retained, as it will get back the bulk of its model data automatically from greenrobot's EventBus.

`QuestionsFragment` also is modified from the Picasso sample to deal with the fact that its model data is now a Cursor, so it uses `SimpleCursorAdapter` to populate the list. To handle loading avatar images from the URLs, `QuestionsFragment` adds a `QuestionBinder` implementation of `ViewHolder` to the `SimpleCursorAdapter`, where `QuestionBinder` handles the Picasso logic from before:

```
private class QuestionBinder implements SimpleCursorAdapter.ViewHolder {
    int size;
```

```
QuestionBinder() {
    size=getActivity()
        .getResources()
        .getDimensionPixelSize(R.dimen.icon);
}

@Override
public boolean setViewValue (View view, Cursor cursor, int columnIndex) {
    switch (view.getId()) {
        case R.id.title:
            ((TextView)view).setText(Html.fromHtml(cursor.getString(columnIndex)));

            return(true);

        case R.id.icon:
            Picasso.with(getActivity()).load(cursor.getString(columnIndex))
                .resize(size, size).centerCrop()
                .placeholder(R.drawable.owner_placeholder)
                .error(R.drawable.owner_error).into((ImageView)view);

            return(true);
    }

    return(false);
}
```

The main activity (MainActivity) sets up the ModelFragment in onCreate(), at least when one does not already exist due to a configuration change:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
        getFragmentManager().beginTransaction()
            .add(android.R.id.content,
                new QuestionsFragment()).commit();
    }

    model=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

    if (model==null) {
        model=new ModelFragment();
        getFragmentManager().beginTransaction().add(model, MODEL).commit();
    }
}
```

This description, though, has skipped over the onEventBackgroundThread() method on the ModelFragment, which we will get to later in this overview.

Adding a SearchView

As is covered in [the chapter on advanced action bar techniques](#), a SearchView can be used to provide the standard “magnifying glass” search icon in the action bar. When tapped, the action bar item expands into a field where the user can type something, which our code can then receive and use to update the UI. In the SearchView sample from the action bar chapter, we saw using a SearchView for filtering. This time, we will use a SearchView for searching.

For a search, we need to know when the user is done typing, which is usually done by the user clicking a submit button. Hence, our code to configure the SearchView (a configureSearchView() method in QuestionsFragment) calls setSubmitButtonEnabled(true):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    search.setOnActionExpandListener(this);
    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setSubmitButtonEnabled(true);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

This, in turn, means that we need to pay attention to onQueryTextSubmit() in our SearchView.OnQueryTextListener implementation. That interface is implemented on QuestionsFragment itself, and delegates its work to a doSearch() method:

```
@Override
public boolean onQueryTextSubmit(String query) {
    doSearch(query);

    return(true);
}
```

That method, in turn, confirms that the search is different than the last one we did (so we do not waste time running the search again), disables the SearchView, and posts a SearchRequestedEvent on the EventBus with the user’s search string:

```
private void doSearch(String match) {
    if (!match.equals(lastQuery)) {
```

```
lastQuery=match;

if (sv != null) {
    sv.setEnabled(false);
}

EventBus.getDefault().post(new SearchRequestedEvent(match));
}
```

That event is picked up by `onEventBackgroundThread()` on `ModelFragment`. The method name `onEventBackgroundThread()` means that the event will be delivered to us on an EventBus-supplied background thread, so we can perform database I/O. In it, we call `loadQuestions()` on the `DatabaseHelper` to perform the search, and post another sticky `ModelLoadedEvent` to update the UI with the search results and re-enable the `SearchView`:

```
public void onEventBackgroundThread(SearchRequestedEvent event) {
    try {
        Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app,
event.match);

        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception searching database", e);
    }
}
```

When the user clears the `SearchView`, such as by pressing the BACK button a few times, the `onMenuItemActionCollapse()` method of `QuestionsFragment` calls a `clearSearch()` method:

```
@Override
public boolean onMenuItemActionCollapse(MenuItem item) {
    clearSearch();

    return(true);
}
```

That `clearSearch()` method simply posts another `SearchRequestedEvent`, this time to load a fresh roster of all questions:

```
private void clearSearch() {
    if (lastQuery!=null) {
        lastQuery=null;

        sv.setEnabled(false);
    }
}
```

```
EventBus.getDefault().post(new SearchRequestedEvent(null));  
}  
}
```

The Results

When you run the app, you are initially presented with the list of questions pulled from the Stack Exchange API:

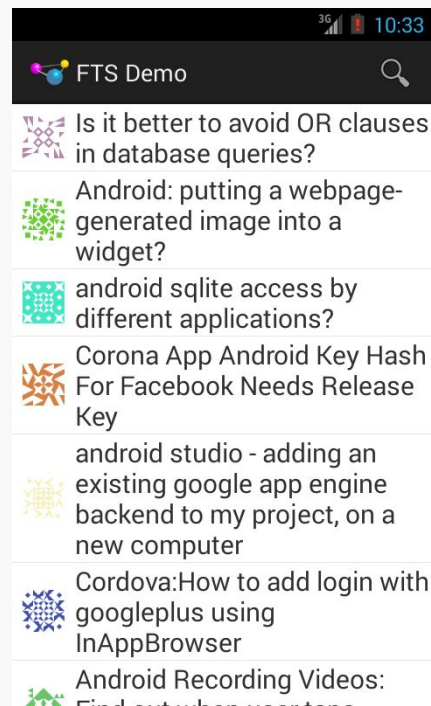

Figure 6o4: FTS Demo, As Initially Launched

Tapping on the SearchView opens it up, as normal, though this time with the “submit” button (the rightward-pointing arrowhead):

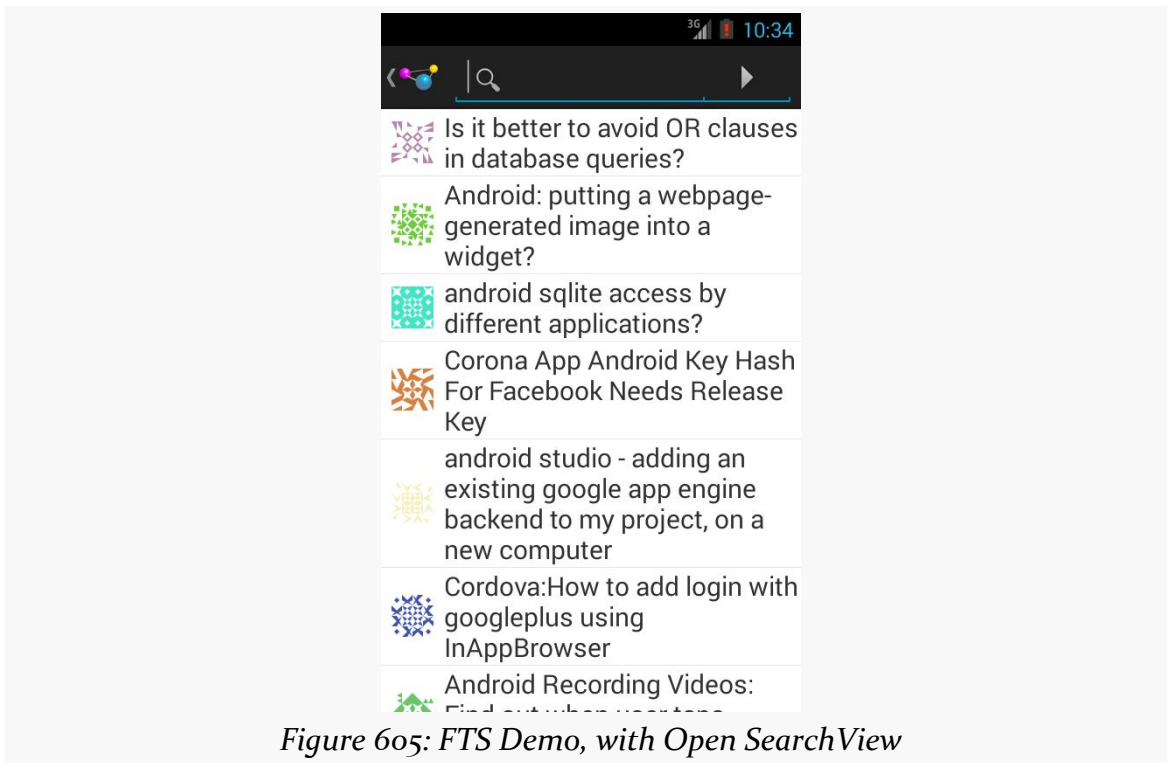

Figure 605: FTS Demo, with Open SearchView

Typing in a search, then tapping the “submit” button, will reload the list with those questions that match the search criteria in the question title:

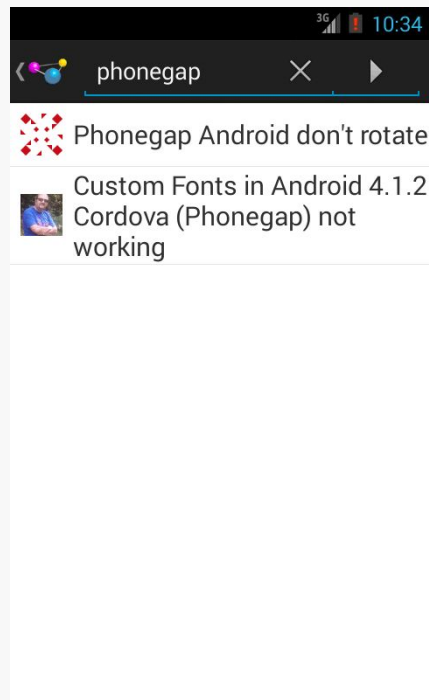

Figure 6o6: FTS Demo, Showing Basic Search

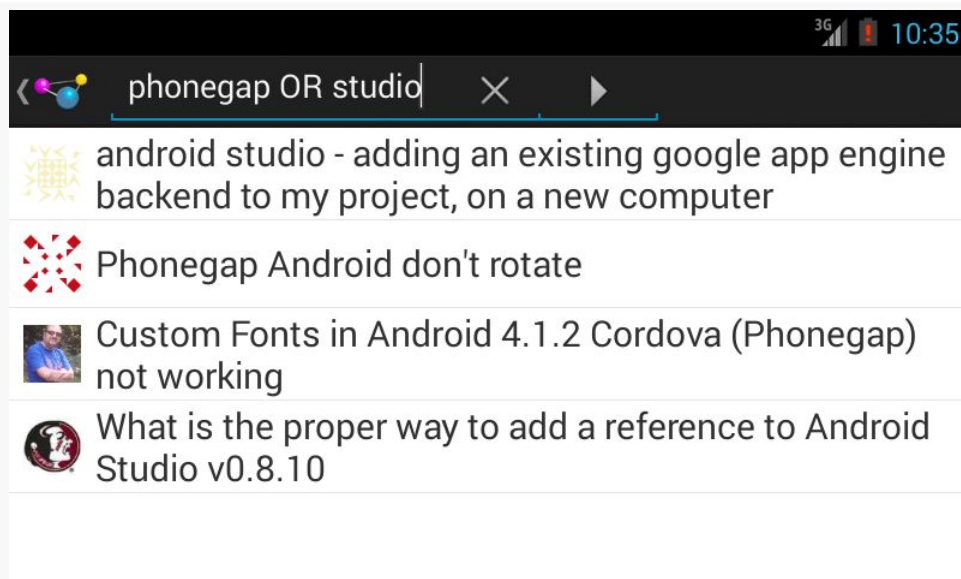

Figure 6o7: FTS Demo, Showing Boolean Search

Using the BACK button to get out of the SearchView reloads the full list of questions.

Getting Snippets

Usually, the content that is being indexed is a lot longer than Stack Overflow question titles. For example, it might be chapters in a book on Android application development. In that case, it would be useful to not only find out what chapters match the search expression, but what the prose is around the search expression, to help the user determine which search results are likely to be useful.

The APK edition of this book stores each paragraph and bullet as a separate entry in a SQLite database in an FTS3-enabled table. The query used when the reader types in a search expression in the app's SearchView is:

```
SELECT ROWID as _id, file, node, snippet(booksearch) AS snippet FROM
booksearch WHERE prose MATCH ?
```

Here, file and node are used to identify where this passage came from within the book, so when the user taps on a search result in the list, the book reader can jump to that particular location.

The snippet() auxiliary function will return, as the name suggests, a snippet of the indexed text, with the search match highlighted. It takes the name of the table booksearch as a mandatory parameter. It also supports optional parameters for what to bracket the search match with (defaults to and) and what to use for an ellipsis for extended prose segments (defaults to ...). In the case of this query, the default formatting of the result is used. The resulting text can then be fed into Html.fromHtml() to generate the text for the ListView row, showing the search match within the snippet highlighted in bold:

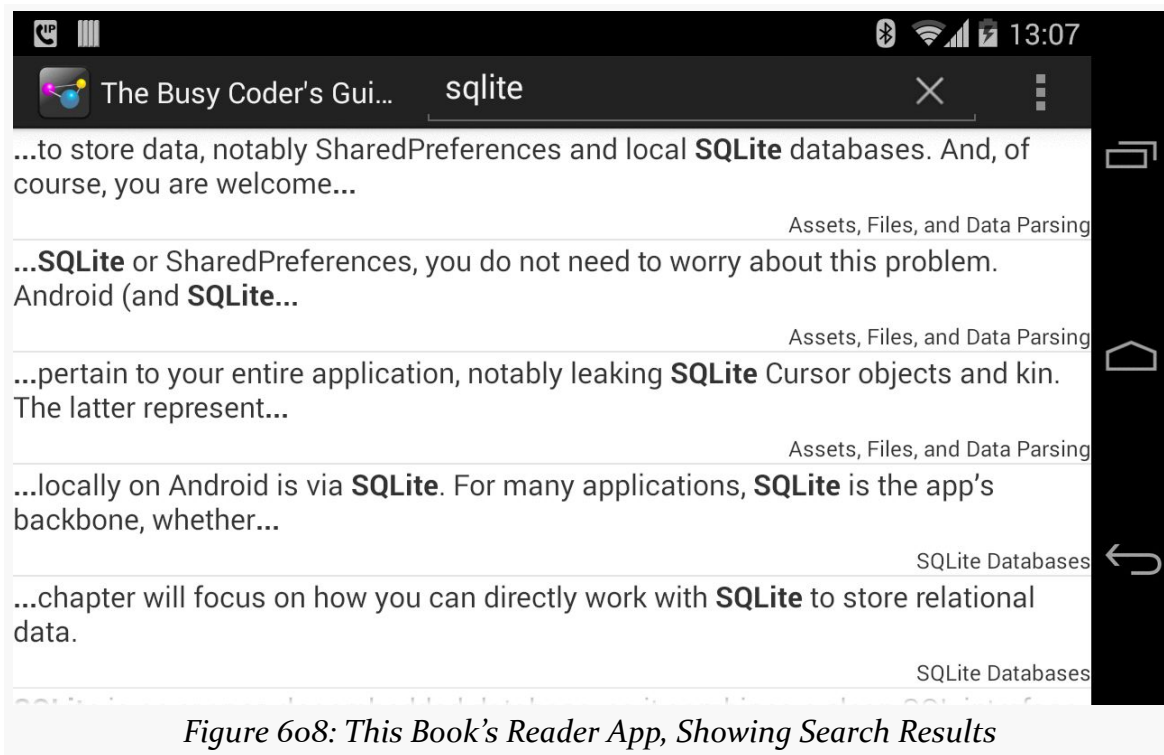

Figure 6o8: This Book's Reader App, Showing Search Results

The app also shows the name of the chapter in the lower-right corner of each row, to help provide larger context for where this snippet comes from.

Miscellaneous Network Capabilities

This chapter is a catch-all for various Android capabilities related to network I/O and the Internet, beyond what is covered elsewhere in the book.

(yes, this chapter could have a more exciting rationale for existing, but the author is subject to “Truth in Advertising” laws...)

Prerequisites

Readers of this chapter should have read the core chapters of the book.

Downloading Files

Android 2.3 introduced a `DownloadManager`, designed to handle a lot of the complexities of downloading larger files, such as:

1. Determining whether the user is on WiFi or mobile data, and if so, whether the download should occur
2. Handling when the user, previously on WiFi, moves out of range of the access point and “fails over” to mobile data
3. Ensuring the device stays awake while the download proceeds

`DownloadManager` itself is less complicated than the alternative of writing all of that stuff yourself. However, it does present a few challenges. In this section, we will examine the [Internet/Download](#) sample project, one that uses `DownloadManager`.

The Permissions

To use `DownloadManager`, you will need to hold the `INTERNET` permission. You will also need the `WRITE_EXTERNAL_STORAGE` permission, as `DownloadManager` can only download to external storage.

For example, here is the manifest for the Internet/Download application, where we request these two permissions:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.downmgr"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET"/>
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".DownloadDemo"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

The Layout

Our sample application has a simple layout, consisting of three buttons:

1. One to kick off a download
2. One to query the status of a download
3. One to display a system-supplied activity containing the roster of downloaded files

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button
    android:id="@+id/start"
    android:text="@string/start_download"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
  <Button
    android:id="@+id/query"
    android:text="@string/query_status"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
    android:enabled="false"
  />
  <Button android:id="@+id/view"
    android:text="@string/view_log"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
</LinearLayout>
```

Requesting the Download

To kick off a download, we first need to get access to the `DownloadManager`. This is a so-called “system service”. You can call `getSystemService()` on any activity (or other Context), provide it the identifier of the system service you want, and receive the system service object back. However, since `getSystemService()` supports a wide range of these objects, you need to cast it to the proper type for the service you requested.

So, for example, here is the `onCreateView()` method of the `DownloadFragment`, in which we get the `DownloadManager`:

MISCELLANEOUS NETWORK CAPABILITIES

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                        Bundle savedInstanceState) {
    mgr=
(DownloadManager)getActivity().getSystemService(Context.DOWNLOAD_SERVICE);

    View result=inflater.inflate(R.layout.main, parent, false);

    query=result.findViewById(R.id.query);
    query.setOnClickListener(this);
    start=result.findViewById(R.id.start);
    start.setOnClickListener(this);

    result.findViewById(R.id.view).setOnClickListener(this);

    return(result);
}
```

Most of these managers have no `close()` or `release()` or `goAwayPlease()` sort of methods — you can just use them and let garbage collection take care of cleaning them up.

Given the manager, we can now call an `enqueue()` method to request a download. The name is relevant — do not assume that your download will begin immediately, though often times it will. The `enqueue()` method takes a `DownloadManager.Request` object as a parameter. The `Request` object uses the builder pattern, in that most methods return the `Request` itself, so you can chain a series of calls together with less typing.

For example, the top-most button in our layout is tied to a `startDownload()` method in `DownloadFragment`, shown below:

```
private void startDownload(View v) {
    Uri uri=Uri.parse("http://commonsware.com/misc/test.mp4");

    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS)
        .mkdirs();

    DownloadManager.Request req=new DownloadManager.Request(uri);

    req.setAllowedNetworkTypes(DownloadManager.Request.NETWORK_WIFI
                                | DownloadManager.Request.NETWORK_MOBILE)
        .setAllowedOverRoaming(false)
        .setTitle("Demo")
        .setDescription("Something useful. No, really.")
        .setDestinationInExternalPublicDir(Environment.DIRECTORY_DOWNLOADS,
                                           "test.mp4");
}
```

```
lastDownload=mgr.enqueue(req);
```

We are downloading a sample MP4 file, and we want to download it to the external storage area. To do the latter, we are using `getExternalStoragePublicDirectory()` on `Environment`, which gives us a directory suitable for storing a certain class of content. In this case, we are going to store the download in the `Environment.DIRECTORY_DOWNLOADS`, though we could just as easily have chosen `Environment.DIRECTORY_MOVIES`, since we are downloading a video clip. Note that the `File` object returned by `getExternalStoragePublicDirectory()` may point to a not-yet-created directory, which is why we call `mkdirs()` on it, to ensure the directory exists.

We then create the `DownloadManager.Request` object, with the following attributes:

1. We are downloading the specific URL we want, courtesy of the `Uri` supplied to the `Request` constructor
2. We are willing to use either mobile data or WiFi for the download (`setAllowedNetworkTypes()`), but we do not want the download to incur roaming charges (`setAllowedOverRoaming()`)
3. We want the file downloaded as `test.mp4` in the downloads area on the external storage (`setDestinationInExternalPublicDir()`)

We also provide a name (`setTitle()`) and description (`setDescription()`), which are used as part of the notification drawer entry for this download. The user will see these when they slide down the drawer while the download is progressing.

The `enqueue()` method returns an ID of this download, which we hold onto for use in querying the download status.

Keeping Track of Download Status

If the user presses the Query Status button, we want to find out the details of how the download is progressing. To do that, we can call `query()` on the `DownloadManager`. The `query()` method takes a `DownloadManager.Query` object, describing what download(s) you are interested in. In our case, we use the value we got from the `enqueue()` method when the user requested the download:

```
private void queryStatus(View v) {  
    Cursor c=  
        mgr.query(new DownloadManager.Query().setFilterById(lastDownload));  
  
    if (c == null) {
```

```
        Toast.makeText(getActivity(), R.string.download_not_found,
                        Toast.LENGTH_LONG).show();
    }
    else {
        c.moveToFirst();

        Log.d(getClass().getName(),
            "COLUMN_ID: "
            + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_ID)));
        Log.d(getClass().getName(),
            "COLUMN_BYTES_DOWNLOADED_SO_FAR: "
            +
            c.getLong(c.getColumnIndex(DownloadManager.COLUMN_BYTES_DOWNLOADED_SO_FAR)));
        Log.d(getClass().getName(),
            "COLUMN_LAST_MODIFIED_TIMESTAMP: "
            +
            c.getLong(c.getColumnIndex(DownloadManager.COLUMN_LAST_MODIFIED_TIMESTAMP)));
        Log.d(getClass().getName(),
            "COLUMN_LOCAL_URI: "
            +
            c.getString(c.getColumnIndex(DownloadManager.COLUMN_LOCAL_URI)));
        Log.d(getClass().getName(),
            "COLUMN_STATUS: "
            + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_STATUS)));
        Log.d(getClass().getName(),
            "COLUMN_REASON: "
            + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_REASON)));

        Toast.makeText(getActivity(), statusMessage(c), Toast.LENGTH_LONG)
            .show();

        c.close();
    }
}
```

The `query()` method returns a `Cursor`, containing a series of columns representing the details about our download. There is a series of constants on the `DownloadManager` class outlining what is possible. In our case, we retrieve (and dump to LogCat):

1. The ID of the download (`COLUMN_ID`)
2. The amount of data that has been downloaded to date (`COLUMN_BYTES_DOWNLOADED_SO_FAR`)
3. What the last-modified timestamp is on the download (`COLUMN_LAST_MODIFIED_TIMESTAMP`)
4. Where the file is being saved to locally (`COLUMN_LOCAL_URI`)
5. What the actual status is (`COLUMN_STATUS`)
6. What the reason is for that status (`COLUMN_REASON`)

Note that `COLUMN_LOCAL_URI` may be unavailable, if the user has deleted the downloaded file between when the download completed and the time you try to access the column.

There are a number of possible status codes (e.g., `STATUS_FAILED`, `STATUS_SUCCESSFUL`, `STATUS_RUNNING`). Some, like `STATUS_FAILED`, may have an accompanying reason to provide more details.

Note that you really should close this `Cursor` when you are done with it. `StrictMode`, for example, will complain if you do not.

Download Broadcasts

To find out about the results of the download, we need to register a `BroadcastReceiver`, to watch for two actions used by `DownloadManager`:

1. `ACTION_DOWNLOAD_COMPLETE`, to let us know when the download is done
2. `ACTION_NOTIFICATION_CLICKED`, to let us know if the user taps on the Notification displayed on the user's device related to our download

So, in `onResume()` of our fragment, we register a single `BroadcastReceiver` for both of those events:

```
@Override
public void onResume() {
    super.onResume();

    IntentFilter f=
        new IntentFilter(DownloadManager.ACTION_DOWNLOAD_COMPLETE);

    f.addAction(DownloadManager.ACTION_NOTIFICATION_CLICKED);

    getActivity().registerReceiver(onEvent, f);
}
```

That `BroadcastReceiver` is unregistered in `onPause()`:

```
@Override
public void onPause() {
    getActivity().unregisterReceiver(onEvent);

    super.onPause();
}
```

The BroadcastReceiver implementation examines the action string of the incoming Intent (via a call to `getAction()`) and either displays a Toast (for `ACTION_NOTIFICATION_CLICKED`) or enables the start-download Button:

```
public void onReceive(Context ctxt, Intent i) {  
    if (DownloadManager.ACTION_NOTIFICATION_CLICKED.equals(i.getAction())) {  
        Toast.makeText(ctxt, R.string.hi, Toast.LENGTH_LONG).show();  
    }  
    else {  
        start.setEnabled(true);  
    }  
}  
};  
}
```

What the User Sees

The user, upon launching the application, sees our three pretty buttons:

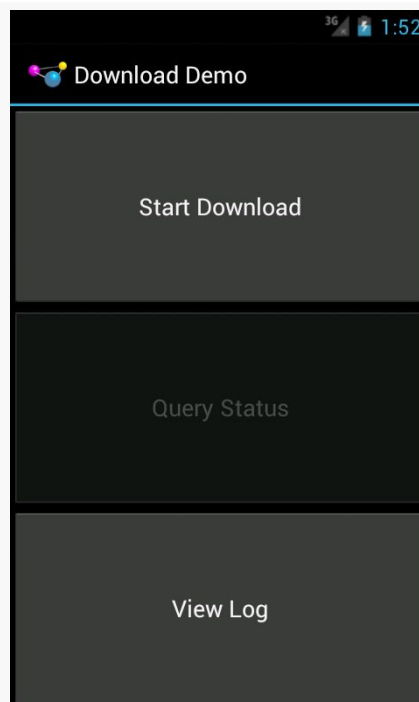

Figure 609: The Download Demo Sample, As Initially Launched

Clicking the first disables the button while the download is going on, and a download icon appears in the status bar (though it is a bit difficult to see, given the poor contrast between Android's icon and Android's status bar):

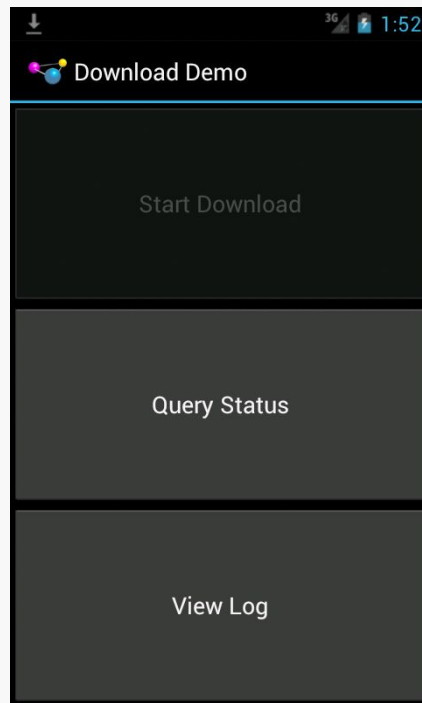

Figure 610: The Download Demo Sample, Downloading

Sliding down the notification drawer shows the user the progress in the form of a ProgressBar widget:

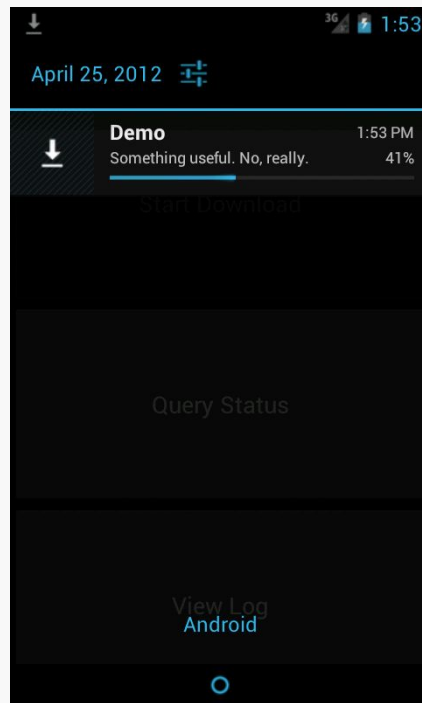

Figure 611: The DownloadManager Notification

Tapping on the entry in the notification drawer returns control to our original activity, where they see a Toast, raised by our BroadcastReceiver.

If they tap the middle button during the download, a different Toast will appear indicating that the download is in progress:

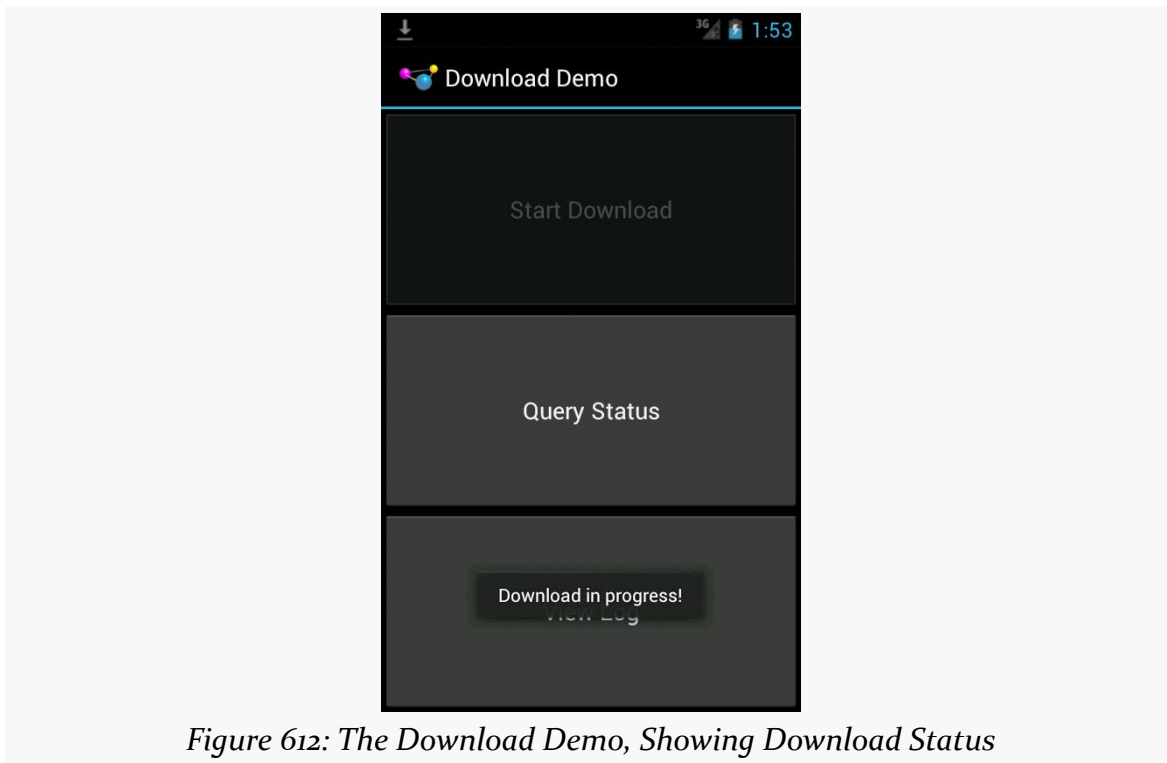

Figure 612: The Download Demo, Showing Download Status

Additional details are also dumped to LogCat, visible via DDMS or `adb logcat`:

```
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_ID: 12  
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_BYTES_DOWNLOADED_SO_FAR: 615400  
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988696232  
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_LOCAL_URI: file:///mnt/sdcard/Download/test.mp4  
12-10 08:45:01.299: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_STATUS: 2  
12-10 08:45:01.299: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_REASON: 0
```

Once the download is complete, tapping the middle button will indicate that the download is, indeed, complete, and final information about the download is emitted to LogCat:

```
12-10 08:49:27.360: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_ID: 12  
12-10 08:49:27.360: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_BYTES_DOWNLOADED_SO_FAR: 6219229  
12-10 08:49:27.370: DEBUG/com.commonware.android.download.DownloadDemo(372):
```

MISCELLANEOUS NETWORK CAPABILITIES

```
COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988713409
12-10 08:49:27.370: DEBUG/com.commonware.android.download.DownloadDemo(372):
COLUMN_LOCAL_URI: file:///mnt/sdcard/Download/test.mp4
12-10 08:49:27.370: DEBUG/com.commonware.android.download.DownloadDemo(372):
COLUMN_STATUS: 8
12-10 08:49:27.370: DEBUG/com.commonware.android.download.DownloadDemo(372):
COLUMN_REASON: 0
```

Tapping the bottom button brings up the activity displaying all downloads, including both successes and failures:

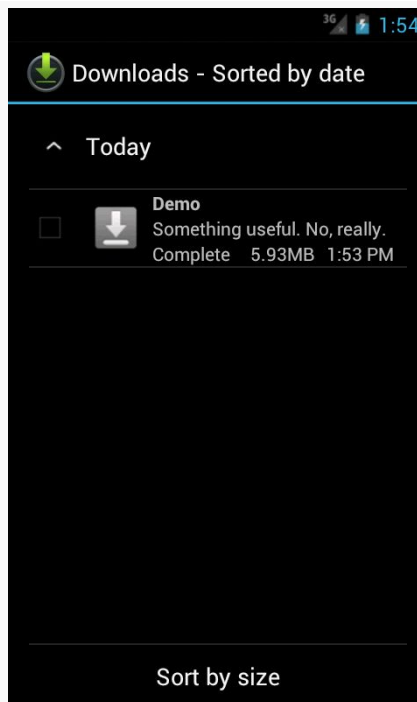

Figure 613: The DownloadManager Results

And, of course, the file is downloaded. In the emulator, our chosen location maps to `/mnt/sdcard/Downloads/test.mp4`.

Limitations

While `DownloadManager` nowadays supports HTTPS (SSL) URLs, that was not the case when it was introduced back in Android 2.3. You will want to test any HTTPS URLs you intend to use with `DownloadManager` if you are supporting older versions of Android.

MISCELLANEOUS NETWORK CAPABILITIES

If you display the list of all downloads, and your download is among them, it is a really good idea to make sure that some activity (perhaps one of yours) is able to respond to an `ACTION_VIEW` Intent on that download's MIME type. Otherwise, when the user taps on the entry in the list, they will get a Toast indicating that there is nothing available to view the download. This may confuse users. Alternatively, use `setVisibleInDownloadsUi()` on your request, passing in `false`, to suppress it from this list.

Trail: Media

Audio Playback

Whether it comes in the form of simple beeps or in the form of symphonies (or gangster rap or whatever), Android applications often need to play audio. A few things in Android can play audio automatically, such as [a Notification](#). However, once you get past those, you are on your own.

Fortunately for you, Android offers support for audio playback, and we will examine some of the options in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Get Your Media On

In Android, you have five different places you can pull media clips from — one of these will hopefully fit your needs:

- You can package audio clips as raw resources (`res/raw` in your project), so they are bundled with your application. The benefit is that you're guaranteed the clips will be there; the downside is that they cannot be replaced without upgrading the application.
- You can package audio clips as assets (`assets/` in your project) and reference them via `file:///android_asset/` URLs in a `Uri`. The benefit over raw resources is that this location works with APIs that expect `Uri` parameters instead of resource IDs. The downside — assets are only replaceable when the application is upgraded — remains.

- You can store media in an application-local directory, such as content you download off the Internet. Your media may or may not be there, and your storage space isn't infinite, but you can replace the media as needed.
- You can store media — or make use of media that the user has stored herself — that is on an SD card. There is likely more storage space on the card than there is on the device, and you can replace the media as needed, but other applications have access to the SD card as well.
- You can, in some cases, stream media off the Internet, bypassing any local storage

Remember that on Android 1.x/2.x devices, internal storage space is at a premium. That means you should only package small clips in your app (`assets/` or `res/raw/`) and download larger clips to external storage.

MediaPlayer for Audio

If you want to play back music, particularly material in MP3 format, you will want to use the `MediaPlayer` class. With it, you can feed it an audio clip, start/stop/pause playback, and get notified on key events, such as when the clip is ready to be played or is done playing.

You have three ways to set up a `MediaPlayer` and tell it what audio clip to play:

- If the clip is a raw resource, use `MediaPlayer.create()` and provide the resource ID of the clip
- If you have a `Uri` to the clip, use the `Uri`-flavored version of `MediaPlayer.create()`
- If you have a string path to the clip, just create a `MediaPlayer` using the default constructor, then call `setDataSource()` with the path to the clip

Next, you need to call `prepare()` or `prepareAsync()`. Both will set up the clip to be ready to play, such as fetching the first few seconds off the file or stream. The `prepare()` method is synchronous; as soon as it returns, the clip is ready to play. The `prepareAsync()` method is asynchronous — more on how to use this version later.

Once the clip is prepared, `start()` begins playback, `pause()` pauses playback (with `start()` picking up playback where `pause()` paused), and `stop()` ends playback. One caveat: you cannot simply call `start()` again on the `MediaPlayer` once you have called `stop()` — we'll cover a workaround a bit later in this section.

To see this in action, take a look at the [Media/Audio](#) sample project. The layout is pretty trivial, with three buttons and labels for play, pause, and stop:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <LinearLayout
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:padding="4dip"
        >
        <ImageButton android:id="@+id/play"
            android:src="@drawable/play"
            android:layout_height="wrap_content"
            android:layout_width="wrap_content"
            android:paddingRight="4dip"
            android:enabled="false"
            />
        <TextView
            android:text="Play"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:gravity="center_vertical"
            android:layout_gravity="center_vertical"
            android:textAppearance="?android:attr/textAppearanceLarge"
            />
    </LinearLayout>
    <LinearLayout
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:padding="4dip"
        >
        <ImageButton android:id="@+id/pause"
            android:src="@drawable/pause"
            android:layout_height="wrap_content"
            android:layout_width="wrap_content"
            android:paddingRight="4dip"
            />
        <TextView
            android:text="Pause"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:gravity="center_vertical"
            android:layout_gravity="center_vertical"
            android:textAppearance="?android:attr/textAppearanceLarge"
            />
    </LinearLayout>
</LinearLayout>
```

```
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:padding="4dip"
    >
        <ImageButton android:id="@+id/stop"
            android:src="@drawable/stop"
            android:layout_height="wrap_content"
            android:layout_width="wrap_content"
            android:paddingRight="4dip"
        />
        <TextView
            android:text="Stop"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:gravity="center_vertical"
            android:layout_gravity="center_vertical"
            android:textAppearance="?android:attr/textAppearanceLarge"
        />
    </LinearLayout>
</LinearLayout>
```

The Java, of course, is where things get interesting:

```
package com.commonware.android.audio;

import android.app.Activity;
import android.app.AlertDialog;
import android.content.Context;
import android.content.SharedPreferences;
import android.media.MediaPlayer;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.ImageButton;
import android.widget.Toast;

public class AudioDemo extends Activity
    implements MediaPlayer.OnCompletionListener {

    private ImageButton play;
    private ImageButton pause;
    private ImageButton stop;
    private MediaPlayer mp;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        play=(ImageButton)findViewById(R.id.play);
        pause=(ImageButton)findViewById(R.id.pause);
```

```
stop=(ImageButton)findViewById(R.id.stop);

play.setOnClickListener(new View.OnClickListener() {
    public void onClick(View view) {
        play();
    }
});

pause.setOnClickListener(new View.OnClickListener() {
    public void onClick(View view) {
        pause();
    }
});

stop.setOnClickListener(new View.OnClickListener() {
    public void onClick(View view) {
        stop();
    }
});

setup();
}

@Override
public void onDestroy() {
    super.onDestroy();

    if (stop.isEnabled()) {
        stop();
    }
}

public void onCompletion(MediaPlayer mp) {
    stop();
}

private void play() {
    mp.start();

    play.setEnabled(false);
    pause.setEnabled(true);
    stop.setEnabled(true);
}

private void stop() {
    mp.stop();
    pause.setEnabled(false);
    stop.setEnabled(false);

    try {
        mp.prepare();
        mp.seekTo(0);
        play.setEnabled(true);
    }
}
```

```
        catch (Throwable t) {
            goBlooley(t);
        }
    }

    private void pause() {
        mp.pause();

        play.setEnabled(true);
        pause.setEnabled(false);
        stop.setEnabled(true);
    }

    private void loadClip() {
        try {
            mp=MediaPlayer.create(this, R.raw.clip);
            mp.setOnCompletionListener(this);
        }
        catch (Throwable t) {
            goBlooley(t);
        }
    }

    private void setup() {
        loadClip();
        play.setEnabled(true);
        pause.setEnabled(false);
        stop.setEnabled(false);
    }

    private void goBlooley(Throwable t) {
        AlertDialog.Builder builder=new AlertDialog.Builder(this);

        builder
            .setTitle("Exception!")
            .setMessage(t.toString())
            .setPositiveButton("OK", null)
            .show();
    }
}
```

In `onCreate()`, we wire up the three buttons to appropriate callbacks, then call `setup()`. In `setup()`, we create our `MediaPlayer`, set to play a clip we package in the project as a raw resource. We also configure the activity itself as the completion listener, so we find out when the clip is over. Note that, since we use the static `create()` method on `MediaPlayer`, we have already implicitly called `prepare()`, so we do not need to call that separately ourselves.

The buttons simply work the `MediaPlayer` and toggle each others' states, via appropriately-named callbacks. So, `play()` starts `MediaPlayer` playback, `pause()` pauses playback, and `stop()` stops playback and resets our `MediaPlayer` to play

again. The `stop()` callback is also used for when the audio clip completes of its own accord.

To reset the `MediaPlayer`, the `stop()` callback calls `prepare()` on the existing `MediaPlayer` to enable it to be played again and `seekTo()` to move the playback point to the beginning. If we were using an external file as our media source, it would be better to call `prepareAsync()`.

The UI is nothing special, but we are more interested in the audio in this sample, anyway:

Streaming Limitations

You can use the same basic code for streaming media, using an `http://` or `rtsp://` URL. However, bear in mind that Android does not support streaming MP3 over RTSP, as that exceeds the relevant RTSP specifications. That being said, there *are* MP3-over-RTSP streams in the world, and clients and servers that have negotiated an ad-hoc extension to the specification to accommodate this. Android cannot play these streams.

Other Ways to Make Noise

While MediaPlayer is the primary audio playback option, particularly for content along the lines of MP3 files, there are other alternatives if you are looking to build other sorts of applications, notably games and custom forms of streaming audio.

SoundPool

The SoundPool class's claim to fame is the ability to overlay multiple sounds, and do so in a prioritized fashion, so your application can just ask for sounds to be played and SoundPool deals with each sound starting, stopping, and blending while playing.

This may make more sense with an example.

Suppose you are creating a first-person shooter. Such a game may have several sounds going on at any one time:

1. The sound of the wind whistling amongst the trees on the battlefield
2. The sound of the surf crashing against the beach in the landing zone
3. The sound of booted feet crunching on the sand
4. The sound of the character's own panting as the character runs on the beach
5. The sound of orders being barked by a sergeant positioned behind the character
6. The sound of machine gun fire aimed at the character and the character's squad mates
7. The sound of explosions from the gun batteries of the battleship providing suppression fire

And so on.

In principle, SoundPool can blend all of those together into a single audio stream for output. Your game might set up the wind and surf as constant background sounds, toggle the feet and panting on and off based on the character's movement, randomly add the barked orders, and tie the gunfire based on actual game play.

In reality, your average smartphone will lack the CPU power to handle all of that audio without harming the frame rate of the game. So, to keep the frame rate up, you tell SoundPool to play at most two streams at once. This means that when nothing else is happening in the game, you will hear the wind and surf, but during

the actual battle, those sounds get dropped out — the user might never even miss them — so the game speed remains good.

AudioTrack

The lowest-level Java API for playing back audio is `AudioTrack`. It has two main roles:

1. Its primary role is to support streaming audio, where the streams come in some format other than what `MediaPlayer` handles. While `MediaPlayer` can handle RTSP, for example, it does not offer SIP. If you want to create a SIP client (perhaps for a VOIP or Web conferencing application), you will need to convert the incoming data stream to PCM format, then hand the stream off to an `AudioTrack` instance for playback.
2. It can also be used for “static” (versus streamed) bits of sound that you have pre-decoded to PCM format and want to play back with as little latency as possible. For example, you might use this for a game for in-game sounds (beeps, bullets, or “boing”s). By pre-decoding the data to PCM and caching that result, then using `AudioTrack` for playback, you will use the least amount of overhead, minimizing CPU impact on game play and on battery life.

ToneGenerator

If you want your phone to sound like... well... a phone, you can use `ToneGenerator` to have it play back [dual-tone multi-frequency](#) (DTMF) tones. In other words, you can simulate the sounds played by a regular “touch-tone” phone in response to button presses. This is used by the Android dialer, for example, to play back the tones when users dial the phone using the on-screen keypad, as an audio reinforcement.

Note that these will play through the phone’s earpiece, speaker, or attached headset. They do not play through the outbound call stream. In principle, you might be able to get `ToneGenerator` to play tones through the speaker loud enough to be picked up by the microphone, but this probably is not a recommended practice.

Audio Recording

Most Android devices have microphones. On such devices, it might be nice to get audio input from those microphones, whether to record locally, process locally (e.g., speech recognition), or to stream out over the Internet (e.g., voice over IP).

Not surprisingly, Android has some capabilities in this area. Also, not surprisingly, there are multiple APIs, with varying mixes of power and complexity, to allow you to capture microphone input. In this chapter, we will examine `MediaRecorder` for recording audio files and `AudioRecord` for raw microphone input.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on [audio playback](#) is probably also a good idea. And, for the section on playing back local streams, you will want to have read up on content providers, particularly [the chapter on provider patterns](#).

Recording by Intent

Just as the easiest way to take a picture with the camera is [to use the device's built-in camera app](#), the easiest way to record some audio is to use a built-in activity for it. And, as with using the built-in camera app, the built-in audio recording activity has some significant limitations.

Requesting the built-in audio recording activity is a matter of calling `startActivityForResult()` for a `MediaStore.Audio.Media.RECORD_SOUND_ACTION` action. You can see this in the [Media/SoundRecordIntent](#) sample project, specifically the `MainActivity`:

AUDIO RECORDING

```
package com.commonware.android.soundrecord;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.MediaStore;
import android.widget.Toast;

public class MainActivity extends Activity {
    private static final int REQUEST_ID=1337;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Intent i=new Intent(MediaStore.Audio.Media.RECORD_SOUND_ACTION);

        startActivityForResult(i, REQUEST_ID);
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode,
                                     Intent data) {
        if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
            Toast.makeText(this, "Recording finished!", Toast.LENGTH_LONG)
                .show();
        }

        finish();
    }
}
```

As with a few other sample apps in this book, the Media/SoundRecordIntent uses a Theme.NoDisplay activity, eschewing its own UI. Instead, in onCreate(), we immediately call startActivityForResult() for MediaStore.Audio.Media.RECORD_SOUND_ACTION. That will bring up a recording activity:

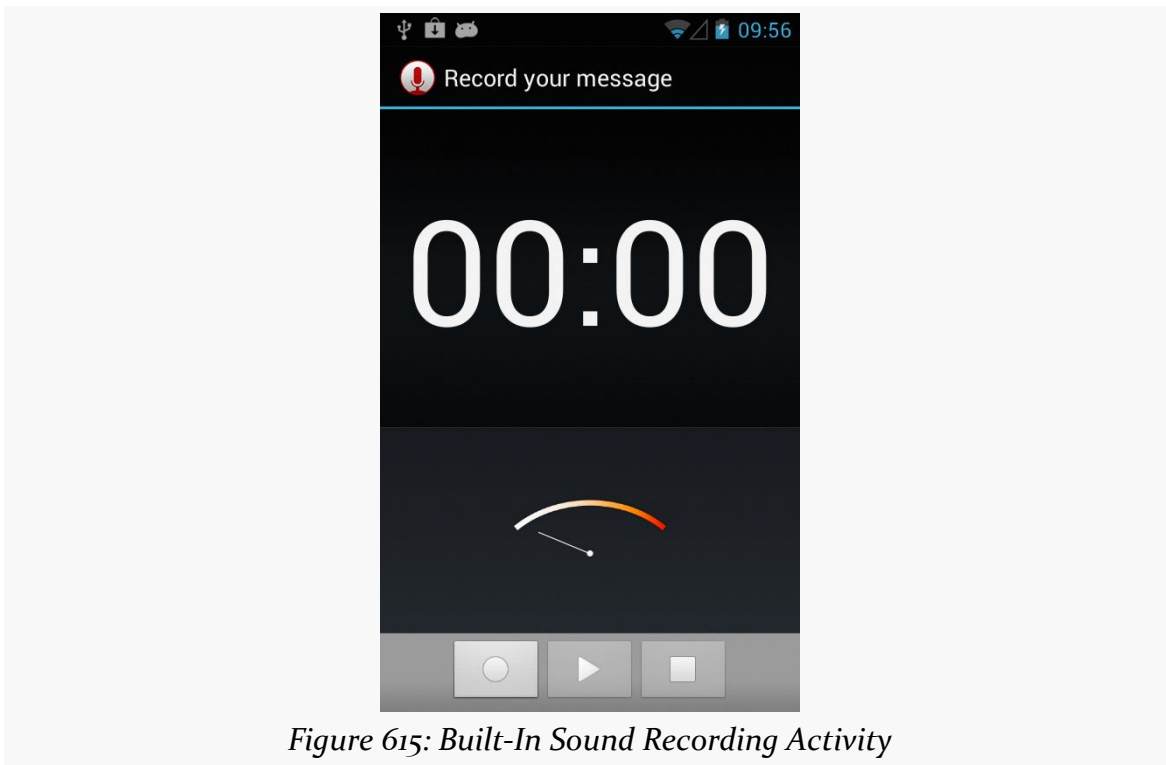

Figure 615: Built-In Sound Recording Activity

If the user records some audio via the “record” `ImageButton` (one with the circle icon) and the “stop” `ImageButton` (one with the square icon), you will get control back in `onActivityResult()`, where you are passed an `Intent` whose `Uri` (via `getData()`) will point to this audio recording in the `MediaStore`.

However:

- You have no control over where the file is stored or what it is named. It appears that, by default, these files are dumped unceremoniously in the root of external storage.
- You have no control over anything about the way the audio is recorded, such as codecs or bitrates. For example, it appears that, by default, the files are recorded in AMR format.
- `ACTION_VIEW` may not be able to play back this audio (leastways, it failed to in testing on a few devices). Whether that is due to codecs, the way the data is put in `MediaStore`, or the limits of the default audio player on Android, is unclear.

Hence, in many cases, while this works, it may not work well enough — or controlled enough — to meet your needs. In that case, you will want to handle the recording yourself, as will be described in the next couple of sections.

Recording to Files

If your objective is to record a voice note, a presentation, or something along those lines, then `MediaRecorder` is probably the class that you want. It will let you specify what sort of media you wish to record, in what format, and to what location. It then handles the actual act of recording.

To illustrate this, let us review the [Media/AudioRecording](#) sample project.

Our activity's layout consists of a single `ToggleButton` widget named `record`:

```
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/record"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:textAppearance="?android:attr/textAppearanceLarge"/>
```

In `onCreate()` of `MainActivity`, we load the layout and set the activity itself up as the `OnCheckedChangeListener`, to find out when the user toggles the button:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ((ToggleButton)findViewById(R.id.record)).setOnCheckedChangeListener(this);
}
```

Also, in `onResume()`, we initialize a `MediaRecorder`, setting the activity up as being the one to handle info and error events about the recording. Similarly, we `release()` the `MediaRecorder` in `onPause()`, to reduce our overhead when we are not in the foreground:

```
@Override
public void onResume() {
    super.onResume();

    recorder=new MediaRecorder();
    recorder.setOnErrorListener(this);
    recorder.setOnInfoListener(this);
}
```

```
@Override
public void onPause() {
    recorder.release();
    recorder=null;

    super.onPause();
}
```

Most of the work occurs in `onCheckedChanged()`, where we get control when the user toggles the button. If we are now checked, we begin recording; if not, we stop the previous recording:

```
@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {

    if (isChecked) {
        File output=
            new File(
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS),
                BASENAME);

        recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
        recorder.setOutputFormat(MediaRecorder.OutputFormat.THREE_GPP);
        recorder.setOutputFile(output.getAbsolutePath());

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD_MR1) {
            recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AAC);
            recorder.setAudioEncodingBitRate(160 * 1024);
        }
        else {
            recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
        }

        recorder.setAudioChannels(2);

        try {
            recorder.prepare();
            recorder.start();
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception in preparing recorder", e);
            Toast.makeText(this, e.getMessage(), Toast.LENGTH_LONG).show();
        }
    }
    else {
        try {
            recorder.stop();
        }
        catch (Exception e) {
            Log.w(getClass().getSimpleName(),
```

```
        "Exception in stopping recorder", e);
        // can fail if start() failed for some reason
    }

    recorder.reset();
}
}
```

To record audio, we:

- Create a File object representing where the recording should be stored, in this case using `Environment.getExternalStoragePublicDirectory()` to find a location on external storage
- Tell the `MediaRecorder` that we wish to record from the microphone, through a call to `setAudioSource()`, that we wish to record a 3GP file via a call to `setOutputFormat()`, and that we wish to record the results to our File via a call to `setOutputFile()`
- If we are running on Android 2.3.3 or higher, we can also configure our encoder to be AAC via `setAudioEncoder()` and set our requested bitrate to 160Kbps via `setAudioEncodingBitRate()` — otherwise, we use `setAudioEncoder()` to request AMR narrowband
- Indicate how many audio channels we want via `setAudioChannels()`, such as 2 to attempt to record in stereo
- Kick off the actual recording via calls to `prepare()` (to set up the output file) and `record()`

Stopping the recording, when the user toggles off the button, is merely a matter of calling `stop()` on the `MediaRecorder`.

Because we told the `MediaRecorder` that our activity was our `OnErrorListener` and `OnInfoListener`, we have to implement those interfaces on the activity and implement their required methods (`onError()` and `onInfo()`, respectively). In the normal course of events, neither of these should be triggered. If they are, we are passed an `int` value (typically named `what`) that indicates what happened:

```
@Override
public void onInfo(MediaRecorder mr, int what, int extra) {
    String msg=getString(R.string.strange);

    switch (what) {
        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_DURATION_REACHED:
            msg=getString(R.string.max_duration);
            break;

        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_FILESIZE_REACHED:
```

```
        msg=getString(R.string.max_size);
        break;
    }

    Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}

@Override
public void onError(MediaRecorder mr, int what, int extra) {
    Toast.makeText(this, R.string.strange, Toast.LENGTH_LONG).show();
}
```

Here, we just raise a Toast in either case, with either a generic message or a specific message for the cases where the maximum time duration or the maximum file size for our recording has been reached.

We also need to hold the `RECORD_AUDIO` and `WRITE_EXTERNAL_STORAGE` permissions. `RECORD_AUDIO`, in particular, is needed to let the user know that we intend to record information off of the microphone.

The results are that we get a recording on external storage (typically in a Downloads directory) after we toggle the button on, record some audio, then toggle the button off.

`MediaRecorder` is rather fussy about the order of method calls for its configuration. For example, you must call `setAudioEncoder()` *after* the call to `setOutputFormat()`.

Also, the available codecs and file types are rather limited. Notably, Android lacks the ability to record to MP3 format, perhaps due to patent licensing issues.

On the flip side, `MediaRecorder` also supports recording video, a topic which is not presently covered in this book.

Recording to Streams

The nice thing about recording to files is that Android handles all of the actual file I/O for us. The downside is that because Android handles all of the actual file I/O for us, it can only write files that are accessible to it and our process, meaning external storage. This may not be suitable in all cases, such as wanting to record to some form of private encrypted storage.

The good news is that Android does support recording to streams, in the form of a pipe created by `ParcelFileDescriptor` and `createPipe()`. This follows the same

basic pattern that we saw in [the chapter on content provider patterns](#), where we [served a stream via a pipe](#). However, as you will see, there are some limits on how well we can do this.

To demonstrate and explain, let us examine the [Media/AudioRecordStream](#) sample project. This is nearly a complete clone of the previous sample, so we will only focus on the changes in this section.

The author would like to thank Lucio Maciel for his assistance in [getting this example to work](#).

Setting Up the Stream

The biggest change, by far, is in our `setOutputFile()` call. Before, we supplied a path to external storage. Now, we supply the write end of a pipe:

```
recorder.setOutputFile(getStreamFd());
```

Our `getStreamFd()` method looks a lot like the `openFile()` method of our pipe-providing provider:

```
private FileDescriptor getStreamFd() {
    ParcelFileDescriptor[] pipe=null;

    try {
        pipe=ParcelFileDescriptor.createPipe();

        new TransferThread(new AutoCloseInputStream(pipe[0]),
                           new FileOutputStream(getOutputFile())).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    }

    return(pipe[1].getFileDescriptor());
}
```

We create our pipe with `createPipe()`, spawn a `TransferThread` to copy the recording from an `InputStream` to a `FileOutputStream`, and return the write end of the pipe. However, `setOutputFile()` on `MediaRecorder` takes the actual integer file descriptor, not a `ParcelFileDescriptor`, so we use `getFileDescriptor()` to retrieve the file descriptor and return that.

Our TransferThread is similar to the one from the content provider sample, except that we pass over a FileOutputStream, so we can not only flush() but also sync() when we are done writing:

```
static class TransferThread extends Thread {
    InputStream in;
    FileOutputStream out;

    TransferThread(InputStream in, FileOutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
    public void run() {
        byte[] buf=new byte[8192];
        int len;

        try {
            while ((len=in.read(buf)) >= 0) {
                out.write(buf, 0, len);
            }

            in.close();

            out.flush();
            out.getFD().sync();
            out.close();
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                "Exception transferring file", e);
        }
    }
}
```

Changes in Recording Configuration

The biggest limitation of a pipe's stream is that it is *purely* a stream. You cannot rewind re-read earlier bits of data. In other words, the stream is not seekable.

That is a problem with MediaRecorder in some configurations. For example, a 3GP file contains a header with information about the overall file, information that MediaRecorder does not know until the recording is complete. In the case of a file, MediaRecorder can simply rewind and update the header with the final data when everything is done. However, that is not possible with a pipe-based stream.

However, some configurations will work, notably “raw” ones that just have the recorded audio, with no type of header. That is what we use in this sample.

Specifically, we now write to a .amr file:

```
private static final String BASENAME="recording-stream.amr";
```

We also set our output format to RAW_AMR, and our encoder to AMR_NB:

```
recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
recorder.setOutputFormat(MediaRecorder.OutputFormat.RAW_AMR);
recorder.setOutputFile(getStreamFd());
recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
recorder.setAudioChannels(2);
```

This combination works. Other combinations might also work. But our approach of writing the 3GP file, as in the file-based example, will not work.

Raw Audio Input

Just as `AudioTrack` allows you to play audio supplied as raw 8- or 16-bit PCM input, `AudioRecord` allows you to record audio from the microphone, supplied to you in PCM format. It is then up to you to actually do something with the raw byte PCM data, including converting it to some other format and container as needed.

Note that you need `RECORD_AUDIO` to work with `AudioRecord`, just as you need it to work with `MediaRecorder`.

Requesting the Microphone

As noted in the opening paragraph of this chapter, most Android devices have microphones. The key word there is *most*. Not all Android devices will have microphones, as only some tablets (and fewer Android TV devices) will support microphone input.

As with most of this optional hardware, the solution is to use `<uses-feature>`. In that case, you would request the `android.hardware.microphone` feature, with `android:required="false"` if you felt that you do not absolutely *need* a microphone. In that case, you would use `hasSystemFeature()` on `PackageManager` to determine at runtime if you do indeed have a microphone.

AUDIO RECORDING

Note that the `RECORD_AUDIO` permission implies that you need a microphone. Hence, even if you skip the `<uses-feature>` element, your app will still only ship to devices that have a microphone. If the microphone is optional, be sure to include `android:required="false"`, so your app will be available to devices that lack a microphone.

Video Playback

Just as Android supports audio playback, it also supports video playback of local and streaming content. Unlike audio playback – which supports a mix of high-level and low-level APIs – video playback offers a purely high-level interface, in the form of the same `MediaPlayer` class you used for audio playback. To keep things a bit simpler, though, Android does offer a `VideoView` widget you can drop in an activity or fragment to play back video.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with [the chapter on audio playback](#).

Moving Pictures

Video clips get their own widget, the `VideoView`. Put it in a layout, feed it an MP4 video clip, and you get playback!

For example, take a look at this layout, from the [Media/Video](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <VideoView
        android:id="@+id/video"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
```

```
/>  
</LinearLayout>
```

The layout is simply a full-screen video player. Whether it will use the full screen will be dependent on the video clip, its aspect ratio, and whether you have the device (or emulator) in portrait or landscape mode.

Wiring up the Java is almost as simple:

```
package com.commonware.android.video;  
  
import java.io.File;  
import android.app.Activity;  
import android.graphics.PixelFormat;  
import android.os.Bundle;  
import android.os.Environment;  
import android.widget.MediaController;  
import android.widget.VideoView;  
  
public class VideoDemo extends Activity {  
    private VideoView video;  
    private MediaController ctrlr;  
  
    @Override  
    public void onCreate(Bundle icle) {  
        super.onCreate(icle);  
        getWindow().setFormat(PixelFormat.TRANSLUCENT);  
        setContentView(R.layout.main);  
  
        File clip=new File(Environment.getExternalStorageDirectory(),  
                           "test.mp4");  
  
        if (clip.exists()) {  
            video=(VideoView)findViewById(R.id.video);  
            video.setVideoPath(clip.getAbsolutePath());  
  
            ctrlr=new MediaController(this);  
            ctrlr.setMediaPlayer(video);  
            video.setMediaController(ctrlr);  
            video.requestFocus();  
            video.start();  
        }  
    }  
}
```

Here, we:

1. Confirm that our video file exists on external storage
2. Tell the VideoView which file to play

VIDEO PLAYBACK

3. Create a `MediaController` pop-up panel and cross-connect it to the `VideoView`
4. Give the `VideoView` the focus and start playback

The biggest trick with `VideoView` is getting a video clip onto the device. While `VideoView` does support some streaming video, the requirements on the MP4 file are fairly stringent. If you want to be able to play a wider array of video clips, you need to have them on the device, preferably on an SD card.

The crude `VideoDemo` class assumes there is an MP4 file named `test.mp4` in the root of external storage on your device or emulator. Once there, the Java code shown above will give you a working video player:

Tapping on the video will pop up the playback controls:

VIDEO PLAYBACK

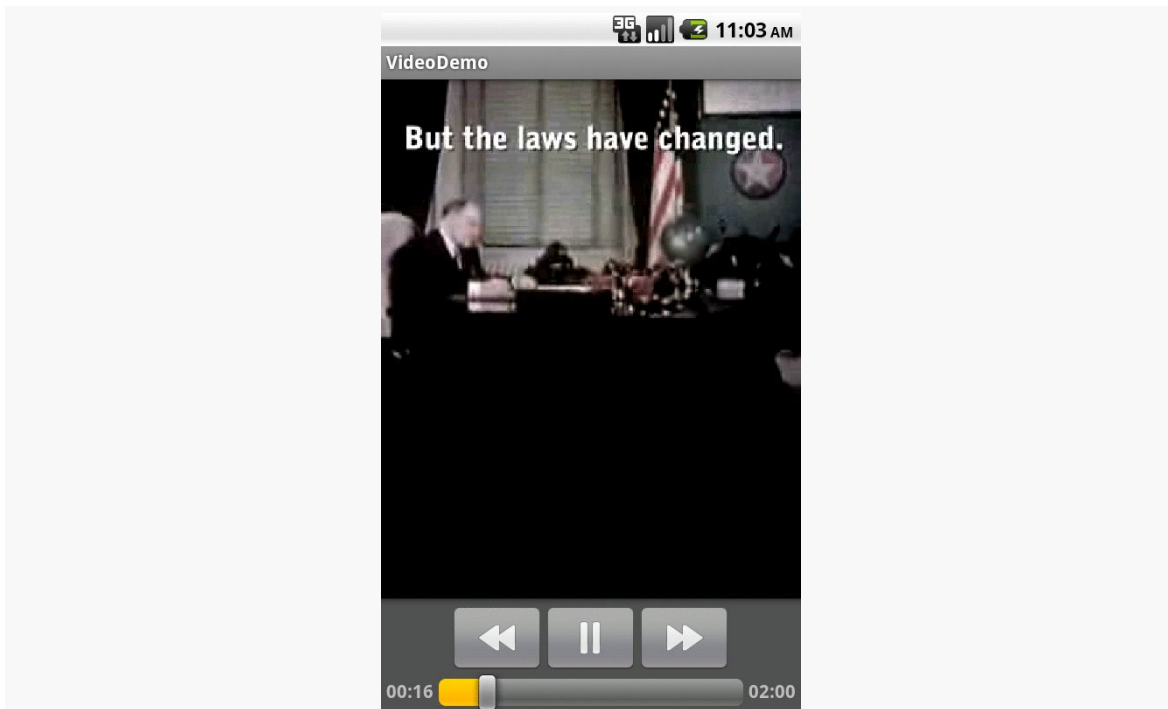

Figure 617: The VideoDemo sample application, with the media controls displayed

The video will scale based on space, as shown in this rotated view of the emulator (<Ctrl>-<F12>):

Figure 618: The VideoDemo sample application, in landscape mode, with the video clip scaled to fit

NOTE: playing video on the Android emulator may work for you, but it is not terribly likely. Video playback requires graphic acceleration to work well, and the emulator does not have graphics acceleration — regardless of the capabilities of the actual machine the emulator runs on. Hence, if you try playing back video in the emulator, expect problems. If you are serious about doing Android development with video playback, you definitely need to acquire a piece of Android hardware.

Using the Camera via 3rd-Party Apps

Most Android devices will have a camera, since they are fairly commonplace on mobile devices these days. You, as an Android developer, can take advantage of the camera, for everything from snapping tourist photos to scanning barcodes. If you wish to let other apps do the “heavy lifting” for you, working with the camera can be fairly straightforward. If you want more control, you can work with the camera directly, though this control comes with greater complexity.

You can also record videos using the camera. Once again, you have the option of either using a third-party activity, or doing it yourself.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the material on [implicit Intents](#).

Being Specific About Features

If your app needs a camera — by any of the means cited in this chapter – you should include a `<uses-feature>` element in the manifest indicating your requirements. However, you need to be fairly specific about your requirements here.

For example, the Nexus 7 has a camera... but only a front-facing camera. This facilitates apps like video chat. However, the `android.hardware.camera` implies that you need a high-resolution rear-facing camera, [even though this is undocumented](#). Hence, to work with the Nexus 7’s camera, you need to:

- Require the `CAMERA` permission (if you are using the Camera directly)

- Not require the `android.hardware.camera` feature (`android:required="false"`)
- Optionally require the `android.hardware.camera.front` feature (if your app definitely needs a front-facing camera)

At runtime, you would use `hasSystemFeature()` on `PackageManager`, or interrogate the `Camera` class for available cameras, to determine what you have access to.

Note that if you want to record audio when recording videos, you should also consider the `android.hardware.microphone` feature.

Still Photos: Letting the Camera App Do It

The easiest way to take a picture is to not take the picture yourself, but let somebody else do it. The most common implementation of this approach is to use an `ACTION_IMAGE_CAPTURE` Intent to bring up the user's default camera application, and let it take a picture on your behalf.

To see this in use, take a look at the [Camera/Content](#) sample project. This trivial app will use system-supplied activities to take a picture, then view the result, without actually implementing any of its own UI.

The Implementation

Of course, we still need an activity, so our code can be launched by the user. We just set it up with `Theme.NoDisplay`, so no UI will be created for it:

```
<activity
    android:name=".CameraContentDemoActivity"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.NoDisplay">
    <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>
```

The activity itself — `CameraContentDemoActivity` — consists solely of `onCreate()` and `onActivityResult()` methods:

```
@Override
public void onCreate(Bundle savedInstanceState) {
```

USING THE CAMERA VIA 3RD-PARTY APPS

```
super.onCreate(savedInstanceState);

Intent i=new Intent(MediaStore.ACTION_IMAGE_CAPTURE);
File dir=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DCIM);

output=new File(dir, "CameraContentDemo.jpeg");
i.putExtra(MediaStore.EXTRA_OUTPUT, Uri.fromFile(output));

startActivityForResult(i, CONTENT_REQUEST);
}

@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == CONTENT_REQUEST) {
        if (resultCode == RESULT_OK) {
            Intent i=new Intent(Intent.ACTION_VIEW);

            i.setDataAndType(Uri.fromFile(output), "image/jpeg");
            startActivity(i);
            finish();
        }
    }
}
```

In `onCreate()`, we create our `ACTION_IMAGE_CAPTURE` Intent. We add an extra, keyed as `MediaStore.EXTRA_OUTPUT`, indicating where we want the app to save the resulting picture. In our case, we store that in a `CameraContentDemo.jpeg` file in the default external storage directory for photos (identified by `Environment.DIRECTORY_DCIM`). The documentation for `ACTION_IMAGE_CAPTURE` indicates that this needs to be in the form of a `Uri` object, which is why we use `Uri.fromFile()` to convert our string path into the `Uri`.

At that point, we call `startActivityForResult()` to bring up the user's chosen camera app to take our picture. We next get control in `onActivityResult()`. There, we create an `ACTION_VIEW` Intent, pointing at our output file, indicating the MIME type is `image/jpeg`, and start up an activity for that. This should bring up the Gallery or another app capable of displaying the photo on the screen.

The Caveats

There are several downsides to this approach.

First, you have no control over the camera app itself. You do not even really know what app it is. You cannot dictate certain features that you would like (e.g., resolution, color effects). You simply blindly ask for a photo and get the result.

Also, since you do not know what the camera app is or behaves like, you cannot document that portion of your application's flow very well. You can say things like “at this point, you can take a picture using your chosen camera app”, but that is about as specific as you can get.

Finally, some camera apps misbehave, returning odd results, such as a thumbnail-sized image rather than a max-resolution image. There is little you can do about this.

So, while this approach is easy, it may pose some quality-control issues.

Scanning with ZXing

If your objective is to scan a barcode, it is *much* simpler for you to integrate Barcode Scanner into your app than to roll it yourself.

[Barcode Scanner](#) – one of the most popular Android apps of all time — can scan a wide range of 1D and 2D barcode types. They offer an integration library that you can add to your app to initiate a scan and get the results. The library will even lead the user to the Play Store to install Barcode Scanner if they do not already have the app.

One limitation is that while the ZXing team (the authors and maintainers of Barcode Scanner) make the integration library available, they only do so in [source form](#), requiring you to check out a bunch of source code and run a command-line build to get a JAR. Or, you can [download a JAR](#) that is used in the sample project for this section, if you prefer.

That sample project — [Camera/ZXing](#) – has a UI dominated by a “Scan!” button. Clicking the button invokes a `doScan()` method in our sample activity:

```
public void doScan(View v) {  
    (new IntentIntegrator(this)).initiateScan();  
}
```

This passes control to Barcode Scanner by means of the integration JAR and the IntentIntegrator class. `initiateScan()` will validate that Barcode Scanner is installed, then will start up the camera and scan for a barcode.

Once Barcode Scanner detects a barcode and decodes it, the activity invoked by `initiateScan()` finishes, and control returns to you in `onActivityResult()` (as the Barcode Scanner scanning activity was invoked via `startActivityForResult()`). There, you can once again use IntentIntegrator to find out details of the scan, notably the type of barcode and the encoded contents:

```
public void onActivityResult(int request, int result, Intent i) {
    IntentResult scan=IntentIntegrator.parseActivityResult(request,
                                                            result,
                                                            i);

    if (scan!=null) {
        format.setText(scan.getFormatName());
        contents.setText(scan.getContents());
    }
}
```

Some notes:

- Barcode Scanner's scanning activity only works in landscape
- Even though you are not using the camera directly yourself, you should consider including the `<uses-feature>` element declaring that you need a camera, if your app cannot function without barcodes
- If you wish to add Barcode Scanner logic directly to your app, and avoid the dependency on the third-party APK, that is possible, but the process for doing it is not well documented

Videos: Letting the Camera App Do It

Just as `ACTION_IMAGE_CAPTURE` can be used to have a third-party app supply you with still images, there is an `ACTION_VIDEO_CAPTURE` on MediaStore that can be used as an Intent action for asking a third-party app capture a video for you. As with `ACTION_IMAGE_CAPTURE`, you use `startActivityForResult()` with `ACTION_VIDEO_CAPTURE` to find out when the video has been recorded.

There are two extras of note for `ACTION_VIDEO_CAPTURE`:

- `MediaStore.EXTRA_OUTPUT`, which indicates where on external storage the video should be written, and

USING THE CAMERA VIA 3RD-PARTY APPS

- `MediaStore.EXTRA_VIDEO_QUALITY`, which should be an integer, either 0 for low quality/low size videos or 1 for high quality

If you elect to skip `EXTRA_OUTPUT`, the video will be written to the default directory for videos on the device (typically a “Movies” directory in the root of external storage), and the `Uri` you receive on the `Intent` in `onActivityResult()` will point to this file.

The impacts of skipping `EXTRA_VIDEO_QUALITY` are undocumented.

The [Media/VideoRecordIntent](#) sample project is a near-clone of the `Camera/Content` sample from earlier in this chapter. Instead of requesting a third-party app take a still image, though, this sample requests that a third-party app record a video:

```
package com.commonware.android.videorecord;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.os.Environment;
import android.provider.MediaStore;
import java.io.File;

public class MainActivity extends Activity {
    private static final int REQUEST_ID=1337;
    private Uri result=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        File video=
            new File(
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_MOVIES),
                "sample.mp4");

        if (video.exists()) {
            video.delete();
        }

        Intent i=new Intent(MediaStore.ACTION_VIDEO_CAPTURE);

        result=Uri.fromFile(video);
        i.putExtra(MediaStore.EXTRA_OUTPUT, result);
        i.putExtra(MediaStore.EXTRA_VIDEO_QUALITY, 1);

        startActivityForResult(i, REQUEST_ID);
    }
}
```

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
        Intent view=
            new Intent(Intent.ACTION_VIEW).setDataAndType(result,
                                                         "video/mp4");

        startActivity(view);
    }
    finish();
}
```

onCreate() of MainActivity starts by setting up a File object pointing to a sample.mp4 file in the standard location for movies on the device. If the file already exists, onCreate() deletes it. Then, onCreate() sets up the Intent to request that a third-party app record a movie to that location, at high quality (EXTRA_VIDEO_QUALITY set to 1).

The call to startActivityForResult() will trigger the third-party app to record the video. When control returns to MainActivity, onActivityResult() creates an ACTION_VIEW Intent for the same file, then calls startActivity() to request that some app play back the video.

Directly Working with the Camera

Of course, you can bypass these third-party apps and work directly with the camera if you so choose. This is very painful... unless you use some wrapper code published by the author of this book, in which case working with the camera directly is somewhat less painful than normal.

The [next chapter](#) will explain all of this in great detail.

Working Directly with the Camera

Letting third-party apps take the pictures and videos for you is all well and good, but there will be times where you need more control than that. It is possible for you to work directly with the device cameras, via the `Camera` class.

(note that there are two classes in Android named `Camera` — the one of relevance for this chapter is `android.hardware.Camera`)

Working with `Camera` is ridiculously complicated, which is why the author of this book has created a `CameraFragment` to help streamline the implementation of a camera-using app.

Hence, first, we will cover the use of `CameraFragment` for simple picture-taking scenarios — this may be all that you need for your particular app.

As we get into more complex use cases for `CameraFragment`, we will explain a bit about the `Camera` and `MediaRecorder` APIs that `CameraFragment` uses “under the covers”, so you have some context for how to work with `CameraFragment` and some idea of what you need to do if `CameraFragment` is ill-suited to your particular use case.

NOTE: The `Camera` API covered here — `android.hardware.Camera` — is deprecated as of Android 5.0. However, it is highly unlikely that there will ever be a backport of the replacement `android.hardware.camera2` API. Hence, you will need to use the `Camera` API until such time as your `minSdkVersion` rises to 21 or higher. The `CameraFragment` discussed in this chapter also uses the `Camera` API, not the new `android.hardware.camera2` API.

Prerequisites

This chapter assumes that you have read [the previous chapter](#) covering Intent-based uses of the camera and [the chapter on audio recording](#).

Basic CameraFragment Usage

CameraFragment resides in [the CWAC-Camera project](#). While in principle it is an Android library project, in practice you will probably use [the published JAR](#) instead, or integrate it as an AAR for your Gradle-based build.

With that in mind the steps for adding a CameraFragment to your app include:

Step #1: Download the JAR and put it in the `libs/` directory of your project (or, if you prefer, clone the GitHub repo and add it as a library project to your main project). Alternatively, follow the instructions on [the CWAC-Camera project](#) to add it to your `build.gradle` file.

Step #2: Add a CameraFragment to your UI. You have two versions of CameraFragment to choose from:

- `com.commonware.cwac.camera.CameraFragment` for use with native API Level 11+ fragments
- `com.commonware.cwac.camera.ac1.CameraFragment` for use with the Android Support package's backport of fragments and [ActionBarSherlock](#), supporting API Level 9 and 10

(note: if you choose the latter, your project will also need to have the ActionBarSherlock library project, and you will need a second CWAC-Camera JAR file containing these backported classes)

The CameraFragment is responsible for rendering your preview, so you need to size and position it as desired.

Step #3: Call `takePicture()` on the CameraFragment when you want to take a picture, which will be stored in the default digital photos directory (e.g., DCIM) on external storage as `Photo_yyyyMMdd_HHmss.jpg`, where `yyyyMMdd_HHmss` is replaced by the current date and time.

Step #3b: Call `startRecording()` and `stopRecording()` on the `CameraFragment` to record a video. **NOTE** that this is presently only available on `com.commonware.cwac.camera.CameraFragment` for use with native API Level 11+ fragments. The resulting video will be stored in the default videos directory (e.g., `Movies`) on external storage as `Video_yyyyMMdd_HHmss.mp4`, where `yyyymmdd_HHmss` is replaced by the current date and time.

Step #4: Optionally add `android:largeHeap="true"` to the `<application>` element in the manifest.

And that's it.

`CameraFragment` (and its underlying `CameraView`) will handle:

- Showing the preview using an optimal preview frame size, and managing the aspect ratio of the on-screen preview `View` so that your previews do not appear stretched
- Dealing with configuration changes and screen rotation, so your camera activity can work in portrait or landscape
- Following the appropriate recipes for taking still pictures and videos, including choosing the largest-available image size for the resolution
- Opening and closing the camera at the appropriate times, so when you are in the foreground you have exclusive camera access, but other apps will have access to the camera while your activity is not in the foreground
- And more!

Simple Configuration and Usage

Of course, there are probably plenty of things that you will want to configure about the process of taking photos and videos. There are many hooks in CWAC-Camera to allow you to do just that.

Much of this configuration involves creating a custom `CameraHost`. `CameraHost` is your primary interface with the CWAC-Camera classes for configuring the behavior of the camera. `CameraHost` is an interface, one that you are welcome to implement in full. Most times, though, you will be better served extending `SimpleCameraHost`, the default implementation of `CameraHost`, so that you can override only those methods where you want behavior different from the default.

SimpleCameraHost also offers SimpleCameraHost.Builder that you can use for some simple configuration, instead of creating a subclass of SimpleCameraHost and overriding methods. Create an instance of the Builder (passing in a Context to the constructor, such as your activity), call the various builder-style setters for configuration, and call build() to get your customized SimpleCameraHost instance.

You can pass your customized instance of CameraHost to setHost() on your CameraFragment, to replace the default. **Do this in onCreate() of a CameraFragment subclass** (or, if practical, just after instantiating your fragment) to ensure that the right CameraHost is used everywhere.

PictureTransaction

The takePicture() method has a zero-argument version that just takes a picture. It also has a one-argument version, where the argument is an instance of PictureTransaction. This will allow you to configure details of this particular picture to be taken. You can create a PictureTransaction using its constructor, which takes an instance of your CameraHost as a parameter.

Various sections below will mention using builder-style setters on PictureTransaction to control how a picture is taken.

PictureTransaction has a tag(Object) method that allow you to attach arbitrary data to the transaction, without having to bother with a subclass. You can retrieve that object later via the zero-argument tag() method.

Controlling the Names and Locations of Output Files

There are a series of methods that you can override on SimpleCameraHost to control where photos and videos are stored once taken. These methods will be called for each takePicture() or startRecording() call, so you can create customized results for each distinct photo or video.

Specifically:

- Override getPhotoFilename() to return the base name of the file to use to store the photo
- Override getPhotoDirectory() to return the name of the directory in which to store the photo
- Override getPhotoPath() to return the complete File object pointing to the desired file in the desired directory (the default implementation combines

the results of `getPhotoDirectory()` and `getPhotoFilename()`, so overriding `getPhotoPath()` replaces all of that)

There are equivalent `getVideoFilename()`, `getVideoDirectory()`, and `getVideoPath()` for controlling the output of the next video to be taken.

`SimpleCameraHost.Builder` offers `photoDirectory()` and `videoDirectory()` setters, where you provide the `File` pointing to your desired directory.

By default, if you are using `SimpleCameraHost`, your image will be indexed by the `MediaStore`. If you do not want this, override `scanSavedImage()` to return `false` in your `SimpleCameraHost` subclass (or, call `scanSavedImage()` and pass in a boolean to use by default). This is called on a per-image basis.

Controlling Which Camera is Used

If you override `useFrontFacingCamera()` on `SimpleCameraHost` to return `true`, the front-facing camera will be used, instead of the default rear-facing camera. You can also call `useFrontFacingCamera()` on your `SimpleCameraHost.Builder`, passing in a boolean default value to use.

Or, override `getDeviceId()` (available on `CameraHost`), and you can provide the ID of the specific camera you want. This would involve your choosing an available camera based on your own criteria. See the [JavaDocs for Android's Camera class](#), notably [getNumberOfCameras\(\)](#) and [getCameraInfo\(\)](#) for more. You can also call `deviceId()` on `SimpleCameraHost` to supply the camera ID to use.

Controlling FFC Mirror Correction

By default, the pictures taken from the front-facing camera are a mirror image of what is shown on the preview. If you wish for the front-facing camera photos to match the preview, override `mirrorFFC()` on your `CameraHost` and have it return `true`, and `CWAC-Camera` will reverse the image for you before saving it. Or, call `mirrorFFC()` on your `SimpleCameraHost.Builder`, supplying a boolean value to use as the default. Or, call `mirrorFFC()` on your `PictureTransaction`, to control this for an individual picture.

Handling Exceptions

There are some exceptions that are thrown by the Camera class (and kin, like MediaRecorder). Those are passed to your host's `handleException()` method. The default implementation displays a Toast and logs the message to LogCat as an error, but you probably will want to replace that with something else that integrates better with your UI.

Supporting “Full-Bleed Preview”

The original default behavior of CameraFragment and CameraView was to show the entire preview, as supplied by the underlying Camera API. Since the aspect ratio of the preview frames may be different than the aspect ratio of the CameraView, this results in a “letterbox” effect, where the background will show through on one axis on the sides.

The new default behavior is to completely fill the CameraView, at the cost of cropping off some of the actual preview frame, what is known as “full-bleed preview” (stealing some terminology from the world of print media).

To control this behavior:

- Have your CameraHost return true or false from `useFullBleedPreview()`
- Or, call `useFullBleedPreview()` on your `SimpleCameraHost.Builder`, passing in a boolean value to use by default.

Note that the pictures and videos taken by this library are unaffected by `useFullBleedPreview()`. Hence, if `useFullBleedPreview()` returns true, the picture or video may contain additional content on the edges that was not visible in the preview.

Wrapping the Preview UI

From a UI standpoint, the CameraFragment solely handles the preview pane. Presumably, you will need more to your UI than this, such as buttons to allow users to take pictures or record videos. You have two major options here:

1. You can put that UI as a peer to the CameraFragment, such as by having action bar items, as the demo apps do.

2. You can subclass `CameraFragment` and override `onCreateView()`. Chain to the superclass to get the `CameraFragment`'s own UI, then wrap that in your own container with additional widgets, and return the combined UI from your `onCreateView()`. You can see this in the main demo app, which adds a `SeekBar` or `VerticalSeekBar` for zoom levels.

It is also possible to replace `onCreateView()` completely with your own implementation, or otherwise use `CameraView` from a layout resource. This is covered later in this document.

Auto-Focus

You can call `autoFocus()` on `CameraFragment` or `CameraView` to trigger any auto-focus behavior that you have configured via `setFocusMode()` on `Camera.Parameters`. You can call `cancelAutoFocus()` on `CameraFragment` or `CameraView` to ensure that auto-focus mode has been canceled.

Note that auto-focus is only available in certain conditions, notably when the preview mode is enabled. You can call `isAutoFocusAvailable()` on `CameraFragment` or `CameraView` to determine if auto-focus is presently available for use. Calling `autoFocus()` when auto-focus is not available will have no effect.

`CameraHost` implementations will need to implement an `onAutoFocus()` method, coming from [the `Camera.AutoFocusCallback` interface](#) that `CameraHost` extends. `SimpleCameraHost` has a default implementation of `onAutoFocus()` that plays a device-standard sound upon completion (API Level 16+ only).

`CameraHost` implementations will also need `autoFocusAvailable()` and `autoFocusUnavailable()` methods, to be notified when auto-focus is available or not. This can be used to trigger whether action bar items are enabled, etc. `SimpleCameraHost` has no-op implementations of these callbacks.

Single-Shot Mode

By default, the result of taking a picture is to return the `CameraFragment` to preview mode, ready to take the next picture. If, instead, you only need the one picture, or you want to send the user to some other bit of UI first and do not want preview to start up again right away, override `useSingleShotMode()` in your `CameraHost` to return `true`. Or, call `useSingleShotMode()` on your `SimpleCameraHost.Builder`, passing in a boolean to use by default. Or, call `useSingleShotMode()` on your `PictureTransaction`, to control this for an individual picture.

You will then probably want to use your own `saveImage()` implementation in your `CameraHost` to do whatever you want instead of restarting the preview. For example, you could start another activity to do something with the image. However, bear in mind that an `Intent` is limited to ~1MB, and so passing an image to another activity via an `Intent` extra is likely to be unreliable. You will need to do something else, such as (carefully) use a static data member.

Preview mode will re-enable automatically after an `onPause()/onResume()` cycle of your `CameraFragment`, or you can call `restartPreview()` on your `CameraFragment` (or `CameraView`).

Zoom Support

To zoom the camera, call `zoomTo()` on the `CameraView` or `CameraFragment`, supplying the integer zoom level that you want. This level must be between 0 and what `Camera.Parameters` returns from `getMaxZoom()`. The `adjustPreviewParameters()` callback method in your `CameraHost` is a good time to get this value and configure your UI (e.g., `SeekBar`) to allow the user to zoom the camera.

`zoomTo()` returns a `ZoomTransaction`. This has a series of builder-style methods (a.k.a., a fluent interface) that allow you to configure the transaction, where the methods return the transaction so you can chain on the next call. The configuration methods are:

- `onComplete()` to supply a `Runnable` to be executed when we have reached the zoom level
- `onChange()` to supply a `Camera.OnZoomChangeListener` to be called as we progress to the desired zoom level

Once configured, call `go()` to run the transaction.

If the camera supports smooth zoom, the zoom transaction will take a few moments, and you can cancel the operation by calling `cancel()` on the `ZoomTransaction`. If the camera does not support smooth zoom, the zoom level is just immediately changed.

Note that your `OnZoomChangeListener` supplied to `onChange()` will be called before the `onComplete()` `Runnable`, if you happen to supply both.

The main demo app adds a `SeekBar` and a `VerticalSeekBar` to control zoom levels, so you can see how this is used.

Note that some devices lie about their zoom capabilities. For example, the Motorola RAZR i's front-facing camera apparently does not support zoom, where `getMaxZoom()` still returns a positive value. `doesZoomReallyWork()` on your `CameraFragment` or `CameraView` will return `false` if zoom is known to be broken for the current camera on the current device. In this case, do not zoom, or your code may go “boom”.

Camera? #FAIL

If `getCameraId()` of your `CameraHost` returns a negative value, `CameraView` will assume that there are no valid cameras (e.g., your app is running on a game console). In addition to avoiding anything that tries to touch the camera, your `CameraHost` will be called with `onCameraFail()`, where you will be supplied with a `FailureReason` of `NO_CAMERAS_REPORTED`.

If anything else goes wrong when trying to open the camera (e.g., a device admin policy has disabled the camera), your `onCameraFail()` method will be called with a `FailureReason` of `UNKNOWN`.

While `SimpleCameraHost` has a trivial `onCameraFail()` implementation (just logging to `LogCat`), you are strongly encouraged to override this and inform your users of the problem.

Fixing Up Images... And Your Heap

There are a few fixups that the library performs on your images, to provide consistent output. The biggest one is to rotate the image to the proper orientation, rather than rely on EXIF headers, as not all image viewers use those headers.

The problem is that these fixups take a lot of heap space. By default, the library will always try to perform these fixups, and for a high-resolution image on a low-memory device, an `OutOfMemoryError` may result.

You have two means of managing this, and you are welcome to apply one or both of them:

1. You can add `android:largeHeap="true"` to the `<application>` element of your manifest. On API Level 11+ devices, you will get more heap space, making it more likely that the fixup will succeed. However, this will hurt the user, in that your app will tend to kick other apps out of memory more quickly, which the user may not appreciate.

2. Your CameraHost can return a value between 0.0f and 1.0f from `maxPictureCleanupHeapUsage()`. The default implementation on `SimpleCameraHost` returns 1.0f, which says “the byte array of image data from the camera can be as big as our heap limit, and we should still try to do the cleanup work”. A value of 0.0f would indicate that the cleanup work should never be done, and the images will be saved in their natural state. A value in between represents a portion of the heap space; if the byte array is that size or smaller, go ahead and try to do the fixups. Note that this determination is made on the compressed JPEG byte array length, not the size of the decoded Bitmap, and the JPEG may be compressed ~90% compared to its uncompressed size.

Core Camera Concepts

This section will outline the basic concepts of working with the Camera and MediaRecorder APIs for simple operations: displaying a preview, taking a still picture, and recording some video. It will do so in the context of reviewing [the CWAC-Camera demo application](#) and some of the more advanced configuration options for working with CameraFragment.

The Permission and the Features

First, you need permission to use the camera. That way, when end users install your application off of the Internet, they will be notified that you intend to use the camera, so they can determine if they deem that appropriate for your application.

You simply need the CAMERA permission in your `AndroidManifest.xml` file, along with whatever other permissions your application logic might require.

Your manifest also should contain one or more `<uses-feature>` elements, declaring what you need in terms of camera hardware. By default, asking for the CAMERA permission indicates that you *need* a camera. More specifically, asking for the CAMERA permission indicates that you need an *auto-focus* camera.

If you plan to record video, using MediaRecorder, you will also want to request the RECORD_AUDIO permission, assuming that you were not intending to record a silent film.

A Camera is Optional

If you would like a camera, but having one is not essential for the use of your app, put the following `<uses-feature>` element in your manifest:

```
<uses-feature android:name="android.hardware.camera" android:required="false" />
```

This indicates that you would like a camera, but it is not required. This reverses the default established by the CAMERA permission.

A Camera is Required

Technically, you would not need any `<uses-feature>` element in your manifest to indicate that you need a camera, as the CAMERA permission would handle that for you. However, it is good form to explicitly declare it anyway:

```
<uses-feature android:name="android.hardware.camera" android:required="true" />
```

Not only does that make your manifest more self-documenting, but it also helps protect you in case the default behavior of the CAMERA permission changes.

Other Camera Features

There are three other camera features that you could consider having `<uses-feature>` elements for:

1. `android.hardware.camera.autofocus`, to indicate whether or not the device needs a camera with auto-focus capability.
2. `android.hardware.camera.flash`, to indicate whether or not the device must support a camera flash
3. `android.hardware.camera.front`, to indicate whether or not the app needs a front-facing camera specifically (`android.hardware.camera` requests a rear-facing camera)

Of these, the only one you should definitely include in your app is `android.hardware.camera.autofocus`, once again because of the default effects of requesting the CAMERA permission. In particular, if you do not absolutely need auto-focus capabilities, you can use `android:required="false"` to reverse the CAMERA default requirement.

What the Demo Uses

The CWAC-Camera demo app requests three permissions: CAMERA, RECORD_AUDIO, and WRITE_EXTERNAL_STORAGE. The latter permission is so that we can save our photos and videos to external storage.

The demo app also indicates that:

- A camera is required to use this app (android.hardware.camera)
- Neither a front-facing camera (android.hardware.camera.front) nor an auto-focus camera (android.hardware.camera.autofocus) is required

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.cwac.camera.demo"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="17"/>

    <uses-permission android:name="android.permission.CAMERA"/>
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>
    <uses-permission android:name="android.permission.RECORD_AUDIO"/>

    <uses-feature

<activity
    android:name="DisplayActivity"
    android:label="@string/app_name">
</activity>
</application>

</manifest>
```

Warning: Do Not Use `android.hardware.camera.any` Yet

`android.hardware.camera.any` was added in API Level 17 (Android 4.2), to address the issues caused by the Nexus 7 and potential other future devices with a front-facing camera and no rear-facing camera. This feature would indicate that your app can work with *any* camera, not just a front-facing or rear-facing camera.

Alas, as of mid-December 2012, [the Play Store did not support this specific <uses-feature> variant](#), causing your app to be unavailable to most devices.

Until there are signs that `android.hardware.camera.any` support has been added to the Play Store, you are best off avoiding this particular `<uses-feature>` element.

The Preview Surface

The camera preview is basically a stream of images, taken by the camera, usually at less than full resolution. Mostly, that stream is to be presented to the user on the screen, to help them “see what the camera sees”, so they can line up the right picture.

For presenting the preview stream to the user, there are two typical solutions: `SurfaceView` and `TextureView`.

SurfaceView for the Camera

`SurfaceView` is used as a raw canvas for displaying all sorts of graphics outside of the realm of your ordinary widgets. In this case, Android knows how to display a live look at what the camera sees on a `SurfaceView`, to serve as a preview pane. A `SurfaceView` is also used for [video playback](#), and a variation of `SurfaceView` called `GLSurfaceView` is used for OpenGL animations.

That being said, `SurfaceView` is a subclass of `View`, and so it can be added to your UI the same as any other widget:

- Include it in a layout
- Return it as the `View` from `onCreateView()` of a `Fragment`
- Instantiate it in Java and add it to some container via `addView()`
- Etc.

If your app will support API Level 10 and older, you will want to call `getSurfaceHolder().getType(SurfaceHolder.SURFACE_TYPE_PUSH_BUFFERS)` on the `SurfaceView`. A “push buffers” `SurfaceView` is one designed to have images pushed to the surface, usually from video playback or camera previews. A `SurfaceHolder` is a quasi-controller object for the `SurfaceView` — most interactions with the `SurfaceView` come by way of the `SurfaceHolder`. This bit of configuration is not needed on API Level 11 and higher, as Android handles it for us automatically as the `SurfaceView` is put to use.

TextureView for the Camera

`SurfaceView`, however, has some limitations. This is mostly tied back to the way it works, by “punching a hole” in the UI to allow some lower-level component (like the camera) to render stuff into it. While there is a transparent layer on top of this “hole”, for use in alpha-compositing in any overlapping widgets, the `SurfaceView` *content* is not rendered as part of the normal view hierarchy. The net effect is that you cannot readily move, animate, or otherwise transform a `SurfaceView`.

`TextureView` was added in API Level 14 and works for camera previews as of API Level 15. `TextureView` serves much the same role as does `SurfaceView`, for showing camera previews, playing videos, or rendering OpenGL scenes. However, `TextureView` behaves as a regular `View` and so therefore can be animated and such without issue. However, to do this, `TextureView` relies upon hardware acceleration, so environments without hardware acceleration cannot use `TextureView`.

What CWAC-Camera Does

CWAC-Camera makes a decision of what to use for the preview pane based on the API level of the device (by default). On Android 4.1 and higher, CWAC-Camera will use a `TextureView`; otherwise, CWAC-Camera will use a `SurfaceView`.

The actual logic for dealing with the preview surfaces is wrapped up in a `PreviewStrategy` class, with `SurfacePreviewStrategy` and `TexturePreviewStrategy` implementations. That way, if some device-specific tweaks are needed, the changes may be able to be isolated into some new `PreviewStrategy` flavor.

Obtaining and Initializing the Camera

Android devices may have zero, one, or more than one camera. Usually, “more than one” winds up being “two”, a rear-facing camera and a front-facing camera. Usually, devices with only one camera have that camera be rear-facing, but not always (e.g., the Nexus 7 has only a front-facing camera).

Hence, you need to select what camera you want, then arrange to open and close access to that camera as needed.

Choosing a Camera

The simplest way to choose a camera is to not choose at all, and arrange to open the default camera. That default camera is the first rear-facing camera on the device. However, devices that have *no* rear-facing cameras effectively have no default camera, and so going with the default is rarely the correct choice.

Instead, you should iterate over the available cameras, to find the one that you want. Note, however, that this approach only works for API Level 9 and above — on older devices, you have no choice but to try to open the default camera.

To find out how many cameras there are for the current device, you can call the static `getNumberOfCameras()` method on the `Camera` class.

To find out details about a particular camera, you can call the static `getCameraInfo()` method on `Camera`. This takes two parameters:

- the ID of the camera to open, which will be a number from 0 to the number of available camera minus 1
- a `Camera.CameraInfo` object, into which `getCameraInfo()` will pour details about the camera

The most notable field on `Camera.CameraInfo` is `facing`, which tells you if this is a rear-facing (`Camera.CameraInfo.CAMERA_FACING_BACK`) or front-facing (`Camera.CameraInfo.CAMERA_FACING_FRONT`) camera.

WORKING DIRECTLY WITH THE CAMERA

In CWAC-Camera, the CameraHost interface requires a `getCameraId()` method implementation, which returns the camera ID that you choose. SimpleCameraHost chooses an implementation based upon the available cameras and what you return from `useFrontFacingCamera()`:

```
@Override
public int getCameraId() {
    if (cameraId == -1) {
        initCameraId();
    }

    return(cameraId);
}

private void initCameraId() {
    int count=Camera.getNumberOfCameras();
    int result=-1;

    if (count > 0) {
        result=0; // if we have a camera, default to this one

        Camera.CameraInfo info=new Camera.CameraInfo();

        for (int i=0; i < count; i++) {
            Camera.getCameraInfo(i, info);

            if (info.facing == Camera.CameraInfo.CAMERA_FACING_BACK
                && !useFrontFacingCamera()) {
                result=i;
                break;
            }
            else if (info.facing == Camera.CameraInfo.CAMERA_FACING_FRONT
                && useFrontFacingCamera()) {
                result=i;
                break;
            }
        }
    }

    cameraId=result;
}
```

If what you want is not available (e.g., you ask for a front-facing camera, and the device has none), we use the default camera ID (0).

Opening and Closing the Camera

Old code samples would open the camera by calling a zero-parameter static `open()` method on the Camera class. This opens the default camera, and as noted above, this

WORKING DIRECTLY WITH THE CAMERA

is rarely a good idea. However, it is your only option on API Level 8 and below, if you are still supporting such devices.

Instead, if you have the ID of the camera that you wish to open, call the one-parameter static `open()` method, passing in the ID of the camera.

Both flavors of `open()` return an instance of `Camera`, which you can hold onto in your activity or fragment that is working with the camera.

While you have access to this camera, no other process can. Hence, it is important to release the camera when you are no longer needing it. To release the camera, call `release()` on your `Camera` instance, after which it is no longer safe to use the camera. A common pattern is to `open()` the camera in `onStart()` or `onResume()` and `release()` it in `onPause()` or `onStop()`, so you tie up the camera only while you are in the foreground.

For example, `CameraView` — the class in `CWAC-Camera` that contains most of the smarts behind the two flavors of `CameraFragment` — opens the camera in `onResume()`, among other things:

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH)
public void onResume() {
    addView(previewStrategy.getWidget());

    if (camera == null) {
        cameraId=getHost().getCameraId();

        if (cameraId >= 0) {
            try {
                camera=Camera.open(cameraId);

                if (getActivity().getRequestedOrientation() !=
ActivityInfo.SCREEN_ORIENTATION_UNSPECIFIED) {
                    onOrientationChange.enable();
                }

                setCameraDisplayOrientation();

                if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH
                    && getHost() instanceof Camera.FaceDetectionListener) {
camera.setFaceDetectionListener((Camera.FaceDetectionListener)getHost());
                }
            } catch (Exception e) {
                getHost().onCameraFail(FailureReason.UNKNOWN);
            }
        }
    }
}
```

```
else {  
    getHost().onCameraFail(FailureReason.NO_CAMERAS_REPORTED);  
}  
}  
}
```

Showing the Camera Preview

The user needs some sort of preview of what the camera lens sees, in order to line up a picture. In some cases, the preview is all that matters, such as so-called “mirror” apps that use the front-facing camera to show the user what they look like.

To successfully show a preview, you need to configure the preview, then have Android start (and stop) showing the preview on your supplied `SurfaceView` or `TextureView`.

Configuring the Preview

The biggest thing that we need to do to configure the preview is determine what size of preview images should be used. Devices cannot support arbitrary-sized previews. Instead, we need to ask the camera what preview sizes it supports, choose one, then configure the camera to use that specific preview size.

To do any of this, we need the `Camera.Parameters` associated with our chosen and open `Camera`. `Camera.Parameters` serves two roles:

- It tells us what is possible, in terms of camera capabilities, above and beyond the limited information reported by `Camera.Info`
- It is where we stipulate what behavior we want, by updating the parameters and associating the updated parameters with the `Camera`

Getting the `Camera.Parameters` object from a `Camera` is a simple matter of calling `getParameters()`.

To find out what the valid preview sizes are, we can call `getSupportedPreviewSizes()` on the `Camera.Parameters` object. This will return a `List` of `Camera.Size` objects, with each `Camera.Size` holding a width and a height as integers.

Choosing a preview size is a bit of an art form. The biggest constraint is that you do not want a preview size that is bigger than the space you have reserved for the

WORKING DIRECTLY WITH THE CAMERA

preview area. Beyond that, it is up to you what to use. Whatever size you choose, you can pass to `setPreviewSize()` on the `Camera.Parameters`.

Then, you can call `setParameters()` on the `Camera`, passing in your modified `Camera.Parameters` object, to affect this change.

You will wind up with a block of code resembling:

```
Camera.Parameters parameters=camera.getParameters();
Camera.Size
previewSize=figureOutWhatPreviewSizeYouWant(parameters.getSupportedPreviewSizes());

parameters.setPreviewSize(previewSize.width, previewSize.height);

camera.setParameters(parameters);
```

(where you get to supply the `figureOutWhatPreviewSizeYouWant()` implementation)

In CWAC-Camera, your `CameraHost` will be called with `getPreviewSize()`, where you need to return a valid `Camera.Size` indicating the desired size of the preview frames. `getPreviewSize()` is passed:

- the display orientation, in degrees, with 0 indicating landscape, 90 indicating portrait, etc.
- the available width and height for the preview
- the `Camera.Parameters` object, from which you can determine the valid preview sizes by calling `getSupportedPreviewSizes()`

The `CameraUtils` class — also in the CWAC-Camera library – contains a pair of static methods with stock algorithms for choosing the preview size:

1. `getOptimalPreviewSize()` uses the algorithm found in the SDK camera sample app
2. `getBestAspectPreviewSize()` finds the preview size that most closely matches the aspect ratio of our available space

`SimpleCameraHost` uses `getBestAspectPreviewSize()` for the default implementation of `getPreviewSize()`. You can override `getPreviewSize()` and substitute in your own selection algorithm. Just make sure that the returned size is one of the ones returned by `getSupportedPreviewSizes()`.

However, `SimpleCameraHost` also calls `mayUseForVideo()` on your subclass. If this returns `true` (the default), `SimpleCameraHost` calls `getPreferredPreviewSizeForVideo()` on `Camera.Parameters`, to get a preview size that will work for both still images and video. If you know that you will not be recording any video, you can override `mayUseForVideo()` to return `false`, and you may get a better preview size as a result.

Starting and Stopping the Preview

In principle, there are just three steps:

1. You attach your preview surface to the Camera by calling `setPreviewDisplay()` (if you are using a `SurfaceView`) or `setPreviewTexture()` (if you are using a `SurfaceTexture`)
2. You show the preview on-screen by calling `startPreview()` on the Camera
3. You stop showing the preview by calling `stopPreview()` on the Camera

However, timing is important.

You also cannot call `setPreviewDisplay()` or `startPreview()` before your preview surface is ready. To know when *that* is, you will need to register a listener with your surface:

- You can register a `SurfaceHolder.Callback` with the `SurfaceHolder` of your `SurfaceView` by calling `addCallback()` on the `SurfaceHolder`. Your `SurfaceHolder.Callback` will be called with `surfaceChanged()` when the surface is ready for use, at which point it is safe to call `setPreviewDisplay()` and `startPreview()`.
- You can register a `TextureView.SurfaceTextureListener` with your `TextureView` by means of the `setSurfaceTextureListener()` call. Your `TextureView.SurfaceTextureListener` will be called with `onSurfaceTextureAvailable()` at the point in time when it is safe to call `setPreviewTexture()` and `startPreview()`.

You also need to stop the preview before you `release()` the Camera. And, as we will see in the next section, you also need to restart your preview after taking a photo.

Taking a Photo

Taking a photo with a Camera is a matter of calling `takePicture()` on the Camera object. There are two flavors of `takePicture()`, for which three parameters are in common:

- a `Camera.ShutterCallback`, which will be called the moment the picture is taken, so that you can customize the “shutter” sound
- two `Camera.PictureCallback` objects, for raw (uncompressed) and JPEG photo data

The four-parameter version of `takePicture()` also takes a third `Camera.PictureCallback`, to be called when “a scaled, fully processed postview image is available”. This explanation probably means something to somebody, but the author of this book has no idea what it means.

You cannot call `takePicture()` until *after* `startPreview()` has been called to set up a preview pane. `takePicture()` will automatically stop the preview. At some point, if you want to be able to take another photo, you will need to call `startPreview()` again. Note, though, that you *cannot* call `startPreview()` until after the final compressed photo has been delivered to your `Camera.PictureCallback` object.

Before you call `takePicture()`, you are going to want to adjust the `Camera.Parameters` to configure how the photo should be taken. The primary setting to adjust is the size of the picture to take. Just as you ask `Camera.Parameters` for available preview sizes and choose one, you can call `getSupportedPictureSizes()`, which returns a `List` of `Camera.Size` objects. You can then choose a size and pass its width and height to `setPictureSize()` on the `Camera.Parameters`. Other things to potentially adjust include:

- flash mode (`getSupportedFlashModes()` and `setFlashMode()`)
- focus mode (`getSupportedFocusModes()` and `setFocusMode()`)
- white balance (`getSupportedWhiteBalance()` and `setWhiteBalance()`)
- geo-tagging (`setGpsLatitude()`, `setGpsLongitude()`, `setGpsAltitude()`, etc.)
- JPEG image quality (`setJpegQuality()`)
- and so on

Your `CameraHost` will be called with `getPictureSize()`, for you to return the desired `Camera.Size` of the still images taken by the camera. You are simply passed the

WORKING DIRECTLY WITH THE CAMERA

`Camera.Parameters`, on which you can call `getSupportedPictureSizes()` to find out the possible picture sizes that you can choose from.

CWAC-Camera's `CameraUtils` class has a pair of methods for simple algorithms for choosing a picture size:

1. `getLargestPictureSize()` returns the `Camera.Size` that is the largest in area
2. `getSmallestPictureSize()` returns the `Camera.Size` that is the smallest in area

`SimpleCameraHost` uses `getLargestPictureSize()` for the default implementation of `getPictureSize()`. You can override `getPictureSize()` and substitute in your own selection algorithm. Just make sure that the returned size is one of the ones returned by `getSupportedPictureSizes()`.

Your `CameraHost` can also override `adjustPictureParameters()`, where you are passed a `Camera.Parameters` object and can alter it as needed for settings to apply to the photo that is about to be taken. In addition, you can override `getShutterCallback()` to return the `Camera.ShutterCallback` to use, where the default is null to use the device's default shutter sound.

The Rest of the Demo

Our subclass of `CameraFragment` is `DemoCameraFragment`. The reasons we are extending `CameraFragment` are:

- The fragment can support either a front-facing camera or a rear-facing camera, and we need to track which one this particular fragment instance is supposed to work with, by using the arguments `Bundle`
- Our fragment contributes items to the action bar to take a picture and to start/stop video recording
- We have a custom subclass of `SimpleCameraHost`, called `DemoCameraHost`, mostly for indicating whether or not we should be using the front-facing camera

```
package com.commonware.cwac.camera.demo;

import android.annotation.TargetApi;
import android.content.Context;
import android.content.Intent;
import android.hardware.Camera;
import android.hardware.Camera.Face;
import android.hardware.Camera.Parameters;
```

```
import android.os.Bundle;
import android.os.SystemClock;

Most of this is fairly straight-forward, except perhaps the video recording action bar items, which we will examine [later in this chapter](#).

Recording a Video

All of that was simply to set up the camera preview and to take a picture. To record a video, there is yet *more* work to be done, once again largely handled for you by CameraFragment.

Back in [the chapter on recording audio](#), we saw MediaRecorder and how it can be used to record audio. MediaRecorder also records video, through a similar process. However, the particular recipe for recording video is very specific — doing things in the wrong order can easily screw up the recording.

The MediaRecorder Recipe

First, you need to set up the camera preview, just as you would for taking a still photo. After all, the user needs to have some idea of what is going to be recorded.

At the point in time of starting the recording, you need to `unlock()` the Camera. This basically says that you will want to start using the Camera again later, but you want to allow another process — specifically, the Stagefright process that implements MediaRecorder — to be able to use the Camera temporarily.

Then, after creating your MediaRecorder instance, you must do the following, in the stated sequence:

- Call `setCamera()` on MediaRecorder, handing it the just-unlocked Camera
- Call `setAudioSource()` on MediaRecorder, indicating where the audio for the recording should come from (typically `MediaRecorder.AudioSource.CAMCORDER`)
- Call `setVideoSource()` on MediaRecorder, indicating where the video to be recorded should come from (typically `MediaRecorder.VideoSource.CAMERA`)
- Call `setProfile()` on MediaRecorder, choosing one of the available recording profiles (e.g., `CamcorderProfile.get(cameraId, CamcorderProfile.QUALITY_HIGH)`)
- Call `setOutputFile()` on MediaRecorder, supplying the file path or `FileDescriptor` where the recorded video should be stored
- Call `setOrientationHint()` on MediaRecorder, indicating whether or not the camera is in portrait or landscape, so that information can be added to the metadata included in the video
- Call `setPreviewDisplay()` on MediaRecorder, to connect the MediaRecorder to the `SurfaceView` or `TextureView` that you are using for preview images, so it knows where to display the “preview” of what is being recorded
- Call `prepare()`, and then `start()`, on MediaRecorder to actually do the recording

Note that prior to Android 2.2, you cannot call `setProfile()`, but instead have to call a series of methods, like `setOutputFormat()` instead.

When you are done recording, you can call `stop()` and `release()` on the MediaRecorder, then call `reconnect()` on the Camera to return you to the state you were in prior to initiating the recording in the first place.

Recording in CWAC-Camera

DemoCameraFragment starts off with a visible/enabled record action bar item. When clicked, it calls `record()` on `CameraFragment` to begin the recording, then calls `invalidateOptionsMenu()` to refresh the action bar. Its `onCreateOptionsMenu()` takes into account whether or not it is recording (via the `isRecording()` method on `CameraFragment`) and makes the stop action bar item visible (and record invisible) when recording is going on. Tapping the stop action bar item triggers a call to `stopRecording()`, plus refreshes the action bar once again to switch the items back to normal mode.

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.camera, menu);

    takePictureItem=menu.findItem(R.id.camera);
    singleShotItem=menu.findItem(R.id.single_shot);
    singleShotItem.setChecked(getContract().isSingleShotMode());
    autoFocusItem=menu.findItem(R.id.autofocus);
    flashItem=menu.findItem(R.id.flash);
    recordItem=menu.findItem(R.id.record);
    stopRecordItem=menu.findItem(R.id.stop);
    mirrorFFC=menu.findItem(R.id.mirror_ffc);

    if (isRecording()) {
        recordItem.setVisible(false);
        stopRecordItem.setVisible(true);
        takePictureItem.setVisible(false);
    }
}
```

`record()` on `CameraFragment` eventually routes to `record()` on `CameraView`, which goes through the aforementioned recipe:

```
public void record() throws Exception {
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.HONEYCOMB) {
        throw new UnsupportedOperationException(
            "Video recording supported only on
API Level 11+");
    }

    if (displayOrientation != 0 && displayOrientation != 180) {
        throw new UnsupportedOperationException(
            "Video recording supported only in
landscape");
    }

    Camera.Parameters pictureParams=camera.getParameters();
    setCameraPictureOrientation(pictureParams);
}
```

WORKING DIRECTLY WITH THE CAMERA

```
camera.setParameters(pictureParams);

stopPreview();
camera.unlock();

try {
    recorder=new MediaRecorder();
    recorder.setCamera(camera);
    getHost().configureRecorderAudio(cameraId, recorder);
    recorder.setVideoSource(MediaRecorder.VideoSource.CAMERA);
    getHost().configureRecorderProfile(cameraId, recorder);
    getHost().configureRecorderOutput(cameraId, recorder);
    recorder.setOrientationHint(outputOrientation);
    previewStrategy.attach(recorder);
    recorder.prepare();
    recorder.start();
}
catch (IOException e) {
    recorder.release();
    recorder=null;
    throw e;
}
}
```

record() uses three hooks supplied to CameraHost for configuring the recording:

- configureRecorderAudio(), where SimpleCameraHost uses MediaRecorder.AudioSource.CAMCORDER:

```
@Override
public void configureRecorderAudio(int cameraId,
                                   MediaRecorder recorder) {
    recorder.setAudioSource(MediaRecorder.AudioSource.CAMCORDER);
}
```

- configureRecorderProfile(), where SimpleCameraHost uses the QUALITY_HIGH profile:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void configureRecorderProfile(int cameraId,
                                   MediaRecorder recorder) {
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.HONEYCOMB
        || CamcorderProfile.hasProfile(cameraId,
                                       CamcorderProfile.QUALITY_HIGH)) {
        recorder.setProfile(CamcorderProfile.get(cameraId,
                                                  CamcorderProfile.QUALITY_HIGH));
    }
    else if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB
             && CamcorderProfile.hasProfile(cameraId,
                                             CamcorderProfile.QUALITY_LOW)) {
        recorder.setProfile(CamcorderProfile.get(cameraId,
```

```
CamcorderProfile.QUALITY_LOW));  
    }  
    else {  
        throw new IllegalStateException(  
            "cannot find valid CamcorderProfile");  
    }  
}
```

- `configureRecorderOutput()`, where `SimpleCameraHost` calls `getVideoPath()` and uses that location for the output

```
@Override  
public void configureRecorderOutput(int cameraId,  
                                   MediaRecorder recorder) {  
    recorder.setOutputFile(getVideoPath().getAbsolutePath());  
}
```

Advanced CWAC-Camera Features

`CameraFragment` and `CameraHost` provide other hooks as well, for you to use to further configure the way your app takes pictures and videos.

Controlling Preview Sizes

Your `CameraHost` will be called with `getRecordingHint()`, to determine if the preview should be optimized for possible video recording, or not (i.e., only still images will be taken). You can return a `CameraHost.RecordingHint` enum: `STILL_ONLY`, `VIDEO_ONLY`, or `ANY`.

Usually, your `CameraHost` will be called with `getPreviewSize()`, where you need to return a valid `Camera.Size` indicating the desired size of the preview frames. `getPreviewSize()` is passed:

- the display orientation, in degrees, with 0 indicating landscape, 90 indicating portrait, etc.
- the available width and height for the preview
- the `Camera.Parameters` object, from which you can determine the valid preview sizes by calling `getSupportedPreviewSizes()`

The `CameraUtils` class contains three static methods with stock algorithms for choosing the preview size:

1. `getOptimalPreviewSize()` uses the algorithm found in the SDK camera sample app
2. `getBestAspectPreviewSize()` finds the preview size that most closely matches the aspect ratio of our available space
3. `getBestAspectPreviewSize(double)` finds the preview size that offers the biggest preview size that only differs from the desired aspect ratio by the supplied `closeEnough` value (`closeEnough` of `0.0d` would give the same results as does `getBestAspectPreviewSize()`)

`SimpleCameraHost` uses `getBestAspectPreviewSize()` for the default implementation of `getPreviewSize()`. You can override `getPreviewSize()` and substitute in your own selection algorithm. Just make sure that the returned size is one of the ones returned by `getSupportedPreviewSizes()`.

If `getRecordingHint()` returns `ANY` or `VIDEO_ONLY`, though, `CameraHost` supplies the preview size via `getPreferredPreviewSizeForVideo()` instead of `getPreviewSize()`. If you wish to use a different preview size for video, return it, otherwise return `null` and we will use the results from `getPreviewSize()` instead.

`getPreferredPreviewSizeForVideo()` is passed a `Camera.Size` as a hint from the device for a value to use, instead of anything you might get yourself from `Camera.Parameters` — while using the hinted value is probably a good idea (if it is not `null`), it is not required.

Controlling Picture Sizes

Similarly, your `CameraHost` will be called with `getPictureSize()`, for you to return the desired `Camera.Size` of the still images taken by the camera. You are simply passed the `Camera.Parameters`, on which you can call `getSupportedPictureSizes()` to find out the possible picture sizes that you can choose from.

The `CameraUtils` class has a pair of methods for simple algorithms for choosing a picture size:

1. `getLargestPictureSize()` returns the `Camera.Size` that is the largest in area
2. `getSmallestPictureSize()` returns the `Camera.Size` that is the smallest in area

`SimpleCameraHost` uses `getLargestPictureSize()` for the default implementation of `getPictureSize()`. You can override `getPictureSize()` and substitute in your own selection algorithm. Just make sure that the returned size is one of the ones returned by `getSupportedPictureSizes()`.

Arbitrary Preview Configuration

When setting up the camera preview, your `CameraHost` will be called with `adjustPreviewParameters()`, passing in a `Camera.Parameters`. Here, you can make any desired adjustments to the camera preview, *except* the preview size (which you should be handling in `getPreviewSize()`). `adjustPreviewParameters()` returns the revised `Camera.Parameters`, where the stock implementation in `SimpleCameraHost` just returns the passed-in parameters unmodified.

Arbitrary Photo Configuration

Shortly after you call `takePicture()` on your `CameraFragment`, your `CameraHost` will be called with `adjustPictureParameters()`, passing in a `Camera.Parameters`. Here, you can make any desired adjustments to the parameters related to taking photos, *except* the image size (which you should be handling in `getPictureSize()`). `adjustPictureParameters()` returns the revised `Camera.Parameters`, where the stock implementation in `SimpleCameraHost` just returns the passed-in parameters unmodified.

Arbitrary Video Configuration

Shortly after you call `startRecording()`, your `CameraHost` will be called with:

- `configureRecorderAudio()`
- `configureRecorderProfile()`
- `configureRecorderOutput()`

in that order. Here, you can help tailor the way videos get recorded. Each of these is passed the ID of the camera being used for recording plus the `MediaRecorder` instance that does the actual recording.

The stock `SimpleCameraHost` does the following:

- In `configureRecorderAudio()`, `SimpleCameraHost` calls `setAudioSource(MediaRecorder.AudioSource.CAMCORDER)` on the `MediaRecorder`
- In `configureRecorderProfile()`, `SimpleCameraHost` calls `setProfile(CamcorderProfile.get(cameraId, CamcorderProfile.QUALITY_HIGH))` on the `MediaRecorder`

- In `configureRecorderOutput()`, `SimpleCameraHost` calls `setOutputFile(getVideoPath().getAbsolutePath())` on the `MediaRecorder` (where `getVideoPath()` was described earlier in this document)

While these are reasonable defaults, you are welcome to override these implementations to do something else.

Overriding Photo Saving

The default `SimpleCameraHost` logic for saving photos uses the `getPhotoPath()` and related methods discussed above. Actually saving the photo is done in `saveImage()`, called on your `CameraHost`, where `SimpleCameraHost` has a `saveImage()` implementation that writes the supplied byte array out to the desired location.

You are welcome to override `saveImage()` and do something else with the byte array, such as send it over the Internet. `saveImage()` is called on a background thread, so you do not have to do your own asynchronous work.

Another use for this is to find out when the saving is complete, so that you can use the resulting image. Just override `saveImage()`, chain to the superclass implementation, and when that returns, the image is ready for use.

There is also a `saveImage(PictureTransaction, Bitmap)` callback, giving you a decoded `Bitmap` instead of a byte array.

By default, the `saveImage()` that takes a byte array will be called, and not `saveImage(PictureTransaction, Bitmap)`. To change this, call `needBitmap(boolean)` and/or `needByteArray(boolean)` on your `PictureTransaction`, passing that `PictureTransaction` to `takePicture()`.

Note that if you say that you need the `Bitmap`, you are responsible for the `Bitmap` (e.g., calling `recycle()` on it) once it is handed to your host.

Controlling the Shutter Callback

You can subclass `PictureTransaction` and override `onShutter()` to do something when the shutter is pressed.

Also, your `CameraHost` implementation can return a `Camera.ShutterCallback` object via `getShutterCallback()`, which will be used in the underlying `takePicture()` call

on the Android Camera, giving you control to play a “shutter click” sound. `SimpleCameraHost` returns null from `getShutterCallback()`, to give you the device default behavior.

Detecting Faces

If you wish to use the face detection APIs available on API Level 14+, do the following:

1. Have your `CameraHost` implementation also implement `Camera.FaceDetectionListener`.
2. Override `adjustPreviewParameters()` in your `CameraHost` and take that opportunity to check the value of `getMaxNumDetectedFaces()`, a method on `Camera.Parameters`. If that returns 0, face detection is not supported by the device. **NOTE:** a better API for this may be added in the future.
3. Override `autoFocusAvailable()` in your `CameraHost`, and if face detection is enabled, call `startFaceDetection()` on your `CameraFragment` or `CameraView`. **NOTE:** a dedicated callback for this may be added in the future — this is a stop-gap to allow this fix to go in a patch release
4. Similarly, override `autoFocusUnavailable()` in your `CameraHost` and, if face detection is enabled, call `stopFaceDetection()` on your `CameraFragment` or `CameraView`. **NOTE:** a dedicated callback for this may be added in the future.

Note that this capability was added to version 0.5.1 of this library. Also note that, while you can safely call `startFaceDetection()` and `stopFaceDetection()` regardless of API level, `getMaxNumDetectedFaces()` should only be called on API Level 14+ devices, or you will be hit with a `VerifyError` or the equivalent.

Choosing a DeviceProfile

`CameraHost` exists to provide a hook for you to determine how your app should handle taking pictures and videos. `DeviceProfile`, on the other hand, provides information about how the *device* handles taking pictures and videos. Different devices do slightly different things when working with the camera. Sometimes this is based on API level, sometimes it is based on how the device manufacturer tinkered with Android, and sometimes it is based on the underlying camera hardware. `DeviceProfile` provides a place for the CWAC-Camera project to isolate these differences.

CameraHost has a `getDeviceProfile()` method that should return an instance of the `DeviceProfile` to use for the device that is running the app. The implementation of `getDeviceProfile()` on `SimpleCameraHost` calls the static `getInstance()` method on `DeviceProfile`, which chooses a `DeviceProfile` based on internal heuristics. If you encounter problems with certain devices, you can detect those in your `getDeviceProfile()` method and return a `DeviceProfile` that addresses your needs, otherwise settling for using the library's own choice of `DeviceProfile`.

Note that `SimpleCameraHost.Builder` also has a `deviceProfile()` setter method that you can call, passing in a `DeviceProfile` that will be used as the default, replacing the system default.

The stock `DeviceProfile` is largely driven by XML resources. These resources' names are of the form `cwac_camera_profile_XXX_YYY`, where `XXX` is the `Build.MANUFACTURER` and `YYY` is the `Build.MODEL`. Both `Build.MANUFACTURER` and `BUILD.MODEL` are converted to lowercase and have non-alphanumeric values converted to underscores, to ensure that we wind up with a valid resource filename. Each of those XML resource files has a `<deviceProfile>` root element, containing child elements for different values that can be overridden:

- `<doesZoomActuallyWork>` (a boolean, true or false) overrides the default zoom detection logic, with false meaning that the device lies and zoom is not really supported
- `<maxPictureHeight>` (an integer) is the largest number of pixels high to use for the camera picture; a `Camera.Size` taller than this is ignored
- `<minPictureHeight>` (an integer) is the smallest number of pixels high to use for the camera picture; a `Camera.Size` shorter than this is ignored
- `<pictureDelay>` (an integer) is a time in milliseconds to delay taking the picture after updating `Camera.Parameters` with the picture settings, for devices that seem to reset themselves when the parameters are updated, resulting in messed-up pictures
- `<portraitFFCFlipped>` (a boolean, true or false) indicates if the image cleanup work needs to flip the image if it was taken in portrait mode from the front-facing camera
- `<useDeviceOrientation>` (a boolean, true or false) indicates if we should skip the `setRotation()` call on `Camera.Parameters` due to a device bug, and instead should just use physical orientation in the image cleanup phase to get the picture to turn out right
- `<useTextureView>` (a boolean, true or false) overrides the default choice of whether to use a `SurfaceView` or a `TextureView` for the preview, normally driven by API level

So long as the resource exists with the right filename, the library should pick it up, so you can add ones in your app if needed.

Working Directly with CameraView

If you wish to eschew fragments, you are welcome to work with CameraView directly. To do this:

- Add it in Java code by calling its one-parameter constructor, taking your Activity as a parameter. At the present time, CameraView does not support being placed in a layout resource.
- Call `setHost()` on the CameraView as early as possible, to make sure that the CameraView is working with the right CameraHost implementation. Alternatively, override `getHost()` and return the right CameraHost there.
- Forward the `onResume()` and `onPause()` lifecycle events from your activity or fragment to the CameraView.

Otherwise, CameraView should work as a regular View... so long as you do not try to use it in a layout resource.

Using CameraView in a Layout Resource

If you want to use CameraView in a layout resource, you can, but your activity will need to implement the CameraHostProvider interface. This has one required method: `getCameraHost()`, which returns the CameraHost instance to be used with the CameraView. You would implement this in lieu of calling `setHost()` yourself.

If you want to take advantage of this and use your own layout in a CameraFragment subclass, simply override `onCreateView()` and do what you want. The only requirement, other than the CameraHostProvider mentioned above, is that your `onCreateView()` needs to call the `setCameraView()` method, supplying the CameraView instance to the superclass.

The `demo-layout/` directory contains a small sample project that demonstrates this technique.

Flash Modes

CameraView, as well as CameraFragment, has a `getFlashMode()` which returns the flash mode from `Camera.Parameters`.

WORKING DIRECTLY WITH THE CAMERA

To adjust the flash mode, you can call `flashMode()` on your `PictureTransaction` to specify a mode to apply when the picture is taken. Or, call `setFlashMode()` on `CameraView` or `CameraFragment` when needed. Or, you can manually configure the `Camera.Parameters` object in `adjustPictureParameters()` and/or `adjustPreviewParameters()`.

The `CameraUtils` class has a `findBestFlashModeMatch()` method that takes a `Camera.Parameters` object, plus one or more `String` names of flash modes (e.g., `Camera.Parameters.FLASH_MODE_ON`), and returns the mode that appears first in your list of strings that is supported by the current camera.

Media Routes

Android can send audio and video to a variety of places, such as:

- Bluetooth headsets or headphones
- External displays, like a TV or monitor
- External devices that themselves play back media, such as a Chromecast

There is a common API for determining which of these “places” are available and allowing the user to choose which of these “places” should be used for a given bit of media. This common API centers around a `MediaRouter`, which is the focus of this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book. In addition, you should read the chapters on [advanced action bar techniques](#) and [the AppCompat action bar backport](#).

Terminology

First, we need to establish some common ground in terms of..., well, terms.

Media

In this chapter, “media” refers to audio or video. This includes both media that may be stored on the device as well as media that may be streamed from some other source, frequently over the Internet.

Route

A route indicates where media should be played. There are three categories of routes that concern us:

- Where should we be playing live audio, in terms of speakers or headphones or other things connected to the device?
- Where should we be playing live video: on the device's own screen or on some other screen connected via a cable?
- Is there any sort of “remote playback” device available, such as a Chromecast, that can play back media on its own under our direction, rather than requiring our own app to play back the media itself

MediaRouter

MediaRouter is the name of a class (actually, two classes) that know what routes are possible given the current environment and what routes are selected for the different categories (by default or by user choice).

A Tale of Three MediaRouters

MediaRouter and its related classes represent a curious API. There are two versions of the MediaRouter class and up to *three* versions of some of the related support classes that will concern you as a developer.

android.media

MediaRouter debuted in Android in API Level 16, through classes added to the `android.media` package. This version of MediaRouter can work with live audio and live video routes, but not the Chromecast-style remote playback routes.

`android.media` also contains other classes that pertain to routes, such as `MediaRouteActionProvider`, a way to allow the user to choose media routes via an action bar item. The version of these classes in `android.media` work with native API Level 11 versions of the action bar and fragments.

android.support.v7.media

In 2013, an update to the Android Support package was released that contained another version of MediaRouter and kin, in `android.support.v7` packages. These are

contained in a dedicated Android library project that you can add to your app, found in the `extras/android/support/v7/mediareouter` directory of your Android SDK installation, if you have a current Android Support package installed.

While the native version of `MediaRouter` is a system service — obtained via `getSystemService()` — the v7 version of `MediaRouter` is a singleton, obtained from a static `getInstance()` method on the `MediaRouter` class.

The good news is that this updated version of `MediaRouter` can work with all three categories of routes, including the Chromecast-style remote playback routes.

CWAC-MediaRouter

However, the bad news is that the v7 version of `MediaRouter`'s support classes only support the Android Support backports of fragments and the action bar. This requires you to inherit from `ActionBarActivity` and use the v4 version of `Fragment` and kin. This is a rather annoying limitation, considering that many developers have specifically started dropping support for older API levels to be able to *avoid* using this backport.

Fortunately, you have an alternative.

The author of this book has published [the CWAC-MediaRouter library](#). This library contains a complete cross-port of the `mediareouter-v7` library, to remove the dependency upon `appcompat-v7` and support the native action bar.

Note that using `CWAC-MediaRouter` still requires the `mediareouter` Android library project, as the `CWAC` library only contains those classes that needed modification.

The samples in this chapter will illustrate the use of both Google's and CommonsWare's versions of the classes.

Attaching to MediaRouter

To be able to take advantage of all that `MediaRouter` has to offer, we need to obtain an instance of it and connect to that instance, via method calls and registering callbacks.

Getting a `MediaRouter` Instance

To get an instance of the `android.support.v7.media.MediaRouter` flavor of `MediaRouter`, call `getInstance()` on `MediaRouter`.

This is in contrast to the `android.media.MediaRouter` variant, which is a system service, obtained by calling `getSystemService()`.

Note that the `android.support.v7.media.MediaRouter` flavor is global for your process, but weakly held from a garbage collection standpoint. You need to ensure that you hold onto your instance of `MediaRouter` as long as you need it. Once your application code lets go of the `MediaRouter` instance, it becomes eligible for garbage collection, disposing of any registered callbacks and such along the way.

Working with Routes

`MediaRouter` has a `getSelectedRoute()` method that returns the media route chosen by the user, or the overall default if the user has not yet had a chance in your app to choose a route. This method returns a `MediaRouter.RouteInfo` object, containing details about the route. In particular, you can call `supportsControlCategory()` to determine if the route is a live audio route, a live video route, or a remote playback route, so you can take advantage of it accordingly.

There is also `getDefaultRoute()`, which, as the name suggests, returns the `MediaRouter.RouteInfo` instance that is the overall default for your app.

You can call `getRoutes()` to obtain a list of all routes known at the present time. You might use this to allow the user to choose a route, though `MediaRouteActionProvider` is generally a better choice, as will be seen [later in this chapter](#).

Given that you have a `MediaRouter.RouteInfo` instance from somewhere, you can call `selectRoute()` to make this route the active one, replacing whatever the previously-selected route was.

Registering a Callback

You can also call `addCallback()` to provide a `MediaRouter.Callback` instance that will be invoked at various points in time based on the changes in media routes. `addCallback()` also takes a `MediaRouteSelector`, which describes what sorts of

routes you are interested in. We will examine `MediaRouteSelector` in greater detail in the coverage of `MediaRouteActionProvider` [later in this chapter](#).

There are two flavors of `addCallback()`. Both take the `MediaRouteSelector` and the `MediaRouter.Callback`, but one also takes an `int` supplying flags to control the behavior of `addCallback()`. One flag of particular importance is `CALLBACK_FLAG_REQUEST_DISCOVERY`. This tells `MediaRouter` to not only set up the callback, but to attempt to find new routes previously unknown to it. Mostly, this is for remote callback routes, which require network I/O to find and are not necessarily known if not specifically scanned for.

`MediaRouter.Callback` is a class, not an interface. You create your own subclass of `MediaRouter.Callback` and override the callback methods that interest you. Some noteworthy callback methods include:

- `onRouteAdded()` and `onRouteRemoved()`, which are called when routes are newly detected or have been lost, such as when a user plugs in or unplugs an HDMI cable from the device
- `onRouteSelected()` is called when a new route is selected, either by the user (e.g., via `MediaRouteActionProvider`) or by you (e.g., via `selectRoute()`)
- `onRouteUnselected()` is also called when a new route is selected, but in this case, you are notified about the *old* route being unselected

When you are done with the callback, call `removeCallback()` on the `MediaRouter`, passing in the same `MediaRouter.Callback` instance you supplied to `addCallback()`.

We will see examples of using `MediaRouter.Callback` [in the next section](#).

User Route Selection with `MediaRouteActionProvider`

To give the user some measure of control over where media is played, you can add a `MediaRouteActionProvider` to your action bar. This will add a button that, when tapped, will allow the user to choose routes of relevance to your app (live audio, live video, remote playback).

However, this does not really work the way you (or the user) might expect, simply because some routes are automatically applied by the OS. Depending upon what the Android device is connected to will determine what routes are automatically applied and which ones the user can choose via `MediaRouteActionProvider`. For example,

while Android will route live video to an HDMI-connected external display automatically, the user must opt into connecting to a Chromecast for remote playback capability.

This section outlines how to use `MediaRouteActionProvider` — both the Google and CWAC versions — and what the user will see for various circumstances. Most of the sections will be focusing on the [MediaRouter/ActionProvider](#) sample project, which uses the Google version of `MediaRouteActionProvider`.

The Basic Project and Dependencies

The project has dependency on the `mediarouter` Android library project. Projects that need `mediarouter` will need to have access to the Android Support library from the SDK Manager and follow [the instructions to add it to your project](#). Since `mediarouter` depends upon `appcompat`, you will need both library projects.

The `AppCompatActivity` backport of the action bar requires that your activities use a theme extending from `Theme.AppCompat`. Hence, we have a `res/values/styles.xml` resource that defines `AppTheme` in the context of `Theme.AppCompat.Light.DarkActionBar`:

```
<resources>

    <style name="AppBaseTheme" parent="@style/
Theme.AppCompat.Light.DarkActionBar"></style>

    <style name="AppTheme" parent="AppBaseTheme">
        <!-- All customizations that are NOT specific to a particular API-level can
go here. -->
    </style>
</resources>
```

And our `<activity>` in the manifest, pointing to `MainActivity`, refers to that theme:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.mrap"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="18"/>

    <application
```

```
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name="com.commonware.android.mrap.MainActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />

            <category android:name="android.intent.category.LAUNCHER" />
        </intent-filter>
    </activity>
</application>
</manifest>
```

The Menu Resource

Since `MediaRouteActionProvider` is an action provider, we can add it to our action bar via an `actionProviderClass` attribute in a menu resource. And, since the Google implementation of `MediaRouteActionProvider` works with the `AppCompatActivity` action bar backport, we specifically need to use the `AppCompatActivity` approach to adding `actionProviderClass`, putting it in our app's custom XML namespace:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <item
        android:id="@+id/route_provider"
        android:title="@string/route_provider_title"
        app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
        app:showAsAction="always" />

</menu>
```

Initializing the `MediaRouter` and `Selector`

Our activity (`MainActivity`) is an `ActionBarActivity` subclass, following the rules for using the `AppCompatActivity` action bar backport:

```
package com.commonware.android.mrap;

import android.os.Bundle;
import android.support.v4.view.MenuItemCompat;
import android.support.v7.app.ActionBarActivity;
import android.support.v7.app.MediaRouteActionProvider;
import android.support.v7.media.MediaControlIntent;
import android.support.v7.media.MediaRouteSelector;
```

MEDIA ROUTES

```
import android.support.v7.media.MediaRouter;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.TextView;

public class MainActivity extends ActionBarActivity {
    private MediaRouteSelector selector=null;
    private MediaRouter router=null;
    private TextView selectedRoute=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
        selectedRoute=(TextView)findViewById(R.id.selected_route);

        router=MediaRouter.getInstance(this);
        selector=
            new
MediaRouteSelector.Builder().addControlCategory(MediaControlIntent.CATEGORY_LIVE_AUDIO)

.addControlCategory(MediaControlIntent.CATEGORY_LIVE_VIDEO)

.addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
                .build();

    }

    @Override
    public void onResume() {
        super.onResume();

        router.addCallback(selector, cb,
                           MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
    }

    @Override
    public void onPause() {
        router.removeCallback(cb);

        super.onPause();
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.main, menu);

        MenuItem item=menu.findItem(R.id.route_provider);
        MediaRouteActionProvider provider=
            (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

        provider.setRouteSelector(selector);

        return(true);
    }
}
```

MEDIA ROUTES

```
}  
  
private MediaRouter.Callback cb=new MediaRouter.Callback() {  
    @Override  
    public void onRouteSelected(MediaRouter router,  
                               MediaRouter.RouteInfo route) {  
        selectedRoute.setText(route.toString());  
    }  
};  
}
```

In `onCreate()` we obtain an instance of `MediaRouter`. More specifically, we obtain an instance of `android.support.v7.media.MediaRouter`.

We also will need a `MediaRouteSelector` instance. `MediaRouteSelector` expresses rules for what sorts of media routes we are interested in. The simplest way to set up a `MediaRouteSelector` is to use the `MediaRouteSelector.Builder` inner class, which follows the fluent API style of other Android Builder classes (e.g., `Notification.Builder`, `AlertDialog.Builder`). Here, we call `addControlCategory()` three times, indicating three categories of routes that we are interested in:

- `MediaControlIntent.CATEGORY_LIVE_AUDIO`
- `MediaControlIntent.CATEGORY_LIVE_VIDEO`
- `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK`

Calling `build()` on the resulting `Builder` gives us our `MediaRouteSelector`, which we will use elsewhere in the activity.

Configuring the ActionProvider

In `onCreateOptionsMenu()` of `MainActivity`, we inflate our menu resource and pull out the `MediaRouteActionProvider`. To obtain an action provider from the `AppBar` action bar, the simplest solution is to use the `MenuItemCompat` helper class from the Android Support package, calling its static `getActionProvider()` method. This will work both with the `AppBar` backport of the action bar *and* with the native API Level 11+ action bar, though you do not need to use `MenuItemCompat` for the latter if you do not want.

We then call the `setRouteSelector()` method on our `MediaRouteActionProvider` instance, passing in the `MediaRouteSelector` we configured back in `onCreate()`. This tells the action provider what routes the user should be able to configure. In

our case, that is all three major categories of routes (live audio, live video, and remote playback).

Registering for Route Changes

Interestingly enough, that is insufficient to make the `MediaRouteActionProvider` work. We *also* need to register a `MediaRouter.Callback` with the `MediaRouter`, to be informed about events related to media routes. Our `cb` private data member is an instance of an anonymous inner class extending `MediaRouter.Callback`, overriding the `onRouteSelected()` method. This method will be called whenever a new route is selected, telling us the `MediaRouter.RouteInfo` of the newly-selected route. In our case, we just update a `TextView` that is our activity's UI with the details of that route, courtesy of calling `toString()` on the `RouteInfo` object.

To inform `MediaRouter` about our desire for such callbacks, we need to call `addCallback()` on the `MediaRouter`, and later on call `removeCallback()` when we no longer need to know about such events. In `MainActivity`, these steps are done in `onResume()` and `onPause()`, respectively.

Note that we provide the `CALLBACK_FLAG_REQUEST_DISCOVERY` flag in the `addCallback()` method, to trigger a search for any Chromecast or other remote playback-capable devices that can serve as media routes.

The Results

Running this on an emulator is largely pointless, as emulators do not emulate media routes.

Running this on a device will give varying results, depending upon what other media-related accessories are available to that device. If there are no user-selectable media routes available, the `MediaRouteActionProvider` is marked as invisible, so the user does not see the icon and perhaps get confused by why tapping on it has no effect.

However, our `TextView` will show some initial route that was chosen by the device:

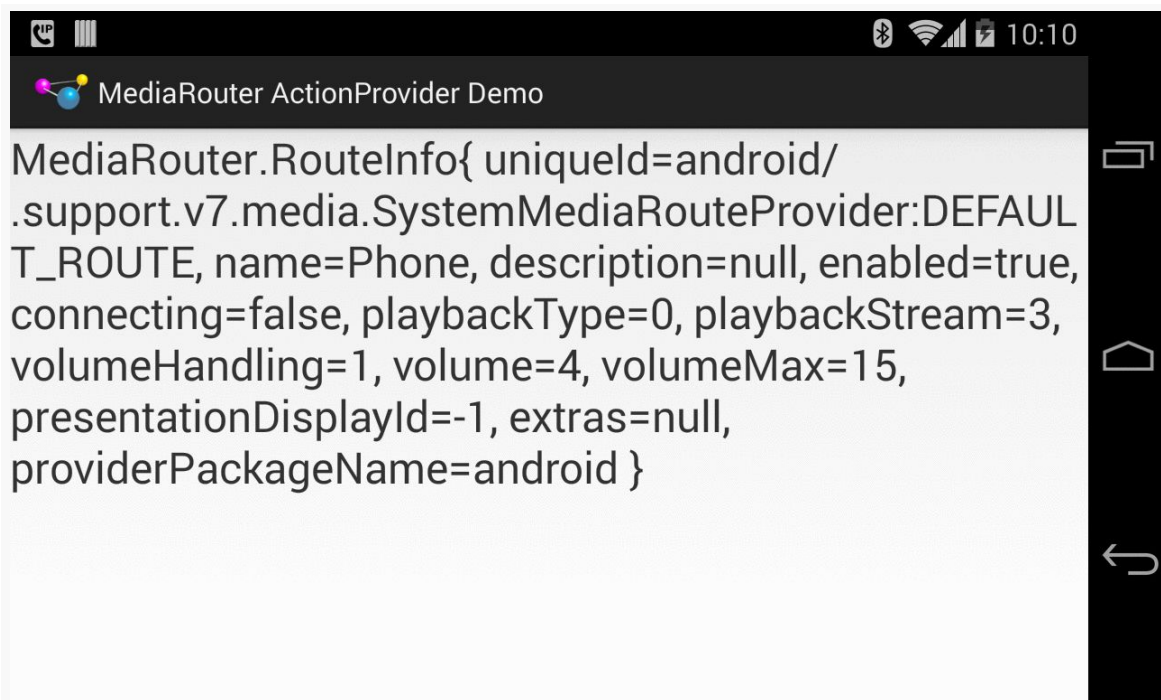

Figure 619: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route

Live Audio Routes

If you launch the demo with some form of external headset or speakers attached, such as via Bluetooth, you will see the route for that is automatically selected:

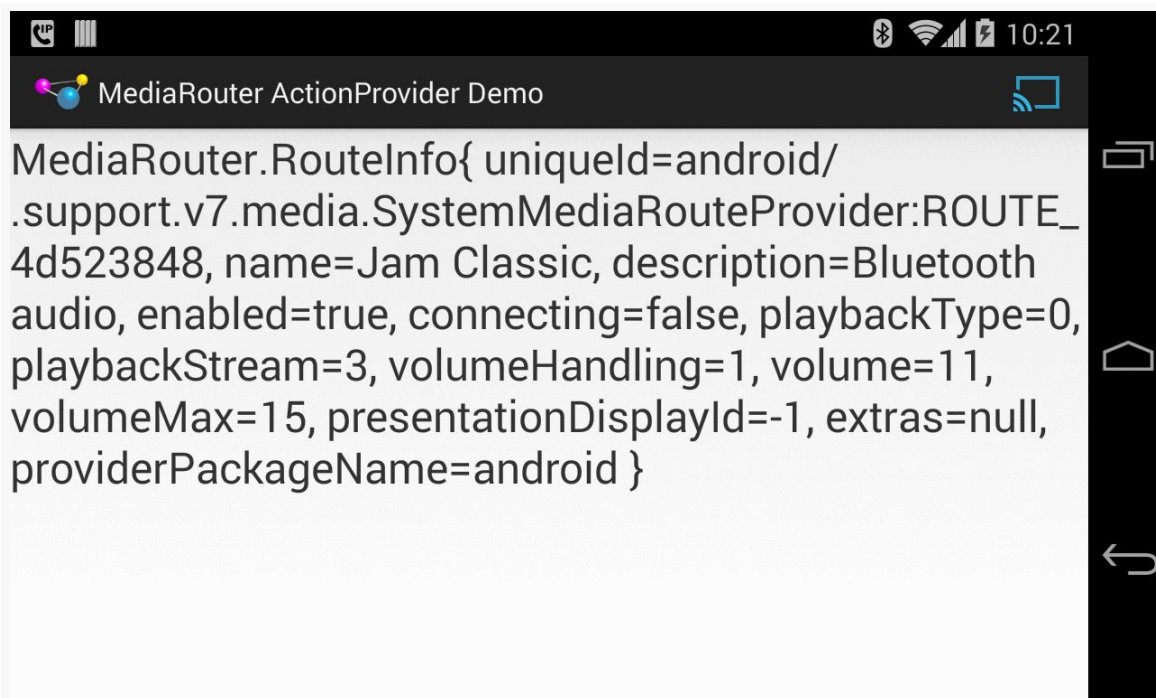

Figure 62o: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Audio Route

The `MediaRouteActionProvider` appears, with a blue highlight, indicating an active selected route. More importantly, the blue highlight indicates that the route is configurable by tapping on it to bring up a dialog:

MEDIA ROUTES

Figure 621: MediaRouter ActionProvider Demo, on a Nexus 4, Live Audio Route Configuration

Here, we can adjust the volume, plus disconnect from the route. Disconnecting shows our MediaRouteActionProvider with the default white highlight:

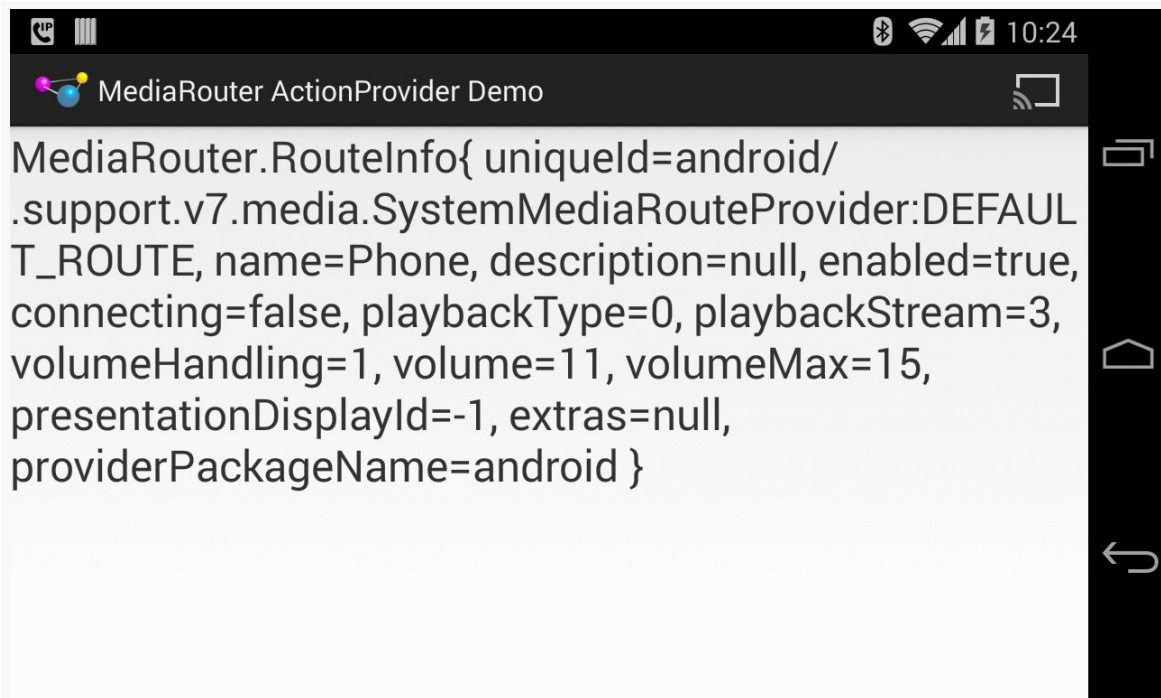

Figure 622: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route and Provider

The white highlight means that there are possible routes, though none in use. Tapping the icon brings up a connection dialog:

Figure 623: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Routes

Live Video Routes

If you launch the demo with some form of external display attached — HDMI, MHL, SlimPort, etc. — you still will not see the `MediaRouteActionProvider`, as live video routes are automatically selected, at least if there is only one such route.

However, `onRouteSelected()` will still be called as part of starting up the activity, so the `TextView` will reflect the live video route:

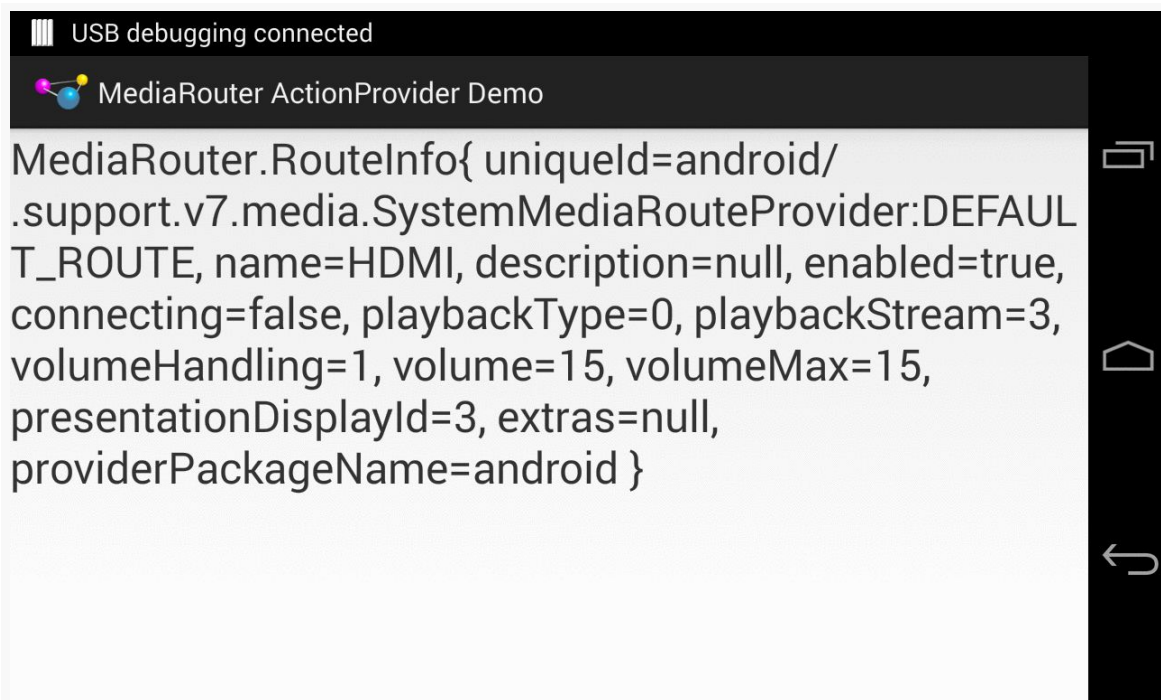

Figure 624: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Video Route

Remote Playback Routes

Since the user has to opt into remote playback media routes, the `MediaRouteActionProvider` *will* appear if you configure it to show such routes and a route is available:

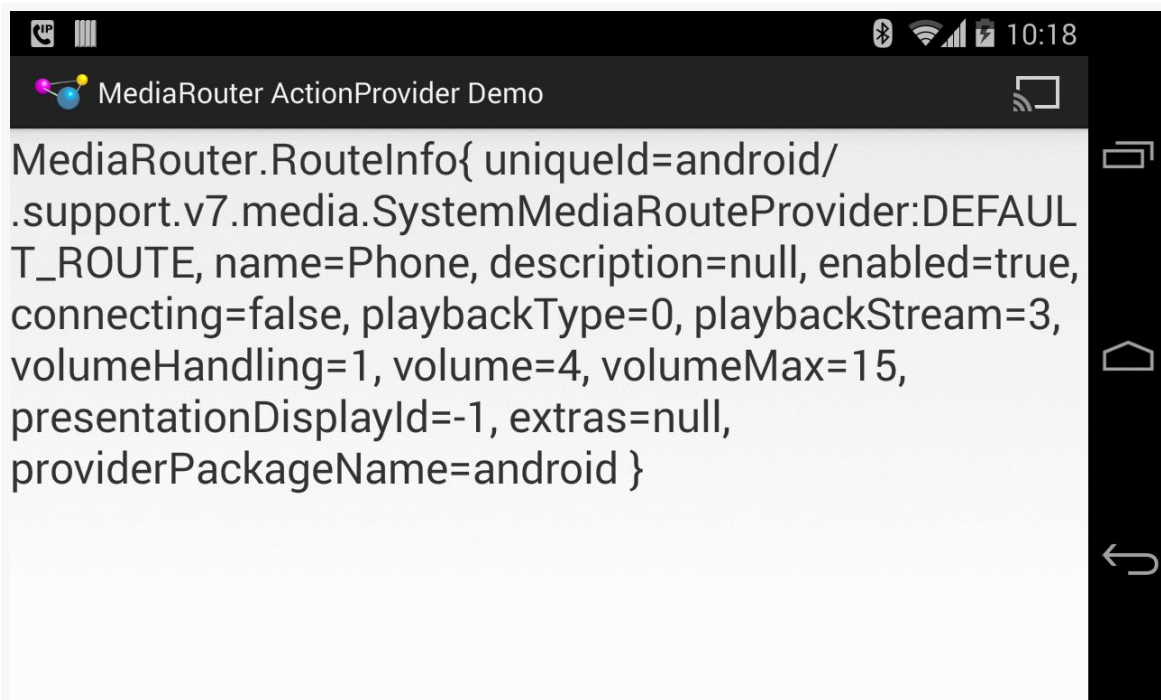

Figure 625: MediaRouter ActionProvider Demo, on a Nexus 4, Showing ActionProvider

The MediaRouteActionProvider, when tapped, will pop up a dialog of available routes that the user can select:

MEDIA ROUTES

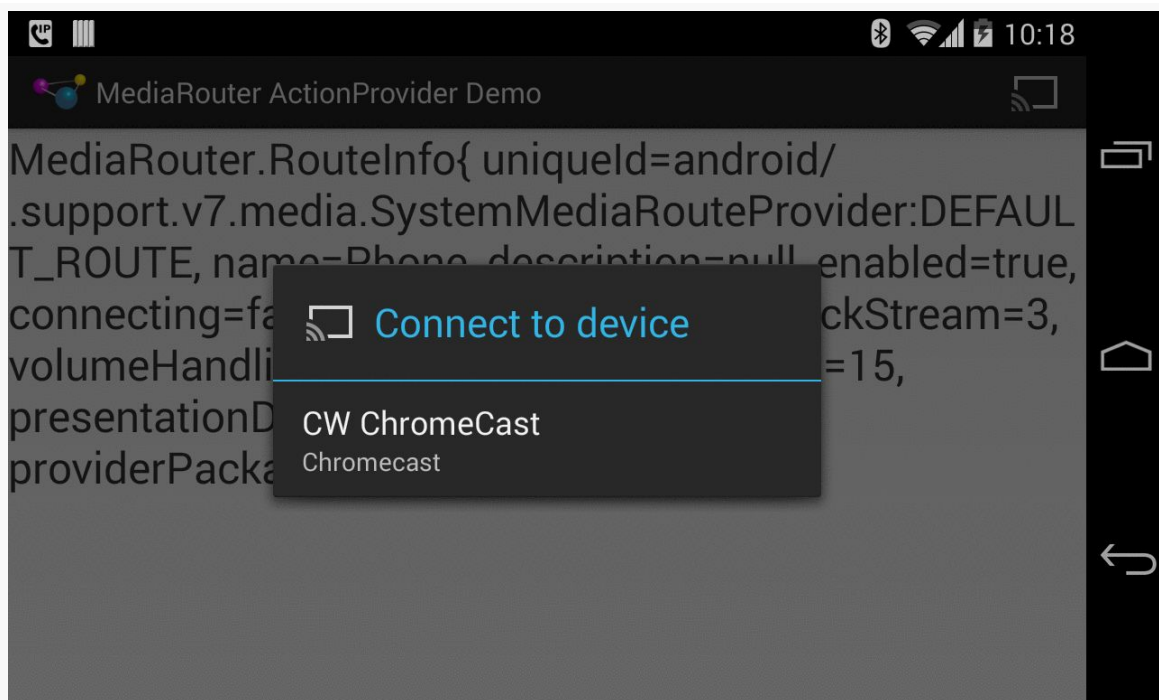

Figure 626: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Chromecast Route

Note that if the device has both a Bluetooth audio connection *and* access to a remote playback route (like a Chromecast), and you requested both live audio and remote playback routes, then the route selection dialog could have multiple choices:

MEDIA ROUTES

Figure 627: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Multiple Available Routes

If the user chooses a route from the dialog, our `onRouteSelected()` method will be called to reflect the new selection:

MEDIA ROUTES

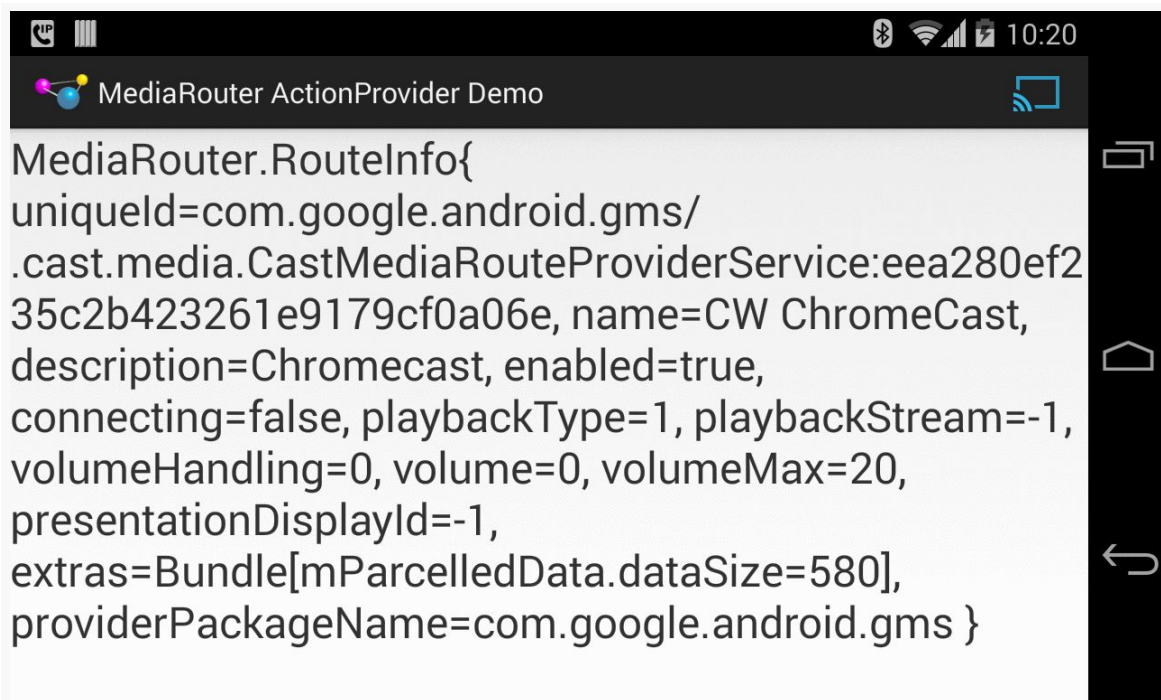

Figure 628: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Selected Chromecast Route

Also note that the MediaRouteActionProvider color changes from white to blue, indicating an altered route.

Tapping the action provider again pops up a dialog to control the volume of the route, plus a “Disconnect” button:

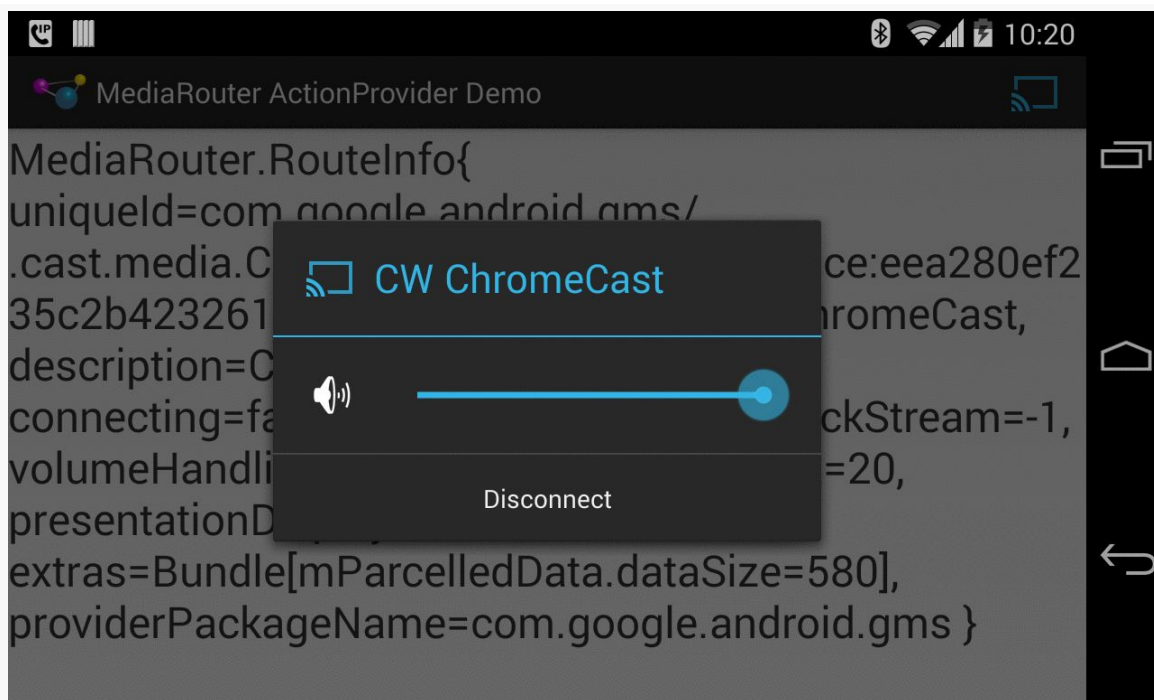

Figure 629: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Route Dialog

Tapping that “Disconnect” button returns everything to its original state.

The CWAC-MediaRouter Version

If you wish to use the regular Activity class, in conjunction with native API Level 11+ versions of the action bar and fragments, you can have nearly identical code by means of the CWAC-MediaRouter library. With that library added to your project, you can remove the AppCompatActivity code from your app, such as switching to a regular theme (e.g., Theme.Holo.Light.DarkActionBar) and inheriting from Activity instead of ActionBarActivity.

However, you will need to use `com.commonware.cwac.mediarouter.MediaRouteActionProvider` as your `android:actionProvider` in your menu resource:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/route_provider"
        android:actionProviderClass=
            "com.commonware.cwac.mediarouter.app.MediaRouteActionProvider"
        android:showAsAction="always">
```

```
android:title="@string/route_provider_title"/>
</menu>
```

Similarly, your Java code will need to import `com.commonware.cwac.mediarouter.MediaRouteActionProvider` instead of `android.support.v7.app.MediaRouteActionProvider`. However, you will still use the `mediarouter-v7` versions of the other `MediaRouter`-related classes, such as `MediaRouter` itself. The CWAC-MediaRouter library only contains ports for those classes that depended upon the backported action bar and fragments.

Otherwise, though, your code would be unchanged from the version that uses `mediarouter-v7` for everything, yet your `MediaRouteActionProvider` will work using native API Level 11+ fragments and the action bar.

Using Live Audio Routes

Using live audio routes will be covered in a future edition of this book.

Using Live Video Routes

A live video route is designed to be used with `Presentation`, a class that enables you to render your own content on the external display, much like how you would render your own content in a `Dialog`.

The use of `Presentation` is covered [in an upcoming chapter](#).

Using Remote Playback Routes

In principle, `RemotePlaybackClient` allows you to work with remote playback routes, to specify `Uri` values to play back.

In practice, not even Google's own sample code for `RemotePlaybackClient` works reliably, let alone as documented.

That being said, let's take a look at the [MediaRouter/RemotePlayback](#) sample project, to see how `RemotePlaybackClient` works and where the current problems lie.

Setting Up MediaRouteActionProvider

Much of the basic setup of this application mirrors the `MediaRouteActionProvider` sample shown [earlier in this chapter](#). One difference is that the UI is now encapsulated in a `PlaybackFragment`, with `MainActivity` simply setting up that fragment when needed:

```
package com.commonware.android.remoteplayback;

import android.os.Bundle;
import android.support.v7.app.ActionBarActivity;

public class MainActivity extends ActionBarActivity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        if (getSupportFragmentManager().findFragmentById(android.R.id.content) ==
null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PlaybackFragment()).commit();
        }
    }
}
```

Note that this sample does not use the `CWAC-MediaRouter` project, so `MainActivity` is an `ActionBarActivity`, and so on.

`PlaybackFragment`, when it is created, opts into being retained on configuration changes, tells Android that it wishes to add items to the action bar, and sets up a `MediaRouteSelector` for `CATEGORY_REMOTE_PLAYBACK` routes:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
    selector=
        new MediaRouteSelector.Builder()

.addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK).build();
}
```

Then, in `onAttach()` — called when the `PlaybackFragment` is attached to the hosting activity — we obtain a `MediaRouter` instance:

```
@Override
public void onAttach(Activity host) {
```

MEDIA ROUTES

```
super.onAttach(host);

router=MediaRouter.getInstance(host);
}
```

In `onResume()`, we hook a `cb` data member — an instance of `MediaRouter.Callback` up to the `MediaRouter`, also requesting that the `MediaRouter` initiate discovery of available routes. We remove our callback in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    router.addCallback(selector, cb,
                      MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
}

@Override
public void onPause() {
    router.removeCallback(cb);

    super.onPause();
}
```

We will examine `cb`'s declaration later in this section.

Later on, as part of our `onCreateOptionsMenu()` processing, we configure the `MediaRouteActionProvider` as before:

```
MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);
```

All of this is very similar to the earlier examples. From here, though, we will actually use the route once the user selects it, to play back some media.

The Rest of the User Interface

The UI of the `PlaybackFragment` — other than the action bar — consists of a “transcript”. This is a `TextView` inside of a `ScrollView`:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
```

MEDIA ROUTES

```
        android:id="@+id/transcript"  
        android:layout_width="wrap_content"  
        android:layout_height="wrap_content"  
        android:textSize="20sp"/>
```

```
</ScrollView>
```

As with most fragments, we inflate this layout in `onCreateView()`, holding onto the `TextView` and `ScrollView` widgets:

```
@Override  
public View onCreateView(LayoutInflater inflater,  
                        ViewGroup container,  
                        Bundle savedInstanceState) {  
    scroll=  
        (ScrollView)inflater.inflate(R.layout.activity_main, container,  
                                     false);  
  
    transcript=(TextView)scroll.findViewById(R.id.transcript);  
  
    logToTranscript("Started");  
  
    return(scroll);  
}
```

The `logToTranscript()` method will append a `String` to the `TextView` contents on a new line, plus scroll to the bottom to ensure that the new text is visible:

```
private void logToTranscript(String msg) {  
    if (client != null) {  
        String sessionId=client.getSessionId();  
  
        if (sessionId != null) {  
            msg("(" + sessionId + ") " + msg;  
        }  
    }  
  
    transcript.setText(transcript.getText().toString() + msg + "\n");  
    scroll.fullScroll(View.FOCUS_DOWN);  
}
```

The `client` data member referred to in `logToTranscript()` is our `RemotePlaybackClient` instance, which will be covered in the next section.

What the user sees when first running the sample is the action bar (with our `MediaRouteActionProvider`) and the transcript, with a simple “Started” message:

Figure 630: RemotePlaybackClient Demo, on a Nexus 4, As Initially Launched

As before, tapping on the “cast” action bar item pops up our dialog of available routes:

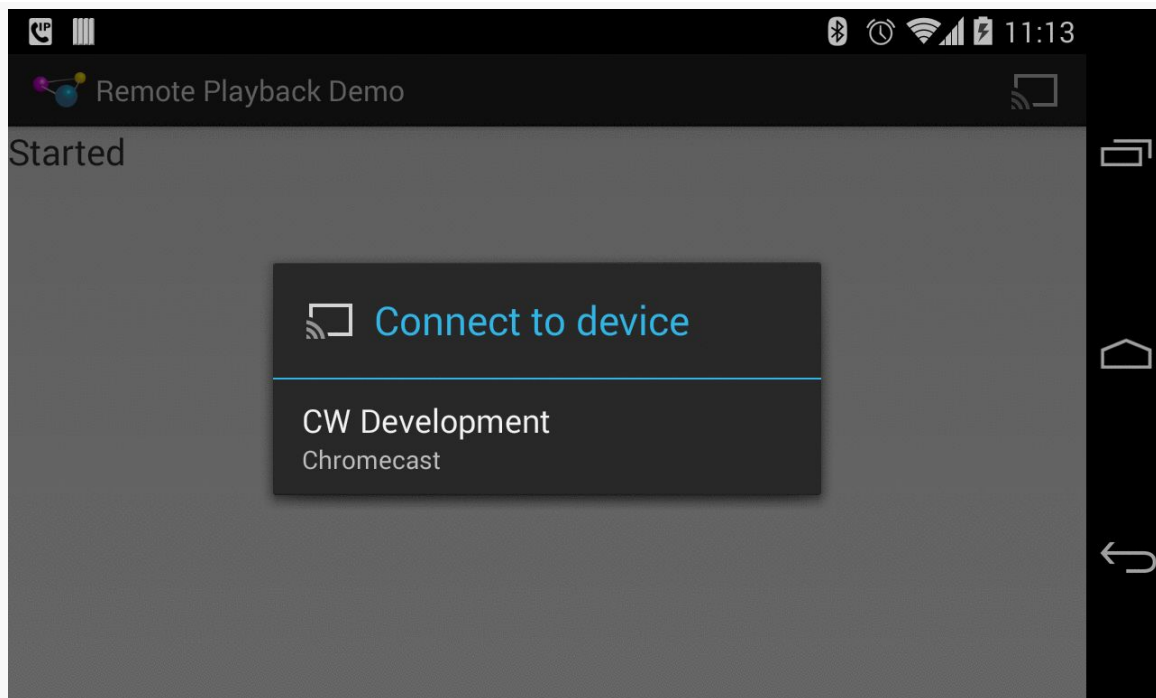

Figure 631: RemotePlaybackClient Demo, on a Nexus 4, Showing Available Routes

Connecting and Session Management

When the user selects a route, our `MediaRouter.Callback (cb)` is called with `onRouteSelected()`. Similarly, if the user elects to disconnect via the `MediaRouteActionProvider`, our `Callback` is called with `onRouteUnselected()`. In the `MediaRouter.Callback` implementation inside `PlaybackFragment`, those events route to `connect()` and `disconnect()` methods, respectively, after logging a message to the transcript:

```
private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                               MediaRouter.RouteInfo route) {
        logToTranscript(getActivity().getString(R.string.route_selected));
        connect(route);
    }

    @Override
    public void onRouteUnselected(MediaRouter router,
                                  MediaRouter.RouteInfo route) {
        logToTranscript(getActivity().getString(R.string.route_unselected));
        disconnect();
    }
}
```

```
}  
};
```

The `connect()` method handles connecting to the remote playback device and starting a session:

```
private void connect(MediaRouter.RouteInfo route) {  
    client=  
        new RemotePlaybackClient(getActivity().getApplication(), route);  
  
    if (client.isRemotePlaybackSupported()) {  
        logToTranscript(getActivity().getString(R.string.connected));  
  
        if (client.isSessionManagementSupported()) {  
            client.startSession(null, new SessionActionCallback() {  
                @Override  
                public void onResult(Bundle data, String sessionId,  
                                     MediaSessionStatus sessionStatus) {  
                    logToTranscript(getActivity().getString(R.string.session_started));  
                    updateMenu();  
                }  
  
                @Override  
                public void onError(String error, int code, Bundle data) {  
                    logToTranscript(getActivity().getString(R.string.session_failed));  
                }  
            });  
        }  
        else {  
            getActivity().supportInvalidateOptionsMenu();  
        }  
    }  
    else {  
        logToTranscript(getActivity().getString(R.string.remote_playback_not_supported));  
        client=null;  
    }  
}
```

All of that, though, requires a bit more explanation.

What's a Session?

The objective of the `connect()` method is to establish a “session” with the `RemotePlaybackClient`. In Android’s terms, a “session” is the state associated with an application’s interactions with the remote playback client. In principle, the session could be shared among several instances of the app, such as several people contributing tracks to a dynamic playlist for audio playback at a party. Here, though, we are simply focused on having this one application instance have a session.

In principle, not all remote playback clients may support session management. In those cases, everybody is considered to be part of the same session. The test device for this sample (Chromecast) does support session management, however.

Connecting the Client

Connecting to the remote playback device is simply a matter of creating an instance of `RemotePlaybackClient`, specifying the route to connect to:

```
client=  
    new RemotePlaybackClient(getActivity().getApplication(), route);
```

Here, we use `getActivity().getApplication()` in the `RemotePlaybackClient` constructor. That is because we want to hold onto this `RemotePlaybackClient` instance across configuration changes, so we can easily maintain our session. Since we do not know what `RemotePlaybackClient` may hold onto given the supplied `Context`, and since we do not want to leak our activity by retaining a reference to it, we use the global `Application` instance, for a “leak-resistant” `Context`.

We also call `isRemotePlaybackSupported()` to confirm that, indeed, the `RemotePlaybackClient` is connected to something that supports remote playback. This should always return `true` in this case, as we are only interested in remote playback routes. But, a little defensive programming never hurts.

Assuming that is all OK, we log a “connected” message to the transcript and continue on to start our session.

Starting a Session

`isSessionManagementSupported()` on `RemotePlaybackClient` will indicate if the device supports explicit session management or not. If not, we will use the default implicit session and just continue on.

Otherwise, we call `startSession()` to explicitly start a session. This takes an optional `Bundle` of additional information to send in the start-session request to the device (or `null` if unused), plus a `SessionActionCallback`. The `SessionActionCallback` is supposed to be called when the session is ready for use. Surprisingly enough, this actually works... for `startSession()`.

The `SessionActionCallback` will be called with `onResult()` for success and `onError()` for failure. In either case, we log a message to the transcript indicating the status.

In addition, if we have a session — either explicitly created via `startSession()` or implicitly created for devices without explicit session management — we call an `updateMenu()` method to update the action bar items.

About the Action Bar

The fragment maintains two boolean values representing key states in the operation of the playback:

1. `isPlaying` indicates if playback was started and not yet stopped
2. `isPaused` indicates if playback was paused and not yet resumed

The aforementioned `updateMenu()` implementation uses those, plus the existence of a non-null `client`, to configure the action bar items:

```
private void updateMenu() {
    if (menu != null) {
        menu.findItem(R.id.stop).setVisible(client != null && isPlaying);
        menu.findItem(R.id.pause).setVisible(client != null && isPlaying
                                             && !isPaused);
        menu.findItem(R.id.play)
            .setVisible(client != null && (!isPlaying || isPaused));
    }
}
```

Specifically:

- When we are not playing, the play item is visible; when we *are* playing, the stop item is visible
- When we are not paused, the pause item is visible (play serves “double duty”, handling starting playback from a stopped state and resuming playback from a paused state)

This is based on a cached copy of the `Menu` object, saved in `onCreateOptionsMenu()` as part of setting up the action bar:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    this.menu=menu;
    inflater.inflate(R.menu.main, menu);
}
```

```
updateMenu();

MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);
}
```

This is also where the logic shown previously for configuring the `MediaRouteActionProvider` resides.

Session IDs

A session has a `String` identifier. In principle, this can be shared with other instances of your application, to allow for shared management of the session.

In the case of this sample, the session ID is merely logged to the transcript for all messages that are tied to an active session.

Hence, when the user chooses a remote playback route from the `MediaRouteActionProvider`, the resulting UI should resemble:

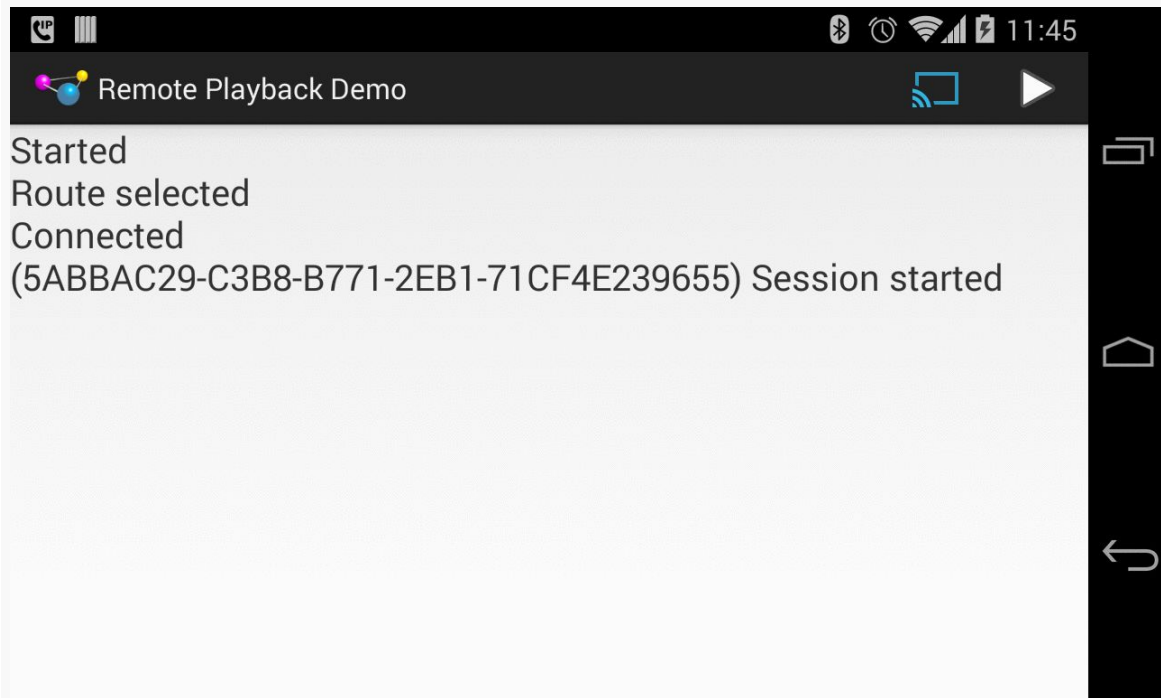

Figure 632: *RemotePlaybackClient Demo, on a Nexus 4, Showing an Active Session*

We see that we have connected to the client and started our session, and the play action bar item is now available to start playback of some media.

Playing

The play action bar item is tied to a `play()` method via `onOptionsItemSelected()`, if we are not paused:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.play:
            if (isPlaying && isPaused) {
                resume();
            }
            else {
                play();
            }

            return(true);

        case R.id.stop:
            stop();
            return(true);
    }
}
```

```
        case R.id.pause:
            pause();
            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

play(), in turn, uses the play() method on RemotePlaybackClient to play back a copy of [“Elephants Dream”](#), a Creative Commons-licensed video, hosted on CommonsWare’s corner of the Amazon S3 service:

```
private void play() {
    logToTranscript(getActivity().getString(R.string.play_requested));

    ItemActionCallback playCB=new ItemActionCallback() {
        @Override
        public void onResult(Bundle data, String sessionId,
                               MediaSessionStatus sessionStatus,
                               String itemId, MediaItemStatus itemStatus) {
            logToTranscript(getActivity().getString(R.string.playing));
            isPlaying=true;
            updateMenu();
        }

        @Override
        public void onError(String error, int code, Bundle data) {
            logToTranscript(getActivity().getString(R.string.play_error)
                            + error);
        }
    };

    client.play(Uri.parse("http://misc.commonsware.com/ed_hd_512kb.mp4"),
                "video/mp4", null, 0, null, playCB);
}
```

The play() method on RemotePlaybackClient takes a few parameters:

- The Uri of the media to be played back
- The MIME type of that media (or null if you do not know the MIME type)
- An optional Bundle of metadata about the media to be played, where the Bundle keys come from MediaItemMetadata class (or null if none)
- The starting offset in the media to begin playback from (use 0 to start from the beginning)
- An optional Bundle of additional data to pass to the device
- An instance of ItemActionCallback to be notified when playback has started or has failed

MEDIA ROUTES

`ItemActionCallback` is reminiscent of `SessionActionCallback`, in that `onResult()` will be called when playback begins and `onError()` will return when playback ends. The method signature of `onResult()` is slightly different, offering an ID and status of this particular media item.

In our case, we log a message to the transcript before requesting playback, then again on success or failure. On success, we also update `isPlaying` to be true and refresh the action bar.

Hence, once the user begins playback by tapping the play action bar item, the UI will look like this:

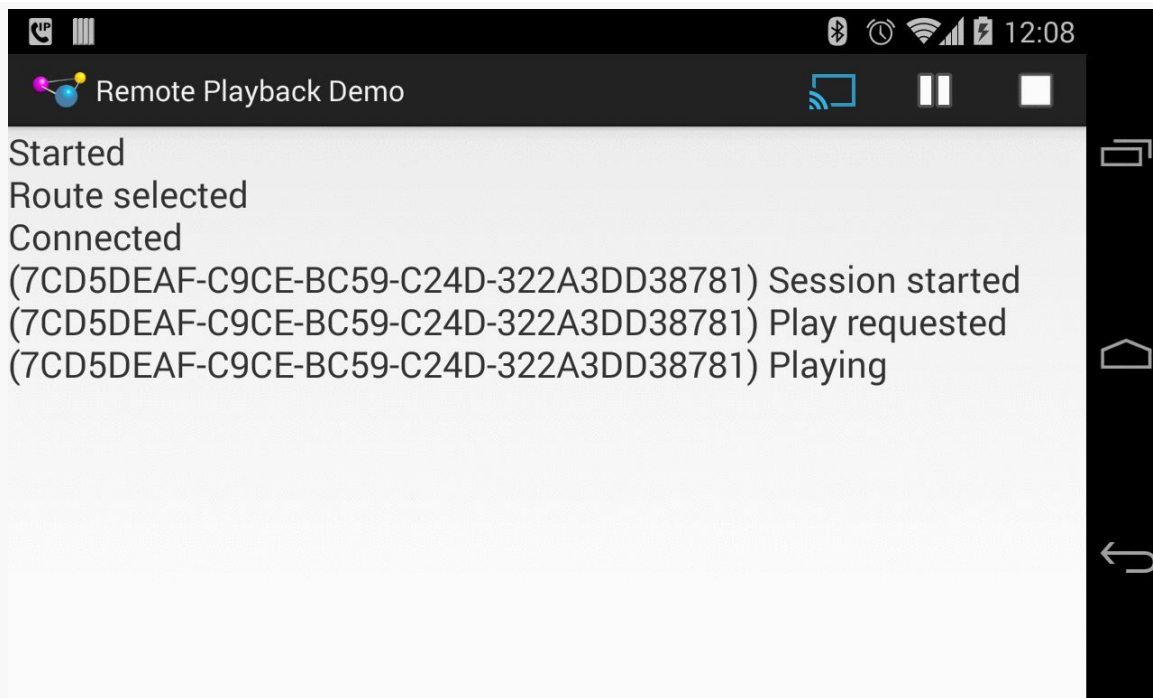

Figure 633: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Started

And, of course, the movie should be showing up on your remote playback device.

Stopping, and a Bug

The `stop()` action bar item is tied to a `stop()` method in `PlaybackFragment`. You would think that this would be very similar to starting playback — call some `stop()` method on `RemotePlaybackClient` and update the UI after playback has stopped.

And, indeed, that is what we do... except that we have to deal with a bug:

```
private void stop() {
    logToTranscript(getActivity().getString(R.string.stop_requested));

    StopCallback stopCB=new StopCallback();

    client.stop(null, stopCB);
    transcript.postDelayed(stopCB, 1000);
}
```

The stop() Call, and the Bug

stop() on RemotePlaybackClient takes an optional Bundle (here, null) and a SessionActionCallback. The SessionActionCallback is supposed to be called when playback has stopped (onResult()) or if there was some error in processing the request (onError()).

In practice, [neither happen when testing this on a Chromecast](#). This same behavior can be seen with [Google's own sample code](#), so it would not appear to be a problem with the author's own sample.

What actually happens is that playback is indeed stopped, but the SessionActionCallback is not called with onResult() or onError().

The Workaround: RunnableSessionActionCallback

Since we cannot rely upon onResult() to be called for us, if we have work that we need to do in that case, we have to have some sort of fallback mechanism. One crude fallback is to assume that the request succeeded if we have not received a specific response after a period of time (say, 1000 milliseconds).

To that end, this sample has RunnableSessionActionCallback, a SessionActionCallback that implements Runnable:

```
abstract class RunnableSessionActionCallback extends
    SessionActionCallback implements Runnable {
    abstract protected void doWork();

    private boolean hasRun=false;

    @Override
    public void onResult(Bundle data, String sessionId,
        MediaSessionStatus sessionStatus) {
        transcript.removeCallbacks(this);
    }
}
```

```
        run();
    }

    @Override
    public void run() {
        if (!hasRun) {
            hasRun=true;
            doWork();
        }
    }
}
```

The `run()` method sees whether or not the callback has already been run from a previous `run()` call. If not, it does the work specified by the abstract `doWork()` method, to be implemented in subclasses.

`StopCallback`, as seen in the `stop()` method above, extends `RunnableSessionActionCallback` and overrides `doWork()`:

```
private class StopCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPlaying=false;
        isPaused=false;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.stopped));
    }
}
```

`stop()` then not only passes the `StopCallback` to the `stop()` implementation on `RemotePlaybackClient`, but also schedules it as a `Runnable` to be invoked in 1000 milliseconds, via a call to `postDelayed()` on the `TextView` portion of the transcript. The `onResult()` implementation in `RunnableSessionActionCallback` calls `removeCallbacks()`, so we do not bother invoking the posted `Runnable` if that is not needed.

The `doWork()` implementation in `StopCallback` updates our flags, refreshes the action bar, and logs a message to the transcript. The result will look like:

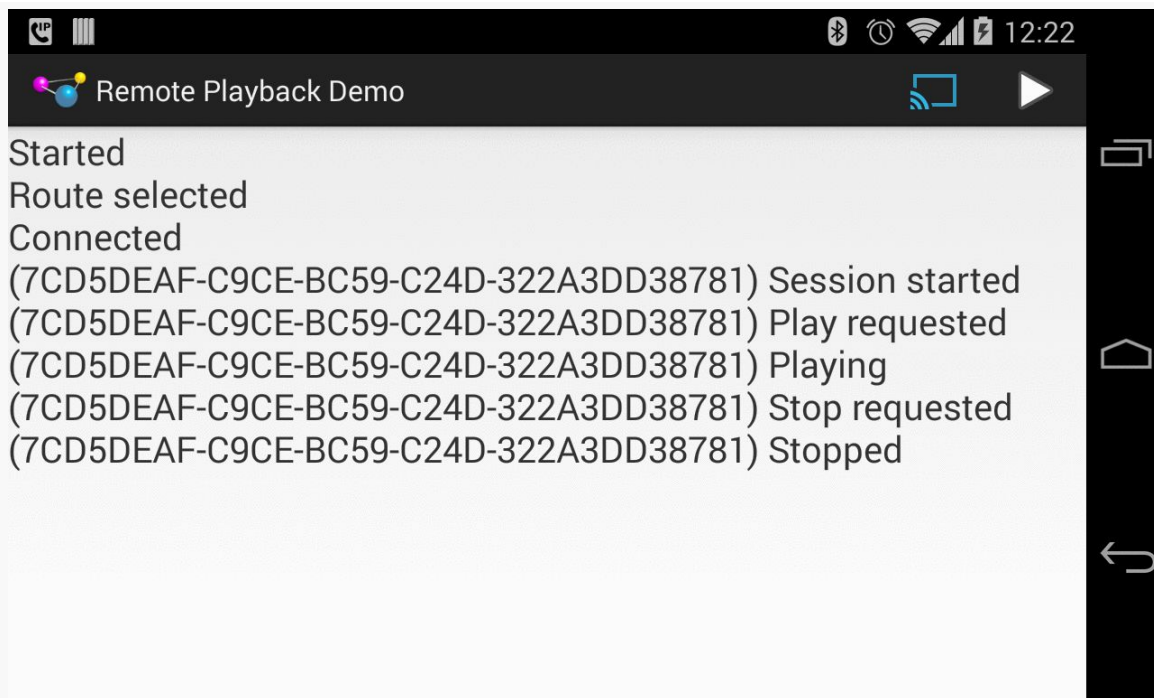

Figure 634: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Stopped

This sample also does not handle the case where the media completes playback on its own, insofar as this event is not detected, to update the action bar. This will be added in a future version of this sample, if further bugs allow such support to actually work.

Pausing and Resuming

Similarly, the pause action bar item forwards to a `pause()` method that calls `pause()` on the `RemotePlaybackClient`:

```
private void pause() {  
    logToTranscript(getActivity().getString(R.string.pause_requested));  
  
    PauseCallback pauseCB=new PauseCallback();  
  
    client.pause(null, pauseCB);  
    transcript.postDelayed(pauseCB, 1000);  
}
```

That, in turn, uses `PauseCallback`:

MEDIA ROUTES

```
private class PauseCallback extends RunnableSessionActionCallback {  
    @Override  
    protected void doWork() {  
        isPaused=true;  
        updateMenu();  
        logToTranscript(getActivity().getString(R.string.paused));  
    }  
}
```

This updates the action bar and logs messages to the transcript, similar to the `stop()` behavior. It also should successfully pause playback on the remote device.

The play action bar item routes to `resume()` if playback is paused:

```
private void resume() {  
    logToTranscript(getActivity().getString(R.string.resume_requested));  
  
    ResumeCallback resumeCB=new ResumeCallback();  
  
    client.resume(null, resumeCB);  
    transcript.postDelayed(resumeCB, 1000);  
}
```

That, in turn, uses `ResumeCallback`:

```
private class ResumeCallback extends RunnableSessionActionCallback {  
    @Override  
    protected void doWork() {  
        isPaused=false;  
        updateMenu();  
        logToTranscript(getActivity().getString(R.string.resumed));  
    }  
}
```

This too updates the action bar and logs messages to the transcript, in addition to resuming playback on the remote device.

Disconnecting

A call to `disconnect()` on `PlaybackFragment` is triggered from two locations:

- `onRouteUnselected()` in our `MediaRouter.Callback`, such as when the user uses the `MediaRouteActionProvider` to disconnect from the route
- `onDestroy()`, as part of general cleanup of the fragment

`disconnect()` should reverse the work done in `connect()`, ending our session and releasing the client:

```
private void disconnect() {
    isPlaying=false;
    isPaused=false;

    if (client != null) {
        logToTranscript(getActivity().getString(R.string.session_ending));
        EndSessionCallback endCB=new EndSessionCallback();

        if (client.isSessionManagementSupported()) {
            client.endSession(null, endCB);
        }

        transcript.postDelayed(endCB, 1000);
    }
}
```

This simply calls the `endSession()` method on the `RemotePlaybackClient`, supplying an `EndSessionCallback` to be notified (theoretically) of when the session has been torn down. But it only calls `endSession()` if session management is supported; otherwise, we would get a runtime error.

To be sure we complete the disconnection, though, we schedule the `EndSessionCallback` as seen in the `stop()`, `pause()`, and `resume()` methods. `EndSessionCallback` calls `release()` on the `RemotePlaybackClient`, to indicate that we are done with it, before setting `client` to `null`, refreshing the action bar, and logging something to the transcript:

```
private class EndSessionCallback extends
    RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        client.release();
        client=null;

        if (getActivity() != null) {
            updateMenu();
            logToTranscript(getActivity().getString(R.string.session_ended));
        }
    }
}
```

Other Remote Playback Features

There are other things that `RemotePlaybackClient` offers that are not shown in this sample:

- `enqueue()` allows you to build up a queue of media to be played back in the current session. This could be used by an individual or, in principle, by

several people using the same app with a shared session ID. `remove()` allows you to remove specific items from the playback queue. These methods only work if `isQueueingSupported()` returns true.

- `getStatus()` will return information about the currently-playing piece of media, while `getSessionStatus()` will return information about the overall session. You can also find out about these changes on the fly by registering with `setStatusCallback()`.
- `seek()` allows you to move the playback to a new offset within the media, for “rewind” and “fast-forward” functionality. The status APIs (above) can tell you where you are in the playback, so you can determine the appropriate offset to seek to.

The CWAC-MediaRouter Version

A version of this sample project, using the CWAC-MediaRouter edition of `MediaRouteActionProvider`, can be found in [the demo-remoteplayback/ directory of the CWAC-MediaRouter repository](#).

Supporting External Displays

Android 4.2 inaugurated support for applications to control what appears on an external or “secondary” display (e.g., TV connected via HDMI), replacing the default screen mirroring. This is largely handled through a `Presentation` object, where you declare the UI that goes onto the external display, in parallel with whatever your activity might be displaying on the primary screen.

In this chapter, we will review how Android supports these external displays, how you can find out if an external display is attached, and how you can use `Presentation` objects to control what is shown on that external display.

The author would like to thank Mark Allison, whose “Multiple Screens” blog post series helped to blaze the trail for everyone in this space.

Prerequisites

In addition to the core chapters, you should read [the chapter on dialogs](#) and [the chapter on `MediaRouter`](#) before reading this chapter.

A History of External Displays

In this chapter, “external displays” refers to a screen that is temporarily associated with an Android device, in contrast with a “primary screen” that is where the Android device normally presents its user interface. So, most Android devices connected to a television via HDMI would consider the television to be a “external display”, with the touchscreen of the device itself as the “primary screen”. However, a [Android TV](#) box or OUYA console connected to a television via HDMI would consider the television to be the “primary screen”, simply because there is no other

screen. Some devices themselves may have multiple screens, such as the [Sony Tablet P](#) — what those devices do with those screens will be up to the device.

Historically, support for external displays was manufacturer-dependent. Early Android devices had no ability to be displayed on an external display except through so-called “software projectors” like Jens Riboe’s [Droid@Screen](#). Some Android 2.x devices had ports that allowed for HDMI or composite connections to a television or projector. However, control for what would be displayed resided purely in the hands of the manufacturer. Some manufacturers would display whatever was on the touchscreen (a.k.a., “mirroring”). Some manufacturers would do that, but only for select apps, like a built-in video player.

Android 3.0 marked the beginning of Android’s formal support for external displays, as the Motorola XOOM supported mirroring of the LCD’s display via an micro-HDMI port. This mirroring was supplied by the core OS, not via device-dependent means. Any Android 3.0+ device with some sort of HDMI connection (e.g., micro-HDMI port) should support this same sort of mirroring capability.

However, mirroring was all that was possible. There was no means for an application to have something on the external display (e.g., a video) and something *else* on the primary screen (e.g., playback controls plus IMDB content about the movie being watched).

Android 4.2 changed that, with the introduction of Presentation.

What is a Presentation?

A Presentation is a container for displaying a UI, in the form of a View hierarchy (like that of an activity), on an external display.

You can think of a Presentation as being a bit like a Dialog in that regard. Just as a Dialog shows its UI separate from its associated activity, so does a Presentation. In fact, as it turns out, Presentation *inherits from* Dialog.

The biggest difference between a Presentation and an ordinary Dialog, of course, is where the UI is displayed. A Presentation displays on an external display; a Dialog displays on the primary screen, overlaying the activity. However, this difference has a profound implication: the *characteristics* of the external display, in terms of size and density, are likely to be different than those of a primary screen.

Hence, the resources used by the UI on an external display may be different than the resources used by the primary screen. As a result, **the Context of the Presentation is not the Activity**. Rather, it is a separate Context, one whose Resources object will use the proper resources based upon the external display characteristics.

This seemingly minor bit of bookkeeping has some rippling effects on setting up your Presentation, as we will see as this chapter unfolds.

Playing with External Displays

To write an app that uses an external display via a Presentation, you will need Android 4.2 or higher.

Beyond that, though, you will also need an external display of some form. Presently, you have three major options: emulate it, use a screen connected via some sort of cable, or use Miracast for wireless external displays.

Emulated

Even without an actual external display, you can lightly test your Presentation-enabled app via the Developer Options area of Settings on your Android 4.2 device. There, in the Drawing category, you will see the “Simulate secondary displays” preference:

SUPPORTING EXTERNAL DISPLAYS

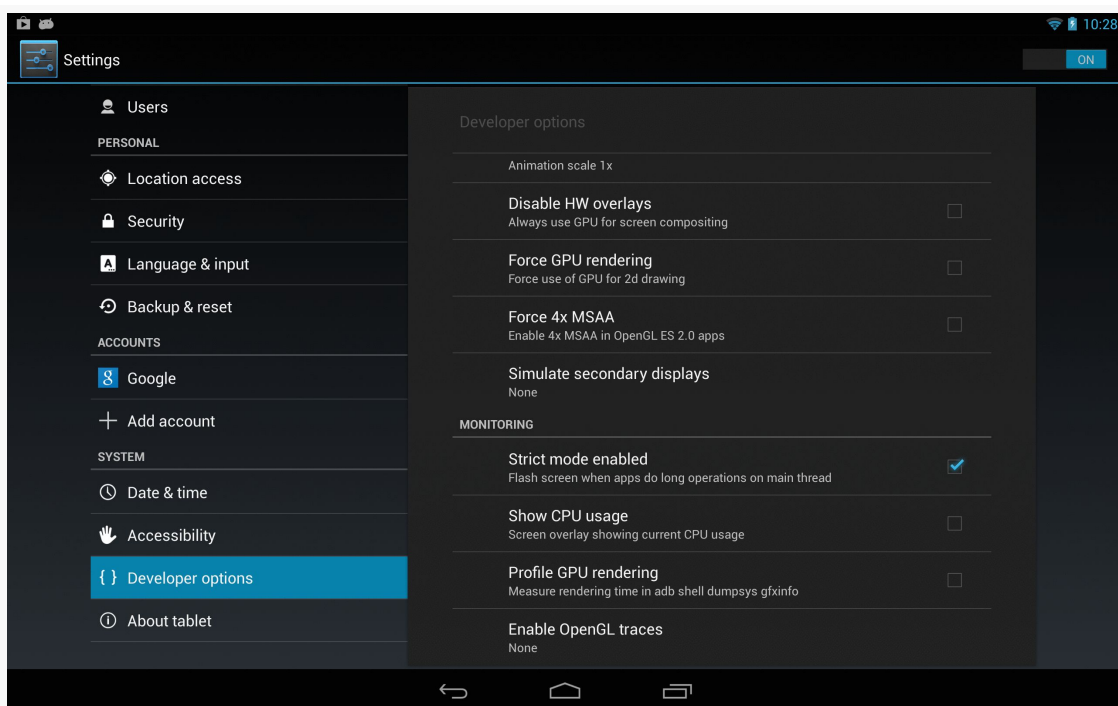

Figure 635: Nexus 10 “Simulate secondary displays” Preference

Tapping that will give you various options for what secondary display to emulate:

SUPPORTING EXTERNAL DISPLAYS

Figure 636: Nexus 10 “Simulate secondary displays” Options

Tapping one of those will give you a small window in the upper-left corner, showing the contents of the external display, overlaid on top of your regular screen:

SUPPORTING EXTERNAL DISPLAYS

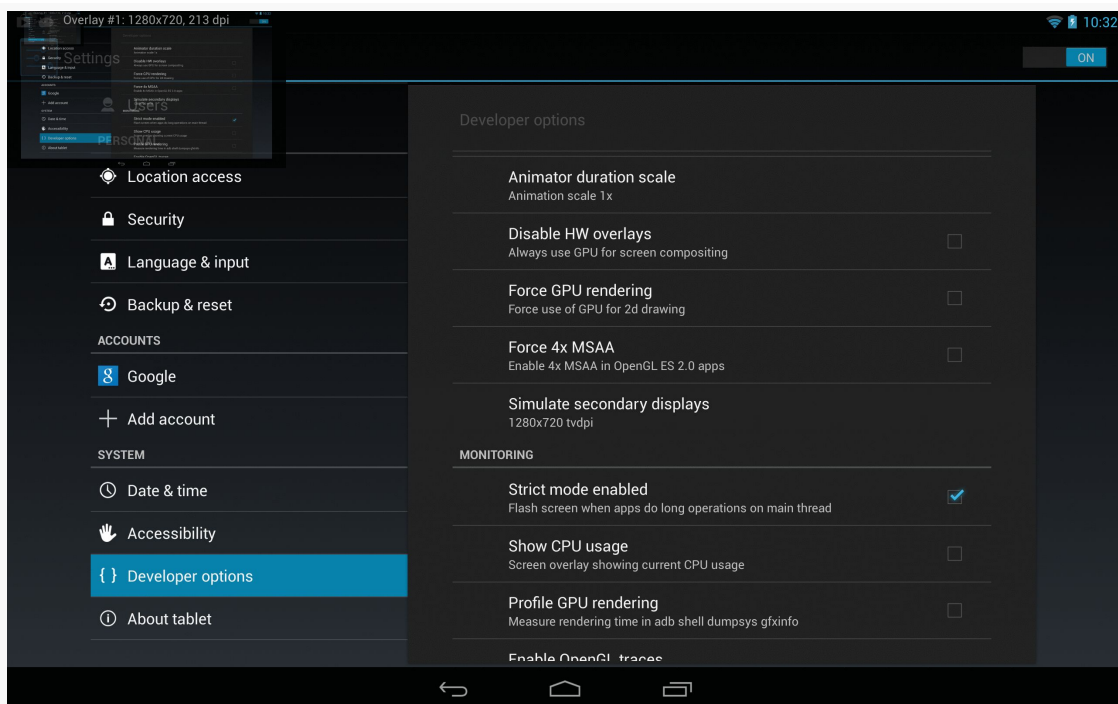

Figure 637: Nexus 10, Simulating a 720p external display

Normally, that will show a mirrored version of the primary screen, but with a Presentation-enabled app, it will show what is theoretically shown on the real external display.

However, there are limits with this technology:

- You will see this option on an Android emulator, but it may not work, particularly if you are not capable of using the “Host GPU Support” option. At the time of this writing, it works on the x86 Android 4.2 emulator image, but not the x86 Android 4.3 or 4.4 emulator image, and the ARM emulators are likely to be far too slow.
- The external display is rather tiny, making it difficult for you to accurately determine if everything is sized appropriately.
- The external display occludes part of the screen, overlaying your activities, though you can at least drag it around the screen to move it out of your way as needed.

In practice, before you ship a Presentation-capable app, you will want to test it with an actual physical external display.

HDMI

If you have a device with HDMI-out capability, and you have the appropriate cable, you can simply plug that cable between your device and the display. “Tuning” the display to use that specific HDMI input port should cause your device’s screen contents to be mirrored to that display. Once this is working, you should be able to control the contents of that display using Presentation.

MHL

Mobile High-Definition Link, or MHL for short, is a relatively new option for connections to displays. On many modern Android devices, the micro USB port supports MHL as well. Some external displays have MHL ports, in which case a male-to-male MHL direct cable will connect the device to the display. Otherwise, MHL can be converted to HDMI via adapters, so an MHL-capable device can attach to any HDMI-compliant display.

SlimPort

SlimPort is another take on the overload-the-micro-USB-port-for-video approach. MHL is used on substantially more devices, but SlimPort appears on several of the Nexus-series devices (Nexus 4, Nexus 5, and the 2013 generation of the Nexus 7). Hence, while users will be more likely to have an MHL device, *developers* may be somewhat more likely to have a SlimPort device, given the popularity of Nexus devices among Android app developers.

From the standpoint of your programming work, MHL and SlimPort are largely equivalent — there is nothing that you need to do with your Presentation to address either of those protocols, let alone anything else like native HDMI.

Miracast

There are a few wireless display standards available. Android 4.2 supports Miracast, based upon WiFiDirect. This is also supported by some devices running earlier versions of Android, such as some Samsung devices (where Miracast is sometimes referred to as “AllShare Cast”). However, unless and until those devices get upgraded to Android 4.2, you cannot control what they display, except perhaps through some manufacturer-specific APIs.

SUPPORTING EXTERNAL DISPLAYS

On a Miracast-capable device, going into Settings > Displays > Wireless display will give you the ability to toggle on wireless display support and scan for available displays:

Figure 638: Nexus 4 Wireless Display Settings

You can then elect to attach to one of the available wireless displays and get your screen mirrored, and later use this with your Presentation-enabled app.

Of course, you also need some sort of Miracast-capable display. As of early 2013, there were few of these. However, you can also get add-on boxes that connect to normal displays via HDMI and make them available via Miracast. One such box is the [Netgear PTV3000](#), whose current firmware supports Miracast along with other wireless display protocols.

Note that Miracast uses a compressed protocol, to minimize the bandwidth needed to transmit the video. This, in turn, can cause some lag.

Note that Intel's WiDi is an extended version of Miracast.

WirelessHD

An up-and-coming competitor to Miracast is WirelessHD. WirelessHD has greater bandwidth requirements. On the other hand, it avoids compression, and therefore the lag that you experience with Miracast. At the time of this writing, though, no WirelessHD-native Android devices are available.

Detecting Displays

Of course, we can only present a Presentation on an external display if there is, indeed, such a screen available. There are two approaches for doing this: using `DisplayManager` and using `MediaRouter`. We examined `MediaRouter` for detecting live video routes [in a preceding chapter](#), so let's focus here on `DisplayManager`.

`DisplayManager` is a system service, obtained by calling `getSystemService()` and asking for the `DISPLAY_SERVICE`.

Once you have a `DisplayManager`, you can ask it to give you a list of all available displays (`getDisplay()` with zero arguments) or all available displays in a certain category (`getDisplay()` with a single `String` parameter). As of API Level 17, the only available display category is `DISPLAY_CATEGORY_PRESENTATION`. The difference between the two flavors of `getDisplay()` is just the sort order:

- The zero-argument `getDisplay()` returns the `Display` array in arbitrary order
- The one-argument `getDisplay()` will put the `Display` objects matching the identified category earlier in the array

These would be useful if you wanted to pop up a list of available displays to ask the user which `Display` to use.

You can also register a `DisplayManager.DisplayListener` with the `DisplayManager` via `registerDisplayListener()`. This listener will be called when displays are added (e.g., HDMI cable was connected), removed (e.g., HDMI cable was disconnected), or changed. It is not completely clear what would trigger a “changed” call, though possibly an orientation-aware display might report back the revised height and width.

Note that while `DisplayManager` was added in API Level 17, `Display` itself has been around since API Level 1, though some additions have been made in more recent

Android releases. But, this may mean that you can pass the `Display` object around to code supporting older devices without needing to constantly check for SDK level or add the `@TargetApi()` annotation.

A Simple Presentation

Let's take a look at a small sample app that demonstrates how we can display custom content on an external display using a `Presentation`. The app in question can be found in the [Presentation/Simple](#) sample project.

The Presentation Itself

Since `Presentation` extends from `Dialog`, we provide the UI to be displayed on the external display via a call to `setContentView()`, much like we would do in an activity. Here, we just create a `WebView` widget in Java, point it to some Web page, and use it:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private class SimplePresentation extends Presentation {
    SimplePresentation(Context ctxt, Display display) {
        super(ctxt, display);
    }

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        WebView wv=new WebView(getContext());

        wv.loadUrl("http://commonsware.com");

        setContentView(wv);
    }
}
```

However, there are two distinctive elements of our implementation:

- Our constructor takes a `Context` (typically the `Activity`), along with a `Display` object indicating where the UI should be presented.
- Our call to the `WebView` constructor uses `getContext()`, instead of the `Activity` object. In this case, that may have no real-world effect, as `WebView` is not going to be using any of our resources. But, had we used a `LayoutInflater` for inflating our UI, we would need to use one created from `getContext()`, not from the activity itself.

Detecting the Displays

We need to determine whether there is a suitable external display when our activity comes into the foreground. We also need to determine if an external display was added or removed while we are in the foreground.

So, in `onResume()`, if we are on an Android 4.2 or higher device, we will get connected to the `MediaRouter` to handle those chores:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onResume() {
    super.onResume();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        if (cb==null) {
            cb=new RouteCallback();
            router=(MediaRouter)getSystemService(MEDIA_ROUTER_SERVICE);
        }

        handleRoute(router.getSelectedRoute(MediaRouter.ROUTE_TYPE_LIVE_VIDEO));
        router.addCallback(MediaRouter.ROUTE_TYPE_LIVE_VIDEO, cb);
    }
}
```

Specifically, we:

- Create an instance of `RouteCallback`, an inner class of our activity that extends `SimpleCallback`
- Use `getSystemService()` to obtain a `MediaRouter`
- Call a `handleRoute()` method on our activity that will update our UI based upon the current video route, obtained by calling `getSelectedRoute()` on the `MediaRouter`
- Register the `RouteCallback` object with the `MediaRouter` via `addCallback()`

The `RouteCallback` object simply overrides `onRoutePresentationDisplayChanged()`, which will be called whenever there is a change in what screens are available and considered to be the preferred modes for video. There, we just call that same `handleRoute()` method that we called in `onResume()`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN)
private class RouteCallback extends SimpleCallback {
    @Override
    public void onRoutePresentationDisplayChanged(MediaRouter router,
                                                RouteInfo route) {
```

```
        handleRoute(route);  
    }  
}
```

Hence, our business logic for showing the presentation is isolated in one method, `handleRoute()`.

Our `onPause()` method will undo some of the work done by `onResume()`, notably removing our `RouteCallback`. We will examine that more closely in the next section.

Showing and Hiding the Presentation

Our `handleRoute()` method will be called with one of two parameter values:

- The `RouteInfo` of the active route we should use for displaying the Presentation
- `null`, indicating that there is no route for such content, other than the primary screen

If we are passed the `RouteInfo`, it may represent the route we are already using, or possibly it may represent a different route entirely.

We need to handle all of those cases, even if some (switching directly from one route to another) may not necessarily be readily testable.

Hence, our `handleRoute()` method does its best:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)  
private void handleRoute(RouteInfo route) {  
    if (route == null) {  
        clearPreso();  
    }  
    else {  
        Display display=route.getPresentationDisplay();  
  
        if (route.isEnabled() && display != null) {  
            if (preso == null) {  
                showPreso(route);  
                Log.d(getClass().getSimpleName(), "enabled route");  
            }  
            else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {  
                clearPreso();  
                showPreso(route);  
                Log.d(getClass().getSimpleName(), "switched route");  
            }  
            else {  
                // no-op: should already be set  
            }  
        }  
    }  
}
```

```
    }  
  }  
  else {  
    clearPreso();  
    Log.d(getClass().getSimpleName(), "disabled route");  
  }  
}  
}
```

There are five possibilities handled by this method:

- If the route is null, then we should no longer be displaying the Presentation, so we call a `clearPreso()` method that will handle that
- If the route exists, but is disabled or is not giving us a Display object, we also assume that we should no longer be displaying the Presentation, so we call `clearPreso()`
- If the route exists and seems ready for use, and we are not already showing a Presentation (our `preso` data member is null), we need to show the Presentation, which we delegate to a `showPreso()` method
- If the route exists, seems ready for use, but we are already showing a Presentation, and the ID of the new Display is different than the ID of the Display our Presentation had been using, we use *both* `clearPreso()` and `showPreso()` to switch our Presentation to the new Display
- If the route exists, seems ready for use, but we are already showing a Presentation on this Display, we do nothing and wonder why `handleRoute()` got called

Showing the Presentation is merely a matter of creating an instance of our `SimplePresentation` and calling `show()` on it, like we would a regular Dialog:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)  
private void showPreso(RouteInfo route) {  
    preso=new SimplePresentation(this, route.getPresentationDisplay());  
    preso.show();  
}
```

Clearing the Presentation calls `dismiss()` on the Presentation, then sets the `preso` data member to null to indicate that we are not showing a Presentation:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)  
private void clearPreso() {  
    if (preso != null) {  
        preso.dismiss();  
        preso=null;  
    }  
}
```

Our `onPause()` uses `clearPreso()` and `removeCallback()` to unwind everything:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onPause() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        clearPreso();

        if (router != null) {
            router.removeCallback(cb);
        }
    }

    super.onPause();
}
```

The Results

If you run this with no external display, you will just see a plain `TextView` that is the UI for our primary screen:

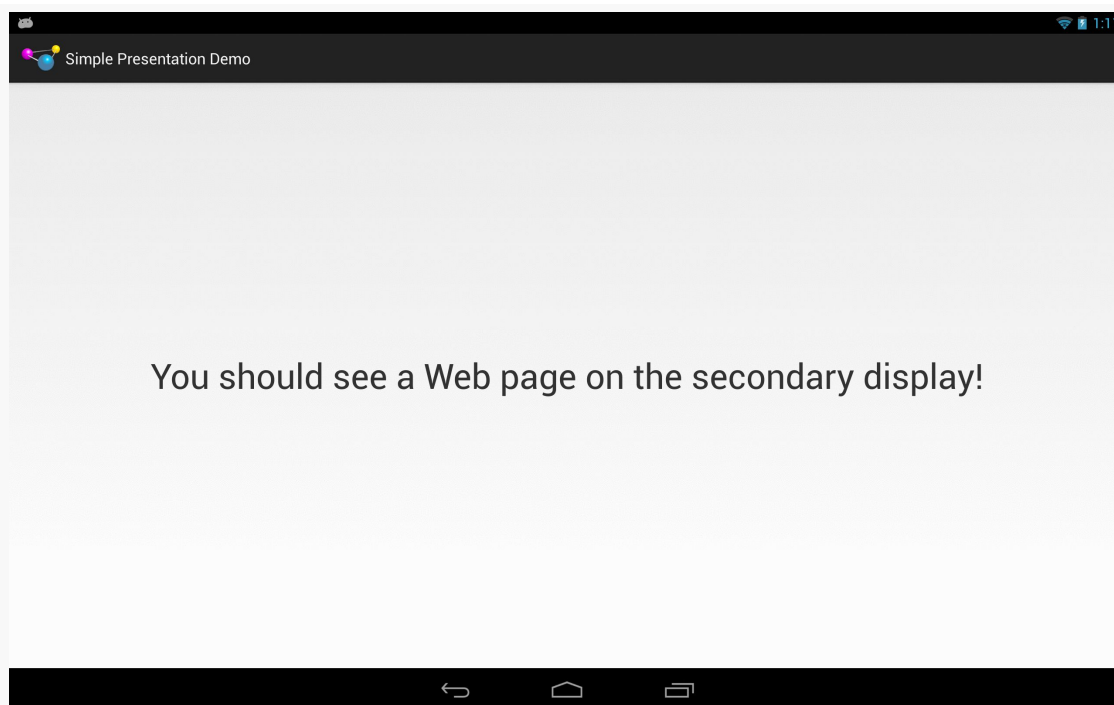

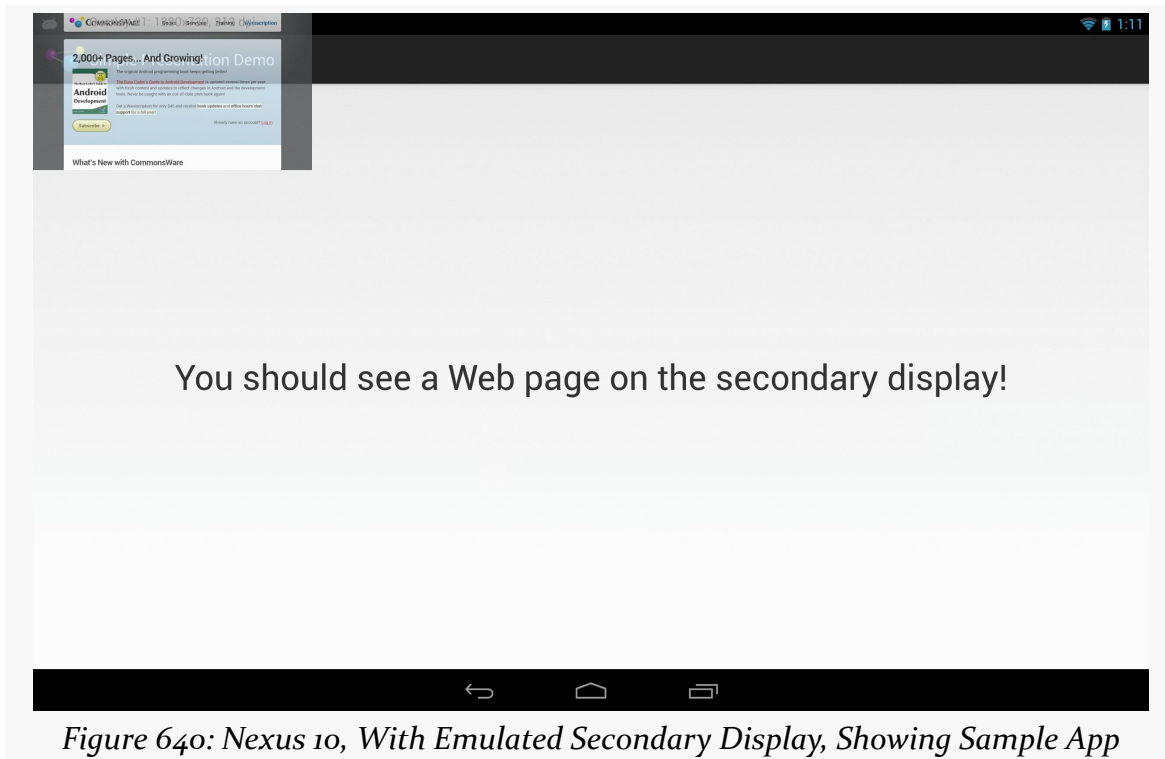

Figure 639: Nexus 10, No Emulated Secondary Display, Showing Sample App

If you run this *with* an external display, the external display will show our `WebView`:

A Simpler Presentation

There was a fair bit of code in the previous sample for messing around with `MediaRouter` and finding out about changes in the available displays.

To help simplify apps using `Presentation`, the author of this book maintains a library, [CWAC-Presentation](#), with various reusable bits of code for managing `Presentations`.

One piece of this is `PresentationHelper`, which isolates all of the display management logic in a single reusable object. In this section, we will examine how to use `PresentationHelper`, then how `PresentationHelper` itself works, using `DisplayManager` under the covers.

Getting a Little Help

Our [Presentation/Simpler](#) sample project has the `CWAC-Presentation` JAR in its `libs/` directory, giving us access to `PresentationHelper`. Our `MainActivity` in the

sample creates an instance of `PresentationHelper` in `onCreate()`, stashing the object in a data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    helper=new PresentationHelper(this, this);
}
```

The constructor for `PresentationHelper` takes two parameters:

- a `Context` object, one that should be valid for the life of the helper, typically the `Activity` that creates the helper, and
- a implementation of `PresentationHelper.Listener` — in this case, the interface is implemented on `MainActivity` itself

The activity that creates the helper must forward `onPause()` and `onResume()` lifecycle methods to the equivalent methods on the helper:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

The implementer of `PresentationHelper.Listener` also needs to have `showPreso()` and `clearPreso()` methods, much like the ones from the original `Presentation` sample in this chapter. `showPreso()` will be passed a `Display` object and should arrange to display a `Presentation` on that `Display`:

```
@Override
public void showPreso(Display display) {
    preso=new SimplerPresentation(this, display);
    preso.show();
}
```

`clearPreso()` should get rid of any outstanding `Presentation`. It is passed a boolean value, which will be true if we simply lost the `Display` we were using (and so the activity might want to display the `Presentation` contents elsewhere, such as in the

activity itself), or false if the activity is moving to the background (triggered via `onPause()`):

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

The implementations here are pretty much the same as the ones used in the previous example. `PresentationHelper` has handled all of the `Display`-management events – our activity can simply focus on showing or hiding the `Presentation` on demand.

Help When You Need It

In many respects, the `PresentationHelper` from the `CWAC-Presentation` project works a lot like the logic in the original `Presentation` sample's `MainActivity`, detecting various states and calling `showPreso()` and `clearPreso()` accordingly. However, `PresentationHelper` uses a different mechanism for this — `DisplayManager`.

The `PresentationHelper` constructor just stashes the parameters it is passed in data members and obtains a `DisplayManager` via `getSystemService()`, putting it in another data member:

```
public PresentationHelper(Context ctxt, Listener listener) {
    this.listener=listener;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        mgr=
            (DisplayManager)ctxt.getSystemService(Context.DISPLAY_SERVICE);
    }
}
```

`onResume()` calls out to a private `handlePreso()` method to initialize our state, and tells the `DisplayManager` to let it know as displays are attached and detached from the device, by means of `registerDisplayListener()`:

```
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        handleRoute();
        mgr.registerDisplayListener(this, null);
    }
}
```

```
}  
}
```

The PresentationHelper itself implements the DisplayListener interface, which requires three callback methods:

- onDisplayAdded() is called when a new output display is available
- onDisplayChanged() is called when an existing attached display changes its characteristics
- onDisplayRemoved() is called whenever a previously-attached output display has been detached

In our case, all three methods route to the same handleRoute() method, to update our state:

```
@Override  
public void onDisplayAdded(int displayId) {  
    handleRoute();  
}  
  
@Override  
public void onDisplayChanged(int displayId) {  
    handleRoute();  
}  
  
@Override  
public void onDisplayRemoved(int displayId) {  
    handleRoute();  
}
```

handleRoute() is where the bulk of the “business logic” of PresentationHelper resides:

```
private void handleRoute() {  
    if (isEnabled()) {  
        Display[] displays=  
            mgr.getDisplays(DisplayManager.DISPLAY_CATEGORY_PRESENTATION);  
  
        if (displays.length == 0) {  
            if (current != null || isFirstRun) {  
                listener.clearPreso(true);  
                current=null;  
            }  
        }  
        else {  
            Display display=displays[0];  
  
            if (display != null && display.isValid()) {  
                if (current == null) {
```

```
        listener.showPreso(display);
        current=display;
    }
    else if (current.getDisplayId() != display.getDisplayId()) {
        listener.clearPreso(true);
        listener.showPreso(display);
        current=display;
    }
    else {
        // no-op: should already be set
    }
}
else if (current != null) {
    listener.clearPreso(true);
    current=null;
}
}

isFirstRun=false;
}
```

We get the list of attached displays from the `DisplayManager` by calling `getDisplays()`. By passing in `DISPLAY_CATEGORY_PRESENTATION`, we are asking for returned array of `Display` objects to be ordered such that the preferred display for presentations is the first element.

If the array is empty, and we already had a current `Display` from before (or if this is the first time `handlePreso()` has run), we call `clearPreso()` to inform the listener that there is no `Display` for presentation purposes.

If we do have a valid `Display`:

- If we were not displaying anything before, we call `showPreso()` to inform the listener to start displaying things, plus keep track of the current `Display` in a data member
- If we were displaying something before, but now the preferred `Display` for a Presentation is different (the ID value of the `Display` objects differ), we call `clearPreso()` and `showPreso()` to get the listener to switch to the new `Display`
- Otherwise, this was a spurious call to `handlePreso()`, so we do not do anything of note

If, for whatever reason, the best `Display` is not valid, we do the same thing as if we had no `Display` at all: call `clearPreso()`.

Finally, in `onPause()`, we call `clearPreso()` to ensure that we are no longer attempting to display anything, plus call `unregisterDisplayListener()` so we are no longer informed about changes to the mix of `Display` objects that might be available:

```
public void onPause() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        listener.clearPreso(false);
        current=null;

        mgr.unregisterDisplayListener(this);
    }
}
```

Presentations and Configuration Changes

One headache when using `Presentation` comes from the fact that it is a `Dialog`, which is owned by an `Activity`. If the device undergoes a configuration change, the activity will be destroyed and recreated by default, forcing you to destroy and recreate your `Dialog`. This, in turn, causes flicker on the external display, as the display briefly reverts to mirroring while this goes on.

Devices that support external displays may be orientation-locked to landscape when an external display is attached (e.g., an HDMI cable is plugged in). This reduces the odds of a configuration change considerably, as the #1 configuration change is an orientation change. However, that is not a guaranteed “feature” of Android external display support, and there are other configuration changes that could go on (e.g., devices gets plugged into a keyboard dock).

You can either just live with the flicker, or use `android:configChanges` to try to avoid the destroy/re-create cycle for the configuration change. As was noted back in [the chapter on configuration changes](#), this is a risky approach, as it requires you to remember all your resources that might change on the configuration change and reset them to reflect the configuration change.

A “middle ground” approach is to ensure that your activity running the `Presentation` is orientation-locked to landscape mode, by adding `android:orientation="landscape"` to your `<activity>` in the manifest, then use `android:configChanges` to handle the configuration changes related to orientation:

- `orientation`
- `keyboardHidden`

- screenSize
- screenLayout

For those configuration changes, nothing should be needed to be modified in your activity, since you want to be displaying in landscape all of the time, and so you will not need to modify your use of resources. This leaves open the possibility of other configuration changes that would cause flicker on the external display, but those are relatively unlikely to occur while your activity is in the foreground, and so it may not be worth trying to address the flicker in all those cases.

Presentations as Fragments

Curiously, the support for Presentation is focused on View. There is nothing built into Android 4.2 that ties a Presentation to a Fragment. However, this can be a useful technique, one we can roll ourselves... with a bit of difficulty.

The Reuse Reality

There will be a few apps that will only want to deliver content if there is a external display on which to deliver it. However, the vast majority of apps supporting external displays will do so optionally, still supporting regular Android devices with only primary screens.

In this case, though, we have a problem: we need to show that UI *somewhere* if there is no external display to show it on. Our only likely answer is to have it be part of our primary UI.

Fragments would seem to be tailor-made for this. We could “throw” a fragment to the external display if it exists, or incorporate it into our main UI (e.g., as another page in a ViewPager) if the external display does not exist, or even have it be shown by some separate activity on smaller-screen devices like phones. Our business logic will already have been partitioned between the fragments — it is merely a question of where the fragment shows up.

Presentations as Dialogs

The nice thing is that Presentation extends Dialog. We already have a DialogFragment as part of Android that knows how to display a Dialog populated by a Fragment implementation of onCreateView(). DialogFragment even knows how to handle either being part of the main UI *or* as a separate dialog.

Hence, one could imagine a `PresentationFragment` that extends `DialogFragment` and adds the ability to either be part of the main UI on the primary screen *or* shown on an external display, should one be available.

And, in truth, it is possible to create such a `PresentationFragment`, though there are some limitations.

The Context Conundrum

The biggest limitation comes back to the `Context` used for our UI. Normally, there is only one `Context` of relevance: the `Activity`. In the case of `Presentation`, though, there is a separate `Context` that is tied to the display characteristics of the external display.

This means that `PresentationFragment` must manipulate *two* `Context` values:

- The `Activity`, if the fragment should be part of our main UI
- Some other `Context` supplied by the `Presentation`, if the fragment should be displayed in the `Presentation` on the external display

This makes creating a `PresentationFragment` class a bit tricky... though not impossible. After all, if it *were* impossible, these past several paragraphs would not be very useful.

A `PresentationFragment` (and Subclasses)

The [Presentation/Fragment](#) sample project has the same UI as the `Presentation/Simple` project, if there is an external display. If there is only the primary screen, though, we will elect to display the `WebView` side-by-side with our `TextView` in the main UI of our activity. And, to pull this off, we will create a `PresentationFragment` based on `DialogFragment`.

Note that this sample project has its `android:minSdkVersion` set to 17, mostly to cut down on all of the “only do this if we are on API Level 17” checks and `@TargetApi()` annotations. Getting this code to work on earlier versions of Android is left as an exercise for the reader.

In a simple `DialogFragment`, we might just override `onCreateView()` to provide the contents of the dialog. The default implementation of `onCreateDialog()` would create an empty `Dialog`, to be populated with the `View` returned by `onCreateView()`.

SUPPORTING EXTERNAL DISPLAYS

In our `PresentationFragment` subclass of `DialogFragment`, though, we need to override `onCreateDialog()` to use a `Presentation` instead of a `Dialog`... if we have a `Presentation` to work with:

```
package com.commonware.android.preso.fragment;

import android.app.Dialog;
import android.app.DialogFragment;
import android.app.Presentation;
import android.content.Context;
import android.os.Bundle;
import android.view.Display;

abstract public class PresentationFragment extends DialogFragment {
    private Display display=null;
    private Presentation preso=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        if (preso == null) {
            return(super.onCreateDialog(savedInstanceState));
        }

        return(preso);
    }

    public void setDisplay(Context ctxt, Display display) {
        if (display == null) {
            preso=null;
        }
        else {
            preso=new Presentation(ctxt, display, getTheme());
        }

        this.display=display;
    }

    public Display getDisplay() {
        return(display);
    }

    protected Context getContext() {
        if (preso != null) {
            return(preso.getContext());
        }

        return(getActivity());
    }
}
```

We also expose `getDisplay()` and `setDisplay()` accessors, to supply the `Display` object to be used if this fragment will be thrown onto an external display.

`setDisplay()` also creates the `Presentation` object wrapped around the display, using the three-parameter `Presentation` constructor that supplies the theme to be used (in this case, using the `getTheme()` method, which a subclass could override if desired).

`PresentationFragment` also implements a `getContext()` method. If this fragment will be used with a `Display` and `Presentation`, this will return the `Context` from the `Presentation`. If not, it returns the `Activity` associated with this `Fragment`.

This project contains a `WebPresentationFragment`, that pours the same basic Android source code used elsewhere in this book for a `WebViewFragment` into a subclass of `PresentationFragment`:

```
package com.commonware.android.preso.fragment;

import android.annotation.TargetApi;
import android.os.Build;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebView;

public class WebPresentationFragment extends PresentationFragment {
    private WebView mWebView;
    private boolean mIsWebViewAvailable;

    /**
     * Called to instantiate the view. Creates and returns the
     * WebView.
     */
    @Override
    public View onCreateView(LayoutInflater inflater,
                            ViewGroup container,
                            Bundle savedInstanceState) {
        if (mWebView != null) {
            mWebView.destroy();
        }

        mWebView=new WebView(getContext());
        mIsWebViewAvailable=true;
        return mWebView;
    }

    /**
     * Called when the fragment is visible to the user and
     * actively running. Resumes the WebView.
     */
    @TargetApi(11)
    @Override
```

```
public void onPause() {
    super.onPause();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        mWebView.onPause();
    }
}

/**
 * Called when the fragment is no longer resumed. Pauses
 * the WebView.
 */
@TargetApi(11)
@Override
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        mWebView.onResume();
    }

    super.onResume();
}

/**
 * Called when the WebView has been detached from the
 * fragment. The WebView is no longer available after this
 * time.
 */
@Override
public void onDestroyView() {
    mIsWebViewAvailable=false;
    super.onDestroyView();
}

/**
 * Called when the fragment is no longer in use. Destroys
 * the internal state of the WebView.
 */
@Override
public void onDestroy() {
    if (mWebView != null) {
        mWebView.destroy();
        mWebView=null;
    }
    super.onDestroy();
}

/**
 * Gets the WebView.
 */
public WebView getWebView() {
    return mIsWebViewAvailable ? mWebView : null;
}
}
```

(and, as noted in Tutorial #9, where WebViewFragment was introduced, the flawed comments came from the original Android open source code from which this fragment was derived)

The only significant difference, besides the superclass, is that the onCreateView() method uses getContext(), not getActivity(), as the Context to use when creating the WebView.

And, the project has a SamplePresentationFragment subclass of WebPresentationFragment, where we use the factory-method-and-arguments pattern to pass a URL into the fragment to use for populating the WebView:

```
package com.commonware.android.preso.fragment;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class SamplePresentationFragment extends WebPresentationFragment {
    private static final String ARG_URL="url";

    public static SamplePresentationFragment newInstance(Context ctxt,
                                                         Display display,
                                                         String url) {
        SamplePresentationFragment frag=new SamplePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putString(ARG_URL, url);
        frag.setArguments(b);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=
            super.onCreateView(inflater, container, savedInstanceState);

        getWebView().loadUrl(getArguments().getString(ARG_URL));

        return(result);
    }
}
```

```
}  
}
```

Using PresentationFragment

Our activity's layout now contains not only a TextView, but also a FrameLayout into which we will slot the PresentationFragment if there is no external display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    xmlns:tools="http://schemas.android.com/tools"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:orientation="horizontal"  
    tools:context=".MainActivity">  
  
    <TextView  
        android:id="@+id/prose"  
        android:layout_width="0px"  
        android:layout_height="wrap_content"  
        android:layout_gravity="center"  
        android:layout_weight="1"  
        android:gravity="center"  
        android:text="@string/secondary"  
        android:textSize="40sp"/>  
  
    <FrameLayout  
        android:id="@+id/preso"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
        android:layout_weight="1"  
        android:visibility="gone"/>  
  
</LinearLayout>
```

Note that the FrameLayout is initially set to have gone as its visibility, meaning that only the TextView will appear. Based on the widths and weights, the TextView will take up the full screen when the FrameLayout is gone, or they will split the screen in half otherwise.

In the onCreate() implementation of our activity (MainActivity), we inflate that layout and grab both the TextView and the FrameLayout, putting them into data members:

```
@Override  
protected void onCreate(Bundle savedInstanceState) {  
    super.onCreate(savedInstanceState);  
  
    setContentView(R.layout.activity_main);  
}
```

```
inline=findViewById(R.id.preso);
prose=(TextView)findViewById(R.id.prose);
}
```

Our `onResume()` method, and our `RouteCallback`, are identical to those from the previous sample. Our `handleRoute()` method is *nearly* identical to the original, as is our `onPause()` method. The difference is that we need to distinguish whether we have lost an external display (and therefore want to move the Web page into the main UI) or if we are going away entirely (and therefore just wish to clean up the external display, if any). Hence, `clearPreso()` takes a boolean parameter (`switchToInline`), true if we want to show the fragment in the main UI, false otherwise. And, our `onPause()` and `handleRoute()` methods pass the appropriate value to `clearPreso()`:

```
@Override
protected void onPause() {
    clearPreso(false);

    if (router != null) {
        router.removeCallback(cb);
    }

    super.onPause();
}

private void handleRoute(RouteInfo route) {
    if (route == null) {
        clearPreso(true);
    }
    else {
        Display display=route.getPresentationDisplay();

        if (route.isEnabled() && display != null) {
            if (preso == null) {
                showPreso(route);
                Log.d(getClass().getSimpleName(), "enabled route");
            }
            else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
                clearPreso(true);
                showPreso(route);
                Log.d(getClass().getSimpleName(), "switched route");
            }
            else {
                // no-op: should already be set
            }
        }
        else {
            clearPreso(true);
            Log.d(getClass().getSimpleName(), "disabled route");
        }
    }
}
```

```
}  
}
```

`showPreso()` is called when we want to display the Presentation on the external display. Hence, we need to remove the `WebPresentationFragment` from the main UI if it is there:

```
private void showPreso(RouteInfo route) {  
    if (inline.getVisibility() == View.VISIBLE) {  
        inline.setVisibility(View.GONE);  
        prose.setText(R.string.secondary);  
  
        Fragment f=getFragmentManager().findFragmentById(R.id.preso);  
  
        getFragmentManager().beginTransaction().remove(f).commit();  
    }  
  
    preso=buildPreso(route.getPresentationDisplay());  
    preso.show(getFragmentManager(), "preso");  
}
```

Creating the actual `PresentationFragment` is delegated to a `buildPreso()` method, which employs the `newInstance()` method on the `SamplePresentationFragment`:

```
private PresentationFragment buildPreso(Display display) {  
    return(SamplePresentationFragment.newInstance(this, display,  
                                                "http://commonsware.com"));  
}
```

`clearPreso()` is responsible for *adding* the `PresentationFragment` to the main UI, if `switchToInline` is true:

```
private void clearPreso(boolean switchToInline) {  
    if (switchToInline) {  
        inline.setVisibility(View.VISIBLE);  
        prose.setText(R.string.primary);  
        getFragmentManager().beginTransaction()  
            .add(R.id.preso, buildPreso(null)).commit();  
    }  
  
    if (preso != null) {  
        preso.dismiss();  
        preso=null;  
    }  
}
```

With an external display, the results are visually identical to the original sample. Without an external display, though, our UI is presented side-by-side:

Figure 641: Nexus 10, With Inline PresentationFragment

Limits

This implementation of `PresentationFragment` has its limitations, though.

First, we cannot reuse the same fragment *instance* for both the inline UI and the `Presentation` UI, as they use different `Context` objects. Hence, production code will need to arrange to get data out of the old fragment instance and into the new instance when the screen mix changes. You might be able to leverage `onSaveInstanceState()` for that purpose, with a more-sophisticated implementation of `PresentationFragment`.

Also, depending upon the device and the external display, you *may* see multiple calls to `handleRoute()`. For example, attaching an external display may trigger three calls to your `RouteCallback`, for an attach, a detach, and another attach event. It is unclear why this occurs. However, it may require some additional logic in your app to deal with these events, if you encounter them.

Another Sample Project: Slides

At the 2013 Samsung Developer Conference, the author of this book delivered [a presentation on using Presentation](#). Rather than use a traditional presentation package driven from a notebook, the author used [the Presentation/Slides sample app](#). This sample app shows how to show slides on an external display, controlled by a ViewPager on a device's touchscreen.

What the audience saw, through most of the presentation, were simple slides. What the presenter saw was a ViewPager, with tabs, along with action bar items for various actions:

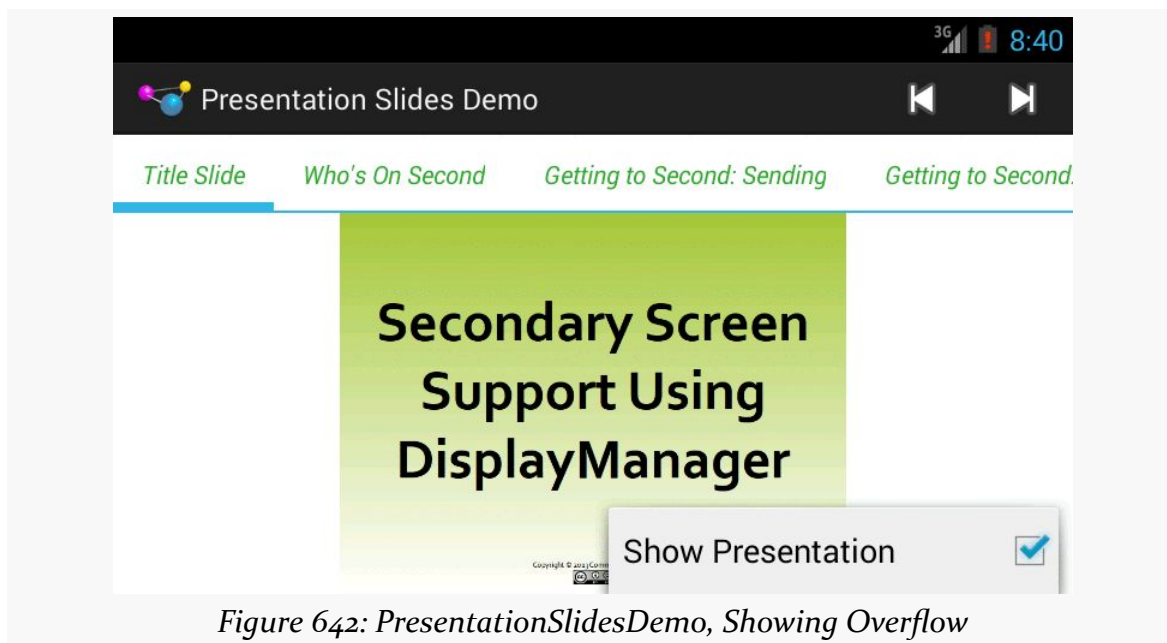

Figure 642: PresentationSlidesDemo, Showing Overflow

The Slides

The slides themselves are a series of 20 drawable resources (img0, img1, etc.), put into the `res/drawable-nodpi/` resource directory, as there is no intrinsic “density” that the slides were prepared for. As we use the slides in `ImageView` widgets, their images will be resized to fit the available `ImageView` space alone, not taking screen density into account.

There is a matching set of 20 string resources (title0, title1, etc.) containing a string representation of the slide titles, for use with getPageTitle() of a PagerAdapter.

The PagerAdapter

That PagerAdapter, named SlidesAdapter, has each slide be visually represented by an ImageView widget. In this case, SlidesAdapter extends PagerAdapter directly, skipping fragments:

```
package com.commonware.android.preso.slides;

import android.content.Context;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;

class SlidesAdapter extends PagerAdapter {
    private static final int[] SLIDES= { R.drawable.img0,
        R.drawable.img1, R.drawable.img2, R.drawable.img3,
        R.drawable.img4, R.drawable.img5, R.drawable.img6,
        R.drawable.img7, R.drawable.img8, R.drawable.img9,
        R.drawable.img10, R.drawable.img11, R.drawable.img12,
        R.drawable.img13, R.drawable.img14, R.drawable.img15,
        R.drawable.img16, R.drawable.img17, R.drawable.img18,
        R.drawable.img19 };
    private static final int[] TITLES= { R.string.title0,
        R.string.title1, R.string.title2, R.string.title3,
        R.string.title4, R.string.title5, R.string.title6,
        R.string.title7, R.string.title8, R.string.title9,
        R.string.title10, R.string.title11, R.string.title12,
        R.string.title13, R.string.title14, R.string.title15,
        R.string.title16, R.string.title17, R.string.title18,
        R.string.title19 };
    private Context ctxt=null;

    SlidesAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);

        page.setImageResource(getPageResource(position));
        container.addView(page,
            new ViewGroup.LayoutParams(
ViewGroup.LayoutParams.MATCH_PARENT,
```

```
ViewPager.LayoutParams.MATCH_PARENT));  
  
    return(page);  
}  
  
@Override  
public void destroyItem(ViewGroup container, int position,  
                        Object object) {  
    container.removeView((View)object);  
}  
  
@Override  
public int getCount() {  
    return(SLIDES.length);  
}  
  
@Override  
public boolean isViewFromObject(View view, Object object) {  
    return(view == object);  
}  
  
@Override  
public String getPageTitle(int position) {  
    return(ctxt.getString(TITLES[position]));  
}  
  
int getPageResource(int position) {  
    return(SLIDES[position]);  
}  
}
```

The data for the SlidesAdapter consists of a pair of static int arrays, one holding the drawable resource IDs, one holding the string resource IDs.

Of note, SlidesAdapter has a getPageResource() method, to return the drawable resource ID for a given page position, which is used by instantiateItem() for populating the position's ImageView.

The PresentationFragment

We also want to be able to show the slide on an external display via a Presentation. As with the preceding sample app, this one uses a PresentationFragment, here named SlidePresentationFragment:

```
package com.commonware.android.preso.slides;  
  
import android.content.Context;  
import android.os.Bundle;  
import android.view.Display;  
import android.view.LayoutInflater;
```

```
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonware.cwac.preso.PresentationFragment;

public class SlidePresentationFragment extends PresentationFragment {
    private static final String KEY_RESOURCE="r";
    private ImageView slide=null;

    public static SlidePresentationFragment newInstance(Context ctxt,
                                                         Display display,
                                                         int initialResource) {
        SlidePresentationFragment frag=new SlidePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putInt(KEY_RESOURCE, initialResource);
        frag.setArguments(b);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        slide=new ImageView(getContext());

        setSlideContent(getArguments().getInt(KEY_RESOURCE));

        return(slide);
    }

    void setSlideContent(int resourceId) {
        slide.setImageResource(resourceId);
    }
}
```

Here, in addition to the sort of logic seen in the preceding sample app, we also need to teach the fragment which image it should be showing at any point in time. We do this in two ways:

1. We pass in an int named `initialResource` to the factory method, where `initialResource` represents the image to show when the fragment is first displayed. That value is packaged into the arguments `Bundle`, and `onCreateView()` uses that value.

2. Actually putting the drawable resource into the ImageView for this Presentation is handled by `setSlideContent()`. This is called by `onCreateView()`, passing in the `initialResource` value.

The Activity

The rest of the business logic for this application can be found in its overall entry point, `MainActivity`.

Setting Up the Pager

`onCreate()` of `MainActivity` is mostly focused on setting up the `ViewPager`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ViewPagerIndicator tabs=(ViewPagerIndicator)findViewById(R.id.titles);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SlidesAdapter(this);
    pager.setAdapter(adapter);
    tabs.setViewPager(pager);
    tabs.setOnPageChangeListener(this);

    helper=new PresentationHelper(this, this);
}
```

The `ViewPager` and our `SampleAdapter` are saved in data members of the activity, for later reference. We also wire in a `TabPageIndicator`, from the `ViewPagerIndicator` library, and arrange to get control in our `OnPageChangeListener` methods when the page changes (whether via the tabs or via a swipe on the `ViewPager` itself).

`onCreate()` also hooks up a `PresentationHelper`, following the recipe used elsewhere in this chapter. And, as `PresentationHelper` requires, we forward along the `onResume()` and `onPause()` events to it:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
```

```
helper.onPause();
super.onPause();
}
```

Setting Up the Presentation

In the `showPreso()` method, required by the `PresentationHelper.Listener` interface, we create an instance of `SlidePresentationFragment`, passing in the resource ID of the current slide, as determined by the `ViewPager`:

```
@Override
public void showPreso(Display display) {
    int drawable=adapter.getPageResource(pager.getCurrentItem());

    preso=
        SlidePresentationFragment.newInstance(this, display, drawable);
    preso.show(getFragmentManager(), "preso");
}
```

We then `show()` the `PresentationFragment`, causing it to appear on the attached `Display`.

The corresponding `clearPreso()` method follows the typical recipe of calling `dismiss()` on the `PresentationFragment`, if one exists:

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

Controlling the Presentation

However, the `SlidesPresentationFragment` now is showing the slide that was current when the `Display` was discovered or attached. What happens if the user changes the slide, using the `ViewPager`?

In that case, our `OnPageChangeListener` `onPageSelected()` method will be called, and we can update the `SlidesPresentationFragment` to show the new slide:

```
@Override
public void onPageSelected(int position) {
    if (preso != null) {
        preso.setSlideContent(adapter.getPageResource(position));
    }
}
```

```
}  
}
```

Offering an Action Bar

The activity also sets up the action bar with three items:

```
<?xml version="1.0" encoding="utf-8"?>  
<menu xmlns:android="http://schemas.android.com/apk/res/android">  
  
    <item  
        android:id="@+id/first"  
        android:icon="@android:drawable/ic_media_previous"  
        android:showAsAction="always"  
        android:title="@string/first">  
    </item>  
    <item  
        android:id="@+id/last"  
        android:icon="@android:drawable/ic_media_next"  
        android:showAsAction="always"  
        android:title="@string/last">  
    </item>  
    <item  
        android:id="@+id/present"  
        android:checkable="true"  
        android:checked="true"  
        android:showAsAction="never"  
        android:title="@string/show_presentation">  
    </item>  
</menu>
```

Two, first and last, simply set the ViewPager position to be the first or last slide, respectively. This will also update the SlidesPresentationFragment, as onPageSelected() is called when we call setCurrentItem() on the ViewPager.

```
@Override  
public boolean onCreateOptionsMenu(Menu menu) {  
    getMenuInflater().inflate(R.menu.activity_actions, menu);  
  
    return(super.onCreateOptionsMenu(menu));  
}  
  
@Override  
public boolean onOptionsItemSelected(MenuItem item) {  
    switch (item.getItemId()) {  
        case R.id.present:  
            boolean original=item.isChecked();  
  
            item.setChecked(!original);  
    }  
}
```

```
        if (original) {
            helper.disable();
        }
        else {
            helper.enable();
        }

        break;

    case R.id.first:
        pager.setCurrentItem(0);
        break;

    case R.id.last:
        pager.setCurrentItem(adapter.getCount() - 1);
        break;
}

return(super.onOptionsItemSelected(item));
}
```

The other action bar item, `present`, is a checkable action bar item, initially set to be checked. This item controls what we are showing on the external display:

- If it is checked, we want to show our Presentation
- If it is unchecked, we want to revert to default mirroring

The theory here is that, in a presentation, we could switch from showing the slides to showing the audience what the presenter has been seeing all along.

Switching between Presentation and default mirroring is a matter of calling `enable()` (to show a Presentation) or `disable()` (to revert to mirroring) on the `PresentationHelper`.

Device Support for Presentation

Alas, there is a problem: not all Android 4.2 devices support Presentation, even though they support displaying content on external displays. Non-Presentation devices simply support classic mirroring.

Generally speaking, it appears that devices that *shipped* with Android 4.2 and higher will support Presentation, assuming that they have some sort of external display support (e.g., MHL). Devices that were *upgraded* to Android 4.2 are less likely to support Presentation.

Unfortunately, at the present time, there is no known way to detect whether or not Presentation will work, let alone any means of filtering on this capability in the Play Store via <uses-feature>. With luck, [this issue](#) will be addressed in the future.

Presentations from a Service

Since Presentation inherits from Dialog, it also “inherits” one of the limitations of Dialog: you can only show one from an Activity. In many cases, that is not a big problem. If you are using the external display as an adjunct to your own app’s use of the primary touchscreen, you would be using an activity anyway. However, it does prevent one from using Presentation to, say, implement a video player app that plays on an external display but does not tie up the touchscreen, so the user can use other apps while the video plays.

However, as it turns out, it is possible to drive the content of an external display from a background app... just not by using a Presentation.

The details of this are a bit tricky, derived from [one Stack Overflow answer](#) and another [Stack Overflow question](#).

However, you do not need to deal with all of the details, courtesy of PresentationService.

PresentationService is a class in the [CWAC-Presentation library](#). PresentationService clones some of the logic from Presentation and Dialog, enough to allow you to define a View that will be shown on external display, driven by a Service. PresentationService is an abstract base class for you to extend, where PresentationService handles showing your content on an external display, and you simply manage that content.

The CWAC-Presentation library has [a demoService/ directory](#) containing a sample use of PresentationService. The recipe is fairly simple and is outlined in the following sections.

Step #1: Attach the Libraries

The [CWAC-Presentation README](#) contains instructions for attaching the libraries to your project, whether via Gradle dependencies, downloading a pair of JARs, or using the source form of the Android library project.

Step #2: Add an Icky Permission

Perhaps the biggest limitation at this time for `PresentationService` is that you need to request the `SYSTEM_ALERT_WINDOW` permission. This permission is what allows services to draw windows over top of the foreground UI. In this case, we actually are not doing that — we are drawing on an external display. However, the check for this permission does not take this into account, so we need it, at least until and unless some future version of Android removes this requirement.

Step #3: Create a Stub `PresentationService`

As is noted above, `PresentationService` is an abstract class, so you will need to create your own concrete subclass of it, under whatever name you wish. And, as with any service, you will need a `<service>` element in the manifest. None of this is especially unusual.

The sample app is a service-based rendition of [the `Presentation/Slides` sample app](#) described earlier in this chapter. It has a `SlideshowService` that will display the slideshow on an external display from the background, switching slides every five seconds.

Step #4: Return the Theme

One of the abstract methods that you will need to implement is `getThemeId()`. This should return the value of the style resource that represents the theme that you wish to use for the widgets you are going to show on the external display.

For example, if your project uses the `@style/AppTheme` approach that is code-generated for you, you can simply return `R.style.AppTheme` from `getThemeId()`, as the sample app does:

```
@Override
protected int getThemeId() {
    return(R.style.AppTheme);
}
```

Step #5: Build the View

The other abstract method you need to implement is `buildPresoView()`. You are passed a `Context` and a `LayoutInflater`, and your job is to use those to build your

UI for the external display, returning the root view. The `LayoutInflater` is already set up to use the theme you provided via `getThemeId()`.

Since this will be called shortly before showing the result on the external display, you can also take this time to initialize other aspects of your presentation. For example, the `SlideshowService` implements `Runnable` and has a `Handler` for the main application thread, initialized in `onCreate()`:

```
private Handler handler=null;

@Override
public void onCreate() {
    handler=new Handler(Looper.getMainLooper());
    super.onCreate();
}
```

`buildPresoView()` not only returns an `ImageView` for the slides, but also calls `run()`, which populates the `ImageView` and calls `postDelayed()` on the `Handler` to schedule `run()` to be called again in five seconds, thereby arranging to update the slide every five seconds:

```
@Override
protected View buildPresoView(Context ctxt, LayoutInflater inflater) {
    iv=new ImageView(ctxt);
    run();

    return(iv);
}

@Override
public void run() {
    iv.setImageResource(SLIDES[iteration % SLIDES.length]);
    iteration+=1;

    handler.postDelayed(this, 5000);
}
```

`onDestroy()` calls `removeCallbacks()` to break the `Handler postDelayed()` loop:

```
@Override
public void onDestroy() {
    handler.removeCallbacks(this);

    super.onDestroy();
}
```

Step #6: Start and Stop the Service

Calling `startService()` on your service will then trigger the presentation. Or, more accurately, it will trigger `PresentationService` to work with a `PresentationHelper` to determine when a presentation should be shown. `PresentationService` will then use `buildPresoView()` to populate the external display. Conversely, calling `stopService()` will stop the presentation.

It is up to you to determine what is the trigger for these calls. The sample app simply starts the service immediately when run and stops the service in response to an action bar item click.

While the service is running, you are welcome to use an [event bus](#) or other means to control the contents of the presentation, by manipulating the widgets you created in `buildPresoView()`.

Note that it is safe to call `startService()` on the service multiple times, if you do not know whether the service is already running and need to ensure that it is running now.

Hey, What About Chromecast?

In February 2014, Google released a long-awaited SDK to allow anyone to write an app that connects to [Chromecast](#), Google's streaming-media HDMI stick. A natural question coming out of that is whether `Presentation` and `DisplayManager` work with Chromecast.

The answer is: not presently.

While Chromecast may physically resemble a wireless display adapter, in truth it is its own device, running a customized mashup of Android and ChromeOS. Chromecast's strength is in playing streaming media from any source, primarily directly off of the Internet. The expectation with the Chromecast SDK is that apps are telling the Chromecast what to stream from, not streaming to the Chromecast itself. As such, the API for Chromecast is distinctly different from that of `Presentation`, and while the two both deal with what the Android device would consider an external display, they are not equivalent solutions.

More coverage of Chromecast can be found in [the next chapter](#).

Google Cast and Chromecast

A popular target for MediaRouter, in some countries, is Chromecast, Google's lightweight streaming media player for televisions and other HDMI displays. Originally, Chromecast was a “closed box”, with no official support for third-party apps (and active work to block unofficial support). In early 2014, though, Google finally opened up Chromecast to developers.

This chapter covers what it takes to enable an Android app to “cast” content to a Chromecast, possibly as part of a broader external display strategy.

Prerequisites

In addition to the core chapters, you should read [the chapter on MediaRouter](#) before reading this chapter.

Here a Cast, There a Cast

You will see two terms used in this chapter and in the online literature regarding all of this: Chromecast and “Google Cast”. Despite the similarities in their names, these are fairly distinct items.

What is Chromecast?

Chromecast, as noted earlier in this chapter, is a streaming media receiver, sold by Google under their own brand.

Figure 643: Google Chromecast

It plugs into an HDMI port of a television or similar display, plus uses micro USB for supplying power.

However, rather than other streaming media receivers, that use Bluetooth or IR (infrared) peripherals for controlling the playback, Chromecast appears to use WiFi, designed to be controlled by a smartphone, tablet, or Chrome Web browser.

Chromecast itself runs its own OS, apparently a hybrid of Android and ChromeOS.

What is Google Cast?

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps (“senders”) can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream.

Google Cast could, in theory, be “baked into” displays (such as a television), in addition to being supported by dedicated media receivers like the Chromecast.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not “locked into” having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

Common Chromecast Development Notes

Chromecast goes to sleep if it detects that it is plugged into a television or monitor that is turned off (or perhaps even not accepting input from the HDMI port the Chromecast is using). While it is in this sleep mode, it may not appear as an available route. You may need to keep the display active to allow Chromecast to work properly. A 720p-capable pico projector, such as [the Vivitek Qumi series](#), can be a handy way to have a test display for Chromecast (or for live video media routes) at your development station, without the bulk of another monitor, if you have a handy surface to project upon.

Also, note that a Chromecast “uses Google’s DNS regardless of what you have defined locally”, according to [a Google engineer](#). That will preclude you from using any local domains on an organization’s own DNS server, without some tricky firewall configuration to route Google DNS requests to the in-house DNS server. Similarly, you cannot use machine names as pseudo-domain names, the way you might be able to using a regular Web browser.

Your API Choices

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in [the chapter on MediaRouter](#). The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use [the Cast SDK](#). This SDK is part of the Play Services framework, not part of Android itself. It also works solely with Google Cast devices, of which Chromecast is the only known example, whereas other sorts of devices are able to publish remote playback media routes. Hence, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

This chapter will focus on the Cast SDK. See [the chapter on MediaRouter](#) for coverage of `RemotePlaybackClient`.

Senders and Receivers

There are three major components to the Google Cast environment:

- The sources of streaming media, usually out on the Internet
- The software on the playback device that plays that streaming media (“receiver”)
- The software on the control device (phone, tablet, Chrome Web browser) that directs the receiver about what to play and when (“sender”)

The Sender App

The sender app is responsible for allowing the user to choose some media to play, then to control the actual playback (pause, start, stop, rewind, fast-forward, etc.).

The details of how to choose some media will depend heavily on the nature of the sender app. For example, a subscription-based streaming video service, such as Netflix, would allow the user to browse and search eligible content hosted by Netflix itself. Netflix presumably has its own Web service APIs that its own sender app would use for this purpose, and it is up to Netflix to offer a sensible UI for choosing a piece of media to watch.

Passing a reference (e.g., URL) to the receiver, and issuing control commands, will either be handled by `RemotePlaybackClient` (on Android) or via a Google-supplied SDK (for Android, iOS, or Chrome Web apps).

The Receiver

The details of how a receiver is implemented is up to the manufacturer of the Google Cast-enabled device. In the case of Chromecast, it is a version of the Chrome Web browser. In principle, the implementation could be anything; in practice, it is likely that the same basic software stack will be used, courtesy of licensing Google Cast technology from Google for streaming media devices.

Official Google Cast receiver software comes in three flavors: default, styled, and custom.

Default Receiver

The default receiver is what you get by default, as you might have guessed. If you do nothing else, your sender will be communicating with the default receiver. In effect, the default receiver is a specific Chrome Web app, running on the Chrome browser inside of the Chromecast, that is responsible for playback of your chosen media.

Other than providing the URLs to the media, plus requests to pause, start, stop, etc. the playback, you have no control over the default receiver, particularly from a look-and-feel standpoint.

Styled Receiver

A styled receiver is one where you, the developer, supply light branding information that is applied to what otherwise is the default receiver, such as a logo.

Whereas using the default receiver requires no explicit registration with Google, using the styled receiver does require you to register your sender app with Google, at which point you will be able to provide a URL pointing to a CSS file that contains the custom styles.

Custom Receiver

If you would rather replace the default receiver functionality with your own, either to offer more functionality, or to consume media types that may require additional configuration (e.g., DRM), you can create a custom receiver. This, in effect, is a Chrome Web app, where you provide not only CSS, but the HTML and JavaScript as well. This is substantially more complicated, and it requires registration with Google (as with the styled receiver). However, you have far greater control over what appears on the television.

Supported Media Types

The [list of supported media types](#) is likely to change over time. At present, Google Cast-enabled devices are supposed to support major media types, such as:

- MP4 and VP8 for video
- MP3, AAC, and Ogg Vorbis for audio
- PNG, JPEG, GIF, BMP, and WEBP for still images (e.g., photos)
- HLS and MPEG-DASH for streaming

Cast SDK Dependencies

Using the Cast SDK to develop for Google Cast devices has a fair number of dependencies... and not just dependencies on particular libraries.

Developer Registration

If you are going to be using the default receiver, *and* you do not need to have debugging access to the device (e.g., to examine JavaScript logs from the Web rendering engine on the Google Cast device), you are welcome to develop your apps independently.

However, if you will use a styled or custom receiver, or you wish to gain debugging access to the device, you will need to [register with Google](#).

This process will involve you agreeing to some terms of service (see below), along with paying a \$5 registration fee.

The Terms of Service

The Google Cast SDK has separate [Developer Terms of Service](#) from anything else. If you are going to use the Google Cast SDK, you will be expected to agree to these terms as part of the registration processes. You are strongly encouraged to review these terms with qualified legal counsel. Failure to comply with the terms may cause your app (or, more accurately, your styled or custom receivers) to “be de-registered”, presumably meaning that it will no longer work.

These terms contain some curious clauses, worth discussing with your attorney, including a requirement to adhere to a massive [design checklist](#), controlling the look-and-feel of your sender and receiver. This includes a specific requirement for the precise icon to be used for initiating communications with the Google Cast receiver. Those agreeing to these terms are also barred from doing things that might allow others to display content on a Google Cast receiver without using the SDK or breaking through any access controls on the Google Cast device (e.g., creating an exploit that roots it).

Device Registration and Development Setup

While registering your device is optional, it may be handy for custom receivers, so that you can debug your custom HTML and JavaScript that is being rendered by the Google Cast device.

First, you should configure your device to publish its serial number to Google when it checks for Google Cast software updates. For the Chromecast, this involves using whatever means you used to configure the Chromecast in the first place for your network (e.g., [the Chromecast Android app](#)). There should be an option for “Send this Chromecast’s serial number when checking for updates” — in the Chromecast Android app, this will be in the “Share Data” section of the device’s settings screen.

Once you have registered as a Cast SDK developer, the [Google Cast SDK Developer Console](#) will have an option for you to “Add New Device”. You will need the Google Cast device’s serial number — in the case of the Chromecast, this is etched on the underside of the device.

Note that it may take some time before your device registration will be complete, as the device will not find out about the registration until it checks for another update, and there does not appear to be a way to trigger this. Hence, you may need to wait a few hours. You will know that you have access once you can successfully connect, via a Web browser, to port 9222 on the IP address of the Google Cast device. For the Chromecast, the easiest way to get that IP address is through your Chromecast configuration tool (e.g., the Chromecast Android app). Note that the Web page may not be much (e.g., “Inspectable WebContents”), but it will not return a 404 or similar error code.

If you wish to use a styled or custom receiver, you will also need to register your application, in the same Cast SDK Console area. This will be covered in a future edition of this book.

The Official Libraries

You will need the Google Play Services SDK, which you may have used already for other portions of the Play Services framework, such as [GCM](#), [Maps V2](#), and so on.

You will also need the same mediarouter Android library project covered in [the chapter on MediaRouter](#), along with its dependencies (e.g., the support-v4 library and the appcompat library).

The CastCompanionLibrary... Or Not

The Play Services SDK (and its dependencies) is all that you need to write Cast SDK applications. However, Google has also published [the Cast Companion Library \(CCL\)](#), containing a lot of helper code to make it a bit easier for you to write apps that adhere to the [design checklist](#)

Developing Google Cast Apps

Coverage of the Cast SDK, including sample apps, will be added to this chapter in a future edition of this book.

The “Ten-Foot UI”

Increasingly, Android devices are being used to drive screens that are somewhat larger than those found on your average phone or tablet:

- Many Android phones and tablets [can directly deliver content to TVs, monitors, and projectors](#) via HDMI, MHL, SlimPort, Miracast, and similar technologies
- Android devices can control the behavior of non-Android presentation engines, like [Chromecast](#)
- Some Android devices themselves use a TV or other display as their primary screen, from big names ([Google](#) and [Amazon](#)), mid-range firms (OUYA), and firms you have never heard of (various Android “HDMI sticks” available on eBay, Alibaba, etc.)

Technically, writing for these displays is a bit different than you would do for a phone or tablet. In some cases, such as with Google Cast, writing for these displays is more substantially different.

However, in all cases, the design of the UI needs to be different, owing to different physical and usage characteristics of large screens. This chapter will focus on this so-called “ten-foot UI” and help you understand what sorts of changes will need to be considered.

Prerequisites

Understanding this chapter requires that you have read the chapter on [focus management](#).

The sample of the “leanback” UI is a revised version of a sample app profiled in [the chapter on the MediaStore ContentProvider](#).

What is the “Ten-Foot UI”?

The “ten-foot UI” is not referring to a UI that is 3.048 meters high or $9.87789527 \times 10^{-17}$ parsecs wide.

Rather, the distance referred to by the “ten-foot UI” indicates the approximate distance between the viewer and the screen. People usually sit farther from TVs, monitors, and projectors than they do phones or tablets when using them. Partly, that is because the screens are a lot bigger, so they do not need to sit as closely. Partly, that is because often times the screens are being “used” by more than one person (e.g., an audience watching a presentation on a projector), and everybody needs to be able to see the screen.

The expression “ten-foot UI” refers to the design constraints inherent in developing user interfaces to be used across such a distance. Even though the screen may be bigger, the *apparent* screen size (or “[visual angle](#)” may be no bigger than phones or tablets, or sometimes even less. That, plus user input differences, technical differences between TVs and other displays, and so on all go into the “ten-foot UI” design guidance that UI experts give us.

Overscan

Television standards have been with us for several decades. Television sets from the dawn of television had significantly lower and more variable quality than today’s devices. The delivery of the signal at the outset had significantly lower and more variable quality than today’s over-the-air HDTV or cable connections. As a result of these two characteristics, the engineers devising television standards made some decisions that, while necessary at the time, add some complexity to delivering apps to televisions, in the form of overscan.

Simply put, not all televisions show exactly the same picture. Depending on device and signal, a television may show up to 12% less of the picture, as measured horizontally and vertically. Hence, the theoretical ideal screen size (e.g., 720p = 1280 x 720 pixels) may be achieved in some cases, but you may get less (e.g., 1128 x 634 pixels) in other cases.

Android TV and Fire TV ignore overscan, relying upon developers to take it into account. As a result, the reported screen resolution is *not* necessarily available to you. Instead, you need to avoid putting anything important in the outer ~10% of the screen, centering the important stuff within the available space.

So, for example, you might have a background for your game (e.g., a starfield). Make sure that there is nothing essential on the background image that the user must see that is along the outside edge. Then, if part of the background is lost due to overscan, there is no particular problem.

The bigger issue, of course, is standard foreground widgets and containers. Android developers are used to being able to have layouts that work edge-to-edge, with just a minor amount of margin so text, icons, and the like do not run right into the edge of the screen. Now, you need more than a “minor amount” of margin. Google and Amazon recommend a 27dp margin on the top and bottom sides of your activities, and a 48dp margin on the left and right sides of your activities.

For activity and fragment layouts that are dedicated for TV presentation, you could elect to put those margins in those layouts, or add them via a theme. However, for activity and fragment layouts that may be used both for a touchscreen device (phone or tablet) and a television, adding the margin on the touchscreen device may be unsuitable.

For that, you could use dimension resources in different resource sets. Define `overscan_horizontal` and `overscan_vertical` to be both 0dp (or whatever) in `res/values/dimens.xml`. Define them to be 48dp and 27dp, respectively, in `res/values-television/dimens.xml`, where `-television` is a resource set qualifier that will be used in Android TV and other TV-based Android devices. Then, you can refer to `@dimen/overscan_horizontal` and `@dimen/overscan_vertical` in activity/fragment layouts, to take overscan into account conditionally.

Navigation

Most televisions, monitors, and projectors are not touchscreens. Users will be changing what is shown either by using some sort of remote control (e.g., Fire TV, Android TV) or by using an app that runs on a touchscreen device (e.g., direct monitor connection, Chromecast).

In the remote control scenarios, in-screen navigation becomes important. Those remote controls usually focus on some sort of D-pad or arrow keys for moving focus

and clicking on widgets. This forces users into a sequential-access model (e.g., click “left” three times then “enter” once) rather than the random-access model that touchscreens offer.

The chapter on [focus management](#) covers these sorts of concerns. Bear in mind that getting focus management implemented properly in your app not only helps with the “ten-foot UI”, but also can help other sorts of users, such as the visually impaired or motion impaired who cannot readily use touchscreens.

Also note that text input is a significant chore when you try to do it using a remote control. Hence, even to the extent it is possible, try to limit the number of places that users *have* to type into EditText widgets and the like in your UI. If possible, offer a way for users to do that sort of thing via a separate app on their phone or tablet, or perhaps through a Web browser that pushes the information to the TV set-top box.

Stylistic Considerations

In addition to structural issues like overscan and focus management, there are some stylistic issues that you will need to take into account when designing your ten-foot UI.

Fonts

With phones and tablets, if the user has some difficulty reading a bit of text, they can usually fix the problem just by moving their hand a bit, to bring the screen closer.

That becomes less likely of a solution as you get into larger screens. People get annoyed if they have to get up off of their sofa to squint and try to read text on a television. In a presentation setting, people may be unable to move into a better viewing position.

To combat this:

- Err on the side of larger fonts, with a medium weight (i.e., not too light or too heavy of strokes that make up the letters)
- Aim to use simpler fonts, particularly sans-serif fonts, as those tend to be more readable at a distance

- Where practical, give the user control over font size within your application, or allow some other sort of “zoom” mechanism, to help see details that they might otherwise be unable to see
- Light text on a dark background tends to be easier to read on televisions, so consider using a theme that supports this (e.g., `Theme.Holo` as opposed to `Theme.Holo.Light`)
- Use fewer words
- Use more line spacing (e.g., via `android:lineSpacingMultiplier` on a `TextView`), so descenders from one line are clearly distinguished from the tops of characters on the next line

Padding and Margins

In addition to adding more line spacing, consider adding more padding and margins to your ten-foot UIs.

Bear in mind that screen density calculations start to go astray as the user moves further away from the screen. We are used to making those calculations based on actual pixels on phones and tablets (a.k.a., “two-foot UI”). The *apparent* size of a television may be no bigger than that of a tablet, once the user’s distance from the screen is taken into account. However, screen density has no good way to take that distance into account, other than by effectively hard-coding the density (e.g., Fire TV considering everything to be `-xhdpi`). Hence, particularly for padding and margins, you may need to “finesse” your values a bit on televisions and the like.

In cases where Android is directly talking to the television (e.g., HDMI/MHL from a phone or tablet, Fire TV, Android TV, Android HDMI sticks), you can use `-notouch` qualifiers on resource sets to provide different values for dimension resources.

Colors

Usually, with the ten-foot UI, we treat televisions, monitors, and projectors equally. They do differ in one key area: color management.

Televisions, for historical reasons, tend to have different color responses than do monitors or projectors. As [Google puts it](#):

TV screens have higher contrast and saturation levels than computer monitors

THE “TEN-FOOT UI”

Even to the extent that those settings could be adjusted, if the television will be used *as a television*, the factory settings may be the proper ones. Beyond that, few television owners think about changing such things.

As a result, you need to be careful with your color choices:

- Pure white (#FFFFFF) can cause problems, such as “ghosting”, so use a very light gray (e.g., #F1F1F1, #EBEBEB) instead. Pure black (#000000) is not a problem.
- Aim for more muted colors, particularly in the blue/green/violet end of the color spectrum, as opposed to bright red or orange. Warm colors tend to bleed more than cool colors.

Aspect Ratio

Bear in mind that different TVs (or other displays) may have different aspect ratios. While many will be 16:9, also consider 4:3 and 21:9 (also known as 2.35:1).

The Leanback UI

In 2014, Google added the `leanback-v17` library to the Android Support package. This contains code to help you create TV-focused user interfaces. While the intention is for this library to help you create UIs for Android TV, there is nothing strictly tied to the Android TV platform in `leanback-v17`. Your user interfaces can work just fine on other TV environments (e.g., Amazon Fire TV). And they still support touchscreen events, and so they can be used on phones and tablets as well, though perhaps not optimally.

Where to Get Leanback

Android Studio users can add a dependency on the `leanback-v17` artifact from the Android Repository:

```
dependencies {  
    compile 'com.nostra13.universalimageloader:universal-image-loader:1.9.3'  
    compile 'com.android.support:leanback-v17:21.0.3'  
}
```

This particular bit of Gradle configuration comes from the [Leanback/VideoBrowse](#) sample application, which will be the focus of this “leanback” UI section. This

THE “TEN-FOOT UI”

project depends not only upon `leanback-v17`, but also upon the [Universal Image Loader](#) (UIL), another image-loading library, akin to Picasso.

If you read through [the chapter on MediaStore](#), this sample app will seem familiar. In the `MediaStore` chapter, we created a sample app that would present a list of videos available on the device in a `ListView`, using UIL for handling the video thumbnails. The `VideoBrowse` “leanback” sample app is the same app, adjusted to use a “leanback” UI instead of a `ListView`.

BrowseFragment

The primary UI element that we get from `leanback-v17` is `BrowseFragment`. `BrowseFragment` is a fragment designed to allow browsing of a roster of content through a two-dimensional scrolling interface. There is a list of “headers” (e.g., categories of videos), and within each header is a horizontal scrolling list of items within that header.

This sort of UI pattern is fairly commonplace in TV-centric apps, as it works well with TV-style remotes:

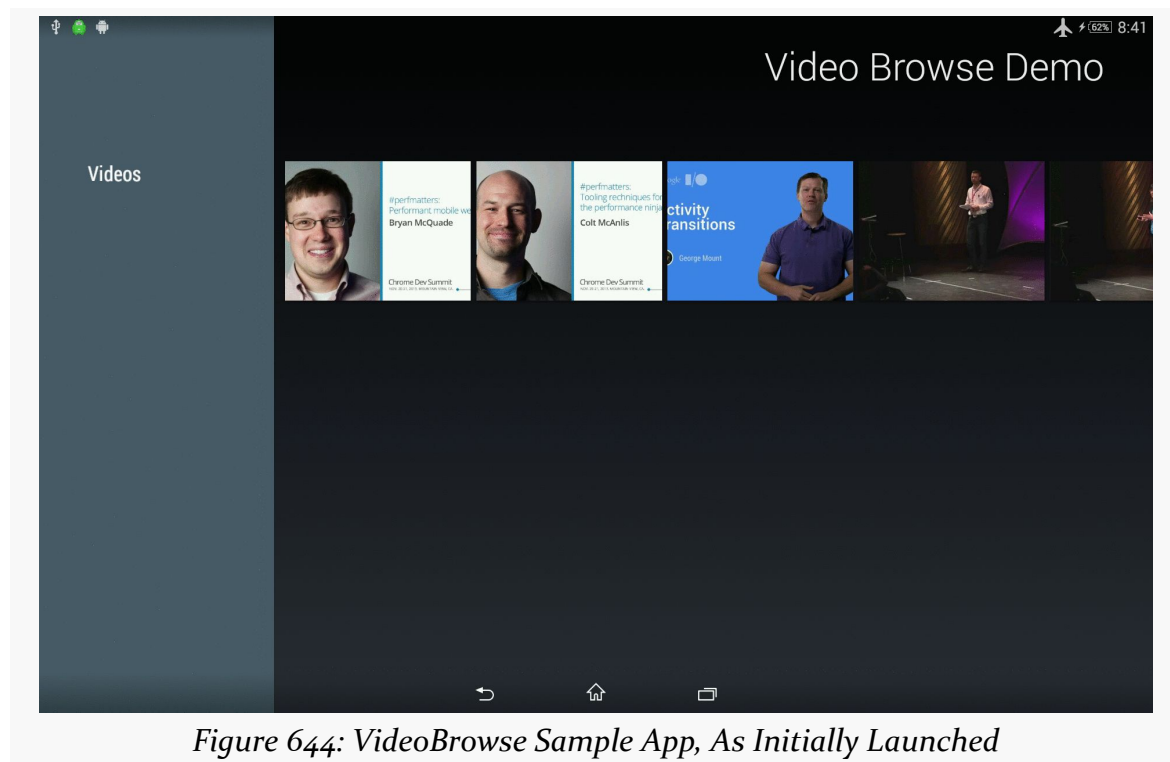

Figure 644: VideoBrowse Sample App, As Initially Launched

The VideoBrowse sample application consists of one activity, hosting a BrowseFragment, that will display the roster of available videos on the device. Clicking on an individual video will bring up the device’s default video player app, just as the VideoList sample did in the chapter on the MediaStore.

Theme and Activity

There is very little specifically required of an activity that hosts a BrowseFragment, particularly on the Java side. So long as the activity gets the BrowseFragment onto the screen, the key work is done.

In the case of our MainActivity, it uses a res/layout/main.xml file, pointing to our VideosFragment, which is a subclass of BrowseFragment:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/videos"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.video.browse.VideosFragment"
/>
```

The Java code simply loads up the layout containing that static fragment, plus has an onVideoSelected() method that will be called if the user clicks on a video:

```
package com.commonware.android.video.browse;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import java.io.File;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void onVideoSelected(String uri, String mimeType) {
        Uri video=Uri.fromFile(new File(uri));
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(video, mimeType);
        startActivity(i);
    }
}
```

However, there are two other requirements of the activity, in terms of what goes in the manifest:

- The activity needs to use a theme that is, or inherits from, `Theme.Leanback`
- To show up as the “launcher activity” for an Android TV device, the activity needs to have an `<action>` of `MAIN` and a `<category>` of `LEANBACK_LAUNCHER`:

```
<application
    android:allowBackup="false"
    android:hardwareAccelerated="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name="MainActivity"
        android:label="@string/app_name"
        android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
        android:screenOrientation="sensorLandscape"
        android:theme="@style/Theme.Leanback">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
            <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
        </intent-filter>
    </activity>
</application>
```

In our case, we match on either the `LAUNCHER` or the `LEANBACK_LAUNCHER` category, as this particular activity can work on either form factor family (touchscreens or TVs). However, other apps might have separate “launcher activity” implementations for phones/tablets versus televisions, and so having a separate `LEANBACK_LAUNCHER` category allows us to indicate which activities serve which role.

This activity also sets its `screenOrientation` to `sensorLandscape`, indicating that it will always present itself in landscape mode, no matter how the device is held. It also uses a `configChanges` attribute to opt out of configuration changes due to orientation changes, as the UI is not changing in those cases.

Loading the Videos

`VideosFragment` is responsible for showing the roster of available videos on the device, using a `BrowseFragment` two-dimensional structure. This means, though, that `VideosFragment` needs to be able to find out what videos are available. As with the `VideoList` sample in [the MediaStore chapter](#), `VideosFragment` will query the

THE “TEN-FOOT UI”

MediaStore ContentProvider to find out about the videos, by means of a CursorLoader.

In onViewCreated(), VideosFragment calls initLoader() to start loading the videos, in addition to indicating that the fragment itself will serve as the controller handling clicks on individual videos, via the setOnItemClickListener() interface:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getLoaderManager().initLoader(0, null, this);
    setOnItemClickListener(this);
}
```

For those calls to work, VideosFragment needs to implement the LoaderManager.LoaderCallbacks<Cursor> interface (for initLoader()) and the OnItemClickListener (for setOnItemClickListener()).

The initLoader() call triggers a call to our onCreateLoader() method, which queries the MediaStore roster of videos for all videos, ordered by title:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(
        getActivity(),
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}
```

That, in turn, will eventually trigger a call to onLoadFinished():

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    mapCursorToModels(c);

    setHeadersState(BrowseFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
    ArrayObjectAdapter listRowAdapter=
        new ArrayObjectAdapter(new VideoPresenter(getActivity()));

    for (Video v : videos) {
        listRowAdapter.add(v);
    }
}
```

```
HeaderItem header=new HeaderItem(0, "Videos", null);

rows.add(new ListRow(header, listRowAdapter));
setAdapter(rows);
}
```

We will get to much of the code in `onLoadFinished()` a bit later in this chapter. However, the first thing that `onLoadFinished()` does is call a `mapCursorToModels()` method. This method will be responsible for taking the data from the `Cursor` we get back from `MediaStore` and using it to populate some model objects that will drive what the `BrowseFragment` displays to the user. `BrowseFragment`'s API is not especially well-suited for working with a `Cursor` directly; it is simpler to have a separate collection of model objects representing the results of the database query.

In our case, the model object will be a `Video`:

```
package com.commonware.android.video.browse;

class Video {
    int id;
    String uri;
    String mimeType;
    String title;

    Video(int id, String uri, String mimeType, String title) {
        this.id=id;
        this.uri=uri;
        this.mimeType=mimeType;
        this.title=title;
    }

    @Override
    public String toString() {
        return(title);
    }
}
```

There are four pieces of data we need to track for the video:

- Its unique `id`, so we can get a thumbnail of the video later on
- Its `Uri` (here, held in a string representation), to be used to play back the video
- Its MIME type, also to be used to play back the video
- Its title, which will be used along with its thumbnail when rendering the video as part of the `BrowseFragment` roster of content

THE “TEN-FOOT UI”

VideosFragment holds onto a collection of these Video objects in a data member named videos:

```
private ArrayList<Video> videos=new ArrayList<Video>();
```

mapCursorToModels() iterates over the Cursor rows and creates a Video object for each row, adding the Video to the videos, and closing the Cursor when done:

```
private void mapCursorToModels(Cursor c) {
    videos.clear();

    int idColumn=c.getColumnIndex(MediaStore.Video.Media._ID);
    int uriColumn=c.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        c.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int titleColumn=
        c.getColumnIndex(MediaStore.Video.Media.TITLE);

    for (c.moveToFirst(); !c.isAfterLast(); c.moveToNext()) {
        videos.add(new Video(c.getInt(idColumn),
                             c.getString(uriColumn),
                             c.getString(mimeTypeColumn),
                             c.getString(titleColumn)));
    }

    c.close();
}
```

Headers and Contents

So, let's look at the full onLoadFinished() method, called when we have our Cursor of videos:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    mapCursorToModels(c);

    setHeadersState(BrowseFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
    ArrayObjectAdapter listRowAdapter=
        new ArrayObjectAdapter(new VideoPresenter(getActivity()));

    for (Video v : videos) {
        listRowAdapter.add(v);
    }

    HeaderItem header=new HeaderItem(0, "Videos", null);
```

THE “TEN-FOOT UI”

```
rows.add(new ListRow(header, listRowAdapter));  
setAdapter(rows);  
}
```

As mentioned, the first thing that we do is map the Cursor contents to Video objects.

We then make two general changes to the look of the BrowseFragment:

- We enable the headers. In truth, that would not make sense for this particular application, as we only have one header. However, we are enabling the headers to show what that looks like, as many uses of BrowseFragment will need the full two-dimensional browsing experience.
- We set the title to be the app_name string resource. This title goes in the upper-right corner and is used to remind the user of what app they are in, much like the title in an action bar would on a phone or tablet.

We then build up the two-dimensional data model and rendering rules for the browsing experience. This involves creating instances of an ObjectAdapter base class, supplied by leanback-v17. ObjectAdapter fills a role reminiscent of Adapter with AdapterView, insofar as it organizes model data and helps with the rendering. However, whereas Adapter does that all itself, ObjectAdapter splits the roles out: it handles the model data and delegates to Presenter implementations for rendering individual items from the model data.

In the two-dimensional browsing model, we need an ObjectAdapter that represents our rows, where each row has a header and a nested ObjectAdapter for the items to appear in that row.

Just as ArrayAdapter is the easiest Adapter class to use, ArrayObjectAdapter is the easiest ObjectAdapter to use. ArrayObjectAdapter adapts arrays of objects, where in this case, “array” really means ArrayList.

Unlike ArrayAdapter, where we primarily build up our array and hand it to the adapter, ArrayObjectAdapter has us populate the “array” via methods like add() on the ArrayObjectAdapter.

So, after calling setHeadersState() and setTitle() as described above, we:

- Create an ArrayObjectAdapter, named rows, that uses the ListRowPresenter supplied by leanback-v17 to render the row

THE “TEN-FOOT UI”

- Create another `ArrayObjectAdapter`, named `listRowAdapter`, that uses a custom `VideoPresenter` that we will examine later in this chapter
- Iterate over the `Video` roster and add each to the `listRowAdapter`
- Create an instance of a `HeaderItem`, supplied by `leanback-v17`, that represents the header entry itself, with a title for that header
- Create an instance of a `ListRow`, supplied by `leanback-v17`, that wraps around the `HeaderItem` and the `listRowAdapter` for the items to show in that row
- Put the `ListRow` in the `rows` `ArrayObjectAdapter`, and pass `rows` to `setAdapter()` to tell the `BrowseFragment` what to display

A more complex app might have several `ListRow` objects in `rows`, one per header. For example, you might group videos by some sort of categorization scheme, where each `HeaderItem` names the category and the `ListRow` also contains the videos specific to that category.

Of the classes cited here, all are stock implementations from `leanback-v17`, with the exception of `VideoPresenter`, which is responsible for rendering a `Video` as an item in the horizontal list of videos.

Presenting the Presenters

A `Presenter`, in the `leanback-v17` system, is an object responsible for converting some model object (e.g., a `Video`) into a visual representation that will be used for an `ObjectAdapter`.

The `Presenter` abstract class enforces a “view holder” approach. A view holder is simply a data structure holding onto a basket of widgets. The idea is that the view holder represents all the widgets for a particular instance of the `Presenter`. So, we now have two levels of indirection over the `Adapter` approach used by `ListView` and `kin`: not only does `ObjectAdapter` not do the rendering, but `Presenter` alone does not do the rendering, but instead involves a view holder.

As a result, a `Presenter` implementation will tend to be artificially complex.

First, let’s look at the view holder, implemented as a static class inside `VideoPresenter`, named `Holder`, that extends the stock `Presenter.ViewHolder` class:

```
static class Holder extends Presenter.ViewHolder {  
    private final ImageLoader imageLoader;
```

THE “TEN-FOOT UI”

```
private final ImageCardView cardView;
private final ImageSize targetSize;

public Holder(View view, ImageLoader imageLoader) {
    super(view);

    cardView=(ImageCardView)view;
    this.imageLoader=imageLoader;

    Resources res=view.getContext().getResources();

    targetSize=
        new ImageSize((int)res.getDimension(R.dimen.card_width),
                      (int)res.getDimension(R.dimen.card_height));
}

protected void updateCardViewImage(String path) {
    DisplayImageOptions opts=new DisplayImageOptions.Builder()
        .showImageOnLoading(R.drawable.ic_media_video_poster)
        .build();

    imageLoader.loadImage(path, targetSize, opts,
        new SimpleImageLoadingListener() {
            @Override
            public void onLoadingComplete(String uri, View v, Bitmap bmp) {
                Drawable bmpDrawable=
                    new BitmapDrawable(cardView.getContext().getResources(),
                                      bmp);

                cardView.setMainImage(bmpDrawable);
            }
        });
}
```

The Presenter will set up the UI, in the form of an ImageCardView – another stock class provided by leanback-v17 that is an ImageView with an associated caption. As we will want to pour video thumbnails into the ImageView, this sample app uses the Universal Image Loader (UIL), the same way the VideoList sample does. Here, the ImageLoader instance is created by the Presenter, to be shared among its Holder instances, and we pass in the ImageLoader to the Holder and, um, hold it in a data member.

We also determine how big the thumbnail should be, creating an ImageSize object for UIL’s use in eventually resizing the thumbnail bitmap. That ImageSize is based on a pair of dimension resources, card_width and card_height:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <dimen name="card_width">400dp</dimen>
```

THE “TEN-FOOT UI”

```
<dimen name="card_height">300dp</dimen>
</resources>
```

The `updateCardViewImage()` will be called when we are ready to use this `ViewHolder` to present the contents of some particular `Video`. We receive the `Uri` to the video (in a `String` representation, as that is what `UIL` will use). We set up a `UIL DisplayImageOptions` object to indicate that we want to show a placeholder image while the thumbnail is loading.

Then, since `UIL` has no knowledge of how to work with an `ImageCardView` from `leanback-v17`, we have to use a different version of `loadImage()`, one that takes:

- the path to the video (for which `UIL` knows how to retrieve thumbnails),
- the desired thumbnail size,
- the `DisplayImageOptions`, and
- a `SimpleImageLoadingListener` that takes the `Bitmap` retrieved by `UIL`, wraps it in a `BitmapDrawable`, and pops that into the `ImageCardView`

Now, given the `Holder`, we can set up the rest of `VideoPresenter`, starting with its constructor:

```
VideoPresenter(Context ctxt) {
    super();

    this.ctxt=ctxt;

    ImageLoaderConfiguration ilConfig=
        new ImageLoaderConfiguration.Builder(ctxt).build();

    imageLoader=ImageLoader.getInstance();
    imageLoader.init(ilConfig);
}
```

Here, mostly, we are setting up the `ImageLoader` from `UIL`, using the same basic recipe as was used in the `VideoList` sample app.

At the point in time that the `VideoPresenter` needs to create a view holder to use for rendering an item, `onCreateViewHolder()` will be called:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
    ImageCardView cardView=new ImageCardView(ctxt);

    cardView.setFocusable(true);
    cardView.setFocusableInTouchMode(true);
}
```

THE “TEN-FOOT UI”

```
return(new Holder(cardView, imageLoader));  
}
```

Here, we set up an `ImageCardView`, marking it as focusable both for the D-pad and for touchscreens, and wrap that in our custom `Holder`.

At the point in time when we are ready to show a `Video` using the widgets managed by the `Holder`, `onBindViewHolder()` is called:

```
@Override  
public void onBindViewHolder(Presenter.ViewHolder viewHolder,  
                             Object item) {  
    Video video=(Video)item;  
    Holder h=(Holder)viewHolder;  
    Resources res=ctxt.getResources();  
  
    h.cardView.setTitleText(video.toString());  
    h.cardView.setMainImageDimensions((int)res.getDimension(R.dimen.card_width),  
(int)res.getDimension(R.dimen.card_height));  
  
    Uri thumbnailUri=  
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,  
        video.id);  
  
    h.updateCardViewImage(thumbnailUri.toString());  
}
```

We are passed in a generic `Object` that is the model data from our `ObjectAdapter` — in this case, it will be a `Video`, as we are using `VideoPresenter` with an `ArrayObjectAdapter` that holds the `Video` instances. We update the `ImageCardView` caption based on the title of the `Video`, then set the size of the `ImageView` based upon the same dimension resources as we used with `UIL`’s `ImageSize`. We construct a `Uri` pointing to the video as known to `MediaStore` (given the video’s id), and pass the `String` representation of that into the `Holder`, which will handle the `UIL` work.

There is one other abstract method that we need to override to satisfy `Presenter`: `onUnbindViewHolder()`:

```
@Override  
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {  
    ((Holder)viewHolder).cardView.setMainImage(null);  
}
```

`onUnbindViewHolder()` can often be skipped. However, if you have memory-intensive stuff in the view holder — like the bitmap in an `ImageView` — this is a fine time to take steps to release that memory. In our case, we null out the image in the

ImageCardView. Ideally, we would somehow work with UIL to arrange to recycle this Bitmap object, since all of our Bitmap objects should be the same size.

Handling Clicks

BrowseFragment automatically handles a lot of input events, such as:

- arrow key events in the list of headers, to move a selection bar up and down the list
- click events on a header, to allow navigation into the row of items for that header
- arrow key events on an item, to navigate to the next or previous item
- BACK button events on an item, to return to the list of headers

It also captures the click event on an item and routes that to the `onItemClicked()` method of the `BrowseFragment`, which we override in `VideosFragment`:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
                        Object o,
                        RowPresenter.ViewHolder rowViewHolder,
                        Row row) {
    Video video=(Video)o;
    ((MainActivity)getActivity()).onVideoSelected(video.uri,
                                                video.mimeType);
}
```

The `Object` passed as the second parameter to `onItemClicked()` is the `Object` in our `ObjectAdapter` for the clicked-upon item. In our case, the `ObjectAdapter` is our `ArrayObjectAdapter` wrapped around our `Video` objects, and so the `Object` passed into `onItemClicked()` is a `Video`. Given that, we can call out to the hosting activity and its `onVideoSelected()` to go play back the selected video.

The Results

Launching the app shows our list of headers (with just the one header), thumbnails of videos in that header, and the “Video Browse Demo” title:

THE “TEN-FOOT UI”

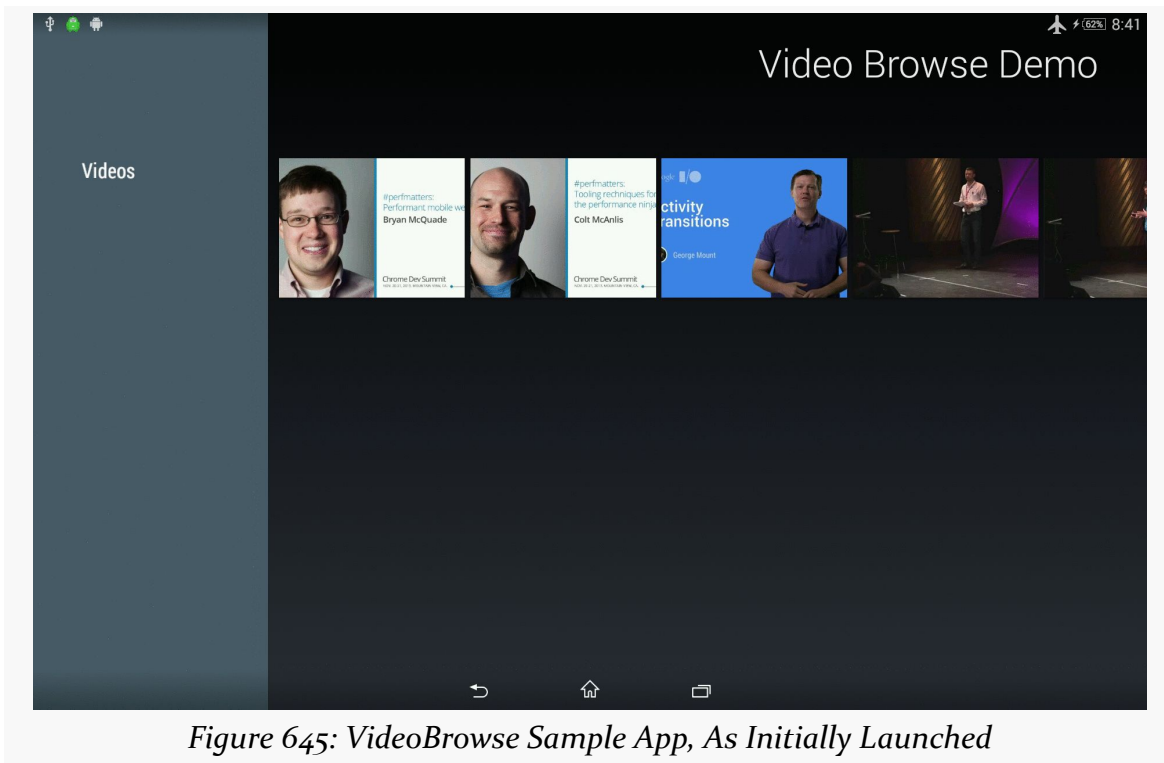

Figure 645: VideoBrowse Sample App, As Initially Launched

Selecting a video slides the headers out of the way and shows the full card for the video, including the video's title:

THE “TEN-FOOT UI”

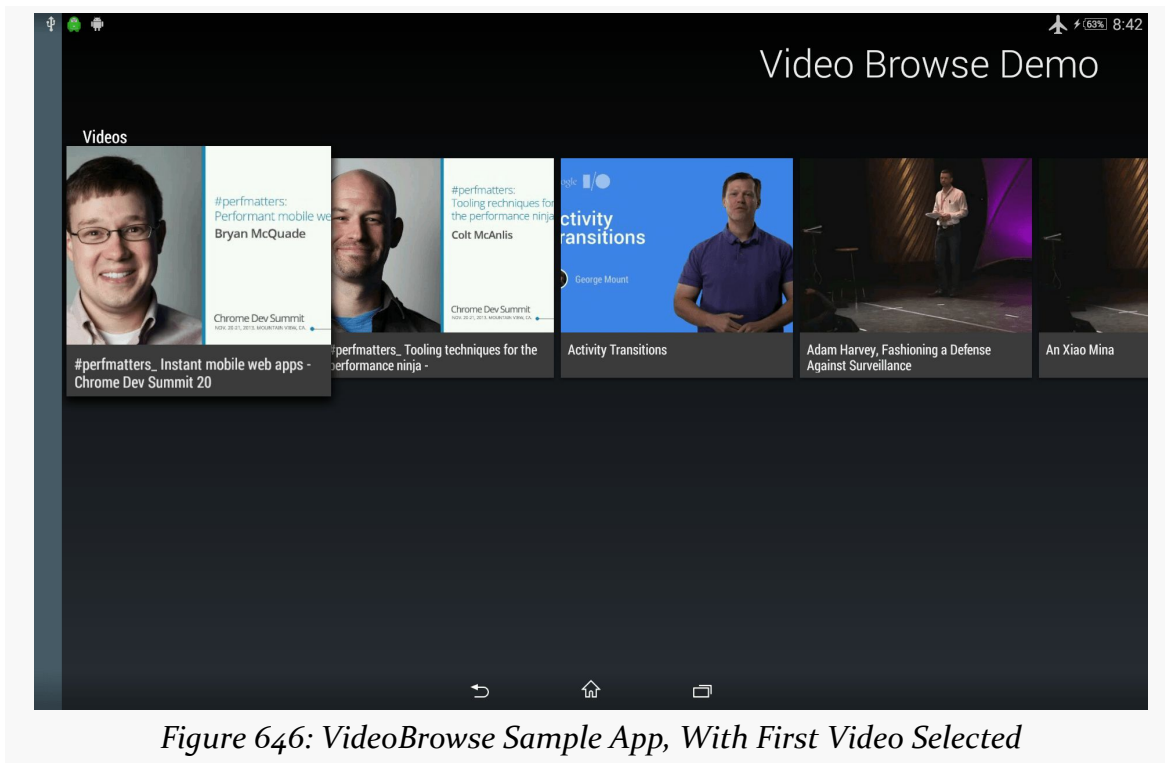

Figure 646: VideoBrowse Sample App, With First Video Selected

Clicking on the selected video brings up the default video player for the device.

Note that this UI is not tied strictly to TV-style displays. For example, the screenshots shown in this section came from an Android tablet, as you can tell by the status bar and navigation bar. The BrowseFragment UI is not completely out of place on a tablet, and it works with touch events as well as the key events that would be emitted by a TV-style remote control. On a phone, the BrowseFragment UI gets a bit cramped, particularly in portrait, though it still works.

Testing Your Theories

Ideally, you test your ten-foot UI in a ten-foot experience, using something connected to a television.

This does not have to be expensive:

- If you have a phone or tablet that can connect to a TV via HDMI, MHL, or Miracast, at most you might need a cable or a Miracast adapter

THE “TEN-FOOT UI”

- Android “HDMI sticks” or other Android set-top boxes can be found on eBay, Alibaba, or elsewhere
- Chromecast and the Fire TV Stick are available in some markets fairly inexpensively

Any of those will cost \$10–75. At the \$100 price point, you can start looking at the Fire TV or Nexus Player as well.

If you need to develop using more traditional hardware (phone or a tablet) or an emulator, the big thing will be to make sure that you are estimating the screen size properly. For example, a 10“ tablet, held fully at arm’s length, will have the same visual angle as a modest television (~26”) at a comfortable seating distance. While this will not help with color saturation, using remote controls, or other aspects of the ten-foot UI, you can at least get a sense of whether your text and UI controls will be large enough to be usable.

Putting the TVs All Together: Decktastic

This book profiles many ways of getting content to a TV:

- By means of `Presentation` and related classes, for touchscreen-enabled devices that also happen to presently have a connection to an external display
- By means of `RemotePlaybackClient`, for use with devices like the Chromecast
- By means of directly displaying output on a TV, for devices where the TV is the primary display (e.g., Android TV devices, Amazon's Fire TV and Fire TV Stick)

It is entirely possible to create one app that can support all of these modes from one code base, though you are constrained by the most limited option. In this case, `RemotePlaybackClient` is the most limited option, as its API is designed to tell some external device to play some media, whereas the other options can support comparatively arbitrary user interfaces rendered through normal Android widgets.

In this chapter, we will review the [Presentation/Decktastic](#) sample application. This app is designed to give the user a roster of slide-based presentations to choose from, then deliver one of those presentations. The presentation will appear on the external display (e.g., TV or projector), while the presenter will be able to control the presentation either from a touchscreen-equipped Android device or a remote control.

Prerequisites

You should read the following chapters before this one:

- [Supporting External Displays](#)
- [Google Cast and Chromecast](#)
- [The “10 Foot UI”](#)

Reading up on specific hardware, like the [Amazon Fire TV](#), is a good idea but not as critical.

Introducing Decktastic

Before we get into discussing the implementation of Decktastic, we should first review what the app looks like and how it functions.

Launcher UI

If you were to [set up Decktastic](#) on some test device and run it, the first thing that you would see is a media browsing UI built from the leanback-v17 support library, showing you a roster of the available presentations to choose from:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

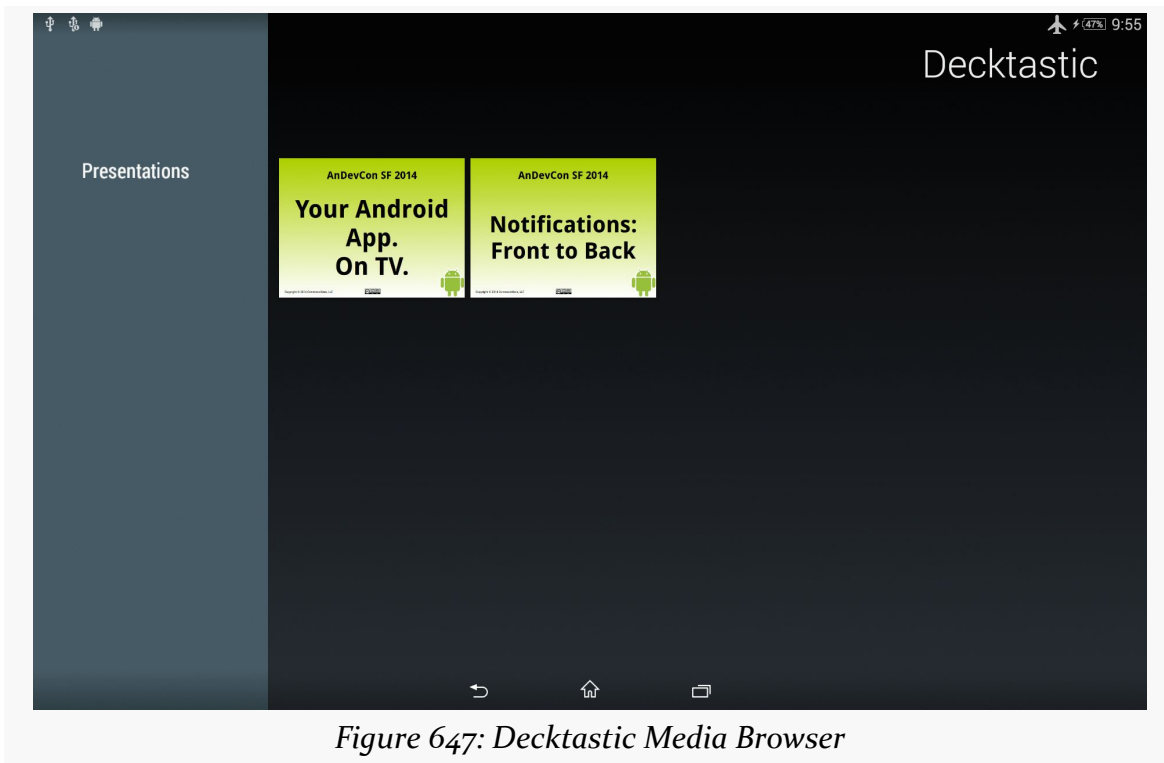

Figure 647: Decktastic Media Browser

This UI works fine on TVs and on tablets. On phones... it gets a bit cramped. |

Tapping on a presentation selects it: |

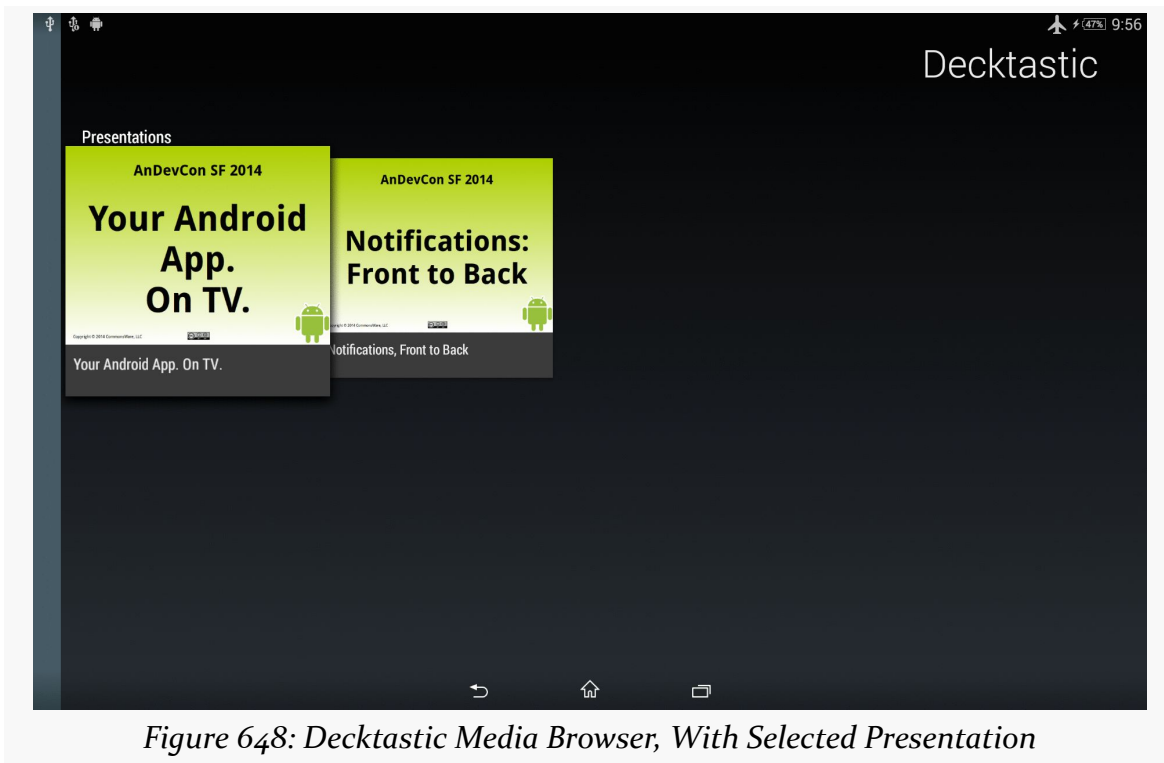

Figure 648: Decktastic Media Browser, With Selected Presentation

Presentation UI

Tapping on the presentation again opens it up into a ViewPager-based UI for the presenter:

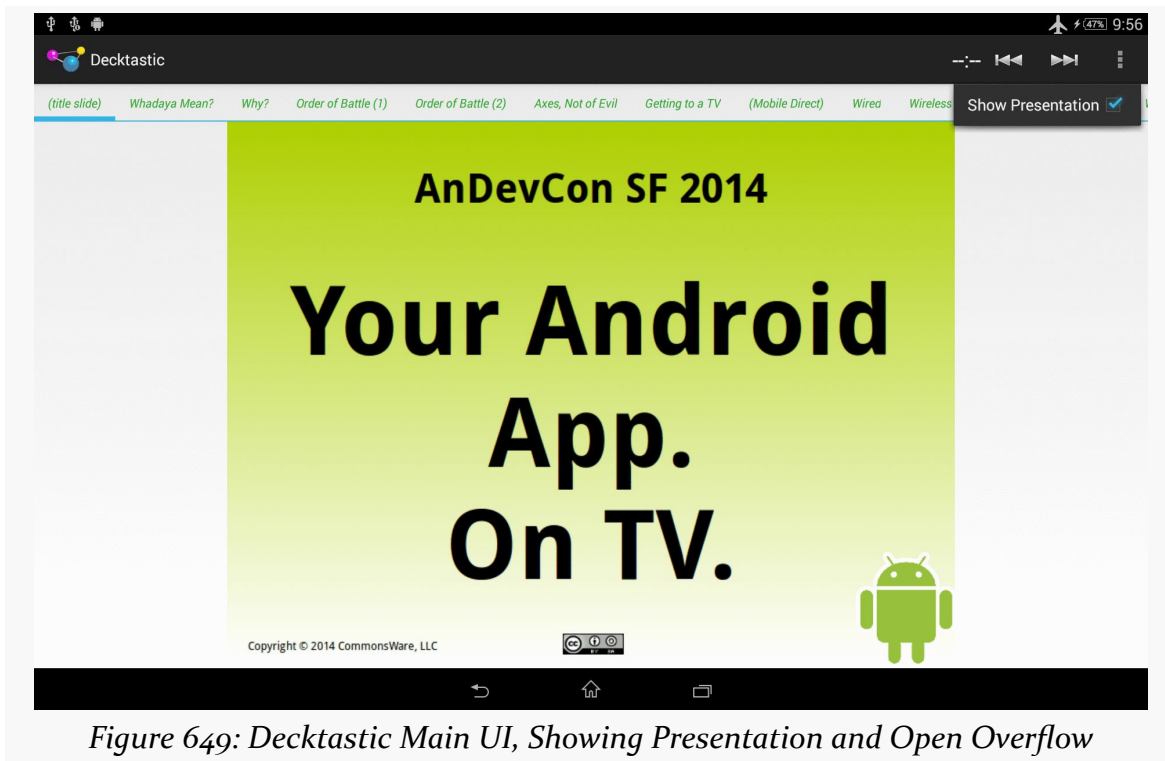

Figure 649: Decktastic Main UI, Showing Presentation and Open Overflow

However, who sees what depends a bit upon the available hardware:

- If you are running this standalone on a phone or tablet, you will see the ViewPager-based UI
- If you are running this on a phone or tablet with a connection to an external display, you will see the ViewPager-based UI, but the *audience* (those looking at the external display) will, by default, just see the slides
- If you are running this on a phone or tablet with a connection to a Chromecast or similar remote playback device, we get the same results as with the external display (you see the full UI, the audience sees the slides)
- If you are running this on an Android TV, Fire TV, or similar device, both you and the audience only see the slides

To move through the slides, you can:

- Swipe the ViewPager
- Use the ViewPager tabs
- Use right or down keys to move forward, or left or up keys to move backward, whether on a QWERTY keyboard (e.g., Bluetooth) or via the D-

pad on some form of remote (for TV-centric scenarios, like Android TV or Fire TV)

Trying Decktastic Yourself

Most of the sample applications in this book stand alone, so all you need to do is run them. Decktastic requires presentations, which means it requires a bit of setup.

If you want to see Decktastic work, you should:

- Run Decktastic once (e.g., from Android Studio). This will show that there are no available presentations. Press BACK to destroy the launcher activity.
- Download [this ZIP archive](#) containing a pair of Decktastic-compatible presentations.
- UnZIP the archive, and copy the contents (not the ZIP file itself) into `Android/data/com.commonware.android.preso.decktastic/files` on your Android device or emulator's external storage.
- Run Decktastic again. This should give you one full presentation ("Your Android App. On TV" from the 2014 AnDevCon San Francisco conference) and one stub presentation (enough to get you a second entry in the list of presentations, but not the full slide set)

Implementing Decktastic

Decktastic is a pair of activities that "stand upon the shoulders of giants", in the form of using eight third-party libraries that provide a lot of the utility code.

The Gradle Dependencies

This project is designed to be built by Android Studio, and therefore it declares all of its dependencies in `build.gradle`. The file structure is suitable for Eclipse, but Eclipse developers would need to attach all of the appropriate dependencies manually.

The project's `build.gradle` file specifies a fair number of dependencies:

```
repositories {  
    maven {  
        url "http://dl.bintray.com/populov/maven"  
    }  
    maven {
```

```
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
    mavenCentral()
}

dependencies {
    compile 'com.viewpagerindicator:library:2.4.1@aar'
    compile 'com.commonsware.cwac:presentation:0.4.+'
    compile 'com.android.support:support-v13:21.0.3'
    compile 'com.google.code.gson:gson:2.3'
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.commonsware.cwac:mediarouter:0.2.+'
    compile 'com.android.support:leanback-v17:21.0.3'
    compile 'com.squareup.picasso:picasso:2.4.0'
}
```

The project uses:

- Two CWAC libraries, cwac-presentation for PresentationHelper and cwac-mediarouter for the cross-port of the MediaRouteActionProvider to the native action bar
- support-v13, to pull in ViewPager and related classes
- The ViewPagerIndicator library
- Google's Gson
- greenrobot's EventBus
- Google's leanback-v17 library, for [“ten-foot UI” elements](#) used in our launcher activity
- Square's Picasso, for asynchronously loading images

The Presentation Format

A Decktastic presentation consists of a JSON file and a series of image files. The image files are the slides themselves, perhaps exported from a traditional presentation package like LibreOffice Impress. The JSON file spells out what the image files are and their order of appearance.

For example, here is a JSON file from the stub presentation included in the aforementioned ZIP archive:

```
``json { "title": "Notifications, Front to Back", "duration": 70, "baseUrl":
"http://misc.commonsware.com/andevcon2014/preso2/", "slides": [ { "title": "(title
slide)", "image": "img0.png" }, { "title": "Order of Battle", "image": "img1.png" } ] } ``
```

The `title` is used on the initial “leanback” activity as part of displaying the available presentations.

The `duration` is how long the presentation should run, in minutes. This will be used for a countdown timer to help the presenter know how much time remains in the presentation.

The `baseUrl` is a URL to a directory on a Web server somewhere that contains the same slide images as are available locally. This is needed to support `RemotePlaybackClient`, as Chromecast and similar devices need to be able to download their content over the network. We do not have an easy way to deliver that content from the phone or tablet that runs Decktastic and so we need a network-hosted copy of the slides as well. If you were willing to dispense with Chromecast support, you would not need this `baseUrl` property.

The `slides` array contains JSON objects, each of which provides the title for a slide and the image associated with that slide. The title will be used for the `ViewPager` tabs, so the presenter knows the upcoming slides and can rapidly switch to a specific slide. The images, of course, are what the presenter and the audience see. Of particular importance is the first slide in the array, as this will be used as the “title slide”, shown on the initial “leanback” activity.

The Model Classes

Given that JSON, we need a model class that will represent it, caching the parsed JSON so that we can use that information to render the presentation. We also need a model class that represents the collection of parsed presentations, so that we have the information necessary to render the “leanback” activity that allows the user to find the presentation to display.

There are two model classes in the book that handle this: `PresoContents` and `PresoRoster`.

PresoContents

`PresoContents` represents the parsed JSON, along with a few other bits of information about the presentation:

```
package com.commonware.android.preso.decktastic;

import java.io.File;
import java.util.List;
```

```
public class PresoContents {
    String title;
    List<Slide> slides;
    int duration;
    String baseURL;
    File baseDir;
    int id=-1;

    static class Slide {
        String image;
        String title;
    }

    @Override
    public String toString() {
        return(title);
    }

    File getSlideImage(int position) {
        return(new File(baseDir, slides.get(position).image));
    }

    String getSlideTitle(int position) {
        return(slides.get(position).title);
    }

    String getSlideURL(int position) {
        return(baseURL+slides.get(position).image);
    }
}
```

The title, slides, duration, and baseURL fields come straight from the JSON. The baseDir field represents the directory in which the presentation was loaded; all images will be assumed to be relative to this directory. Finally, each presentation is given an id, so we can distinguish one presentation from another in our collection of presentations.

PresoContents also has getter methods to retrieve the local image file (getSlideImage()), title (getSlideTitle()), and remote image URL (getSlideURL()) for a slide given its position in the array of slides.

PresoRoster

PresoRoster is a singleton collection of the available presentations. It also contains the model logic for loading the collection of presentations and parsing the JSON to create an individual PresoContents object for a single presentation:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
package com.commonware.android.preso.decktastic;

import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.File;
import java.io.FileInputStream;
import java.io.FileNotFoundException;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.ArrayList;
import java.util.List;

class PresoRoster {
    private static final PresoRoster INSTANCE=new PresoRoster();
    private List<PresoContents> presos=new ArrayList<PresoContents>();

    static PresoRoster getInstance() {
        return(INSTANCE);
    }

    private PresoRoster() {}

    int getPresoCount() {
        return(presos.size());
    }

    PresoContents getPreso(int position) {
        return(presos.get(position));
    }

    PresoContents getPresoById(int id) {
        return(getPreso(id));
    }

    void load(File base) {
        base.mkdirs();

        String[] presoDirs=base.list(new FilenameFilter() {
            @Override
            public boolean accept(File orig, String name) {
                return(new File(orig, name).isDirectory());
            }
        });

        Gson gson=new Gson();

        for (String presoDir : presoDirs) {
            PresoContents c=loadPreso(gson, new File(base, presoDir));

            if (c!=null) {
                c.id=presos.size();
                presos.add(c);
            }
        }
    }

    PresoContents loadPreso(Gson gson, File file) {
        try {
            BufferedReader reader=new BufferedReader(
                new InputStreamReader(new FileInputStream(file)));
            String line;
            PresoContents c=new PresoContents();
            while ((line=reader.readLine())!=null) {
                c.fromJson(line, gson);
            }
            return(c);
        } catch (IOException e) {
            Log.e("DeckTastic", "Error loading file: " + file);
            return(null);
        }
    }
}
```

```
    }  
  }  
}  
  
private PresoContents loadPreso(Gson gson, File base) {  
    PresoContents result=null;  
  
    try {  
        InputStream is=new FileInputStream(new File(base, "preso.json"));  
        BufferedReader reader=  
            new BufferedReader(new InputStreamReader(is));  
  
        result=gson.fromJson(reader, PresoContents.class);  
        result.baseDir=base;  
        is.close();  
    }  
    catch (IOException e) {  
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);  
    }  
  
    return(result);  
}
```

The class includes:

- Getters to retrieve a presentation by index in the array of presentations (getPreso()) and to retrieve a presentation by the ID of the presentation (getPresoById())
- A getPresoCount() method that indicates how many presentations were found
- A load() method that will scan for subdirectories under a given directory, then attempt to parse a preso.json file in the subdirectory (in a private loadPreso() method) using Gson

The result of load() is that the PresoRoster should be populated with all known presentations under the specified root directory. Note, though, that this work is done on the current thread, and therefore load() needs to be called on a background thread. Also note that PresoRoster makes no attempt at thread synchronization, and so load() should be called before anything attempts to use the PresoRoster getter methods like getPresoCount().

The Launcher Activity: LeanbackActivity

As noted previously, our launcher activity is one that implements Google's ["leanback"](#) user interface, specifically a `BrowseFragment` for browsing media content. In this case, that content consists of the roster of available presentations.

The `LeanbackActivity` itself is fairly short:

```
package com.commonware.android.preso.decktastic;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class LeanbackActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager()
                .beginTransaction()
                .add(android.R.id.content, new RosterFragment()).commit();
        }
    }

    public void showPreso(PresoContents preso) {
        startActivity(new Intent(this, MainActivity.class)
            .putExtra(MainActivity.EXTRA_PRESO_ID,
                preso.id));
    }
}
```

All it does is add a `RosterFragment` to the UI managed by the activity, plus add a `showPreso()` method that will be called by that `RosterFragment` when a presentation is selected. `showPreso()`, in turn, will start a separate activity (`MainActivity`), supplying `EXTRA_PRESO_ID` with the ID of the selected presentation, so `MainActivity` knows what presentation to show.

Manifest Entry

To work properly with the `leanback-v17` classes like `BrowseFragment`, `LeanbackActivity` needs to use `Theme.Leanback`, supplied by `leanback-v17`:

```
<activity
    android:name="com.commonware.android.preso.decktastic.LeanbackActivity"
```

```
android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
    android:label="@string/app_name"
    android:screenOrientation="sensorLandscape"
    android:theme="@style/Theme.Leanback">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
        <category android:name="android.intent.category.LEANBACK_LAUNCHER"
/>
    </intent-filter>
</activity>
```

Other noteworthy items in the `<activity>` element in the manifest include:

- Locking the screen orientation to `sensorLandscape`, as we want to stick with a landscape-style orientation, but it could either be “regular” or “reverse” landscape without issue
- Handling orientation-related configuration changes, which are not needed since we are locking the screen orientation to `sensorLandscape`, and therefore the UI does not change on an orientation change
- Having the `LEANBACK_LAUNCHER` category as an option in the `<intent-filter>`, as this will cause this activity to appear on Android TV’s home screen launcher (as opposed to the `LAUNCHER` category used by normal Android devices)

RosterFragment

`RosterFragment` is a `BrowseFragment`, designed to provide the two-dimensional navigation of headers and items in a header. In this case, we will have just one header, “Presentations”, containing all of the presentations found by `PresoRoster`.

In `onAttach()`, we check to see how many presentations are known about. If there are none, we make two assumptions:

1. That this is the first time we have needed to look for presentations, and
2. That there are presentations to be found

So, we fork a `LoadThread` to go load those presentations:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
if (PresoRoster.getInstance().getPresoCount()==0) {  
    new LoadThread(host).start();  
}  
}
```

Of course, those assumptions are a gross simplification. It could be that the user launched our `LeanbackActivity`, pressed `BACK`, then launched it again for some reason, and therefore the first `LoadThread` did not yet finish before we go and fork a second one. Or, it could be that there are no presentations to be found, in which case we scan unnecessarily. A production-grade version of this app should have a more sophisticated means of ensuring a one- (and only one-) time initialization.

`LoadThread` drops our thread priority to background levels, then tells the `PresoRoster` to load presentations from our app's standard spot on external storage. Then, we raise a `RosterLoadedEvent` on greenrobot's `EventBus`:

```
private static class LoadThread extends Thread {  
    private Context ctxt=null;  
  
    LoadThread(Context ctxt) {  
        super();  
  
        this.ctxt=ctxt.getApplicationContext();  
  
        android.os.Process.setThreadPriority(android.os.Process.THREAD_PRIORITY_BACKGROUND);  
    }  
  
    @Override  
    public void run() {  
        PresoRoster.getInstance().load(ctxt.getExternalFilesDir(null));  
  
        EventBus.getDefault().postSticky(new RosterLoadedEvent());  
    }  
}
```

You will notice that we call `postSticky()`, not `post()` on the `EventBus` instance. This says that we not only want to deliver this event to any current registrants, but that the `EventBus` should cache this event and hand it to future registrants.

To respond to the `RosterLoadedEvent`, we register the `RosterFragment` on the bus in `onResume()` and unregister in `onPause()`:

```
@Override  
public void onResume() {  
    super.onResume();  
  
    EventBus.getDefault().registerSticky(this);  
}
```

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

Specifically, we register using `registerSticky()`. This, in conjunction with `postSticky()`, means that if events were sticky-posted in the past, we are delivered those immediately, in addition to future events. This will allow us to handle configuration changes — even though our activity and fragment might be destroyed on a locale change, or if our device is put into some sort of desk dock, we will get the `RosterLoadedEvent` when our fragment is created anew.

In particular, we have `onEventMainThread()` set up to listen for `RosterLoadedEvent`. At this point, we know that we have our data model and should render it on the screen:

```
public void onEventMainThread(RosterLoadedEvent event) {
    setHeadersState(BrowseFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
    PresoRoster roster=PresoRoster.getInstance();
    ArrayObjectAdapter listRowAdapter=new ArrayObjectAdapter(new
PresoPresenter());

    for (int i=0; i < roster.getPresoCount(); ++i) {
        listRowAdapter.add(roster.getPreso(i));
    }

    HeaderItem header=new HeaderItem(0, "Presentations", null);
    rows.add(new ListRow(header, listRowAdapter));

    setAdapter(rows);
}
```

In `onEventMainThread()`, we:

- Indicate that we do want headers (though, in reality, since this app only has one header, you could easily skip the headers)
- Set the title to appear in the upper-right corner
- Create an `ArrayObjectAdapter` for the rows that make up the entirety of the `BrowseFragment` contents, using the standard `ListRowPresenter` for our headers and rows

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

- Create another `ArrayObjectAdapter`, wrapped around a `PresoPresenter`, that will manage the presentations in our one-and-only row
- Pour our `PresoContents` instances into the `ArrayObjectAdapter` for our row
- Attach the “Presentations” title to the row via a standard `ListRow` object
- Tell the `RosterFragment` that the rows represents what it should render

This is all covered in greater detail in the chapter on [the “ten-foot” UI](#).

In `onViewCreated()` of `RosterFragment`, we indicate that the `RosterFragment` itself should be the listener for click events on items (in our case, presentations):

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setOnItemClickListener(this);
}
```

This works because `RosterFragment` implements the `OnItemClickListener` interface and therefore implements the `onItemClicked()` method:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
                        Object o,
                        RowPresenter.ViewHolder rowViewHolder,
                        Row row) {
    ((LeanbackActivity) getActivity()).showPreso((PresoContents) o);
}
```

Here, we ask the hosting `LeanbackActivity` to show the clicked-upon presentation, which causes `LeanbackActivity` to launch a `MainActivity` to do just that.

PresoPresenter

The role of `PresoPresenter` is to render the individual items shown in the `BrowseFragment`. In this case, the items are `PresoContents` model objects; `PresoPresenter` will pour the presentation information into `ImageCardView` widgets. `ImageCardView` is supplied by the `leanback-v17` library and is designed to be used for rendering items in a `BrowseFragment`.

The `Presenter` abstract class — which `PresoPresenter` extends — enforces the view holder pattern. A `Presenter` is really responsible for creating and updating `Presenter.ViewHolder` instances, which in turn are responsible for updating the

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

actual widgets themselves. To that end, the `PresoPresenter.Holder` static class is a subclass of `Presenter.ViewHolder`, one that is responsible for pouring a `PresoContents` into an `ImageCardView`:

```
static class Holder extends Presenter.ViewHolder {
    private ImageCardView cardView;
    private PicassoImageCardViewTarget viewTarget;

    public Holder(View view) {
        super(view);

        cardView=(ImageCardView)view;
        viewTarget=new PicassoImageCardViewTarget(cardView);
    }

    protected void updateCardViewImage(String path) {
        Picasso.with(cardView.getContext())
            .load("file://" + path)
            .resize(convertDpToPixel(cardView.getContext(), CARD_WIDTH),
                convertDpToPixel(cardView.getContext(), CARD_HEIGHT))
            .into(viewTarget);
    }
}
```

Here, we are going to use Picasso to load the initial slide off of disk and put it in the `ImageCardView`. However, Picasso has no built-in knowledge of `ImageCardView`, the way it has built-in knowledge of `ImageView`. We need to teach Picasso how to populate an `ImageCardView`. Picasso's mechanism for this is to define a `Target` implementation (`PicassoImageCardViewTarget` in this case) that is responsible for taking a loaded bitmap and updating the UI with it:

```
private static class PicassoImageCardViewTarget implements Target {
    private ImageCardView imageCardView;

    public PicassoImageCardViewTarget(ImageCardView imageCardView) {
        this.imageCardView=imageCardView;
    }

    @Override
    public void onBitmapLoaded(Bitmap bmp, Picasso.LoadedFrom lf) {
        Drawable bmpDrawable=
            new BitmapDrawable(imageCardView.getContext().getResources(),
                bmp);

        imageCardView.setMainImage(bmpDrawable);
    }

    @Override
    public void onBitmapFailed(Drawable d) {
        imageCardView.setMainImage(d);
    }
}
```

```
}

@Override
public void onPrepareLoad(Drawable d) {
    imageCardView.setMainImage(d);
}
}
```

Target requires implementations of:

- `onBitmapLoaded()`, where we take the image and put it as the “main image” of the `ImageCardView` by means of `setMainImage()`
- `onBitmapFailed()`, where we are given a failure `Drawable` and need to use it, once again by setting it as the `ImageCardView` main image
- `onPrepareLoad()`, where we are given a “loading” `Drawable` and need to use it, once more by setting it as the `ImageCardView` main image

The `PresoPresenter.Holder` class creates an instance of a `PicassoImageCardViewTarget` and uses that for the `into()` method of the `Picasso RequestBuilder` (created via the `with()` static method on the `Picasso` class).

The other thing interesting about our use of Picasso is in the `resize()` call. Particularly since Picasso does not know about `ImageCardView` and how big the image should be, we need to manually tell Picasso what size to make the image. Here, we hard-code the sizes of the card width and height in density-independent pixels:

```
private static final int CARD_WIDTH=400;
private static final int CARD_HEIGHT=300;
```

We then use a static `convertDpToPixel()` method to get the actual number of hardware pixels to use, based upon the current screen density:

```
static int convertDpToPixel(Context ctxt, int dp) {
    float density=ctxt.getResources().getDisplayMetrics().density;

    return(Math.round((float)dp*density));
}
```

Back up in `PresoPresenter` itself, the `Presenter` abstract class requires us to override `onCreateViewHolder()`, where we are responsible for creating a `Presenter.ViewHolder`. In the case of `PresoPresenter`, that comes in the form of the aforementioned `PresoPresenter.Holder`:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
    ImageCardView cardView=new ImageCardView(parent.getContext());

    cardView.setFocusable(true);
    cardView.setFocusableInTouchMode(true);

    return(new Holder(cardView));
}
```

We also have to override `onBindViewHolder()`, where we are given an eligible `Presenter.ViewHolder` and need to populate its widgets from a supplied item:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
    PresoContents preso=(PresoContents)item;
    Holder h=(Holder)viewHolder;

    h.cardView.setTitleText(preso.toString());
    h.cardView.setMainImageDimensions(CARD_WIDTH, CARD_HEIGHT);
    h.updateCardViewImage(preso.getSlideImage(0).getAbsolutePath());
}
```

Here, the item is a `PresoContents` and the `Presenter.ViewHolder` is a `PresoPresenter.Holder`. We update the `ImageCardView` title and image size based on the presentation, plus tell the `Holder` to update the image itself, calling the `updateCardViewImage()` method that contained our Picasso request.

Note that we are passing the density-independent pixels values (`CARD_WIDTH`, `CARD_HEIGHT`) to `setMainImageDimensions()`. Unfortunately, this method is undocumented, and so what the units of measure should be are not disclosed.

The `Presenter` abstract class also requires implementations of `onUnbindViewHolder()` (called when we should no longer be populating those widgets) and `onViewAttachedToWindow()` (called when the widgets associated with a `Presenter.ViewHolder` are now “live”):

```
@Override
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
}

@Override
public void onViewAttachedToWindow(Presenter.ViewHolder viewHolder) {
    // no-op
}
```

The Guts: MainActivity

All of the above was just to handle the launcher activity, to allow the user to choose a presentation. MainActivity is where we actually show the presentation itself.

This is based upon [the Presentation/Slides sample app](#), profiled in [the chapter on Presentation](#). Some of the basic logic, for managing the ViewPager and displaying the current slide on an external display, is identical to that sample. However, the Decktastic app also supports direct-to-TV devices (e.g., Fire TV, Android TV) and remote playback devices (e.g., Chromecast), and so it blends in some of the techniques covered elsewhere in this book.

Basic Setup

onCreate() of MainActivity is responsible for basic setup.

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    preso=PresoRoster.getInstance()
        .getPresoById(getIntent()
            .getIntExtra(EXTRA_PRESO_ID, 0));

    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    helper=new PresentationHelper(this, this);

    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
            .build();
    router=MediaRouter.getInstance(this);
    router.addCallback(selector, routeCB,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);

    if (isDirectToTV()) {
        getActionBar().hide();
    }

    setupPager();
}
```

First, we take the EXTRA_PRESO_ID value received via an Intent extra and uses that to find the PresoContents object representing the presentation to be shown. That PresoContents object is then referenced by a data member named preso.

Next, we load up the `activity_main` layout resource, containing our `ViewPager` and a `TabPageIndicator`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:keepScreenOn="true">

    <com.viewpagerindicator.TabPageIndicator
        android:id="@+id/titles"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:visibility="gone"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>

</LinearLayout>
```

Then, we create a `PresentationHelper`, so that we find out when we should and should not be displaying a `Presentation`. As before, `MainActivity` itself is the `PresentationHelper.Listener` for finding out about these events. We will explore that more [later in this chapter](#).

We then go through some logic for setting up remote playback device support (`MediaRouteSelector.Builder` and kin) and direct-to-TV device support (calling `isDirectToTV()`). Those will be explored later in this chapter, in sections on [remote playback device support](#) and [direct-to-TV device support](#).

Finally, we call `setupPager()`, to populate our `ViewPager`.

The ViewPager

The `setupPager()` method is responsible for putting a `SlidesAdapter` into the `ViewPager` and otherwise setting things up to allow the presenter to control what slide is shown and for us to find out what slide the presenter selects:

```
private void setupPager() {
    durationInSeconds=preso.duration * 60;

    if (rc!=null) {
        rc.setOverallDuration(durationInSeconds);
    }
}
```

```
}

adapter=new SlidesAdapter(this, preso);
pager.setAdapter(adapter);

TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

tabs.setViewPager(pager);
tabs.setOnPageChangeListener(this);

if (isDirectToTV()) {
    tabs.setVisibility(View.GONE);
}
else {
    tabs.setVisibility(View.VISIBLE);
}
}
```

Some of this — specifically the `SlidesAdapter` and `TabPageIndicator` logic — is standard `ViewPager` setup work. The `durationInSeconds` stuff at the top is for setting up a `ReverseChronometer`, as will be discussed [later in this chapter](#). The `isDirectToTV()` call and `if` block will be explained more in the section on [direct-to-TV device support](#) later in this chapter.

`SlidesAdapter` is a fragment-free edition of a `PagerAdapter`, as the slides are purely `ImageView` widgets:

```
package com.commonware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class SlidesAdapter extends PagerAdapter {
    private PresoContents preso;
    private Context ctxt;

    SlidesAdapter(Context ctxt, PresoContents preso) {
        this.ctxt=ctxt;
        this.preso=preso;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);

        container.addView(page,
```

```
        new ViewGroup.LayoutParams(
ViewGroup.LayoutParams.MATCH_PARENT,
ViewGroup.LayoutParams.MATCH_PARENT));

        Picasso.with(ctxt).load(getSlideImageUri(position)).into(page);

        return(page);
    }

    @Override
    public void destroyItem(ViewGroup container, int position,
        Object object) {
        container.removeView((View)object);
    }

    @Override
    public int getCount() {
        return(preso.slides.size());
    }

    @Override
    public boolean isViewFromObject(View view, Object object) {
        return(view == object);
    }

    @Override
    public String getPageTitle(int position) {
        return(preso.getSlideTitle(position));
    }

    Uri getSlideImageUri(int position) {
        return(Uri.fromFile(preso.getSlideImage(position)));
    }
}
```

Of note:

- `instantiateItem()` creates the `ImageView`, adds it to the supplied container (set to fill that container), and tells Picasso to go load the image asynchronously into the `ImageView`
- `destroyItem()` removes the `ImageView` from the container
- `getCount()` returns the number of pages, based on the number of slides in the `PresoContents` supplied to the `SlidesAdapter` via its constructor
- `getPageTitle` returns the page title, obtained from the `PresoContents` object
- `getSlideImageUri()` gets a `Uri` pointing to a local file from the `PresoContents`, for use both by `instantiateItem()` and by the

Presentation object that we will use for external display support (as will be covered [later in this chapter](#))

Supporting the Direct-to-TV Scenario

To determine whether or not our activity is natively displaying on a TV-style screen, we check to see whether the device has either `FEATURE_TELEVISION` or `FEATURE_LEANBACK`, in the private `isDirectToTV()` method on `MainActivity`:

```
private boolean isDirectToTV() {  
    return(getPackageManager().hasSystemFeature(PackageManager.FEATURE_TELEVISION)  
        ||  
        getPackageManager().hasSystemFeature(PackageManager.FEATURE_LEANBACK));  
}
```

Admittedly, not all Android direct-to-TV devices may advertise that they have one of these features. In particular, minor-brand Android HDMI sticks might just be using a fairly vanilla Android device profile, culled from a tablet. There is no good way of detecting such a scenario, though Decktastic could provide some manual option (e.g., checkable action item) to go into direct-to-TV mode if this proved to be important.

We use `isDirectToTV()` in two places. First, in `onCreate()`, we hide the action bar if we are going direct to a TV:

```
if (isDirectToTV()) {  
    getActionBar().hide();  
}
```

Second, in `setupPager()`, we hide the `TabPageIndicator` if we are going direct to a TV:

```
if (isDirectToTV()) {  
    tabs.setVisibility(View.GONE);  
}  
else {  
    tabs.setVisibility(View.VISIBLE);  
}
```

This eliminates the “chrome” from our activity, leaving us with just the contents of the `ViewPager` itself, in the form of our slides. On the plus side, this gives us the visual output we want. However, it comes at a cost: there is no means for the presenter to change slides. After all, there is no touchscreen in this scenario, and so

even though the ViewPager could be swiped, that is not possible without a touchscreen.

To support standard presentation remotes and similar mechanisms, MainActivity overrides onKeyDown():

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    switch(keyCode) {
        case KeyEvent.KEYCODE_SPACE:
        case KeyEvent.KEYCODE_DPAD_RIGHT:
        case KeyEvent.KEYCODE_DPAD_DOWN:
        case KeyEvent.KEYCODE_PAGE_DOWN:
        case KeyEvent.KEYCODE_MEDIA_NEXT:
            if (pager.canScrollHorizontally(1)) {
                pager.setCurrentItem(pager.getCurrentItem()+1, true);
            }

            return(true);

        case KeyEvent.KEYCODE_DPAD_LEFT:
        case KeyEvent.KEYCODE_DPAD_UP:
        case KeyEvent.KEYCODE_PAGE_UP:
        case KeyEvent.KEYCODE_MEDIA_PREVIOUS:
            if (pager.canScrollHorizontally(-1)) {
                pager.setCurrentItem(pager.getCurrentItem()-1, true);
            }

            return(true);
    }

    return(super.onKeyDown(keyCode, event));
}
```

Here, we will advance to the next slide if the user presses:

- the space bar or the Page Down key on a QWERTY keyboard
- right or down arrow keys, D-pad buttons, or the like
- a “next” media button on a media remote

Conversely, we will return to the preceding slide if the user presses:

- the Page Up key on a QWERTY keyboard
- left or up arrow keys, D-pad buttons, or the like
- a “previous” media button on a media remote

This should allow most remotes for direct-to-TV devices to control our slides. Note that we are passing true as the second parameter to the setCurrentItem()

method, and therefore the audience will see an animated transition to the next slide. That may or may not be desirable; an enhanced edition of Decktastic might allow that to be configured (e.g., via a checkable action item).

Note that this is still a bit limited compared to having touchscreen access, as our `onKeyDown()` method only moves a slide at a time. There is no facility to jump to an arbitrary spot, the way you could by swiping and tapping upon `ViewPager` tabs on a touchscreen.

Supporting External Displays

As noted earlier, in `onCreate()` of `MainActivity`, we create an instance of `PresentationHelper`, supplying the activity itself as both the `Context` and the `PresentationHelper.Listener` for presentation-related events:

```
helper=new PresentationHelper(this, this);
```

That, in turn, requires us to forward along `onPause()` and `onResume()` events from our activity to the `PresentationHelper`:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

We also have to implement `showPreso()` and `clearPreso()` methods to satisfy the `PresentationHelper.Listener` interface:

```
@Override
public void clearPreso(boolean showInline) {
    if (presoFrag != null) {
        presoFrag.dismiss();
        presoFrag=null;
    }
}

@Override
public void showPreso(Display display) {
    Uri slide=adapter.getSlideImageUri(pager.getCurrentItem());
```

```
presoSfrag=  
    SlidePresentationFragment.newInstance(this, display, slide);  
presoSfrag.show(getFragmentManager(), "presoSfrag");  
}
```

In `showPreso()`, we obtain the `Uri` for the current slide by calling the `getSlideImageUri()` method we conveniently implemented on the `SlidesAdapter`. Then, we create an instance of a `SlidePresentationFragment`, handing it the slide `Uri`, and we `show()` that fragment. We only `dismiss()` the fragment in `clearPreso()`.

The fragment itself is a `PresentationFragment`, with an `ImageView` as the fragment's UI, populated using `Picasso`, with the `Uri` being transferred from the `newInstance()` factory method to the fragment itself via the arguments `Bundle`:

```
package com.commonware.android.preso.decktastic;  
  
import android.content.Context;  
import android.net.Uri;  
import android.os.Bundle;  
import android.view.Display;  
import android.view.LayoutInflater;  
import android.view.View;  
import android.view.ViewGroup;  
import android.widget.ImageView;  
import com.commonware.cwac.preso.PresentationFragment;  
import com.squareup.picasso.Picasso;  
  
public class SlidePresentationFragment extends PresentationFragment {  
    private static final String KEY_URI="u";  
    private ImageView slide=null;  
  
    public static SlidePresentationFragment newInstance(Context ctxt,  
                                                         Display display,  
                                                         Uri slideUri) {  
        SlidePresentationFragment frag=new SlidePresentationFragment();  
  
        frag.setDisplay(ctxt, display);  
  
        Bundle b=new Bundle();  
  
        b.putParcelable(KEY_URI, slideUri);  
        frag.setArguments(b);  
  
        return(frag);  
    }  
  
    @Override  
    public View onCreateView(LayoutInflater inflater,  
                             ViewGroup container,  
                             Bundle savedInstanceState) {
```

```
slide=new ImageView(getContext());

setSlideContent((Uri) getArguments().getParcelable(KEY_URI));

return(slide);
}

void setSlideContent(Uri slideUri) {
    Picasso.with(getContext()).load(slideUri).into(slide);
}
}
```

This arranges to show the *current* slide, for whatever the current slide is at the time `showPreso()` is called on `MainActivity`. However, we need to update this fragment to reflect changes in the current slide. To accomplish this, we set up `MainActivity` to implement the `OnPageChangeListener` interface, then call `setOnPageChangeListener()` on the `ViewPager` in `setupPager()` to have it forward page-change events to the activity. Of those events, we pay particular attention to `onPageSelected()`, updating the `SlidePresentationFragment` if there is one around:

```
@Override
public void onPageScrollStateChanged(int arg0) {
    // ignored
}

@Override
public void onPageScrolled(int arg0, float arg1, int arg2) {
    // ignored
}

@Override
public void onPageSelected(int position) {
    if (presoFrag != null) {
        presoFrag.setSlideContent(adapter.getSlideImageUri(position));
    }

    if (client!=null) {
        String url=preso.getSlideURL(position);

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
}
```

We will get into the client stuff from `onPageSelected()` in the next section, as that pertains to supporting remote playback devices.

Supporting Chromecast and Remote Playback Devices

The key limitation of Chromecast and other remote playback devices is that they can only play back media that they can access. While Chromecast supports mirroring, that is handled via the Presentation API discussed previously; devices limited to the RemotePlaybackClient API need URLs to media files. That is why our JSON for the presentation contains a URL pointing to a copy of each slide up on some public Web server. To push those URLs over to the Chromecast at the appropriate points, we need to set up the RemotePlaybackClient system.

First, in `onCreate()`, we define a `MediaRouteSelector` for remote playback devices, set up a `MediaRouter`, and add a callback to find out about selected route changes, asking `MediaRouter` to scan for possible routes along the way:

```
selector=
    new MediaRouteSelector.Builder()
        .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
        .build();
router=MediaRouter.getInstance(this);
router.addCallback(selector, routeCB,
    MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
```

All of this is using the `mediarouter-v7` portion of the Android Support package, as the native `MediaRouter` and `kin` do not support remote playback devices.

Our menu resource for our action bar contains, among other things, a `MediaRouteActionProvider`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
    xmlns:android="http://schemas.android.com/apk/res/android"
    tools:ignore="AppCompatResource">

    <item
        android:id="@+id/countdown"
        android:actionViewClass=
            "com.commonware.android.preso.decktastic.ReverseChronometer"
        android:showAsAction="always"
        android:title="This Should Not Be Needed">
    </item>
    <item
        android:id="@+id/route_provider"
        android:title="@string/media_route_provider"
        android:actionProviderClass=
            "com.commonware.cwac.mediarouter.app.MediaRouteActionProvider"
        android:showAsAction="always"/>
    </item>
```

```
        android:id="@+id/first"
        android:icon="@android:drawable/ic_media_previous"
        android:showAsAction="always"
        android:title="@string/first">
    </item>
    <item
        android:id="@+id/last"
        android:icon="@android:drawable/ic_media_next"
        android:showAsAction="always"
        android:title="@string/last">
    </item>
    <item
        android:id="@+id/present"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"
        android:title="@string/show_presentation">
    </item>
</menu>
```

As part of our work in setting up the action bar in `onCreateOptionsMenu()`, we retrieve the `MediaRouteActionProvider` and configure it with the same `MediaRouteSelector` that we used for the `MediaRouter` callback:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    rc=(ReverseChronometer)menu.findViewById(R.id.countdown)
        .getActionView();

    rc.setWarningDuration(5 * 60);
    rc.setOnClickListener(this);
    rc.setOnLongClickListener(this);
    rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
    rc.setTextColor(Color.WHITE);

    if (durationInSeconds>0) {
        rc.setOverallDuration(durationInSeconds);
    }

    MenuItem item=menu.findViewById(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)item.getActionProvider();

    provider.setRouteSelector(selector);

    return(super.onCreateOptionsMenu(menu));
}
```

(the lines in `onCreateOptionsMenu()` pertaining to the `ReverseChronometer` will be explained [later in this chapter](#))

If the user interacts with the `MediaRouteActionProvider` and elects to connect to a remote playback device, our `MediaRouter.Callback` will be notified about the change of route:

```
private MediaRouter.Callback routeCB=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                               MediaRouter.RouteInfo route) {
        connect(route);
    }

    @Override
    public void onRouteUnselected(MediaRouter router,
                                  MediaRouter.RouteInfo route) {
        disconnect();
    }
};
```

Here, we just delegate the `onRouteSelected()` and `onRouteUnselected()` callbacks to `connect()` and `disconnect()` methods on `MainActivity`. `MediaRouter.Callback` is an abstract class, not an interface — otherwise, we would simply have implemented the interface on `MainActivity` and bypassed this anonymous inner class instance.

The `connect()` method on `MainActivity` is responsible for sending over the current slide to the remote playback device:

```
private void connect(MediaRouter.RouteInfo route) {
    client=
        new RemotePlaybackClient(getApplicationContext(), route);

    if (client.isRemotePlaybackSupported()) {
        String url=preso.getSlideURL(pager.getCurrentItem());

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
    else {
        client=null;
    }
}
```

Here, we:

- Create an instance of `RemotePlaybackClient`

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

- Confirm that the remote playback device supports the remote playback protocol (`isRemotePlaybackSupported()`)
- Call `play()`, passing over a URL pointing to the same slide that the `ViewPager` is showing from a local file

The `play()` call requires an `ItemActionCallback` as the last parameter. We really do not need the callback, but passing `null` does not work. So, we have a do-nothing `ItemActionCallback` named `playCB` that we use:

```
ItemActionCallback playCB=new ItemActionCallback() {
    @Override
    public void onResult(Bundle data, String sessionId,
                        MediaSessionStatus sessionStatus,
                        String itemId, MediaItemStatus itemStatus) {
    }

    @Override
    public void onError(String error, int code, Bundle data) {
    }
};
```

That will show the slide that was current as of the time the user connected to the remote playback device. We need to show a new slide when the presenter switches to a new slide, just as we did in the Presentation scenario. This too is handled in `onPageSelected()`, where we make the same sort of `play()` call that we did in `connect()`:

```
@Override
public void onPageSelected(int position) {
    if (presoFrag != null) {
        presoFrag.setSlideContent(adapter.getSlideImageUri(position));
    }

    if (client!=null) {
        String url=preso.getSlideURL(position);

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
}
```

Not only is `disconnect()` called from `MediaRouter.Callback`, but it is also called from `onDestroy()` of `MainActivity`, where we also remove that callback from the `MediaRouter`:

```
@Override
public void onDestroy() {
    disconnect();
    router.removeCallback(routeCB);
}
```

```
super.onDestroy();  
}
```

disconnect() releases the RemotePlaybackClient and ensures that we are back on our default route:

```
private void disconnect() {  
    if (client != null) {  
        client.release();  
        client=null;  
    }  
  
    router.getDefaultRoute().select();  
}
```

The net effect of all of this is that the slides will update on the remote playback device as the presenter switches slides, in addition to when the presenter connects to the remote playback device originally. We are not in control of any transition effects — we simply provide the slides, and it is up to the remote playback device to download and show them, however that device wishes.

The Rest of the Story

One common need of a presenter is to know how much time is remaining in which to deliver the presentation. Presentations are usually time-limited, to fit conference agendas and the like. The JSON structure for a presentation contains the duration of the presentation, and it would be useful to let the presenter know how much of that duration is remaining.

The chapter on custom views has a section outlining the implementation of [a ReverseChronometer widget](#). Chronometer is a standard Android SDK class for counting up time (e.g., a stopwatch). ReverseChronometer is for counting *down* time.

Decktastic puts a ReverseChronometer in the action bar as a custom view, courtesy of our menu XML:

```
<?xml version="1.0" encoding="utf-8"?>  
<menu xmlns:tools="http://schemas.android.com/tools"  
      xmlns:android="http://schemas.android.com/apk/res/android"  
      tools:ignore="AppCompatResource">  
  
    <item  
        android:id="@+id/countdown"  
        android:actionViewClass=
```

```
        "com.commonware.android.preso.decktastic.ReverseChronometer"
        android:showAsAction="always"
        android:title="This Should Not Be Needed">
    </item>
    <item
        android:id="@+id/route_provider"
        android:title="@string/media_route_provider"
        android:actionProviderClass=
            "com.commonware.cwac.mediarouter.app.MediaRouteActionProvider"
        android:showAsAction="always"/>
    <item
        android:id="@+id/first"
        android:icon="@android:drawable/ic_media_previous"
        android:showAsAction="always"
        android:title="@string/first">
    </item>
    <item
        android:id="@+id/last"
        android:icon="@android:drawable/ic_media_next"
        android:showAsAction="always"
        android:title="@string/last">
    </item>
    <item
        android:id="@+id/present"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"
        android:title="@string/show_presentation">
    </item>
</menu>
```

We customize the `ReverseChronometer` through a handful of lines in the `onCreateOptionsMenu()` method:

```
rc=(ReverseChronometer)menu.findItem(R.id.countdown)
    .getActionView();

rc.setWarningDuration(5 * 60);
rc.setOnClickListener(this);
rc.setOnLongClickListener(this);
rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
rc.setTextColor(Color.WHITE);

if (durationInSeconds>0) {
    rc.setOverallDuration(durationInSeconds);
}
```

Here we:

- Retrieve the `ReverseChronometer` from the action item
- Have it change to a “warning” presentation with five minutes remaining

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

- Set up the activity to respond to click and long-click events
- Set the appearance to be 24sp white text

And, if we already know the presentation's overall duration, via the `durationInSeconds` data member, we pour that into the `ReverseChronometer` as well.

`durationInSeconds` is populated via a few lines at the top of `setupPager()`:

```
durationInSeconds=preso.duration * 60;

if (rc!=null) {
    rc.setOverallDuration(durationInSeconds);
}
```

This way, no matter whether `setupPager()` or `onCreateOptionsMenu()` is called first, we pour the duration into the `ReverseChronometer`.

By default, that `ReverseChronometer` does nothing other than show the remaining time... which remains fixed by default. That is where the click and long-click event handlers come into play:

```
@Override
public void onClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    if (rc.isRunning()) {
        rc.stop();
    }
    else {
        if (isFirstRCClick) {
            isFirstRCClick=false;
            rc.reset();
        }

        rc.run();
    }
}

@Override
public boolean onLongClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    rc.reset();

    return(true);
}
```

There are three possibilities when the user taps on the ReverseChronometer:

- It was never clicked before (`isFirstRCClick` is `true`), in which case we ensure that the `ReverseChronometer` is reset to the overall duration before calling `run()` to start the countdown
- It is already running, in which case we call `stop()` to pause the countdown
- It was not already running (but was clicked before), in which case we call `run()` again to resume the countdown

This gives us what from a media standpoint would be play, pause, and resume logic.

A long-click will `reset()` the `ReverseChronometer`, returning the time remaining to the overall duration.

Our action bar also has a few other action items, handled in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            boolean original=item.isChecked();

            item.setChecked(!original);

            if (original) {
                helper.disable();
            }
            else {
                helper.enable();
            }

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;

        case R.id.last:
            pager.setCurrentItem(adapter.getCount() - 1);
            break;
    }

    return(super.onOptionsItemSelected(item));
}
```

Specifically:

- There is a checkable action item to determine whether or not we should be showing a Presentation. If this is unchecked, and an external display is attached, we still disable the PresentationHelper. This will cause normal display mirroring to begin, and the audience will see the same UI that the presenter does, complete with the ViewPager, action bar, and so on. Checking it re-enables the PresentationHelper, so if an external display is available, we start showing the slides again.
- The first and last action bar items are “fast-forward” and “rewind” options, allowing the presenter to quickly jump to the first or the last slide in the presentation. This happens via calls to `setCurrentItem()` on the ViewPager, which will in turn invoke `onPageSelected()`, causing us to update our PresentationFragment or remote playback device, if needed.

Note that since the direct-to-TV mode hides the action bar, none of these options are available to the presenter on a device like Android TV or a Fire TV. This will require the presenter to use something else to track the remaining time in a presentation, such as a countdown timer app running on a separate Android device.

Creating a MediaRouteProvider

As was noted [earlier in the book](#), you can use `MediaRouter` to identify media routes, such as those published by devices like Google's Chromecast. Specifically, remote playback routes let you write apps that tell other devices, like the Chromecast, to play back media on your behalf.

However, not only can you write *clients* for remote playback routes, you can write *providers* of those routes. Perhaps you are working with a hardware manufacturer that is creating a Chromecast-like device. Perhaps you want to allow your app, running on a [Fire TV](#) or an Android HDMI stick, to be controlled by a user's phone or tablet. Or perhaps you are trying to tie Android into specialized media hardware that does not communicate by conventional means (e.g., wireless speakers that do not use normal Bluetooth profiles).

This chapter will outline how you can create code that will publish media routes to users of `MediaRouter`, so that you can then take those requests and forward them to a remote device.

Prerequisites

This chapter assumes that you have read [the chapter on MediaRouter](#). Reading the chapter on [the Chromecast and the Google Cast SDK](#) would also be useful.

Terminology

For the purposes of this chapter:

- The “client device” refers to a phone or tablet that runs an app that should be able to direct what is shown on a streaming media player
- The “player device” refers to the streaming media player itself, which may or may not be running Android
- The “player app” refers to an Android app running on an Android-powered player device

DIY Chromecast

Google’s Chromecast is a nice little device. However, it has issues:

- The device itself is not especially open.
- The Cast SDK that Google encourages for writing Chromecast-enabled apps is not especially open.
- The [terms and conditions](#) for using the Cast SDK may be troublesome for many developers.
- Chromecast is not available globally.
- Chromecast is only one device, and there are plenty of other streaming media devices available that need to be considered.

Some of these issues can be mitigated by the use of `MediaRouter` and `RemotePlaybackClient` instead of the proprietary Cast SDK. You are not bound by any particular license terms (beyond the norm for Android development) and the implementation of the media framework is open.

However, to make this work, the client device needs to know how to talk to the player device.

The good news is that the media routing framework in Android supports plug-in media route providers for just this purpose. The OS ships with such a provider for the Chromecast, and you can create your own providers to talk to whatever else you would like to talk to. The user can then install a small app on their client device that implements this media route provider, and *any* apps already on their client device that use classes like `RemotePlaybackClient` will automatically be able to cast their desired content to the player device.

MediaRouteProvider

The guts of this come in the form of a `MediaRouteProvider`. Your custom subclass of `MediaRouteProvider` will:

- Tell Android what general capabilities you support, such as remote playback, session management, and the like
- Advertise what sorts of content your player device is capable of playing (e.g., certain video MIME types, certain URL schemes like http and rtsp)
- Serve as the recipient of commands from `MediaRouter`, `RemotePlaybackClient`, and the like, for you to forward along asynchronously to the player device

Depending upon your use case, you could elect to keep the `MediaRouteProvider` private to your application. That way, your app can cast to the player device, but no other apps can. Or, you can make your `MediaRouteProvider` available to all apps on the device, with the media routing framework taking care of the IPC details to have those apps tell your `MediaRouteProvider` what the player device should do.

Player Device... and Maybe a Player App

Of course, this assumes the existence of some player device that is not supported by Android out of the box. Since Android only really supports Chromecast, external displays (e.g., HDMI, MHL, Miracast), and some Bluetooth options (e.g., external speakers) for media routes, there are countless player devices that need additional help. These will run the gamut from devices from major players (e.g., Amazon's Fire TV) to no-name devices (e.g., Android HDMI "sticks").

Some player devices will run Android. In that case, you would be writing a player app that would run on the player device that would be the recipient of commands sent to it from your `MediaRouteProvider` on the client device. For example, if you write a video player app, you could augment it with remote control capability driven by a `MediaRouteProvider` on a client device, turning your player app and anything it can run on (e.g., Fire TV, OUYA game console) into a Chromecast-like environment.

Some player devices will not run Android. If they offer some existing remote control over-the-air protocol, you could create a `MediaRouteProvider` that speaks that protocol. Or, perhaps the player devices are programmable, just not via Android (e.g., a Linux program for XMBC), in which case you might be able to write both ends of the communications channel.

Communications Protocol

Somehow, the data from the `MediaRouteProvider` needs to get to the player device (and, where relevant, the player app). Likely candidates include Bluetooth, regular WiFi (if both devices are on the same network), and WiFi Direct.

However, in principle, anything is possible. For example, there is nothing stopping you from sending `MediaRouteProvider` commands to some Web server out on the Internet, which forwards them to some distant location for use. That would be a bit unusual – normally, the user of the client device is controlling something she can see — but it certainly could be done.

The biggest thing to watch out for is the addressability of the media to be played back. There is little point in connecting a `MediaRouteProvider` to some player device, then not have the ability for the player device to access the media that the client device is requesting. The expected pattern is that the media is hosted in some (relatively) central location, like a Web server. However, once again, anything is possible. If you want to have some sort of server on the client device, to allow the player device to play back media from it, and you believe that you can adequately secure this, you are welcome to do so.

Creating the `MediaRouteProvider`

As noted earlier, the core of all of this is a custom `MediaRouteProvider`. Google supplies a [sample application](#) for creating such a `MediaRouteProvider`. However, it is overly complex, and it is undocumented.

This chapter will focus instead on the [MediaRouter/RouteProvider](#) sample project. This is a clone of the `MediaRouter/RemotePlayback` sample project covered [earlier in this book](#), with the addition of a custom `MediaRouteProvider`.

Defining the Supported Actions

A `MediaRouteProvider` advertises — whether to its own app's `MediaRouter` or to the entire device — what sorts of actions it can perform. For example, a remote playback route provider needs to support actions like play, pause, resume, and stop of some piece of media.

The way this is handled in the media routing framework is via a series of `IntentFilter` objects.

CREATING A MEDIAROUTEPROVIDER

Since `IntentFilter` objects do not need a `Context` to be created, it is safe to define them statically, if desired. That's what we do in `DemoRouteProvider`, a custom subclass of `MediaRouteProvider`. It declares a pair of static final `IntentFilter` objects, `ifPlay` and `ifControl`, which are then configured in a static initialization block:

```
private static final IntentFilter ifPlay=new IntentFilter();
private static final IntentFilter ifControl=new IntentFilter();

static {
    ifPlay.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifPlay.addAction(MediaControlIntent.ACTION_PLAY);
    ifPlay.addDataScheme("http");
    ifPlay.addDataScheme("https");
    ifPlay.addDataScheme("rtsp");

    try {
        ifPlay.addDataType("video/*");
    }
    catch (MalformedMimeTypeException e) {
        throw new RuntimeException("Exception setting MIME type", e);
    }

    ifControl.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifControl.addAction(MediaControlIntent.ACTION_PAUSE);
    ifControl.addAction(MediaControlIntent.ACTION_RESUME);
    ifControl.addAction(MediaControlIntent.ACTION_STOP);
    ifControl.addAction(MediaControlIntent.ACTION_GET_STATUS);
    ifControl.addAction(MediaControlIntent.ACTION_SEEK);
}
```

Both stipulate that they are looking for `Intent` objects in the `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK` category. This category is used for all media routing `Intents` that form the foundation of the routing framework.

`ifPlay` is defined as supporting `MediaControlIntent.ACTION_PLAY`, stating that we know how to play back some content. The qualifications for “some content” are handled via scheme and type constraints placed on the `IntentFilter`. Here, we limit the content to be URLs that might be reachable by a playback device (`http`, `https`, `rtsp`) and have a MIME type matching `video/*`. Hence, we are stating that we can play back streaming video.

`ifControl` sets up the remaining actions that we support:

- `MediaControlIntent.ACTION_PAUSE`
- `MediaControlIntent.ACTION_RESUME`
- `MediaControlIntent.ACTION_STOP`

CREATING A MEDIAROUTEPROVIDER

- `MediaControlIntent.ACTION_GET_STATUS`
- `MediaControlIntent.ACTION_SEEK`

These are placed on an independent `IntentFilter` because, technically, we can support these actions on any type of media. In the case of this specific example, the only media we support is streaming video. But, we could configure other `IntentFilter` objects, like `ifPlay` was, stating yet other media types that we handle.

To fully comply with the `RemotePlaybackClient` API, we must advertise that we handle all of those actions... even if our intended client will not use all of them.

We could also:

- Advertise that we support session management actions, like `MediaControlIntent.ACTION_START_SESSION`
- Advertise that we support the “enqueue” operation for stacking up media to be played (e.g., `MediaControlIntent.ACTION_ENQUEUE`) and manipulating that queue (e.g., `MediaControlIntent.ACTION_REMOVE`)
- Define a custom category for other actions that we support that are “out of band” with respect to the standard media routing actions

All of those are demonstrated in Google’s sample app.

Creating the Descriptors

Just because we have some static `IntentFilter` objects does not mean that anything will pay attention to them. We need to actually register them with the media routing framework, wrapped in a pair of “descriptor” objects.

`DemoRouteProvider` calls a private `handleDiscovery()` method from the constructor, where `handleDiscovery()` sets up the descriptors:

```
private void handleDiscovery() {
    MediaRouteDescriptor.Builder mrdBuilder=
        new MediaRouteDescriptor.Builder(DEMO_ROUTE_ID, "Demo Route");

    mrdBuilder.setDescription("The description of a demo route")
        .addControlFilter(ifPlay)
        .addControlFilter(ifControl)
        .setPlaybackStream(AudioManager.STREAM_MUSIC)
        .setPlaybackType(MediaRouter.RouteInfo.PLAYBACK_TYPE_REMOTE)
        .setVolumeHandling(MediaRouter.RouteInfo.PLAYBACK_VOLUME_FIXED);

    MediaRouteProviderDescriptor.Builder mrpdBuilder=
        new MediaRouteProviderDescriptor.Builder();
}
```

CREATING A MEDIAROUTEPROVIDER

```
mrpdBuilder.addRoute(mrdBuilder.build());  
setDescriptor(mrpdBuilder.build());  
}
```

In the end, we need to provide a `MediaRouteProviderDescriptor` to the `MediaRouteProvider` by means of a `setDescriptor()` method. `MediaRouteProviderDescriptor` is, in effect, metadata about the `MediaRouteProvider` itself. At the present time, the only thing this holds is a set of `MediaRouteDescriptor` objects, one for each media route that the `MediaRouteProvider` claims to support.

A `MediaRouteProvider` is made up of several pieces of information, including:

- The `IntentFilter(s)` representing the supported actions and, where relevant, MIME types and schemes
- A locally-unique ID of the route, to distinguish it from any other one that we might configure
- A name and description, which the user will see when they try to connect to this route (e.g., via a `MediaRouteActionProvider`)
- What audio stream is being used for the playback, from the standpoint of volume management, audio ducking, and the like
- Whether the playback is occurring locally on the device to some peripheral (e.g., speaker) or if the playback is occurring remotely on a player device (e.g., Chromecast)
- Whether playback volume is controlled here on the client device or on the player device
- Etc.

These are all configured on a `MediaRouteProvider` by creating a `MediaRouteProvider.Builder` and supplying the values either in the `Builder` constructor or via fluent setter methods. In the particular case of our simple demo provider, we:

- Use various strings for the ID, name, and description
- Use the two `IntentFilter` objects defined earlier to indicate what actions we can perform
- Indicate that the playback stream is `STREAM_MUSIC`, that the playback type is `PLAYBACK_TYPE_REMOTE`, and that the volume handling is `PLAYBACK_VOLUME_FIXED` (i.e., volume should be managed on the TV or whatever the media is being played upon)

It is very likely that you will elect to have several `MediaRouteDescriptor` objects for different client application scenarios. Google's sample app uses a total of four `MediaRouteDescriptor` objects:

- One set up largely like the one in this sample
- One set up with `PLAYBACK_VOLUME_VARIABLE` (so volume is controllable by a client app)
- One set up with variable volume plus queuing actions
- One set up with variable volume plus queuing and session management actions

Receiving the Actions

Now, we have told the media routing framework what actions we support. Some app will then try to use `RemotePlaybackClient` and ask us to perform those actions. Hence, we need to find out when this happens, so we can do the actual work of having the playback device actually play back the media, pause the media, etc.

To do this, we need to create a custom subclass of `MediaRouteProvider.RouteController`. This contains a series of callback methods which we can override to find out when various events occur.

There are four such callback methods that the `DemoRouteController` subclass of `MediaRouteProvider.RouteController` implements:

- `onSelect()`, which will be called when a client app has selected our `MediaRouteProvider` to handle some media on behalf of that client app
- `onUnselect()` and `onRelease()`, which will be called when the client app disconnects from our `MediaRouteProvider`
- `onControlRequest()`, which will be called when some specific action that we advertised is requested, such as playing back a piece of media

The `DemoRouteController` just logs a message to LogCat for the first three callbacks:

```
@Override
public void onRelease() {
    Log.d(getClass().getSimpleName(), "released");
}

@Override
public void onSelect() {
    Log.d(getClass().getSimpleName(), "selected");
}
```

```
@Override
public void onUnselect() {
    Log.d(getClass().getSimpleName(), "unselected");
}
```

The `onControlRequest()` method is a bit more complex, as *all* control requests route through here: play, pause, resume, stop, etc. `onControlRequest()` is passed the Intent identifying the particular action that should be performed, and we can examine the Intent action string to determine what needs to be done. In this case, `onControlRequest()` delegates the real work to action-specific methods like `onPlayRequest()`:

```
@Override
public boolean onControlRequest(Intent i, ControlRequestCallback cb) {
    if (i.hasCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)) {
        if (MediaControlIntent.ACTION_PLAY.equals(i.getAction())) {
            return(onPlayRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_PAUSE.equals(i.getAction())) {
            return(onPauseRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_RESUME.equals(i.getAction())) {
            return(onResumeRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_STOP.equals(i.getAction())) {
            return(onStopRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_GET_STATUS.equals(i.getAction())) {
            return(onGetStatusRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_SEEK.equals(i.getAction())) {
            return(onSeekRequest(i, cb));
        }
    }

    Log.w(getClass().getSimpleName(), "unexpected control request"
        + i.toString());

    return(false);
}
```

`onControlRequest()` should return true if we agree to perform the action and will use the supplied `ControlRequestCallback` object to asynchronously deliver our results. If `onControlRequest()` returns false, that means that we are rejecting the action for some reason, such as it being one that is unrecognized. In `DemoRouteController`, that will occur if the category or the action on the Intent is not one of the supported options.

Note that if you opted into variable volume, there are `onSetVolume()` and `onUpdateVolume()` callback methods that will give you access to those events.

Handling the Actions

For those actions that you advertise and receive in `onControlRequest()`, you need to actually do the work for those actions. The details of this will vary widely depending upon your playback device and playback app that you are supporting. For example, you might establish a WiFi Direct connection in `onSelect()`, then use that connection in handling play, pause, etc. actions.

However, a few aspects of handling these actions will be in common across all implementations:

- `onControlRequest()` must return `true` or `false` as was described in the preceding section
- You must call `onResult()` or `onError()` on the `ControlRequestCallback` object to indicate if the action succeeded or failed
- You must supply an appropriate `Bundle` to those methods, particularly to `onResult()`, containing the right set of values to provide more details about the results of the action

The details of what that `Bundle` must contain are documented on the `MediaControlIntent` class, on the definition of each action string (e.g., `ACTION_PLAY`).

With that in mind, let's look at the six actions supported by `DemoRouteController`.

Play

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_PLAY`, needs three values:

- `EXTRA_SESSION_ID`: if you are implementing session management, this will be the unique session ID (`String`) for the session you are playing the media in. If you are not implementing session management, then what you are supposed to return is undocumented and (hopefully) unused
- `EXTRA_ITEM_ID`: if you are implementing “enqueue” support, this will be the item ID (`String`) for managing this item in the queue of available items. If you are not supporting a playback queue, then what you are supposed to return is undocumented and (hopefully) unused

CREATING A MEDIAROUTEPROVIDER

- EXTRA_ITEM_STATUS: this should point to a Bundle created from a MediaItemStatus object where you indicate what the status is of the playback of this item

You create a MediaItemStatus object via a MediaItemStatus.Builder, where you can pass into the constructor a value indicating the overall status (e.g., MediaItemStatus.PLAYBACK_STATE_PLAYING), plus use fluent setter methods to define additional characteristics of the status, such as the current seek position.

The DemoRouteController logic for ACTION_PLAY, in the onPlayRequest() method, logs the event to LogCat and crafts a valid-but-meaningless result Bundle for use with onResult():

```
private boolean onPlayRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "play: "
        + i.getData().toString());

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putString(MediaControlIntent.EXTRA_SESSION_ID,
        DemoRouteProvider.DEMO_SESSION_ID);
    b.putString(MediaControlIntent.EXTRA_ITEM_ID,
        DemoRouteProvider.DEMO_ITEM_ID);
    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}
```

Pause, Resume, and Stop

The Bundle passed to onResult() of the ControlRequestCallback, when the action is ACTION_PAUSE, ACTION_RESUME, or ACTION_STOP, does not need any particular values at the present time. Hence, the DemoRouteController methods for those actions just log the event to LogCat and pass an empty Bundle to onResult():

```
private boolean onPauseRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "pause");

    cb.onResult(new Bundle());
}
```

```
        return(true);
    }

    private boolean onResumeRequest(Intent i, ControlRequestCallback cb) {
        Log.d(getClass().getSimpleName(), "resume");

        cb.onResult(new Bundle());

        return(true);
    }

    private boolean onStopRequest(Intent i, ControlRequestCallback cb) {
        Log.d(getClass().getSimpleName(), "stop");

        cb.onResult(new Bundle());

        return(true);
    }
}
```

Get Status and Seek

The Bundle passed to onResult() of the ControlRequestCallback, when the action is ACTION_GET_STATUS or ACTION_SEEK, must contain the same sort of MediaItemStatus-built nested Bundle representing the current status. For ACTION_GET_STATUS, the only “work” to be done is to pass back the status; for ACTION_SEEK, you should move the playback position to the location indicated by an extra on the Intent, then return the revised status.

In the case of DemoRouteController, both just log a message to LogCat and return a fairly pointless status:

```
private boolean onGetStatusRequest(Intent i,
                                   ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "get-status");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
               statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}

private boolean onSeekRequest(Intent i, ControlRequestCallback cb) {
```

CREATING A MEDIAROUTEPROVIDER

```
Log.d(getClass().getSimpleName(), "seek");

MediaItemStatus.Builder statusBuilder=
    new MediaItemStatus.Builder(
        MediaItemStatus.PLAYBACK_STATE_PLAYING);

Bundle b=new Bundle();

b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
    statusBuilder.build().asBundle());

cb.onResult(b);

return(true);
}
```

Publishing the Controller

While we have defined our RouteController, we still need to teach our MediaRouteProvider about it. That is through overriding the onCreateRouteController() method and returning an instance of RouteController:

```
@Override
public RouteController onCreateRouteController(String routeId) {
    return(new DemoRouteController());
}
```

onCreateRouteController() is passed the route ID String used in the MediaRouteDescriptor. You can either use that to instantiate a different RouteProvider, pass the String into a common RouteProvider so it knows what to do, or ignore it entirely if you have only one published route. In the case of DemoRouteProvider, we ignore the route ID and always return a DemoRouteController.

Handling Discovery Requests

DemoRouteProvider is always available, largely because it does not do much of anything.

In the real world, your MediaRouteProvider may not always be relevant. For example, the TV you are set up to talk to may be powered down. Or, the user may not be at home where the TV is, so the client device and the TV are not on the same network.

Rather than constantly polling the outside world to see if a route is possible, we only do this when a client app requests “route discovery”, such as by providing the `MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY` flag on an `addCallback()` call to a `MediaRouter`. That in turn triggers an `onDiscoveryRequestChanged()` call on our `MediaRouteProvider`.

There, and in our constructor-triggered setup, we should do work to determine if a route is currently possible and set up our descriptors. This work should be done in a background thread if it involves network I/O.

Note that `onDiscoveryRequestChanged()` is passed a `MediaRouteDiscoveryRequest` object, describing what the consuming app is looking for. If the request is irrelevant for your provider (e.g., the app wants a local audio route, and you provide remote playback routes), simply ignore it.

The `onDiscoveryRequestChanged()` implementation in `DemoRouteProvider` just calls the same `handleDiscovery()` method that the constructor does.

Consuming the MediaRouteProvider

Having a `MediaRouteProvider` is nice, but it is useless if apps are not going to know about it.

You have two main options for consuming the `MediaRouteProvider`: use it only within your own app, or publish it to all apps on the device.

Private Provider

Using a `MediaRouteProvider` for your own app is very simple. Just add a single call to `addProvider()` on your `MediaRouter`, supplying an instance of your `MediaRouteProvider`.

Since our sample project is a fork of the original `RemotePlaybackClient` sample, we still have a `PlaybackFragment` that sets up the `MediaRouter` and `MediaRouteActionProvider`. In `onAttach()` of that `PlaybackFragment`, we can configure our `MediaRouterProvider` after obtaining the `MediaRouter` instance:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);
```

CREATING A MEDIAROUTEPROVIDER

```
router=MediaRouter.getInstance(host);
provider=new DemoRouteProvider(getActivity());
router.addProvider(provider);
}
```

At this point, our DemoRouteProvider will be available as an option for the user, along with any other eligible media routes:

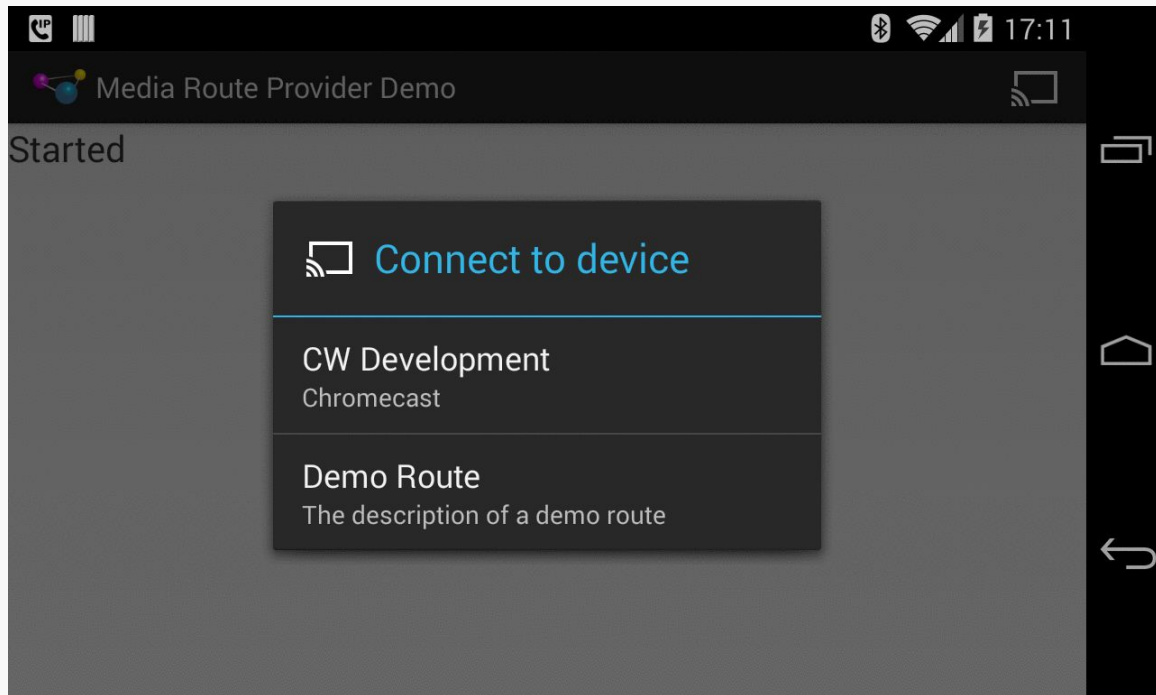

Figure 650: MediaRouteProvider Demo, on a Nexus 4, Showing Available Routes

Choosing the DemoRouteProvider (“Demo Route” in the screenshot) will allow you to use it just like you do a Chromecast... if you do not mind the fact that nothing shows up on your television:

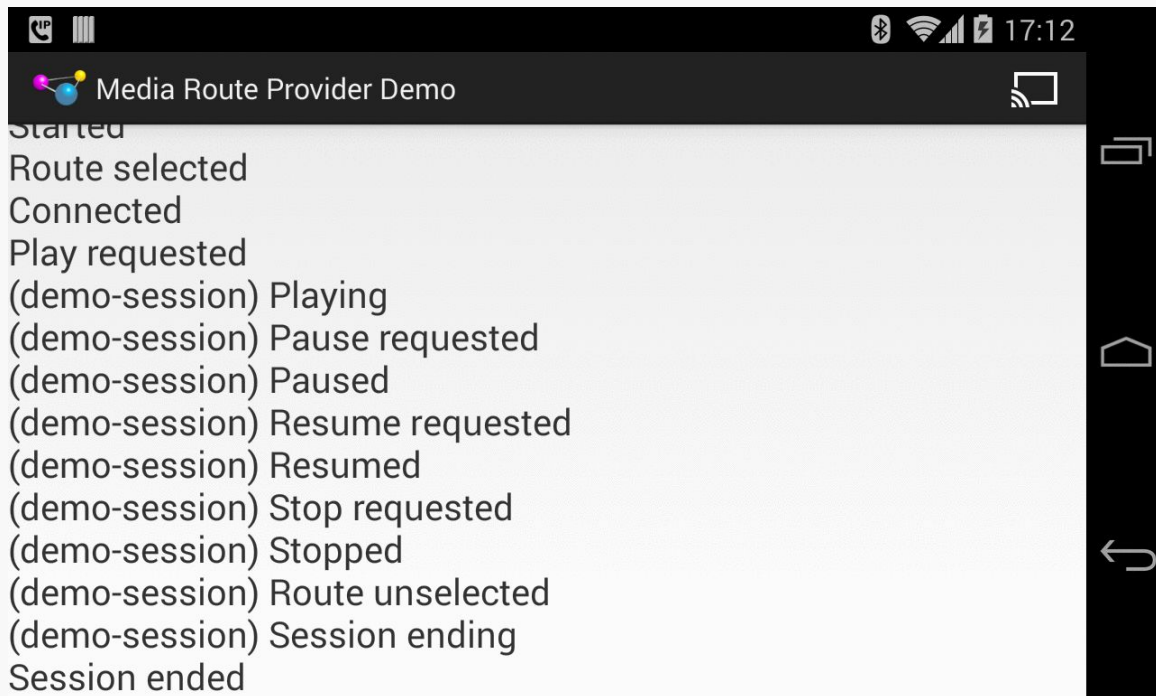

Figure 651: MediaRouteProvider Demo, on a Nexus 4, After Several Commands

As it turns out, the DemoRouteProvider works better than Google's own MediaRouteProvider for the Chromecast, insofar as more of the callbacks work. Specifically, we actually receive callbacks for pause, resume, and stop events, as opposed to having to just assume that those events completed.

Also, we remove the demo provider in `onDetach()`:

```
@Override
public void onDetach() {
    router.removeProvider(provider);

    super.onDetach();
}
```

Among other things, this allows us to correctly handle configuration changes — if we fail to call `removeProvider()` and blindly add another provider in `onAttach()`, we wind up with multiple providers, because our `MediaRouter` is a framework-provided singleton and is not re-created with the new fragment.

Public Provider

If you want your `MediaRouteProvider` to be used by other apps, you will need to create one more Java class: a subclass of `MediaRouteProviderService`. This requires only one method, `onCreateMediaRouteProvider()`, where you return an instance of your `MediaRouteProvider`:

```
package com.commonware.android.mrp;

import android.support.v7.media.MediaRouteProvider;
import android.support.v7.media.MediaRouteProviderService;

public class DemoRouteProviderService extends MediaRouteProviderService {
    @Override
    public MediaRouteProvider onCreateMediaRouteProvider() {
        return(new DemoRouteProvider(this));
    }
}
```

This also needs to be added to your manifest, like any other `Service`. Give it an [intent-filter] looking for the `android.media.MediaRouteProviderService` action, so the media routing framework knows that it can obtain a `MediaRouteProvider` from it:

```
<service
    android:name="DemoRouteProviderService"
    tools:ignore="ExportedService">
    <intent-filter>
        <action android:name="android.media.MediaRouteProviderService"/>
    </intent-filter>
</service>
```

However, do *not* do both `addProvider()` *and* have the `<service>` element. If you use the `<service>` element, your app can use the `MediaRouteProvider`, just as can any other app on the device. Hence, in the published source code for this sample, the `<service>` element is commented out — you will need to uncomment it, and comment out the `addProvider()` call, to test the `DemoRouteProvider` with other apps.

Implementing This “For Realz”

Of course, `DemoRouteProvider` is just a demo and does not actually play any media anywhere. It is here to give you the basic steps for responding to `RemotePlaybackClient` requests. For a production `MediaRouteProvider`, in addition to the usual tightening-up of the code (e.g., better exception handling), you will

need to work on other areas as well, ones that are beyond the scope of the sample app.

Communicating with the Playback Device

Of course, the big one is passing the actions over to the playback device, so you actually *do* play back media.

If you are the developer of the playback device and its protocols (e.g., it is an Android device, and you are writing the playback app for it), then you can choose how you wish to handle the communications. You can work with low-level socket protocols directly, or you can leverage libraries like [AllJoyn](#) or [ZeroMQ](#).

If the playback device “is what it is”, and you cannot change it, then you will need to determine what protocols it offers and how best to map the `MediaControlIntent` actions to that protocol.

Also note that `onControlRequest()` is designed for asynchronous operation. The sample app just invoked the `ControlRequestCallback` during the `onControlRequest()` processing. Usually, though, your communications with the playback device will not be as fast as a call to `Log.d()`. You should arrange to do those communications in a background thread, perhaps via a single-thread thread pool as an `ExecutorService`. Simply pass the `ControlRequestCallback` to that thread along with the rest of the action’s data (e.g., the URL of the media to load), and the thread can call `onResult()` or `onError()` as needed.

Handling Other Actions/Protocols

As was noted in the description of the sample app, that app eschews:

- volume control
- session management
- queue management

Any of those may be of interest to your users, and so you may need to consider offering them at some point. Also note that some potential client apps might need those capabilities and therefore will not see or use your published media routes without them.

Custom Actions

When setting up the `MediaRouteProvider`, we create one or more `MediaRouteDescriptor` objects wrapped around one or more `IntentFilter` objects. Those `IntentFilter` objects indicate what actions we support. The `DemoRouteProvider` uses standard actions (e.g., `ACTION_PLAY`) in a standard category (`CATEGORY_REMOTE_PLAYBACK`).

However, you are not limited to that.

You are welcome to also support custom actions in a custom category, to represent other things that your particular `MediaRouteProvider` offers. You can then use those actions from your own client app, or document them for use by third-party apps.

The client app can use `supportsControlRequest()` and `sendControlRequest()` to determine whether a particular media route supports a particular `Intent` that represents an action to be performed by that route's `MediaRouteProvider`. This way, a client app can work both with your custom `MediaRouteProvider` (taking advantage of your custom actions) and with regular providers that lack such support, assuming that the client can gracefully degrade its functionality.

Trail: Security

The traditional approach to securing HTTP operations is by means of SSL. Android supports SSL, much as ordinary Java does. Most of the time, you can just allow Android to do its thing with respect to SSL, and you will be fine. However, there may be times when you have to play a more direct role in SSL communications, to handle arbitrary SSL-encrypted endpoints, or to help ensure that your app is not the victim of a man-in-the-middle attack.

This chapter will explore various SSL scenarios and how to address them.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on Internet access](#).

Basic SSL Operation

Generally speaking, SSL “just works”, for ordinary sites with ordinary certificates.

If you use an `https:` URL with `URLConnection`, `HttpClient`, or `WebView`, SSL handshaking will happen automatically, and assuming the certificates check out OK, you will get your result, just as if you had requested an `http:` URL.

However, `DownloadManager` only recently added support for SSL. Originally, requesting a download via `DownloadManager` with an `https:` scheme would result in `java.lang.IllegalArgumentException: Can only download HTTP URIs`. As of Android 4.0, SSL is supported. Hence, you need to be careful about making SSL

requests via `DownloadManager` to ensure that you are only doing that on a relatively recent version of Android.

For example, the Retrofit and Picasso sample apps from [the chapter on Internet access](#) both use `https://api.stackexchange.com` for their service endpoint. As a result, those requests — for the API JSON, at least — will go over SSL. You would need to log the URLs used for the image avatars to see whether StackExchange gives you https URLs or not.

Common SSL Problems

It would be nice if SSL always worked, rather than only generally worked. Alas, there are problems that you may well encounter while setting up SSL support, beyond having to deal with possible man-in-the-middle attacks.

This section will outline some of these common problems.

Self-Signed Certificate

SSL certificates used for public Web sites are usually backed by a “root certificate authority” that is well-known. That is not always the case.

One case is when the certificate is “self-signed”, meaning that it was generated by somebody without involving a certificate authority. If you have shipped a production Android app, you created a self-signed certificate when you created your production key store. And you have been using a system-generated self-signed certificate throughout your development, known as the “debug signing key”.

Self-signed certificates are rarely used on public-facing Web sites, as Web browsers are taught to warn users when such certificates are encountered. However, self-signed certificates might be used on internal servers, particularly test servers and other non-production environments.

There are even some benefits for using a self-signed certificate for production servers, if those servers will be talking only to your own apps and not arbitrary Web browsers. This technique will be reviewed [later in this chapter](#).

Wildcard Certificate

Some certificates are difficult to validate because they use wildcards.

For example, Amazon S3 is a file storage and serving “cloud” solution from Amazon.com. They allow you to define “buckets” containing “objects”, where each object then has its own URL. That URL is based on the name of the bucket and the name of the object. One option is for you to have the domain name of the URL be based on the name of the bucket, leaving the path to be solely the name of the object. This works, even with SSL, but Amazon needed to use a “wildcard SSL certificate”, one that matches *.s3.amazonaws.com, not just a single domain name. By default, this will fail on Android, as Android’s stock TrustManager will not validate wildcards for multiple domain name segments (e.g., http://misc.commonsware.com.s3.amazonaws.com/foo.txt). You will get an exception akin to:

```
javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException:  
No subject alternative DNS name matching misc.commonsware.com.s3.amazonaws.com  
found
```

Custom Certificate Authority

Some larger organizations have set up their own certificate authority. Sometimes, they aspire to become a recognized root certificate authority, but have not been adopted by many browsers. Sometimes, they simply want to have more structure than a pure self-signed certificate but do not necessarily want to have all certificates go through a root certificate authority, perhaps due to expense.

In these cases, Android will reject the SSL certificate, for the same reason it rejects self-signed ones: it cannot validate the certificate chain all the way back to a known root certificate authority. But, with a little work, you can enable Android to support these as well.

TrustManagers

Our work in handling these common problems — and some other enhancements that help with other sorts of attacks — revolves around a TrustManager. You may already be familiar with these from standard Java development. Otherwise, this section reviews what a TrustManager is and how you apply one in your Android HTTP operations. Later on, we will discuss where you can get a TrustManager that works the way you want.

What is a TrustManager?

In Java, a TrustManager is responsible for determining if an SSL certificate chain is valid or not for a given request.

An SSL certificate chain, in turn, represents a series of SSL certificates that, as the name suggests, are chained together. Sometimes, the chain will only have one entry (e.g., a self-signed certificate). More often, the chain will have a few entries, starting with the server's certificate, which may chain to some intermediate certificate(s), eventually leading to a certificate that might be from a root certificate authority.

In truth, we often use a collection of TrustManager instances, represented as a simple Java array. And, of course, courtesy of design patterns like the composite pattern, one TrustManager might delegate decision-making to other TrustManager instances.

How Do We Use One?

For the moment, let us assume that we get a TrustManager array handed to us by magic. How would we use it?

The answer depends on what you are using for your HTTP stack, as is outlined below.

HttpsURLConnection

Normally, when using a `java.net.URL`, you open a connection and do not pay much attention to whether the connection object you get back is an `URLConnection` or an `HttpsURLConnection`. If, however, you want to tailor the SSL processing with a custom TrustManager array, you will need to explicitly use `HttpsURLConnection`:

```
SSLContext ssl=SSLContext.getInstance("TLS")
ssl.init(null, builders, null);
HttpsURLConnection conn=(HttpsURLConnection)new URL(url).openConnection();
conn.setSSLSocketFactory(ssl.getSocketFactory());
// conn.getInputStream() and other work to process the HTTPS call
```

(here, builders is the array of TrustManager instances)

OkHTTP

Square's OkHttp works along the same lines:

```
SSLContext ssl=SSLContext.getInstance("TLS")
ssl.init(null, builders, null);
OkHttpClient okHttpClient=new OkHttpClient();
okHttpClient.setSslSocketFactory(ssl.getSocketFactory());
URLConnection conn=okHttpClient.open(new URL(url));
// conn.getInputStream() and other work to process the HTTPS call
```

Something Else

Other HTTP stacks, or libraries that in turn use HTTP directly or indirectly, should offer similar facilities. If not, you may wish to switch to something that does.

What Not To Do

You will find various blog posts, Stack Overflow answers, and the like that suggest that you simply disable SSL certificate validation, by implementing an “accept-all” TrustManager. Such a TrustManager basically implements the interface with empty stubs for methods like checkServerTrusted(), not throwing any exceptions.

Technically, this works. And, *if* you are using this only early on in development and *if* you swear upon a stack of \$RELIGIOUS_TEXTS that you will replace this hack by the time you go to production, it is difficult to complain about this technique.

However, in production, ignoring SSL certificate validation errors opens your app up to man-in-the-middle attacks. We will explore man-in-the-middle attacks in greater detail [later in this chapter](#).

If you think that this is not important, bear in mind that [the US Federal Trade Commission \(FTC\) has sued firms for blindly accepting all SSL certificates](#). It is not out of the question for class action suits, or legal action by other nations, to be forthcoming.

Please do not implement an “accept-all” TrustManager!

TrustManagerBuilder

To simplify handling some of these scenarios, the author of this book has written a TrustManagerBuilder, as part of [the CWAC-Security library](#). The objective of this library is to bundle up some good SSL hygiene practices in an easy-to-use builder-style API. You create an instance of TrustManagerBuilder, call a series of methods on it to configure your desired SSL behavior, then call buildArray() to get the TrustManager array to pass into your init() call on the SSLSocket, as described above.

The following sections are based in part on [the TrustManagerBuilder documentation](#).

Basic Configuration

There are two TrustManagerBuilder constructors: a zero-argument constructor and a one-parameter constructor, taking a Context. Use the one-parameter constructor if you plan on using the builder-style methods that take a raw resource ID or a path into assets/ as parameters.

Of course, the real work is done in the `// configure builder here` parts, using the following builder-style methods:

- `useDefault()`: this tells TrustManagerBuilder to use the system default TrustManager for validating incoming SSL certificates
- `selfSigned()`: this tells TrustManagerBuilder to allow a specific self-signed SSL certificate, based upon a supplied keystore file and password
- `allowCA()`: this tells TrustManagerBuilder to accept certificates signed by a custom certificate authority, based upon a supplied certificate file
- `denyAll()`: this tells TrustManagerBuilder to reject all certificates (mostly for testing purposes)
- `memorize()`: this tells TrustManagerBuilder to only accept SSL certificates approved by the user
- `addAll()`: this tells TrustManagerBuilder to add other trust managers that you may have implemented yourself or obtained from other libraries

In addition, `or()` tells TrustManagerBuilder to logically OR any subsequent configuration with whatever came previously in the build, while `and()` indicates that subsequent configuration should be logically AND-ed with whatever came previously.

Supporting Self-Signed Certificates

Perhaps you are using self-signed certificates for an in-house server, such as a test server for development purposes.

`selfSigned()` will help with that. The simple form of the method takes two parameters. The first parameter is either:

- a `File` pointing to a keystore for your self-signed certificate on the local file system,
- an `int` raw resource ID, if you wish to package the keystore in your app in `res/raw/`, or
- a `String` pointing to a relative path in `assets/` where you have placed your keystore

The second parameter is a char array for the password for the keystore. If you are dynamically retrieving that password (e.g., the user types it in), you can clear out the char array (e.g., set all elements in the array to `x`), to quickly get rid of the password from memory. If your password is more static, just call `toCharArray()` on a `String` to get the char array that you need.

The default `selfSigned()` expect that keystore to be in BKS format; if your keystore is in some other format supported by Android's edition of `KeyStore`, use the three-parameter version of `selfSigned()` that takes the `KeyStore` format name as the last parameter.

If you want to *only* support a specific self-signed certificate, you could set up a `TrustManagerBuilder` as follows:

```
new TrustManagerBuilder(this).selfSigned(R.raw.selfsigned,  
"foobar".toCharArray());
```

(where `this` is a `Context`, like the `IntentService` in which you are making a SSL-encrypted Web service call)

Here, the BKS-formatted keystore would reside in `res/raw/selfsigned.bks` (though the file extension could vary).

If you want to support more than one self-signed certificate — such as when you plan on switching your old certificate to a new one — you could do:

SSL

```
new TrustManagerBuilder(this)
    .selfSigned(R.raw.selfsigned, "foobar".toCharArray())
    .or()
    .selfSigned(R.raw.selfsigned2, "snicklefritz".toCharArray());
```

If you want to use a single TrustManagerBuilder for both your self-signed scenario and regular certificate authority-based certificates, you could do:

```
new TrustManagerBuilder(this)
    .selfSigned(R.raw.selfsigned, "foobar".toCharArray())
    .or()
    .useDefault();
```

Getting the self-signed certificate keystore, and employing the self-signed certificate on your server, is up to you. For example, you could use `openssl` to generate a 4,096-bit self-signed certificate, with a lifespan of 10,000 days:

```
openssl req -new -newkey rsa:4096 -sha1 -days 10000 -nodes -x509 -keyout
selfsigned.key -out selfsigned.crt
```

(note: this should all be on one line; it is split over multiple lines here to fit the page)

That will give you something that you could use with your server. To get a BKS file for use with TrustManagerBuilder, you can use the JAR for [The Legion of the Bouncy Castle](#) in conjunction with the `keytool` command. For example, the following command will take the self-signed certificate from above and create `selfsigned.bks` as output, using `foobar` as the password, assuming that the `bcprov-jdk16-146.jar` JAR file is in the current working directory:

```
keytool -import -file selfsigned.crt -keystore selfsigned.bks -storetype BKS
-provider org.bouncycastle.jce.provider.BouncyCastleProvider -providerpath
bcprov-jdk16-146.jar -storepass foobar
```

(note: this should all be on one line; it is split over several lines here to fit the page)

Supporting Custom Certificate Authorities

The Android developer documentation has some [sample code for validating an SSL certificate against a custom certificate authority \(CA\)](#). That same technique is integrated into TrustManagerBuilder.

```
new TrustManagerBuilder(getContext()).allowCA("uwash-load-der.crt")
```

SSL

Here, `uwash-load-der.crt` is the CA's root certificate (in this case, from [the University of Washington](#)). The parameter to `allowCA()` is similar to the parameter to `selfSigned()`:

- a `File` pointing to the CA's root certificate on the local file system,
- an `int` raw resource ID, if you wish to package the CA's root certificate in your app in `res/raw/`, or
- a `String` pointing to a relative path in `assets/` where you have placed your CA's root certificate

By default, the one-parameter version of `allowCA()` assumes an X.509 certificate file. If your certificate file is in some other format that is supported by Android's edition of the `CertificateFactory` class, you can use the two-parameter version of `allowCA()` that takes the format name as a `String` in the second parameter.

And, of course, `allowCA()` can be combined with the others as well, such as a configuration that supports the default certificate authorities or a custom one:

```
new TrustManagerBuilder(this)
    .allowCA("uwash-load-der.crt")
    .or()
    .useDefault();
```

About That Man in the Middle

Man-in-the-middle (MITM) attacks are a common way of trying to intercept SSL encrypted communications. The “man” in the “middle” might be a proxy server, a different Web site you wind up communicating with via DNS poisoning, etc. The objective of the “man” is to pretend to be the actual Web site or Web service you are trying to communicate with. If your app “falls for it”, your app will open an encrypted channel to the attacker, not your site, and the attacker will have access to the unencrypted data you send over that channel.

Unfortunately, Android apps have a long history of being victims of man-in-the-middle attacks.

Fahl, Harbach, Muders, and Smith of the Leibniz University of Hannover, and Baumgärtner and Freisleben of the Philipps University of Marburg, conducted research on this problem. Their results, as reported in their paper, [“Why Eve and Mallory Love Android: An Analysis of Android SSL \(In\)Security”](#), are depressing. One in six surveyed apps explicitly ignored SSL certificate validation issues, mostly

by means of do-nothing TrustManager implementations as noted above. Out of a selected 100 apps, 41 could be successfully attacked using man-in-the-middle techniques, yielding a treasure trove of credit card information, account credentials for all the major social networks, and so forth.

Their paper outlines a few ways in which apps can screw up SSL management — the following sections outline some of them.

Disabling SSL Certificate Validation

As mentioned above, if you disable SSL certificate validation, by implementing and using a do-nothing TrustManager, you are wide open for man-in-the-middle attacks. A simple transparent proxy server can pretend to be the real endpoint — apps ignoring SSL validation entirely will trust that the transparent proxy is the real endpoint and, therefore, perform SSL key exchange with the proxy rather than the real site. The proxy, as a result, gets access to everything the app sends.

Ignoring Domain Names

A related flaw is when you disable hostname verification. The “common name” (CN) of the SSL certificate should reflect the domain name being requested. Requesting `https://www.foo.com/something` and receiving an SSL certificate for `xkcdhatguy.com` would be indicative of a mis-configured Web server at best and a man-in-the-middle attack at worst.

By default, this is checked, and if there is no match, you will get errors like:

```
javax.net.ssl.SSLException: hostname in certificate didn't match: <...>
```

where the ... is replaced by whatever domain name you were requesting.

But some developers disable this check. Perhaps during development they were accessing the server using a private IP address, and they were getting `SSLExceptions` when trying to access that server. It is very important to allow Android to check the hostname for you, which is the default behavior.

Note that `HttpClient`'s `BrowserCompatHostnameVerifier` — which applies standard Web browser rules for handling hostname verification — is [broken on Android 2.1 and earlier](#), failing to handle wildcard certificates properly.

Hacked CAs

The truly scary issue is when the problem stems from the CA itself.

Comodo, TURKTRUST, and other certificate authorities have been hacked, where nefarious parties gained the ability to create arbitrary certificates backed by the CA. For example, in [the TURKTRUST case](#), Google found that somebody had created a *.google.com certificate that had TURKTRUST as the root CA. Any browser — or Android app — that implicitly trusted TURKTRUST-issued certificates would believe that this certificate was genuine. This is the ultimate in man-in-the-middle attacks, as code that is ordinarily fairly well-written will believe the CA and therefore happily communicate with the attacker.

Self-Signed Certificates, Revisited

As [Moxie Marlinspike points out](#), one way to avoid having your app be the victim of a man-in-the-middle attack due to a hijacked certificate authority is to simply *not use a certificate authority*.

Certificate authorities are designed for use by general-purpose clients (e.g., Web browsers) hitting general-purpose servers (e.g., Web servers). In the case where you control both the client *and* the server, you don't need a certificate authority. You merely need to have a self-signed certificate that both ends know about.

This works well if the Web server is solely functioning as a Web service to deliver data to your Android app, or perhaps other native apps on other platforms for which you can also support self-signed certificates. Depending upon your server's capabilities, you might be able to arrange to have the same server-side application logic be available both from a self-signed certificate on one domain (for use with apps) and from a CA-rooted certificate for another domain (for use with Web browsers).

However, it is very possible that the staff who manage the servers will reject the notion of using a self-signed certificate, perhaps in an effort to minimize the complexity of supporting multiple SSL paths (for browsers and apps). Or, you may not control the server well enough to go with a self-signed certificate, such as if you are using a cloud computing provider.

Certificate Memorizing

If your app needs to connect to arbitrary SSL servers — perhaps ones configured by the user (e.g., email client) or are intrinsic to the app's usage (e.g., URLs in a Web browser) — detecting man-in-the-middle attacks boils down to proper SSL certificate validation... and praying for no hacked CA certificates.

However, one way to incrementally improve security is to use certificate memorizing. With this technique, each time you see a certificate that you have not seen before, or perhaps a different certificate for a site visited previously, you ask the user to confirm that it is OK to proceed.

The idea here is that even if we cannot tell, absolutely, whether a given certificate is genuine or from an attacker, we can detect *differences in certificates over time*. So, if the user has been seeing certificate A, and now all of a sudden receives certificate B instead, there are two main possibilities:

1. The HTTPS server changed certificates for legitimate reasons
2. An attacker is providing an alternative certificate

So, what we do is check certificates against a roster that the user has approved before. If the newly-received certificate is not in that roster, we fail the HTTPS request, but raise a custom exception so that your code can detect this case and ask the user for approval to proceed.

Technically savvy users may be able to deduce whether the certificate is indeed genuine; slightly less-savvy users might simply contact the site to see if this is expected behavior. The downside is that technically unsophisticated users might be baffled by the question of whether or not they should accept the certificate and may take their confusion out on you, the developer of the app that is asking the question.

The Standalone Solution

There is [a standalone implementation of a MemorizingTrustManager](#) that you could consider using. It has been around for a few years, with a slow-but-steady set of updates.

However, that library handles asking the user for acceptance of the certificates for you, rather than raising some event that your app can handle itself. In order to tailor the UI, you would need to modify the library itself.

Moreover, the library attempts to handle this UI *while your SSL request is in process*, by blocking the background thread upon which you are making the HTTPS request. A side-effect of this is that `MemorizingTrustManager` has some fairly unpleasant code for trying to block this thread while interacting with the user on the main application thread. And, if the user takes too long, your request to the server may time out anyway.

The TrustManagerBuilder Solution

The author of this book has created a separate `MemorizingTrustManager` that is part of the `TrustManagerBuilder` of the `CWAC-Security` library. It will simply throw a custom exception if a certificate is not memorized. Your code that request the HTTPS operation is already needing to catch various exceptions. If your code detects this special `CertificateNotMemorizedException`, you can handle asking the user what to do yourself, integrated into your own UI, without threading concerns. If the user elects to proceed, you can have `TrustManagerBuilder` memorize the certificate, after which you can try your HTTPS request again.

This requires a bit more configuration and management than much of the rest of `TrustManagerBuilder`. There is a dedicated demo project in the `demoMemo/` directory of [the CWAC-Security repository](#) that demonstrates how to use certificate memorization. The sections that follow explain how to set up certificate memorization, and are based upon the `TrustManagerBuilder` documentation.

Configuring the TrustManagerBuilder

In addition to other builder methods, you can call `memorize()` on a `TrustManagerBuilder` to indicate that you want to enable certificate memorization. This method takes an instance of a `MemorizingTrustManager.Options` object to configure how memorization works.

The constructor for `MemorizingTrustManager.Options` takes three parameters:

1. A `Context`, used only for the duration of the constructor itself — this `Context` is not retained after the constructor returns.
2. A `String` representing a relative path to a directory, inside of `getFilesDir()`, for working files for certificate memorization. This directory will be created for you if it does not already exist.
3. A `String` that is the password to use for the `KeyStore` that will hold the memorized certificates.

While `MemorizingTrustManager.Options` offers a builder-style API for configuring the options, no other methods are required beyond the constructor for basic use.

The `memorize()` call should be towards the end of the configuration, after an `and()` call, to say “we will accept SSL certificates that match other criteria *and* are ones that are memorized”.

```
options=
    new MemorizingTrustManager.Options(this, "memorize", "snicklefritz");

try {
    builder=
        new TrustManagerBuilder(this).useDefault().and().memorize(options);
}
catch (Exception e) {
    // do something useful
}
```

Detecting Memorization Exceptions

When you perform an HTTPS operation, you may get an `SSLHandshakeException`. That should wrap another exception, retrieved via `getCause()`.

If the wrapped exception is `CertificateNotMemorizedException`, that means that we found a certificate that matched your other criteria (e.g., valid root CA), but was not found in the memorized roster of certificates. The `CertificateNotMemorizedException` contains the certificate chain, retrieved via `getCertificateChain()`.

At this point, you should tell the user that the request failed because of the unrecognized certificate, and ask the user how to proceed. You are welcome to use the contents of the certificate chain to provide technical details regarding the unrecognized certificates to the user, if you so choose.

Bear in mind that your users may be non-technical. Throwing up a dialog with a lot of SSL gibberish may not be effective. Instead, ideally, you should steer them for how to contact somebody who can indicate if it is safe to proceed.

There are three possible avenues that the user could take:

1. The user could elect to not proceed, under the premise that the SSL communications may be compromised. How you handle that is up to you.

2. The user could elect to proceed, but not remember this certificate for very long (“Allow once”).
3. The user could elect to proceed, with you remembering the certificate for a long time, if the certificate is thought to be valid.

Memorizing the Certificate

In cases #2 and #3 above, you can call methods on your `TrustManagerBuilder` to update the memorized roster with the certificate chain that had failed previously. Use `allowCertOnce()` to remember the certificate for the lifetime of your process, and use `memorizeCert()` to remember the certificate indefinitely. Both of these methods take the `X509Certificate` array that is the certificate chain that you got from calling `getCertificateChain()` on the `CertificateNotMemorizedException`.

After you do this, you can re-try your request that failed due to the unrecognized certificate, and it should succeed.

Clearing the Certificate Roster

At any point, you can call `clearMemorizedCerts()` on the `TrustManagerBuilder` to get rid of the certificate roster. Pass `false` as the parameter to only get rid of the “transient” certificates (i.e., the ones you registered via `allowCertOnce()`). Pass `true` as the parameter to get rid of both the transient and the persistent certificates (i.e., the ones you registered via `memorizeCert()`).

Notes on Threading

Because certificate memorization involves reading from and writing to files, setup and use of the `TrustManagerBuilder` should be performed on a background thread. Of course, your network I/O should be on a background thread, anyway.

If you will have several threads that are all performing HTTPS operations, they should *share* a `TrustManagerBuilder` instance, so that there is a central spot for updating the certificate roster. The `MemorizingTrustManager` should be thread-safe; please file issues if you run into threading-related problems.

Using Trust-on-First-Use

The default behavior of certificate memorization is to fail on every unrecognized certificate. The downside of this is that the user will immediately get a failure the

first time the user uses the app, because no certificates will have been memorized by that point.

You have three courses of action to handle this:

1. Live with it.
2. Manage it yourself, by determining when you believe it is safe to memorize the certificate without user involvement.
3. Call `trustOnFirstUse()` on the `MemorizingTrustManager.Options` object when you create it, to indicate that the *first* unrecognized certificate should be memorized automatically, with failures being reported for all subsequent unrecognized certificates.

About `CertificateMemorizationException`

If you encounter a `CertificateMemorizationException` — in a crash log, for example — that indicates that the library encountered some problem when attempting to save a certificate that is being saved automatically via the trust-on-first-use feature. This exception is unlikely to occur.

Pinning

One way to limit the possible damage from hacked CAs is to recognize that most apps do not need to communicate with arbitrary servers. Web browsers, email clients, chat clients, and the like might need to be able to communicate with whatever server the user elects to configure. But many apps just need to communicate back to their developer's own server, such as a native client adjunct to a regular Web app.

In this case, the app does not need to accept arbitrary SSL certificates. The developer knows the actual SSL certificate used by the developer's server, so the developer can arrange to accept only that one certificate. Or, the developer knows the CA that they get their SSL certificates from and can only accept certificates issued by that CA, and not other CAs. This reduces security a bit, but makes it easier for you to handle SSL certificate expiration and replacement without major headaches.

This technique is referred to as [“pinning”](#). Chrome is perhaps the most well-known implementer of pinning: when you access services like Gmail from Chrome, Google (who wrote the browser) knows the valid certificates for Google (who wrote the

server) and can toss out anything that is invalid... such as the TURKTRUST fake certificate mentioned earlier in this chapter.

Nikolay Elenkov has another [blog post](#) outlining certificate pinning support in Android 4.2+. Moxie Marlinspike has an [implementation of pinning](#), with a description in a [blog post](#), and has also released [a pinning library](#) offering a `PinningTrustManager` that you can use following his guidelines.

NetCipher

[The Guardian Project](#) has released an Android library project called [NetCipher](#) — formerly known as OnionKit — designed to help boost Internet security for Android applications.

In particular, NetCipher helps your application integrate with Orbot, a Tor proxy. [Tor](#) (“[The Onion Router](#)”) is designed to help with anonymity, having your Internet requests go through a series of Tor routers before actually connecting to your targeted server through some Tor endpoint. Tor is used for everything from mitigating Web site tracking to helping dissidents bypass national firewalls. NetCipher helps your app:

- Detect if Orbot is installed, and help the user install it if it is not
- Detect if Orbot is running, and help you start it if it is not
- Make HTTP requests by means of Orbot instead of directly over the Internet

Advanced Permissions

Adding basic permissions to your app to allow it to, say, access the Internet, is fairly easy. However, the full permissions system has many capabilities beyond simply asking the user to let you do something. This chapter explores other uses of permissions, from securing your own components to using signature-level permissions (your own or Android's).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on permissions](#) and the chapter on [signing your app](#). The discussion of signature-level permissions will make a bit more sense if you read through [the chapter on plugins](#) as well.

Securing Yourself

Principally, at least initially, permissions are there to allow the user to secure their device. They have to agree to allow you to do certain things, such as reading contacts, that they might not appreciate.

The other side of the coin, of course, is to secure your own application. If your application is mostly activities, security may be just an “outbound” thing, where you request the right to use resources of other applications. If, on the other hand, you put content providers or services in your application, you will want to implement “inbound” security to control which applications can do what with the data.

Note that the issue here is less about whether other applications might “mess up” your data, but rather about privacy of the user's information or use of services that

might incur expense. That is where the stock permissions for built-in Android applications are focused – can you read or modify contacts, can you send SMS, etc. If your application does not store information that might be considered private, security is less an issue. If, on the other hand, your application stores private data, such as medical information, security is much more important.

The first step to securing your own application using permissions is to declare said permissions, once again in the `AndroidManifest.xml` file. In this case, instead of `uses-permission`, you add `permission` elements. Once again, you can have zero or more `permission` elements, all as direct children of the root `manifest` element.

Declaring a permission is slightly more complicated than using a permission. There are three pieces of information you need to supply:

- The symbolic name of the permission. To keep your permissions from colliding with those from other applications, you should use your application's Java namespace as a prefix
- A label for the permission: something short that would be understandable by users
- A description for the permission: something a wee bit longer that is understandable by your users

```
<permission
  android:name="vnd.tlagency.sekrits.SEE_SEKRITS"
  android:label="@string/see_sekrits_label"
  android:description="@string/see_sekrits_description" />
```

This does not enforce the permission. Rather, it indicates that it is a possible permission; your application must still flag security violations as they occur.

Enforcing Permissions via the Manifest

There are two ways for your application to enforce permissions, dictating where and under what circumstances they are required. The easier one is to indicate in the manifest where permissions are required.

Activities, services, and receivers can all declare an attribute named `android:permission`, whose value is the name of the permission that is required to access those items:

```
<activity
  android:name=".SekritApp"
  android:label="Top Sekrit"
```

```
android:permission="vnd.tlagency.sekritis.SEE_SEKRITS">
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category
    android:name="android.intent.category.LAUNCHER"
  />
</intent-filter>
</activity>
```

Only applications that have requested your indicated permission will be able to access the secured component. In this case, “access” means:

1. Activities cannot be started without the permission
2. Services cannot be started, stopped, or bound to an activity without the permission
3. Intent receivers ignore messages sent via `sendBroadcast()` unless the sender has the permission

Enforcing Permissions Elsewhere

In your code, you have two additional ways to enforce permissions.

Your services can check permissions on a per-call basis via `checkCallingPermission()`. This returns `PERMISSION_GRANTED` or `PERMISSION_DENIED` depending on whether the caller has the permission you specified. For example, if your service implements separate read and write methods, you could require separate read versus write permissions in code by checking those methods for the permissions you need from Java.

Also, you can include a permission when you call `sendBroadcast()`. This means that eligible broadcast receivers must hold that permission; those without the permission are ineligible to receive it. We will examine `sendBroadcast()` in greater detail elsewhere in this book.

Requiring Standard System Permissions

While normally you require your own custom permissions using the techniques described above, there is nothing stopping you from reusing a standard system permission, if it would fit your needs.

For example, suppose that you are writing YATC (Yet Another Twitter Client). You decide that in addition to YATC having its own UI, you will design YATC to be a “Twitter engine” for use by third party apps:

- Send timeline updates via broadcast Intents
- Publish the timeline, the user's own tweets, @-mentions, and the like via a `ContentProvider`
- Offer a command-based service interface for posting updates to the timeline
- And so on

You could, and perhaps should, implement your own custom permission. However, since any app can get to Twitter just by having the `INTERNET` permission, one could argue that a third-party app should just need that same `INTERNET` permission to use your API (rather than integrating JTwitter or another third-party JAR).

Signature Permissions

Each permission in Android is assigned a protection level, via an `android:protectionLevel` attribute on the `<permission>` element. By default, permissions are at a normal level, but they can also be flagged as dangerous, `signatureOrSystem`, or `signature`. In the latter two cases, “signature” means that the app requesting the permission and the app requiring the permission should have been signed by the same signing key. In the case of `signatureOrSystem` — only used by the firmware — the app requesting the permission either needs to be signed by the firmware's signing key or reside on the system partition (e.g., come pre-installed with the device).

Firmware-Only Permissions

Most of Android's permissions mentioned in this book are ones that any SDK application can hold, if they ask for them and the user grants them. `INTERNET`, `READ_CONTACTS`, `ACCESS_FINE_LOCATION`, and `kin` all are normal permissions.

`BRICK` is not.

There is a permission in Android, named `BRICK`, that, in theory, allows an application to render a phone inoperable (a.k.a., “brick” the phone). While there is no `brickMe()` method in the Android SDK tied to this permission, presumably there might be something deep in the firmware that is protected by this permission.

The `BRICK` permission cannot be held by ordinary Android SDK applications. You can request it all you want, and it will not be granted.

However, applications that are signed with the same signing key that signed the firmware *can* hold the BRICK permission.

That is because [the system's own manifest](#) has the following <permission> element:

```
<permission android:name="android.permission.BRICK"
    android:label="@string/permlab_brick"
    android:description="@string/permdesc_brick"
    android:protectionLevel="signature" />
```

Some other permissions have `signatureOrSystem` instead of `signature` for `android:protectionLevel`:

```
<permission android:name="android.permission.REBOOT"
    android:label="@string/permlab_reboot"
    android:description="@string/permdesc_reboot"
    android:protectionLevel="signatureOrSystem" />
```

These permissions can be held by applications that are *either* signed by the firmware's signing key *or* by applications that are installed on the firmware's partition. Mostly, this will be apps that are licensed by a manufacturer or carrier for pre-distribution on a device.

Your Own Signature Permissions

You too can require signature-level permissions. That will restrict the holders of that permission to be other apps signed by your signing key. This is particularly useful for inter-process communication between apps in a suite — by using signature permissions, you ensure that only your apps will be able to participate in those communications.

This is what was used in the ContentProvider-based plugin sample [from elsewhere in this book](#). The plugin required a permission that was declared with `android:protectionLevel="signature"`, and the host application requested that permission.

One nice thing about these sorts of signature-level permissions is that the user is not bothered with them. It is assumed that the user will agree to the communication between the apps signed by the same signing key. Hence, the user will not see signature-level permissions at install or upgrade time.

Since in some cases, you may not be sure which app will be installed first, it is best to have all apps in the suite include the *same* <permission> element, in addition to

the corresponding `<uses-permission>` element. That way, no matter which app is installed first, it can declare the permission that all will share.

Though, that has its own problems, as you will see in the next section.

The Custom Permission Vulnerability

NOTE: Some of the material in this section originally appeared in material hosted in [the CWAC-Security project repository](#). In addition, the author would like to thank Mark Carter and “Justin Case” for their contributions in this topic area).

Unfortunately, custom permissions have some undocumented limitations that make them intrinsically risky. Specifically, custom permissions can be defined by anyone, at any time, and “first one in wins”, which opens up the possibility of unexpected behavior.

Here, we will walk through some scenarios and show where the problems arise, plus discuss how to mitigate them as best we can.

Scenarios

All of the following scenarios focus on three major app profiles.

App A is an app that defines a custom permission in its manifest, such as:

```
<permission
  android:name="com.commonware.cwac.security.demo.OMG"
  android:description="@string/perm_desc"
  android:label="@string/perm_label"
  android:protectionLevel="normal"/>
```

App A also defends a component using the `android:permission` attribute, referencing the custom permission:

```
<provider
  android:name="FileProvider"
  android:authorities="com.commonware.cwac.security.demo.files"
  android:exported="true"
  android:grantUriPermissions="false"
  android:permission="com.commonware.cwac.security.demo.OMG">
  <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

ADVANCED PERMISSIONS

App B has a `<uses-permission>` element to declare to the user that it wishes to access components defended by that permission:

```
<uses-permission android:name="com.commonware.cwac.security.demo.OMG"/>
```

App C has the same `<uses-permission>` element. The difference is that App B *also* has the `<permission>` element, just as App A does, albeit with different descriptive information (e.g., `android:description`) and, at times, a different protection level.

All three apps are signed with different signing keys, because in the real world they would be from different developers.

So, to recap:

- A defines a permission and uses it for defense
- B defines the same permission and requests to hold it
- C just requests to hold this permission

With all that in mind, let's walk through some possible scenarios, focusing on two questions:

1. What is the user told, when the app is installed through normal methods (i.e., not via `adb`), regarding this permission?
2. What access, if any, does App B or App C have to the `ContentProvider` from App A?

The Application SDK Case (A, Then C)

Suppose the reason why App A has defined a custom permission is because it wants third-party apps to have the ability to access its secured components... but only with user approval. By defining a custom permission, and having third-party apps request that permission, the user should be informed about the requested permission and can make an informed decision.

Conversely, if an app tries to access a secured component but has not requested the permission, the access attempt should fail.

App C has requested the custom permission via the `<uses-permission>` element. If the permission — defined by App A — has an `android:protectionLevel` of `normal` or `dangerous`, the user will be informed about the requested permission at install

time. If the user continues with the installation, App C can access the secured component.

If, however, the `android:protectionLevel` is `signature`, the user is not informed about the requested permission at install time, as the system can determine on its own whether or not the permission should be granted. In this case, App A and App C are signed with different signing keys, so Android silently ignores the permission request. If the user continues with installation, then App C tries to access App A's secured component, App C crashes with a `SecurityException`.

In other words, this all works as expected.

The Application SDK Problem Case (C, Then A)

However, in many cases, there is nothing forcing the user to install App A before App C. This is particularly true for publicly-distributed apps on common markets, like the Play Store.

When the user installs App C, the user is not informed about the request for the custom permission, presumably because that permission has not yet been defined. If the user later installs App A, App C is not retroactively granted the permission, and so App C's attempts to use the secured component fail.

This works as expected, though it puts a bit of a damper on custom permissions. One way to work around this would be for the user to uninstall App C, then install it again (with App A already installed). This returns us to the original scenario from the preceding section. However, if the user has data in App C, losing that data may be a problem (as in a "let's give App C, or perhaps App A, one-star ratings on the Play Store" sort of problem).

The Peer Apps Case, Part One (A, Then B)

Suppose now we augment our SDK-consuming app (formerly App C) to declare the same permission that App A does, in an attempt to allow the two apps to be installed in either order. That is what App B is: the same app as App C, but where it has the same `<permission>` element as does App A in its manifest.

This scenario is particularly important where both apps could be of roughly equal importance to the user. In cases where App C is some sort of plugin for App A, it is not unreasonable for the author of App A to require App A to be installed first. But,

if Twitter and Facebook wanted to access components of each others' apps, it would be unreasonable for either of those firms to mandate that their app must be installed first. After all, if Twitter wants to be installed first, and Facebook wants to be installed first, one will be disappointed.

If the user installs App A (the app defending a component with the custom permission) before App B, the user will be notified at install time about App B's request for this permission. Notably, the information shown on the installation security screen will contain App A's description of the permission. And, if the user goes ahead and installs App B, App B can indeed access App A's secured component, since it was granted permission by the user.

Once again, everything is working as expected. Going back to the two questions:

1. The user is informed when App B or App C requests the permission defined by App A.
2. App B and App C can hold that permission if and only if they meet the requirements of the protection level

The Peer Apps Case, Part Two (B, Then A)

What happens if we reverse the order of installation? After all, if App A and App B are peers, from the standpoint of the user, there is roughly a 50% chance that the user will install App B before App A.

Here is where things go off the rails.

The user is not informed about App B's request for the custom permission.

The user will be informed about any platform permissions that the app requests via other `<uses-permission>` elements. If there are none, the user is told that App B requests no permissions... despite the fact that it does.

When the user installs App A, the same thing occurs. Of course, since App A does not have a `<uses-permission>` element, this is not all that surprising.

However, at this point, **even though the user was not informed**, App B holds the custom permission and can access the secured component.

This is bad enough when both parties are ethical. App B could be a piece of malware, though, designed to copy the data from App A, ideally without the user's knowledge. And, if App B is installed before App A, that would happen.

So, going to the two questions:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component

The Downgraded-Level Malware Case (B, Then A, Again)

You might think that the preceding problem would only be for normal or dangerous protection levels. If App A defines a permission as requiring a matching signature, and App A marks a component as being defended by that permission, Android must require the signature match, right?

Wrong.

The behavior is identical to the preceding case. Android does not use the *defender's* protection level. It uses the *definer's* protection level, meaning the protection level of whoever was installed first and had the <permission> element.

So, if App A has the custom permission defined as signature, and App B has the custom permission defined as normal, if App B is installed first, the behavior is as shown in the preceding section:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component, despite the signatures not matching

The Peer Apps Case With a Side Order of C

What happens if we add App C back into the mix? Specifically, what if App B is installed first, then App A, then App C?

When App C eventually gets installed, the user is prompted for the custom permission that App C requests via <uses-permission>. However, the description that the user sees is from App B, the one that first defined the custom <permission>. Moreover, the protection level is whatever App B defined it to be. So if App B downgraded the protection level from App A's intended signature to be normal,

App C can hold that permission and access the secured App A component, even if it is signed by another signing key.

Not surprisingly, the same results occur if you install App B, then App C, then App A.

Behavior Analysis

The behavior exhibited in these scenarios is consistent with two presumed implementation “features” of Android’s permission system:

1. First one in wins. In other words, the first app (or framework, in the case of the OS’s platform permissions) that defines a `<permission>` for a given `android:name` gets to determine what the description is and what the protection level is.
2. The user is only prompted to confirm a permission if the app being installed has a `<uses-permission>` element, the permission was already defined by some other app, and the protection level is not signature.

Risk Assessment

The “first one in wins” rule is a blessing and a curse. It is a curse, insofar as it opens up the possibility for malware to hold a custom permission without the user’s awareness of that, and even to downgrade a signature-level permission to normal. However, it is a blessing, in that the malware would have to be installed first; if it is installed second, either its request to hold the permission will be seen by the user (normal or dangerous) or the request to hold the permission will be rejected (signature).

This makes it somewhat unlikely for a piece of malware to try to sneakily make off with data. Eventually, if enough users start to ask publicly why App B needs access to App A’s data (for cases where App A was installed first and the user knows about the permission request), somebody in authority may eventually realize that this is a malware attack. Of course, “eventually” may be a rather long time.

However, there are some situations where Android’s custom permission behavior presents risk even greater than that. If the attacker has a means of being *sure* that their app was installed first, they can hold any permission from any third-party app they want to that was known at install time.

For example:

- Somebody could sell a used Android device, and the buyer could neglect to factory-reset it, and the malware could be installed by the seller
- Somebody could sell a used Android device with a ROM mod preinstalled, based off of a normal ROM mod (e.g., CyanogenMod), but with an additional bit of malware installed, to prevent a factory reset from foiling the attack'
- Somebody could distribute devices to users who might think the device is "factory clean" and not laden with malware (e.g., devices given as gifts)
- Somebody could distribute devices to users who might think that the pre-installed malware is actually a legitimate app (e.g., devices given to employees by an employer wishing to monitor usage by examining protected data from third-party apps)

Android 5.0's "Fix"

Android 5.0 now prevents two apps from defining the same `<permission>` ("same" based on `android:name`) unless they are signed by the same signing key. First one in wins; the second app installation will fail.

On the plus side:

- This solves the security problem, as an attacker (B) cannot get at a defender's (A's) data by virtue of having been installed first, as A simply cannot be installed in this case.
- This has no impact on developers using signature-level `<permission>` elements for their own app suite.

However, it does pose significant limitations on legitimate public uses of custom `<permission>` elements. Only the defender should have the `<permission>` element now. Some client of the defender's app (C) should not have the `<permission>` element and should simply rely upon the fact that the defender should be installed first. If the client were to define the `<permission>`, then either the client *or* the defender cannot be installed, which is pointless.

This has usability issues:

- A client should check, on first run of their app, if an expected defender (and its `<permission>` element) exists. If not, the client should alert the user to this fact and perhaps stop the app from proceeding further. The user would have to uninstall the client, install the defender, then reinstall the client, to

get everything working properly, and the more the user uses the client app, the more painful the uninstall might be.

- It is impossible for two apps to be clients of each other. By definition, one app has to be installed first and the other second, which means only the first-to-be-installed app can have a custom `<permission>`. If Facebook wanted to hold a custom Twitter permission, and Twitter wanted to hold a custom Facebook permission, one of them is out of luck — if Facebook is installed first, it cannot request Twitter's permission (as it does not yet exist) nor can it define Twitter's permission (as if it does, Twitter cannot be installed). This *might* be able to be overcome for apps that are pre-loaded as part of a ROM mod or other custom Android build.

And, of course, this fix is only for Android 5.0 and above.

Mitigation Using PermissionUtils

The “first one in wins” rule also leads us to a mitigation strategy: On first run of our app, see if any other app has defined permissions that we have defined. If that has happened, then we are at risk, and take appropriate steps. If, however, no other app has defined our custom permissions, then the Android permission system should work for us, and we can proceed as normal.

[The CWAC-Security library](#) provides some helper code, in the form of the `PermissionUtils` class, to detect other apps defining the same custom permissions that you define.

The idea is that you call `checkCustomPermissions()` — a static method on `PermissionUtils` — on the first run of your app. It will return details about what other apps have already defined custom permissions that your app defines. If `checkCustomPermissions()` returns nothing, you know that everything is fine, and you can move ahead. Otherwise, you can:

- Check to see if the offending app is on some whitelist, or otherwise meets criteria that suggests that it is OK
- Alert the user, indicating that these already-installed apps will have access to your app secured components
- Upload details about the offending apps to your server, so you can try to track down whether they are legitimate users of some API that you are exposing or are malware
- Whatever else you feel is necessary

Example: Permission Proxy

[The section on ContentProvider proxy plugins](#) involves the use of a custom signature-level permission, to secure communications between the proxy and the host app that uses the proxy.

The idea is that the proxy holds some permission (e.g., `READ_CONTACTS`) and proxies data to some `ContentProvider` protected by that proxy (e.g., `CallLog`). The host app, rather than holding the permission and accessing the protected `ContentProvider` directly, can talk to the proxy. That way, the user only needs to grant permission if they elect to install the proxy; otherwise, the host app is blocked from having access to the protected content.

However, to prevent arbitrary other apps from using the proxy themselves, the host and proxy agree on a custom signature-level permission. The proxy defends itself using that permission, and the host requests the permission. In theory, this would limit communications with the proxy to only be from the host, or from other apps signed with the same signing key as the proxy and host use.

But, as is described above, another app could define the *same* permission, with a normal protection level. If that other app is installed first, not only can any other app access the proxy just by requesting the permission, but the attacker could have requested the same permission that it defined, so the user is unaware that the attacker holds this permission.

Hence, these proxies need to use some defensive measures, and the samples shown in this book employ `PermissionUtils` from the `CWAC-Security` library to do just that.

What the Proxy Does

The proxy is a `ContentProvider`. Specifically, there is an `AbstractCPPProxy` subclass of `ContentProvider` that does the “heavy lifting”, and a `CallLogProxy` subclass of `AbstractCPPProxy` that handles some of the details of proxying the `CallLog` versus something else.

In `onCreate()` of the `AbstractCPPProxy`, we use `PermissionUtils` and `checkCustomPermissions()` to determine whether or not anything was installed before us, that defined our custom permission, *other* than our known host app:

```
@Override
public boolean onCreate() {
    SharedPreferences prefs=
        PreferenceManager.getDefaultSharedPreferences(getContext());

    if (prefs.getBoolean(PREFS_FIRST_RUN, true)) {
        SharedPreferences.Editor editor=
            prefs.edit().putBoolean(PREFS_FIRST_RUN, false);

        HashMap<PackageInfo, ArrayList<PermissionLint>> entries=
            PermissionUtils.checkCustomPermissions(getContext());

        for (Map.Entry<PackageInfo, ArrayList<PermissionLint>> entry :
entries.entrySet()) {
            if
(!"com.commonware.android.cproxy.consumer".equals(entry.getKey().packageName))
{
                tainted=true;
                break;
            }
        }

        editor.putBoolean(PREFS_TAINTED, tainted).apply();
    }
    else {
        tainted=prefs.getBoolean(PREFS_TAINTED, true);
    }

    return(true);
}
```

We use SharedPreferences to hold onto two key pieces of data:

1. Have we already done the check, as determined by PREFS_FIRST_RUN? If yes, we can just look up the results of the previous check. This is not merely an optimization — we do not have to worry about apps installed *after* us somehow redefining our custom permission.
2. When we did the check, did we find some package that had been installed before us, other than the host, that defined our custom permission, as determined by PREFS_TAINTED?

The actual check is accomplished by calling `checkCustomPermissions()` and iterating over the results. If there is an entry in the `HashMap` that represents a package other than ours, our environment is tainted.

The implementation in the book then uses the tainted data member in a `checkTainted()` private method:

```
private void checkTainted() {  
    if (tainted) {  
        throw new RuntimeException(getContext().getString(R.string.tainted_abort));  
    }  
}
```

This is called at the top of each `ContentProvider` method that we are proxying, such as `insert()`:

```
@Override  
public Uri insert(Uri uri, ContentValues values) {  
    checkTainted();  
  
    return(getContext().getContentResolver().insert(convertUri(uri),  
                                                    values));  
}
```

The result is that if we feel that our environment is compromised, we fail any attempt to use the proxy.

Note that the proxy makes no attempt to confirm that the host app really *is* the host app, versus some other app with the same package name, perhaps distributed through other channels. We could augment the proxy with additional logic to handle that case, covered [elsewhere in this book](#), if we wanted.

Also, we could, in theory, use `Binder.getCallingUid()` to confirm whether the request did come from the host app, and in that case, allow the proxy to do its work, failing in all other cases. We could even consider jettisoning the custom permission in this case, as if we know the UID of the other party, we can validate it instead of relying on a permission as a means of validation. However, that only works well in cases where the list of possible valid callers is knowable inside the app — this is fine for host-and-plugin or similar sorts of “hub-and-spoke” architectures but may be impractical in other cases.

What the Provider Could Do

The proxy has no decent means of alerting the user as to the reason for the lockdown. After all, it is a `ContentProvider`, not an `Activity`. In principle, it could use a `Notification`.

Another approach is to have the host app perform the same sorts of checks as does the proxy, and use that information to inform the user on first run of the app.

Restricted Profiles and UserManager

Android 4.2 introduced the concept of having multiple distinct users of a tablet. Each user would get their own portion of internal and external storage, as if they each had their own tablet.

Android 4.3 extends this a bit further, with the notion of setting up restricted profiles. As the name suggests, a restricted profile is restricted, in terms of what it can do on the device. Some restrictions will be device-wide (e.g., can the user install apps?), and some restrictions will be per-app. You can elect to allow your app to be restricted, where you define the possible ways in which your app can be restricted, and the one setting up the restricted profile can then configure the desired options for some specific profile.

This chapter will explain how users set up these restricted profiles, what you can learn about the device-wide restrictions, and how you can offer your own restrictions for your own app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on files](#) and its [section on multiple user accounts](#).

Android Tablets and Multiple User Accounts

The theory is that tablets are likely to be shared, whether among family members, among team members in a business, or similar sorts of group settings. There are three levels of “user” in an Android 4.3+ tablet that we will need to consider.

Primary User

The primary user is whoever first set up the tablet after initial purchase. In a family, this is probably a parent; in a corporate setting, this might be an IT administrator.

Prior to Android 4.2, there was only one user per device, and that user could (generally) do anything. In Android 4.2+, the primary user holds this role.

One thing that the primary user can do is set up other users, via the Users option in the Settings app:

Figure 652: Users Screen in Settings

Tapping the “Add user or profile” entry allows the primary user to set up another user or restricted profile:

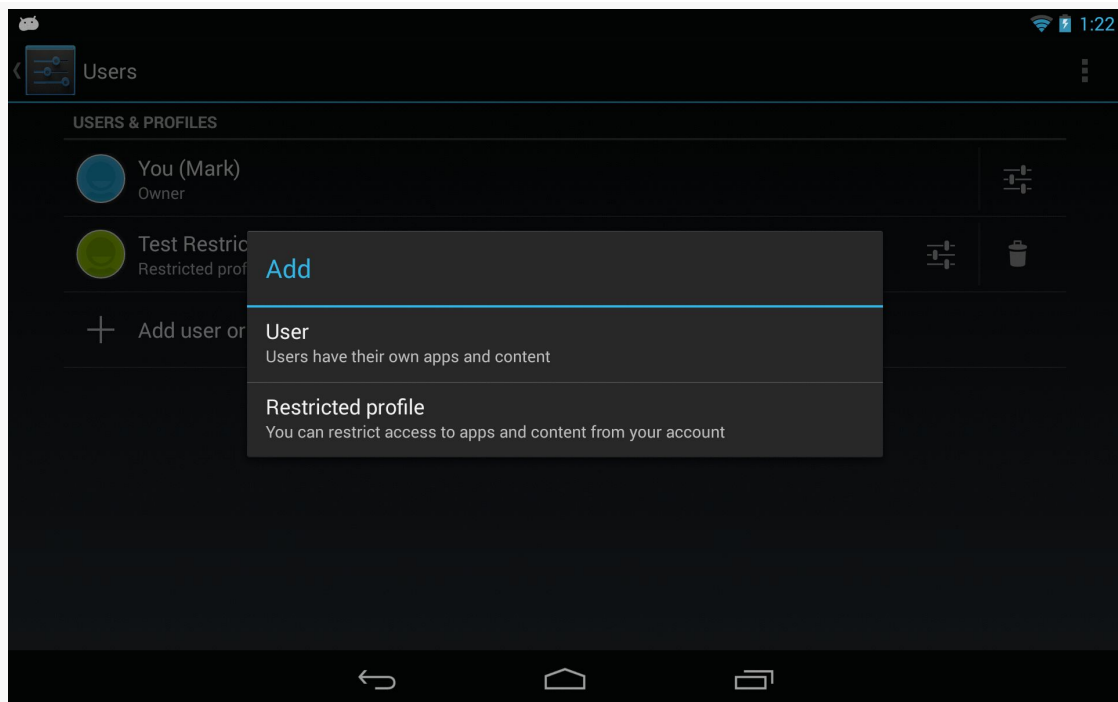

Figure 653: Add Dialog in Users Screen in Settings

Secondary User

Choosing “User” from the Add dialog will define a secondary user of the device. This user has much of the same control as the primary user, in terms of being able to install and run whatever apps are desired.

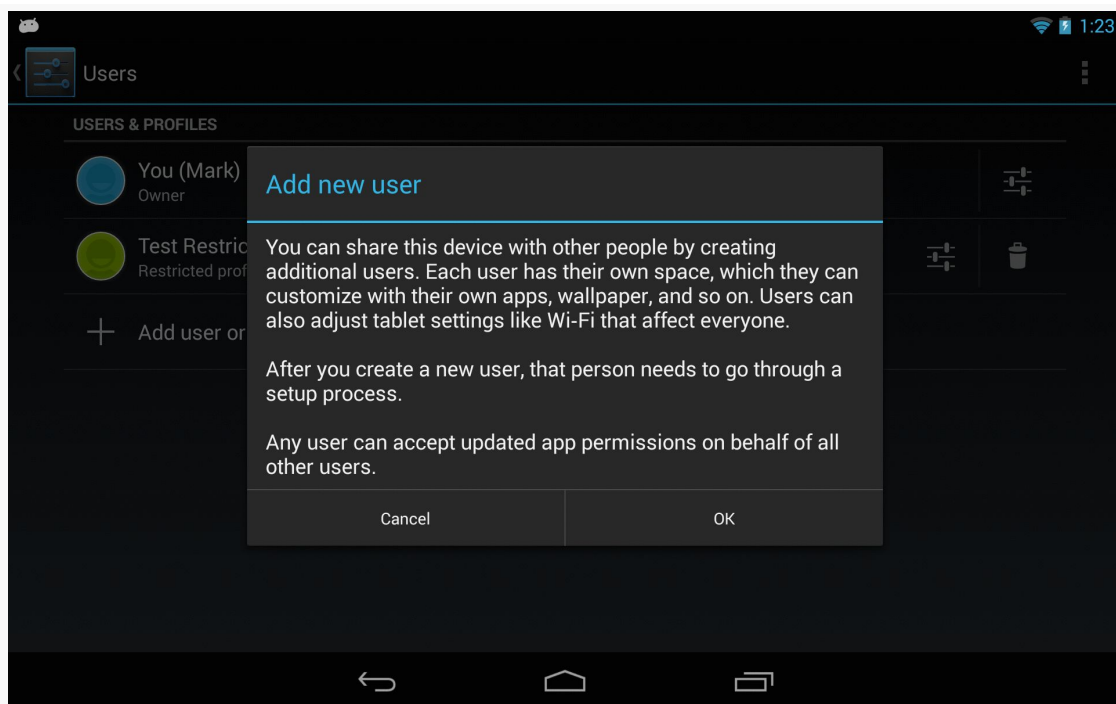

Figure 654: Add New User Warning Dialog in Users Screen in Settings

Restricted Profile

A restricted profile is akin to a secondary user, in that it gets its own separate portion of internal and external storage. Beyond that, though, the primary user can further configure what the restricted profile can access:

Figure 655: Restricted Profile Configuration Screen in Settings

The bulk of the restricted profile configuration screen is a list of apps, with Switch widgets to allow the primary user to allow or deny access to each app.

Some apps will have the “settings” icon to the left of the Switch. Tapping that will either bring up a dedicated activity for restricting operations within that app, or it will add new rows to the list with individual restriction options for that app. For example, tapping the settings icon for the Settings app adds a row where the primary user can block location sharing:

RESTRICTED PROFILES AND USERMANAGER

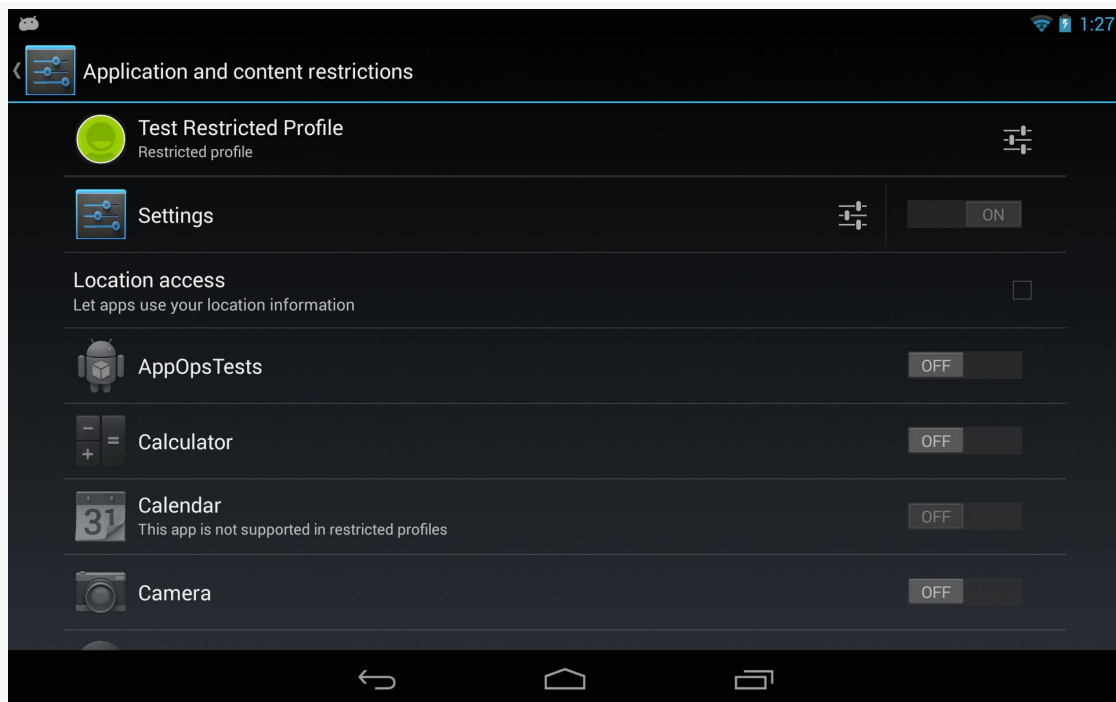

Figure 656: Location Sharing Restrictions

The “settings” icon in the first row, for the profile itself, will allow the primary user to control things for the entire profile, notably its name.

Switching to the restricted profile (e.g., via the lockscreen) will show the constrained set of available apps:

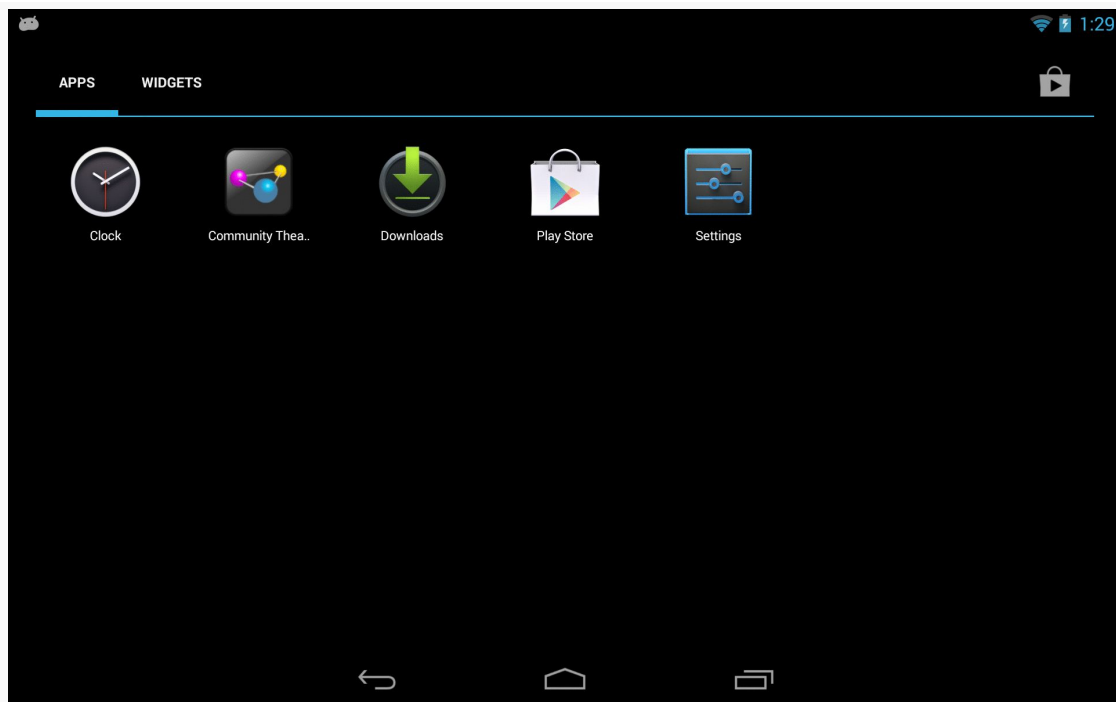

Figure 657: Apps in a Restricted Profile

Determining What the User Can Do

Your app can find out what device-level restrictions were placed on the current user by means of the UserManager system service. Specifically, as you can see in MainActivity of the [RestrictedProfiles/Device](#) sample project, all you need to do is:

- Acquire an instance of a UserManager by calling `getSystemService()` on a Context, passing in `USER_SERVICE` as the service's name
- Calling `getUserRestrictions()` on the UserManager:

```
package com.commonware.android.profile.device;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

RESTRICTED PROFILES AND USERMANAGER

```

    UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
    Bundle restrictions=mgr.getUserRestrictions();

    if (restrictions.keySet().size() > 0) {
        setContentView(R.layout.activity_main);

        RestrictionsFragment f=
(RestrictionsFragment)getFragmentManager().findFragmentById(R.id.contents);

        f.showRestrictions(restrictions);
    }
    else {
        Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
}
```

`getUserRestrictions()` returns a `Bundle`, whose keys are documented on `UserManager` for various device-level restrictions that theoretically can be placed on the user. Here, “theoretically” means that while `UserManager` documents several `DISALLOW_*` constants, only two seem to be directly accessible to the primary user for configuration via Settings:

- `DISALLOW_MODIFY_ACCOUNTS`, to prevent a restricted profile from, among other things, modifying restricted profiles
- `DISALLOW_SHARE_LOCATION`, to prevent the apps run in this restricted profile from gathering location data

`MainActivity` examines the `Bundle` and, if it is empty, just displays a `Toast` and exits via `finish()`. This is the behavior you will see if you run this sample app on a non-restricted profile, such as the primary user. If, however, the `Bundle` has one or more keys, we inflate an `activity_main` layout that contains a `RestrictionsFragment` in a `<fragment>` element:

```

<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/contents"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    class="com.commonware.android.profile.device.RestrictionsFragment"/>
```

We then retrieve the `RestrictionsFragment` from the `FragmentManager` and call `showRestrictions()` on it, passing in the `Bundle`.

RESTRICTED PROFILES AND USERMANAGER

RestrictionsFragment is a ListFragment employing a custom RestrictionsAdapter. The RestrictionsAdapter wraps around the Bundle and an ArrayList of its keys. The RestrictionsAdapter constructor creates the ArrayList by sorting the keySet() of the Bundle. getView() on RestrictionsAdapter lets the superclass handle inflating the row (android.R.layout.simple_list_item_1), then puts an icon on the right side by using setCompoundDrawablesWithIntrinsicBounds(), which can tuck a drawable resource onto any of the four sides of a TextView.

The resulting list will show green icons for keys where the Bundle has stored a true Boolean value, and a red icon for false:

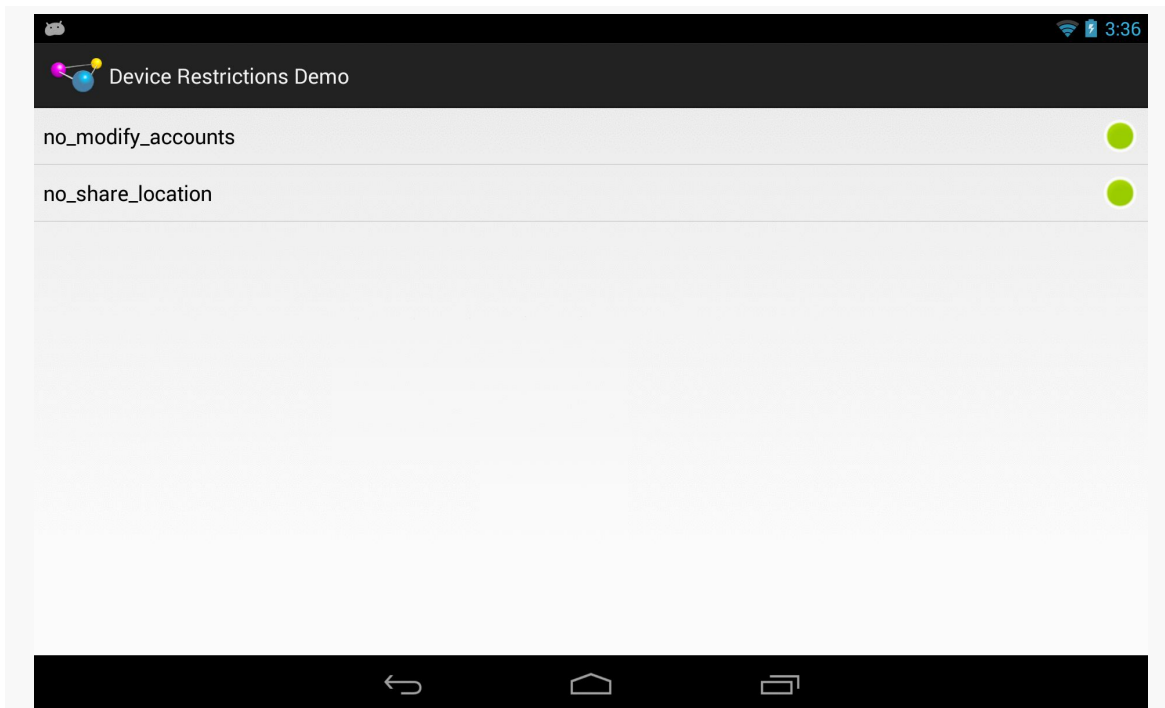

Figure 658: Default Device Restrictions, on a Nexus 7 (2013)

Since the keys are negative in tone (e.g., DISALLOW_MODIFY_ACCOUNTS), true means that the restriction is enforced and the underlying operation (e.g., modifying accounts) *cannot* be done.

Impacts of Device-Level Restrictions

Your app's functionality may be limited by these device-level restrictions. This section outlines some of the results you should expect from a restricted profile.

Restricting Location Access

If a restricted profile is prevented from sharing the device's location with apps, those apps simply will not receive location updates. There is no good way to detect this via the location API (e.g., `isProviderEnabled()` returns `true`), so you will have to detect this via `getUserRestrictions()` on `UserManager` as noted above.

Uninstalling Apps

Even without specific configuration, the restricted profile can only uninstall apps that are available to that profile. However, since apps are really shared between profiles, this only removes that app from the restricted profile; it does not actually uninstall the app from the device as a whole.

Enabling Custom Restrictions

As noted earlier, the list of apps that is shown on the restricted profile configuration screen in Settings can have “settings” icons. The Settings app itself will have a settings icon, to allow the primary user to configure device-level restrictions.

But, what if you want *your* app to have such a settings icon? Maybe it makes sense for your app to allow the primary user to restrain restricted profiles from doing certain things within your app:

- Block in-app purchases
- Only show certain categories of content, not the full roster
- Only allow operation during certain times of the day

The means by which the Settings app restricts profiles is also available to you. You can declare to Android what aspects of your app can be restricted. Android will then collect that restriction data for you. Your app, at runtime, can then determine what restrictions are in place (if any) and take appropriate steps.

All of this will be illustrated using the [RestrictedProfiles/App](#) sample project.

Stating Your Restrictions

The biggest thing that you need to do to restrict your app is teach Android how to collect restrictions. In other words, you need to tell Android what to do when the user taps that settings icon in the restricted profile entry for your app.

You have two major options:

- Provide a list of the restrictions that Android should render and collect itself, or
- Provide an Intent that can be used to start up an activity of your own design where you collect those restrictions

Either approach will require you to set up a manifest-registered BroadcastReceiver, set to respond to the `android.intent.action.GET_RESTRICTION_ENTRIES` action:

```
<receiver android:name="RestrictionEntriesReceiver">  
  <intent-filter>  
    <action android:name="android.intent.action.GET_RESTRICTION_ENTRIES"/>  
  </intent-filter>  
</receiver>
```

That BroadcastReceiver will be called with `sendOrderedBroadcast()`, not so much to affect ordering, but to allow the BroadcastReceiver to send back a result via its `setResultExtras()` method. This provides a Bundle that the broadcaster can eventually retrieve, in this case providing details of what restrictions we wish to collect from the primary user to restrict the profile.

Option #1: RestrictionEntry List

To collect restrictions the way the Settings app does — with restriction rows appearing below your app in the restricted profile screen in Settings – your BroadcastReceiver will need to put an entry into the return Bundle, under the key of `EXTRA_RESTRICTIONS_LIST` (a constant defined on the Intent class). The value needs to be an ArrayList of RestrictionEntry objects, with each RestrictionEntry describing one restriction to collect.

Another thing that the RestrictionEntry objects contain is their current value. Android itself retains these values and supplies them to your BroadcastReceiver via an `EXTRA_RESTRICTIONS_BUNDLE` extra on the incoming Intent. Your app needs to use those current values when constructing its list of RestrictionEntry objects to return.

RESTRICTED PROFILES AND USERMANAGER

So, let's take a look at `RestrictionEntriesReceiver`, the receiver we have set up to handle the `android.intent.action.GET_RESTRICTION_ENTRIES` action for this sample app.

The entry point for `RestrictionEntriesReceiver` is `onReceive()`, as it is for any basic `BroadcastReceiver`:

```
@Override
public void onReceive(Context ctxt, Intent intent) {
    Bundle current=
        (Bundle)intent.getParcelableExtra(Intent.EXTRA_RESTRICTIONS_BUNDLE);
    ArrayList<RestrictionEntry> restrictions=
        new ArrayList<RestrictionEntry>();

    restrictions.add(buildBooleanRestriction(ctxt, current));
    restrictions.add(buildChoiceRestriction(ctxt, current));
    restrictions.add(buildMultiSelectRestriction(ctxt, current));

    Bundle result=new Bundle();

    result.putParcelableArrayList(Intent.EXTRA_RESTRICTIONS_LIST,
                                restrictions);

    setResultExtras(result);
}
```

In `onReceive()`, `RestrictionEntriesReceiver` pulls out the `Bundle` of current restrictions, by retrieving the `EXTRA_RESTRICTIONS_BUNDLE` extra from the `Intent` passed into `onReceive()`. Note that this `Bundle` could very well be empty, if this is the first time we are being asked for restrictions.

`RestrictionEntriesReceiver` creates an empty `ArrayList` of `RestrictionEntry` objects, then calls a series of builder methods to create a total of three such `RestrictionEntry` objects, adding each to the list. `onReceive()` goes on to create a `Bundle` representing the results to be returned, packages the `ArrayList` in that `Bundle` under the `EXTRA_RESTRICTIONS_LIST` key, and returns that `Bundle` to the caller by means of `setResultExtras()`.

The three builder methods are each responsible for defining a single `RestrictionEntry`, including populating it with the current value from the current `Bundle`.

There are three types of `RestrictionEntry`, for boolean, single-selection lists (“choice”), and multi-selection lists. The `RestrictionEntry` constructor takes two parameters:

- The String key under which we will later retrieve this restriction value
- The current value of the restriction

The current value is:

- A boolean for boolean restrictions
- A String for choice restrictions
- A String array for multi-select restrictions

Our first builder, `buildBooleanRestriction()`, populates and returns a `RestrictionEntry` designed to collect a boolean value from the primary user, via a `CheckBox`:

```
private RestrictionEntry buildBooleanRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_BOOLEAN,
                             current.getBoolean(RESTRICTION_BOOLEAN,
                                                  false));

    entry.setTitle(ctxt.getString(R.string.boolean_restriction_title));
    entry.setDescription(ctxt.getString(R.string.boolean_restriction_desc));

    return(entry);
}
```

`buildBooleanRestriction()` retrieves the current value from current `Bundle` to use with the `RestrictionEntry` constructor. In this case, if there is no such entry in the `Bundle`, the overall default value is `false`.

Each `RestrictionEntry` can have a title (`setTitle()`), supplying a string which will be displayed to describe what this restriction is. A boolean restriction can also have a description (`setDescription()`), containing another string with a bit more text. Note that, at the present time, the other two types of restrictions will ignore any description that you include. Also note that the values supplied to `setTitle()` and `setDescription()` need to be strings, and so if you wish to use a string resource, you will need to get the actual string value yourself via `getString()`.

The remaining two builder methods have a similar structure:

```
private RestrictionEntry buildChoiceRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_CHOICE,
                             current.getString(RESTRICTION_CHOICE));
}
```

```
entry.setTitle(ctxt.getString(R.string.choice_restriction_title));
entry.setChoiceEntries(ctxt, R.array.display_values);
entry.setChoiceValues(ctxt, R.array.restriction_values);

return(entry);
}

private RestrictionEntry buildMultiSelectRestriction(Context ctxt,
                                                    Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_MULTI,
                             current.getStringArray(RESTRICTION_MULTI));

    entry.setTitle("A Multi-Select Restriction");
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);

    return(entry);
}
```

As with a `ListPreference`, you provide two string arrays to the `RestrictionEntry`, representing the values the primary user sees (`setChoiceEntries()`) and the corresponding values to be supplied to your app based upon the choice(s) (`setChoiceValues()`). You can supply these either as Java string arrays or as `<string-array>` resources – `RestrictionEntriesReceiver` goes with the latter approach.

Option #2: Custom Restriction Activity

It may be that what you want to collect, in terms of restrictions, cannot readily be represented in the form of `Switch` widgets and list dialogs. For example, to restrict use of your app based on time, it would be nice to use a `TimePickerDialog` or the equivalent.

The alternative to returning an `EXTRA_RESTRICTIONS_LIST` roster of `RestrictionEntry` objects from your `BroadcastReceiver` is to have the result `Bundle` contain `EXTRA_RESTRICTIONS_INTENT`. This key should point to an `Intent` that identifies the activity that you want to start up when the user taps the settings icon. Android will call `startActivityForResult()` on that `Intent` when the user taps on the settings icon.

Your job is to collect the restrictions from the user, using the `EXTRA_RESTRICTIONS_BUNDLE` from the incoming `Intent` to pre-populate your activity, if desired. When the user is done, you should call `setResult()`, passing in an `Intent` that contains another `EXTRA_RESTRICTIONS_BUNDLE` with the revised data,

or optionally a `EXTRA_RESTRICTIONS_LIST` (with the `RestrictionEntry` objects containing the values to be used).

What the Primary User Sees

Given the `RestrictionEntriesReceiver` described above, when the primary user goes to configure a restriction profile, your app will appear with a settings icon next to it:

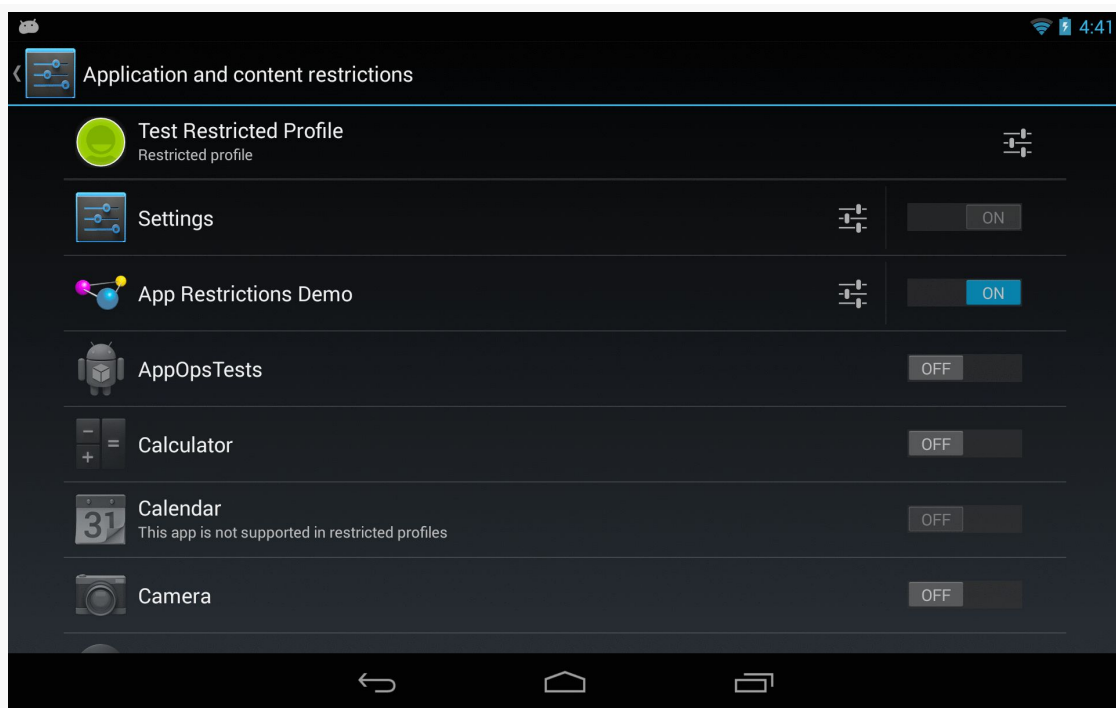

Figure 659: Restricted Profile, Showing App Settings Icon

Tapping that settings icon will “unfold” and display the restrictions that you configured via the `RestrictionEntry` objects:

RESTRICTED PROFILES AND USERMANAGER

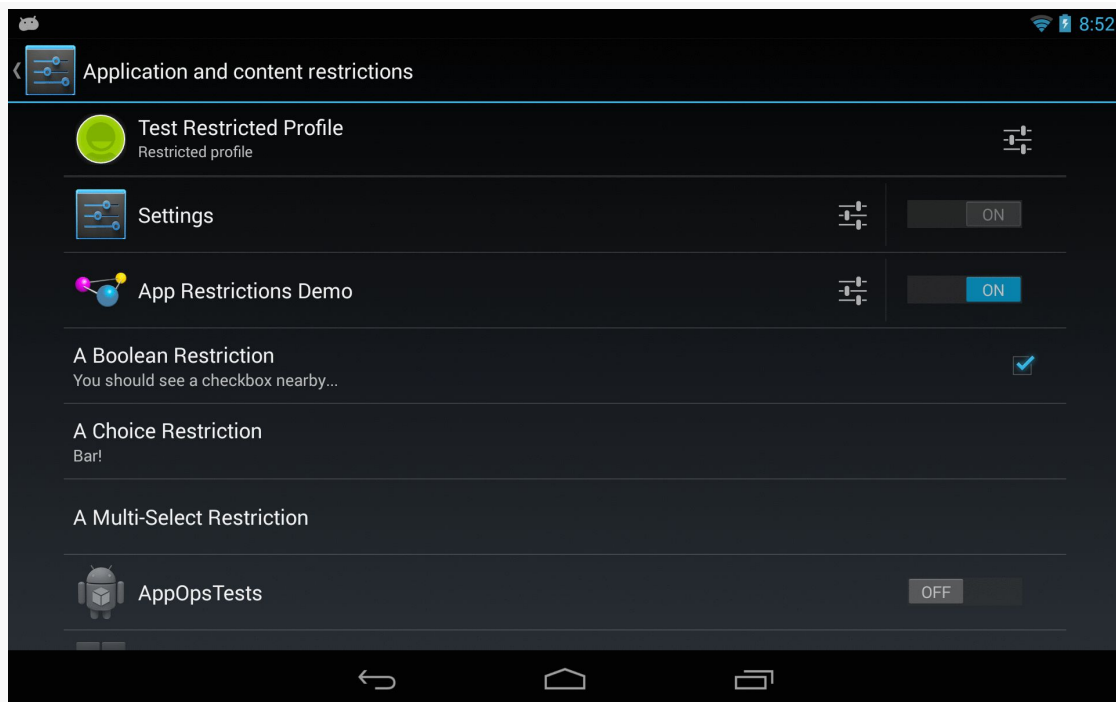

Figure 66o: Restricted Profile, Showing App Restrictions

The primary user can then interact with your restrictions, toggling checkboxes and popping up the list dialogs:

RESTRICTED PROFILES AND USERMANAGER

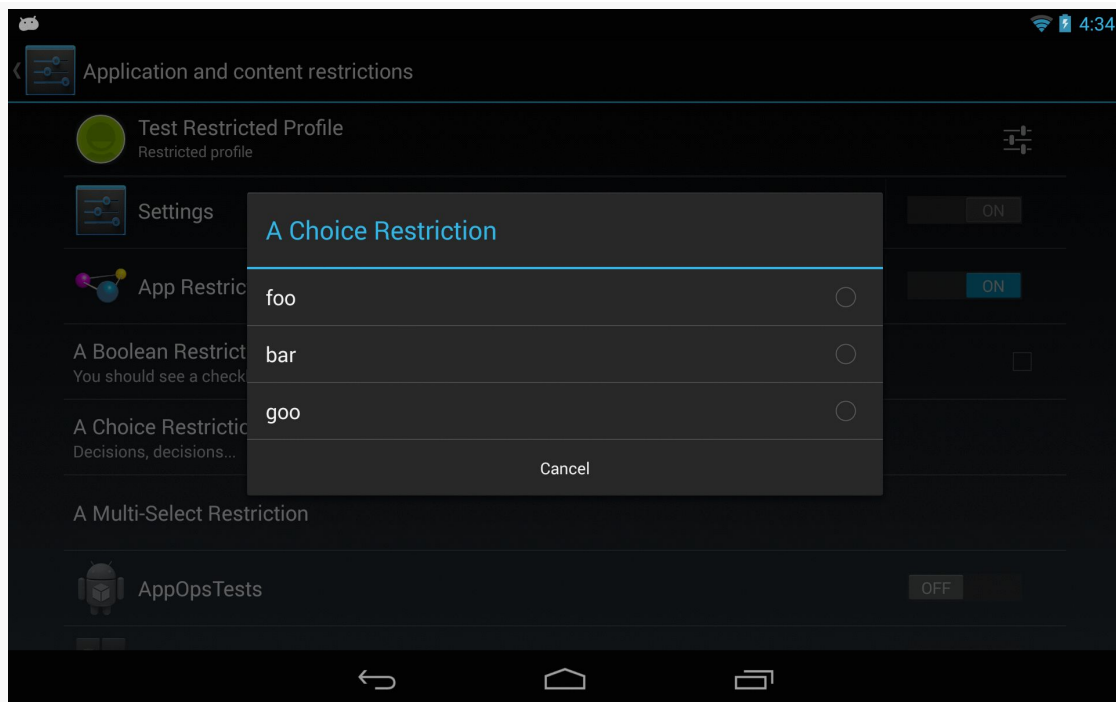

Figure 661: Restricted Profile, Showing Choice Restriction

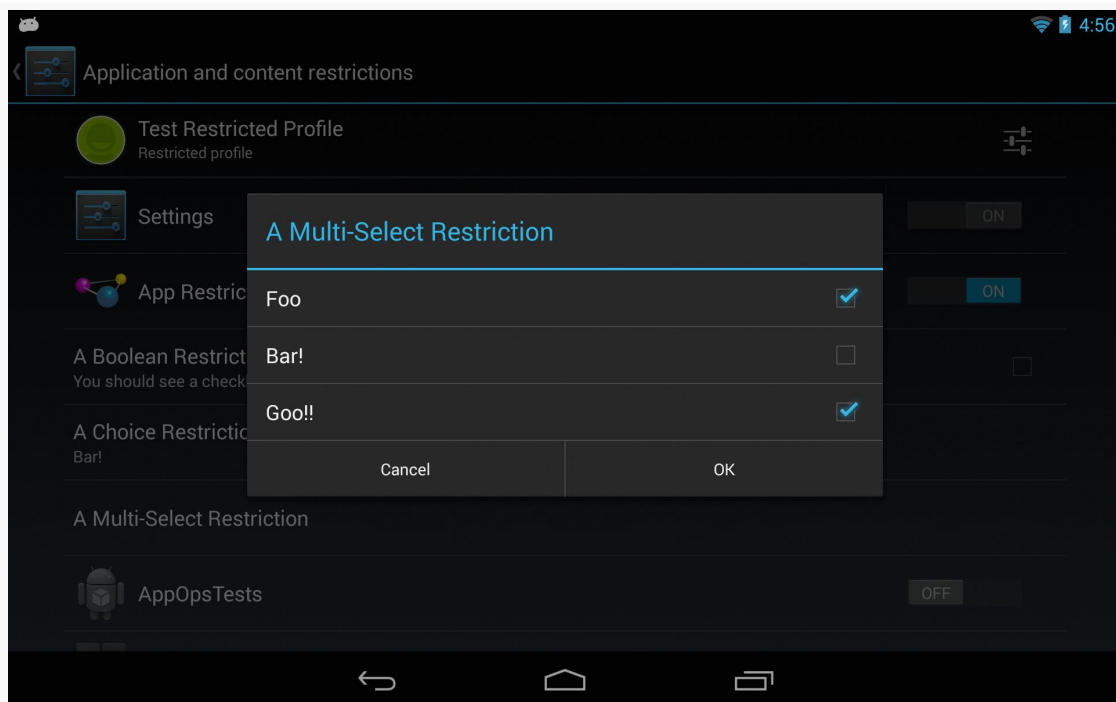

Figure 662: Restricted Profile, Showing Multi-Select Restriction

Finding Out the Current Restrictions

Now, the rest of your app needs to find out what restrictions are placed upon it, so behavior can be tailored accordingly. To do this, call `getApplicationRestrictions()` on `UserManager`, passing in your package name, as seen here in `MainActivity`:

```
package com.commonware.android.profile.app;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
        Bundle restrictions=
            mgr.getApplicationRestrictions(getPackageName());

        if (restrictions.keySet().size() > 0) {
            setContentView(R.layout.activity_main);

            RestrictionsFragment f=
                (RestrictionsFragment)getFragmentManager().findFragmentById(R.id.contents);

            f.showRestrictions(restrictions);
        }
        else {
            Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
                .show();
            finish();
        }
    }
}
```

This `Bundle` could be empty, or it could have values specified by the primary user to restrict the profile that is running your app.

In the case of this sample, we once again set up a `RestrictionsAdapter` to show the results, if the `Bundle` is not empty. However, our adapter is a bit more complicated, as there are more than boolean restrictions now. `getView()` has been updated to handle all three possible restrictions, showing the icon for the boolean restriction, and showing the value(s) from the lists in the other restrictions:

```
package com.commonware.android.profile.app;

import android.app.ListFragment;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.TextView;
import java.util.ArrayList;
import java.util.Collections;

public class RestrictionsFragment extends ListFragment {
    public void showRestrictions(Bundle restrictions) {
        setListAdapter(new RestrictionsAdapter(restrictions));
    }

    class RestrictionsAdapter extends ArrayAdapter<String> {
        Bundle restrictions;

        RestrictionsAdapter(Bundle restrictions) {
            super(getActivity(), android.R.layout.simple_list_item_1,
                new ArrayList<String>());

            ArrayList<String> keys=
                new ArrayList<String>(restrictions.keySet());

            Collections.sort(keys);
            addAll(keys);

            this.restrictions=restrictions;
        }

        @Override
        public View getView(int position, View convertView, ViewGroup parent) {
            TextView row=
                (TextView)super.getView(position, convertView, parent);
            String key=getItem(position);

            if (RestrictionEntriesReceiver.RESTRICTION_BOOLEAN.equals(key)) {
                int icon=
                    restrictions.getBoolean(key) ? R.drawable.ic_true
                    : R.drawable.ic_false;

                row.setCompoundDrawablesWithIntrinsicBounds(0, 0, icon, 0);
            }
            else if (RestrictionEntriesReceiver.RESTRICTION_CHOICE.equals(key)) {
                row.setText(String.format("%s (%s)", key,
                    restrictions.getString(key)));
            }
            else {
                String value=
                    TextUtils.join(" | ", restrictions.getStringArray(key));
            }
        }
    }
}
```

```
        row.setText(String.format("%s (%s)", key, value));
    }

    return(row);
}
}
```

The result, when run on a restricted profile with restrictions placed upon our app, is to show those restrictions:

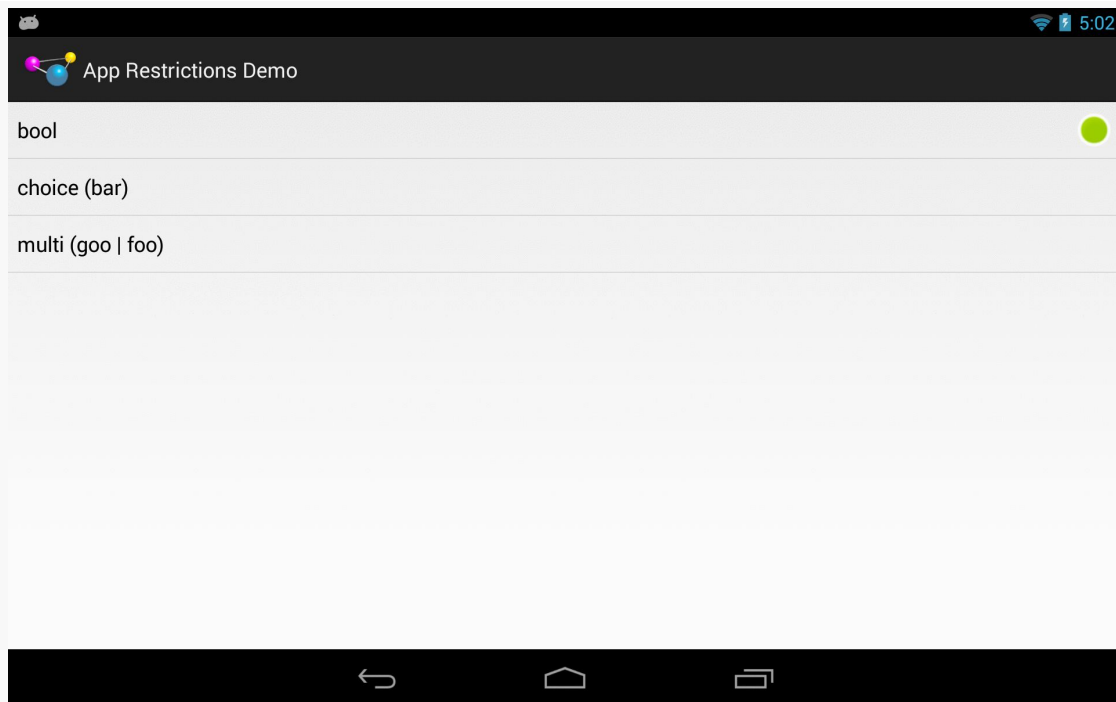

Figure 663: App Restrictions Demo, on a Restricted Profile

The Uninstall Bug

Note that there appears to be [a bug in Android 4.3](#), where an uninstalled app's restrictions remain intact. Your app may continue to show up in the restricted profile, and if the user reinstalls the app later on, whatever original restrictions were placed on a restricted profile return.

Implicit Intents May Go “Boom”

The primary user of a tablet, when setting up a restricted profile, can control what apps are available to that profile. In many cases, if the user is setting up a restricted profile in the first place, the list of apps available to that profile will be fairly limited, such as only allowing a young child to access a few games and educational apps.

`startActivity()` always has the chance of throwing an `ActivityNotFoundException`. However, for certain Intent actions, we often ignore this possibility, because we are certain that there will be an app that can handle our request:

- All Android devices have Web browsers, right?
- All Android devices have some sort of mapping application, right?
- All Android devices let you pick a contact, right?

Now, with restricted profiles, you will need to deal with the `ActivityNotFoundException` case all of the time. You have three basic approaches for this:

1. Wrap all `startActivity()` and `startActivityForResult()` calls in a try/catch block that catches `ActivityNotFoundException` and intelligently handle the problem
2. Use `PackageManager` and `resolveActivity()` *before* trying to start the activity, where if `resolveActivity()` returns null, you know that there is no activity available to handle your desired operation
3. Switch out some of your `startActivity()` and `startActivityForResult()` calls for implementations in your app (e.g., embed [Maps V2](#) rather than try to launch a potentially-nonexistent activity)

You might consider implementing a `safeStartActivity()` utility method that wraps up your particular plan, so you can debug it once.

The Future: App Ops?

Android 4.3 briefly had a leaked activity in the Settings app, that allows users to enable or disable operations on a per-app basis. These operations cover many common scenarios identified by permissions (e.g., read contacts, write contacts, access location), though it is not a pure one-to-one mapping. This activity is referred to as “App Ops”, based upon the title shown in the action bar.

While that activity [has since been removed from the Settings app in AOSP](#), it is perhaps a sign of things to come. Also, Android 4.4 has introduced an AppOpsManager that presumably ties into this Settings activity, though that activity was not enabled in Android 4.4 either. One can imagine that primary users will be able to restrict specific operations for allowed apps for restricted profiles. So while App Ops is not an immediate concern for most Android developers, it is something to keep an eye on.

The author of this book maintains an [App Ops developer FAQ](#) with more information on the subject.

Tapjacking

On the whole, Android's security is fairly good for defending an app from another app. Between using Linux users and filesystems for protecting an application's files from other apps, to the use of custom permissions to control access to public interfaces, an application would seem to be relatively protected.

However, there is one attack vector that existed until Android 4.0.3: tapjacking. This chapter outlines what tapjacking is and what you can do about it to protect your app's users, for as long as you are supporting devices older than 4.0.3.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [broadcast Intents](#)
- [service theory](#)

What is Tapjacking?

Tapjacking refers to another program intercepting and inspecting touch events that are delivered to your foreground activity (or related artifacts, such as the input method editor). At its worst, tapjackers could intercept passwords, PINs, and other private data.

The term “tapjacking” seems to have been coined by Lookout Mobile Security, in a [blog post](#) that originally demonstrated this issue.

You might be wondering how this is possible. There are a handful of approaches to implementing this. The Lookout blog post cited perhaps the least useful approach: making a transparent Toast. The [Tapjacking/Jackalope](#) sample application will illustrate a far more troublesome implementation.

World War Z (Axis)

You may recall that there are three axes to consider with Android user interfaces. The X and Y axes are the ones you typically think about, as they control the horizontal and vertical positioning of widgets in an activity. The Z axis — effectively “coming out the screen towards the user’s eyes” — can be used in applications for sophisticated techniques, such as a pop-up panel.

Normally, you think of the Z axis within the scope of your activity and its widgets. However, there are ways to display “system alerts” – widgets that can float over the top of any activity. A Toast is the one you are familiar with, most likely. A Toast displays something on the screen, yet touch events on the Toast itself will be passed through to the underlying activity. Lookout demonstrated that it is possible to create a fully-transparent Toast. However, the lifetime of a Toast is limited (3.5 seconds maximum), which would limit how long it can try to grab touch events.

However, any application holding the `SYSTEM_ALERT_WINDOW` permission can display their own “system alerts” with custom look and custom duration. By making one that is fully transparent and lives as long as possible, a tapjacker can obtain touch events for any application in the system, including lock screens, home screens, and any standard activity.

Enter the Jackalope

To demonstrate this, let’s take a look at the Jackalope sample application. It consists of a tiny activity and a service, with the service doing most of the work.

The activity employs `Theme.NoDisplay`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0" package="com.commonware.android.tj.jackalope">
    <uses-permission android:name="android.permission.SYSTEM_ALERT_WINDOW" />
    <application android:label="Jackalope">
        <activity android:name=".Jackalope"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
```

TAPJACKING

```
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
    <service android:name=".Tapjacker" />
</application>
</manifest>
```

The activity then just starts up the service and finishes:

```
package com.commonware.android.tj.jackalope;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class Jackalope extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        startService(new Intent(this, Tapjacker.class));
        finish();
    }
}
```

The visible effect is... nothing. Tapping the icon in the launcher appears to have no effect, but it does actually start up the tapjacker. You just cannot see it.

The Tapjacker service does its evil work in a handful of lines of code:

```
package com.commonware.android.tj.jackalope;

import android.app.Service;
import android.content.Intent;
import android.graphics.PixelFormat;
import android.os.IBinder;
import android.util.Log;
import android.view.Gravity;
import android.view.MotionEvent;
import android.view.View;
import android.view.WindowManager;

public class Tapjacker extends Service implements View.OnTouchListener {
    private View v=null;
    private WindowManager mgr=null;

    @Override
    public void onCreate() {
        super.onCreate();

        v=new View(this);
```

```
v.setOnTouchListener(this);
mgr=(WindowManager)getSystemService(WINDOW_SERVICE);

WindowManager.LayoutParams params
    =new WindowManager.LayoutParams(
        WindowManager.LayoutParams.FILL_PARENT,
        WindowManager.LayoutParams.FILL_PARENT,
        WindowManager.LayoutParams.TYPE_SYSTEM_OVERLAY,
        WindowManager.LayoutParams.FLAG_WATCH_OUTSIDE_TOUCH,
        PixelFormat.TRANSPARENT);

params.gravity=Gravity.FILL_HORIZONTAL|Gravity.FILL_VERTICAL;
mgr.addView(v, params);

// stopSelf(); -- uncomment for "component-less" operation
}

@Override
public IBinder onBind(Intent intent) {
    return(null);
}

@Override
public void onDestroy() {
    mgr.removeView(v); // comment out for "component-less" operation

    super.onDestroy();
}

public boolean onTouch(View v, MotionEvent event) {
    Log.w("Tapjacker",
        String.valueOf(event.getX())+"."+String.valueOf(event.getY()));

    return(false);
}
}
```

In `onCreate()`, we create an invisible View in Java code. Note that while you normally create a widget by passing in the Activity to the constructor, any Context will work, and so here we use the Tapjacker service itself.

Then, we access the WindowManager system service and add the invisible View to the system. To do this, we need to supply a `WindowManager.LayoutParams` object, much like you might use `LinearLayout.LayoutParams` or `RelativeLayout.LayoutParams` when putting a View inside of one of those containers. In this case, we:

1. Say that the View is to fill the screen
2. Indicates that the View is to be treated as a “system overlay” (`TYPE_SYSTEM_OVERLAY`), which will be at the top of the Z axis, floating above anything else (activities, dialogs, etc.)

3. Indicates that we are to receive touch events that are beyond the View itself (FLAG_WATCH_OUTSIDE_TOUCH), such as on the system bar in API Level 11+ devices

We attach the Tapjacker service itself as the `OnTouchListener` to the View, and simply log all touch events to LogCat. In `onDestroy()`, we remove the system overlay View.

The result is that every screen tap results in an entry in LogCat – including data entry via the soft keyboard — even though the user is unaware that anything might be intercepting these events.

Note, though, that this does not intercept regular key events, including those from hardware keyboards. Also note that this does not magically give the malware author access to data entered before the tapjacker was set up. Hence, even if the tapjacker can sniff a password, if they do not know the account name, the user may still be safe.

Thinking Like a Malware Author

So, you have touch events. On the surface, this might not seem terribly useful, since the View cannot see what is being tapped upon.

However, a savvy malware author would identify what activity is in the foreground and log that information along with the tap details and the screen size, periodically dumping that information to some server. The malware author can then scan the touch event dumps to see what interesting applications are showing up. With a minor investment – and possibly collaboration with other malware authors — the author can know what touch events correspond to what keys on various input method editors, including the stock keyboards used by a variety of devices. Loading a pirated version of the APK on an emulator can indicate which activity has the password, PIN, or other secure data. Then, it is merely a matter of identifying the touch events applied to that activity and matching them up with the soft keyboard to determine what the user has entered. Over time, the malware author can perhaps develop a script to help automate this conversion.

Hence, the on-device tapjacker does not have to be very sophisticated, other than trying to avoid detection by the user. All of the real work to leverage the intercepted touch events can be handled offline.

Detecting Potential Tapjackers

Tapjacking seems bad.

This raises the question: can we identify when a tapjacker is running? That would allow users and developers to “route around the damage”, such as uninstalling the tapjacker application.

Unfortunately, this does not appear to be possible. There is no obvious way for an application — or the user — to determine if some other application has employed `WindowManager` to add a `TYPE_SYSTEM_OVERLAY` View to the screen. Even if there were, there is no way to determine if this View represents a tapjacker or somebody exploiting this capability for other, less nefarious ends.

All we can do is identify applications that might pose a problem.

Who Holds a Permission?

The biggest identifier of a possible tapjacker is the `SYSTEM_ALERT_WINDOW` permission. This is required to add a `TYPE_SYSTEM_OVERLAY` View to the screen. Relatively few applications request this, since built-in system alerts, like Toast, do not require the permission.

Also, a tapjacker probably needs the `INTERNET` permission, to deliver the results to the malware author. In principle, the tapjacker could be split into two applications, one with `SYSTEM_ALERT_WINDOW` and one with `INTERNET`. However, this adds to deployment complexity and therefore may be avoided by malware authors.

An end user can use programs like `RL Permissions` to examine the applications that have these permissions. A developer can use `PackageManager` to enumerate the installed applications and see which ones hold these permissions. We will examine some code for doing this [later in this chapter](#).

Who is Running?

Of course, a tapjacker is only a threat if it is actually running in the background. Applications might use those two permissions just in the course of normal activity-centric operations, not with an everlasting service trying to maintain the interception View.

We can use `ActivityManager` to enumerate the running processes and what packages' code are in each. Any package that holds the permission combination from the previous section and is running in a process is a possible tapjacking threat. We will examine some code for doing this [in the next section](#).

Note that it is important to examine running processes, not running services. For example, the Tapjacker service from earlier in this chapter could add the interception View and immediately exit. You can see this in action by adjusting the code as indicated in the comments in `onCreate()` and `onDestroy()`. The interception View will remain intact (with the Tapjacker service object leaked) until the process is terminated. That process might be terminated quickly or slowly, depending on what all is going on with the device. A sophisticated malware author might try to run without a running service to increase stealthiness, at the cost of occasionally losing some data.

Combining the Two: TJDetect

To see these techniques in action, take a look at the [Tapjacking/TJDetect](#) sample project. This consists of a single `ListActivity`, whose list is populated with the applications that hold both `SYSTEM_ALERT_WINDOW` and `INTERNET` permissions and are presently running:

```
package com.commonware.android.tj.detect;

import android.app.ActivityManager;
import android.app.ListActivity;
import android.content.pm.PackageInfo;
import android.content.pm.PackageManager;
import android.os.Bundle;
import android.widget.ArrayAdapter;
import java.util.ArrayList;
import java.util.HashSet;

public class TJDetect extends ListActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        ActivityManager am=(ActivityManager) getSystemService(ACTIVITY_SERVICE);
        HashSet<CharSequence> runningPackages=new HashSet<CharSequence>();

        for (ActivityManager.RunningAppProcessInfo proc :
            am.getRunningAppProcesses()) {
            for (String pkgName : proc.pkgList) {
                runningPackages.add(pkgName);
            }
        }
    }
}
```

```
PackageManager mgr=getPackageManager();
ArrayList<CharSequence> scary=new ArrayList<CharSequence>();

for (PackageInfo pkg :
    mgr.getInstalledPackages(PackageManager.GET_PERMISSIONS)) {
    if (PackageManager.PERMISSION_GRANTED==
        mgr.checkPermission(android.Manifest.permission.SYSTEM_ALERT_WINDOW,
            pkg.packageName)) {
        if (PackageManager.PERMISSION_GRANTED==
            mgr.checkPermission(android.Manifest.permission.INTERNET,
                pkg.packageName)) {
            if (runningPackages.contains(pkg.packageName)) {
                scary.add(mgr.getApplicationLabel(pkg.applicationInfo));
            }
        }
    }
}

setListAdapter(new ArrayAdapter<this,
    android.R.layout.simple_list_item_1,
    scary>());
}
```

To find the unique set of packages that are running across all processes, we iterate over the `RunningAppProcessInfo` objects returned by `ActivityManager` from a call to `getRunningAppProcesses()`. One public data member of `RunningAppProcessInfo` is a list of all the packages whose code runs in this process (`pkgList`). We use a simple `HashSet` to come up with the unique set of packages.

Then, we find all installed packages via a call to `getInstalledPackages()` on `PackageManager`. For each package, we use `checkPermission()` on `PackageManager` to see if the package in question holds a permission. Packages that pass those two tests are then checked against the `HashSet` of running packages, and those that are running are recorded in an `ArrayList`, later wrapped in an `ArrayAdapter`.

If you run `TJDetect`, it will not detect Jackalope, since Jackalope lacks the `INTERNET` permission. And, particularly on production hardware, it will detect several packages that may not be tapjackers at all, but rather are system applications installed in the firmware by the device manufacturer.

Defending Against Tapjackers

OK, so users and developers cannot reliably detect tapjackers. And Android 4.0.3 eliminates this attack vector. Surely, for previous versions of Android, there must be

something in the OS that helps defend users and developers against tapjacking, right?

The answer is “yes”, for a generous definition of the term “defend” and an equally generous definition of “users and developers”.

Filtering Touch Events

The only “defense” directly provided by Android is to allow applications to filter out touch events that had been intercepted by a tapjacker, Toast, or any other form of system overlay or alert. Those touch events are simply dropped, never delivered to the underlying activity.

Implementing the Filter

The simplest way to implement the touch event filter is to add the `android:filterTouchesWhenObscured` attribute to a widget or container, setting it to `true`. The equivalent Java setter method on `View` is `setFilterTouchesWhenObscured()`.

For example, take a look at the `res/layout/main.xml` file in the [Tapjacking/RelativeSecure](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:filterTouchesWhenObscured="true">
    <TextView android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="URL:"
        android:layout_alignBaseline="@+id/entry"
        android:layout_alignParentLeft="true"/>
    <EditText
        android:id="@+id/entry"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_toRightOf="@+id/label"
        android:layout_alignParentTop="true"/>
    <Button
        android:id="@+id/ok"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_below="@+id/entry"
```

```
        android:layout_alignRight="@id/entry"
        android:text="OK" />
    <Button
        android:id="@+id/cancel"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_toLeftOf="@id/ok"
        android:layout_alignTop="@id/ok"
        android:text="Cancel" />
</RelativeLayout>
```

Here, we have `android:filterTouchesWhenObscured="true"` on the `RelativeLayout` at the root of the layout resource. This property cascades to a container's children, and so if a tapjacker (or `Toast` or whatever) is above any of the widgets in the `RelativeLayout`, none of the touch events will be processed.

More fine-grained control can be achieved in custom widgets by overriding `onFilterTouchEventForSecurity()`, which gets control before the regular touch event methods. You can determine if a touch event had been intercepted by looking for the `FLAG_WINDOW_IS_OBSCURED` flag in the `MotionEvent` passed to `onFilterTouchEventForSecurity()`, and you can make the decision of how to handle this on an event-by-event basis.

The User Experience and the Hoped-For Security

Normally, the user will not see a difference when interacting with widgets that have this attribute set. However, if a tapjacker is intercepting these events, the user will not see any reaction from the widgets when they are tapped. For example, clicking a `Button` will have no visual effect (e.g., orange flash).

The hope is that users will realize that the UI is not responding to their touch events and therefore will not complete whatever it is they are doing. For example, they might not complete their PIN entry after realizing that the number pad supplied by the app is not responding to their taps.

For some users and some apps, this will be an effective defense. However, there will be some users who will remain oblivious until after completing the attempt to enter the private information.

The Flaws

The user can still use the soft keyboard to enter data into `EditText` widgets. While the soft keyboard will not automatically appear in portrait mode (since the `EditText`

will not respond to the tap), if it has the focus, the user can long-press the MENU button to raise the soft keyboard and enter data that way.

Similarly, if the user is in landscape mode and gets the full-screen soft keyboard, since this is not the EditText widget defended by the touch event filtering, everything works normally — including interception by tapjacking. Developers could try to prevent this by adding `flagNoFullscreen` to the `android:imeOptions` attribute on the EditText in the layout XML, though this may not be honored by all soft keyboards. Developers could also try to prevent this by locking the activity into portrait mode (`android:screenOrientation="portrait"`), but this would be bad for users with side-slider keyboards, Android TV devices, etc.

And, most importantly, the tapjacking still happens. If users keep trying to enter their credentials despite the lack of UI feedback, they may eventually enter the whole thing and therefore become vulnerable to having that information used for ill ends.

Availability

Filtering touch events when the activity is obscured is supported in API Level 9 and above — in other words, Android 2.3 and newer. At the time of this writing, that leaves out ~25% of active Android devices, based on the June 1, 2012 published edition of the [platform versions data](#) from Google.

Detect-and-Warn

You can use the tapjacker detection logic illustrated earlier in this chapter. It is not particularly accurate, but you may feel it is worthwhile.

To minimize hassle for the user, your application should maintain a “whitelist” of approved packages. Any time you detect a package that is not on the approved list, you would raise an AlertDialog (or the equivalent) to let the user know of the potential tapjacker. If they elect to continue onward in your app, add the new package(s) to the whitelist, so you do not bother the user again for the same package.

Why Is This Being Discussed?

Some of you are by this time wondering why this book has a chapter on this subject.

Google's security team indicated to the author that `android:filterTouchesWhenObscured` is sufficient security. If so, developers need to realize when to use it, and for that, developers need to understand what tapjacking is to start with. The code to implement tapjacking is sufficiently trivial that "security by obscurity" of the code seems pointless.

It is eminently possible that `android:filterTouchesWhenObscured` is not sufficient security, despite Google's claim. Since Google seems to have changed their mind, eliminating tapjacking in Android 4.0.3, it would appear that Google thinks that Google's original solution was insufficient. In that case, developers may be able to help inform the public about the dangers of applications that request the `SYSTEM_ALERT_WINDOW` permission.

There are legitimate uses for tapjacking techniques. Some apps use this to provide a universal gesture interface, for example, to get control no matter what application is presently in the foreground. Whether the value that such apps provide is worth the risks inherent in tapjacking is up for debate.

If you feel that tapjacking is a problem and that `android:filterTouchesWhenObscured` is inadequate, you may wish to let Google know when you have the opportunity to interact with Google engineers at conferences and similar events. If you come up with other ways to detect and/or prevent tapjacking, you may wish to distribute that knowledge, so other developers can learn from your discovery.

What Changed in 4.0.3?

As of Android 4.0.3, the tapjacking attack is no longer possible, at least through the techniques outlined in this chapter. A `View` of type `TYPE_SYSTEM_OVERLAY` cannot receive touch events.

Miscellaneous Security Techniques

This chapter outlines some additional security measures that you can consider for your applications that do not necessarily warrant a full chapter on their own at this time.

In other words, it's just a pile of interesting security stuff.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, you should review the [app signing chapter](#) if you are unfamiliar with the signing process. Also, one demo uses [remote services, including using the binding pattern](#), which is also covered in this book.

Public Key Validation

We sign our apps with signing keys all the time. By default, we are signing with a so-called “debug signing key”, created automatically by the build tools. For production, we sign with a different signing key. The primary use of that signing key is to determine equivalence of authorship:

- Is this APK, representing an upgrade to an already-installed app, signed by the same signing key that signed that app?
- Is this APK, that requests firmware-defined signature-level permissions, signed by the same signing key that signed the firmware?

However, as it turns out, information about the public key that signed an APK is visible to us, for our own APK as well as for any other APK on the device. We can

leverage that to help determine whether a given APK was signed by something we recognize. This goes above and beyond using Android's built-in signature-based defenses (e.g., using a custom signature-level permission).

Scenarios

There are several scenarios in which we might imagine that we could employ our own public key validation. How well the technique will work, though, depends on what we are checking and the nature of the attack we are defending against.

Checking Yourself

You might consider checking your own app's public key. After all, if your app is not signed with your production signing key, something very strange is going on, and the natural reaction is that "something strange" is unlikely to be a good thing for you.

However, there are some issues here.

First and foremost, checking your own signing key assumes that whatever caused you to *not* be signed by that key did not also modify your validation algorithm. For example, suppose that you validate your signing key to determine if somebody perhaps reverse-engineered and modified your app, perhaps to remove some license checks. This will only catch an attacker that removed the licensing checks and did not *also* remove your signature validation, or modify the validation to use the attacker's signing key. While it is possible that an attacker will modify one part but not another, it remains unclear how well this defense will work in practice.

Also, bear in mind that you, as a developer, may be opting into services that intentionally change your app's signature. Various providers will "wrap" your app, whether for interstitial ad banners or for quasi-DRM. There are three possible ways that they wrap your app:

1. They sign it with their signing key, which means that your runtime validation of the key will fail, as your app is now signed by their key, not yours. This is also *very* risky, as if for whatever reason you are no longer able to use their service (e.g., they go out of business), you may have difficulty in upgrading your app, as you will not have the right key to use.
2. They sign it with *your* signing key, either one that you upload, or one that they generate for you. In this case, your runtime public key validation logic

could still work. On the other hand, now this other firm is perfectly capable of upgrading your app, or shipping other apps, signed with your production signing key, and this has its own set of risks.

3. They allow you to download the “wrapped” app and have you sign it yourself with your own signing key. This is the best alternative from a security standpoint, but it is the most tedious, as now you have additional work to do to publish your app.

Checking Arbitrary Other Apps

What will tend to be more reliable is to check *other* applications’ public keys. While they might have been cracked, it is unlikely that the same attacker also attacked *your* app, and so you can help detect problems in others.

For example, let us consider a specific scenario: a client-side JAR for integration to a third-party app.

This book outlines many forms of IPC, from content providers to remote services to broadcast Intents. If you are creating an app that offers such IPC endpoints, you may wish to consider also shipping a JAR to make using those endpoints a bit easier. You might create a library that handles all of the details of sending commands to your remote service, or you might create a library that provides a wrapper around the AIDL-generated Java proxy classes for remote binding.

Another thing such a JAR could do is check the integrity of your app. The JAR’s code is in the client’s app, not yours, and while your app might be cracked, the client’s app might not. You could check the validity of the public key of your own app from the client’s app, and fail if there is a detected problem.

This might be especially important depending upon the nature of the app and the JAR that is providing access to it. If the app is an app offering on-device payments (e.g., a Google Wallet sort of app), and the app offers an API for other apps to do payments, it is fairly important that those other apps can trust the payment app. By checking the public key, your JAR can help provide that level of trust... or at least ensure that nobody else has done something specifically to degrade that trust.

This is particularly important for avoiding device-hosted man-in-the-middle attacks on your IPC from client apps to your app. In an ideal world, you would only allow IPC via signature-level permissions, but that will not work in cases where third parties are writing the clients.

If your IPC is based upon a service (command pattern or binding pattern), if multiple service implementations all advertise the same `<intent-filter>`, Android needs to decide which service will handle the request. First, it will take into account the `android:priority` value on the `<intent-filter>` (even though this behavior is currently undocumented). For multiple services with the same priority (e.g., no priority specified), the first one that was installed will be the one that is chosen. In either case, the client has no way to know, short of examining the service's public key, whether the service that will respond to the requests for IPC is the legitimate service or something else advertising that it supports the same Intent action.

The Easy Solution: SignatureUtils

The author of this book has published [the CWAC-Security library](#). Among other things, this library has a `SignatureUtils` class that makes it relatively easy for you to compare the signature of some Android app to a known good value.

All you need to do is call the static `getSignatureHash()` method, supplying some `Context` (any will do) and the package name of the app that you wish to check. This will return the SHA-256 hash of the signing key of the app, as a set of capitalized, colon-delimited hex values.

You can get the same sort of hash by running the Java 7 version of `keytool`. Hence, if the app you wish to test is another one of yours, perhaps signed with a different signing key, you can use `keytool` to get the value to compare with the result of `getSignatureHash()`. Or, during development, create a little utility app that will dump the `getSignatureHash()` value for the third-party app, and run it on a device containing a known good version of that app (i.e., one that does not appear to have been replaced by malware).

Ideally, over time, we will be able to get app developers to publish their SHA-256 hashes on their Web sites, as another means of getting a known value of the hash to compare at runtime.

If you determine that `getSignatureHash()` does *not* return the right value, this means that the app that is installed on the device is written by somebody other than the app's original author. Often times, this will mean the app has malware in it. It is up to you to determine how you wish to respond to this scenario:

- Alert the user?
- Send data back to your server, or to your analytics collection point, with details of the bad APK?

- Block usage of your app, or usage of features that depend upon the flawed third party?
- Something else?

Examining Public Keys

Under the covers, SignatureUtils uses PackageManager and related classes to examine what they somewhat erroneously refer to as “signatures”. The [MiscSecurity/SigDump](#) sample project will allow us to browse the list of installed packages, see a decoded public key on the screen for a package that we select, plus dump the “signature” as a binary file for later comparison using another app.

The UI Structure

In this sample, we use a SlidingPaneLayout for a master-detail pattern presentation, as was demonstrated in [the chapter on dealing with multiple screen sizes](#). The “master” fragment will be the list of packages; the “detail” fragment will be the decoded public key for the selected package.

The master fragment is implemented as PackagesFragment. It implements a typical ListFragment for use with the master/detail pattern, utilizing the activated state to show the context for the detail fragment. The detail will be SignatureFragment, which will display portions of the decoded public key in a TableLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:shrinkColumns="1"
    android:stretchColumns="1">

    <TableRow>

        <TextView
            android:layout_gravity="center"
            android:layout_margin="4dp"
            android:text="@string/subject"
            android:textStyle="bold"/>

        <TextView android:id="@+id/subject"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_gravity="center"
```

```
        android:layout_margin="4dp"
        android:text="@string/issuer"
        android:textStyle="bold"/>

        <TextView android:id="@+id/issuer"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_gravity="center"
            android:layout_margin="4dp"
            android:text="@string/valid_between"
            android:textStyle="bold"/>

        <TextView android:id="@+id/valid"/>
    </TableRow>

</TableLayout>
```

Listing the Packages

Our PackagesFragment needs the list of packages to display. It expects the hosting activity to supply that, by using the contract pattern, and having a `getPackageList()` method on its Contract:

```
interface Contract {
    void onPackageSelected(PackageInfo pkgInfo);

    List<PackageInfo> getPackageList();
}
```

The hosting activity — `MainActivity` — retrieves a `PackageManager` instance in `onCreate()`, caching it in a `mgr` data member. `getPackageList()` then calls `getInstalledPackages()` on `PackageManager`, specifically requesting to retrieve signature information via the `GET_SIGNATURES` flag. The list we get back from `getInstalledPackages()` can be in any order, so we sort the results before returning it for display purposes:

```
@Override
public List<PackageInfo> getPackageList() {
    List<PackageInfo> result=
        mgr.getInstalledPackages(PackageManager.GET_SIGNATURES);

    Collections.sort(result, new Comparator<PackageInfo>() {
        @Override
        public int compare(final PackageInfo a, final PackageInfo b) {
            return(a.packageName.compareTo(b.packageName));
        }
    })
}
```

```
});  
  
    return(result);  
}
```

Note that this is a List of PackageInfo objects, so we need an ArrayAdapter subclass to handle rendering that. Here, we have a PackageListAdapter that knows how to populate list rows using the packageName field of a PackageInfo object, plus using an activated row layout for API Level 11+ devices:

```
package com.commonware.android.signature.dump;  
  
import android.annotation.TargetApi;  
import android.content.pm.PackageInfo;  
import android.os.Build;  
import android.view.View;  
import android.view.ViewGroup;  
import android.widget.ArrayAdapter;  
import android.widget.TextView;  
  
class PackageListAdapter extends ArrayAdapter<PackageInfo> {  
    PackageListAdapter(PackagesFragment packagesFragment) {  
        super(packagesFragment.getActivity(), getRowResourceId(),  
              packagesFragment.getContract().getPackageList());  
    }  
  
    @Override  
    public View getView(int position, View convertView, ViewGroup parent) {  
        View result=super.getView(position, convertView, parent);  
  
        ((TextView)result).setText(getItem(position).packageName);  
  
        return(result);  
    }  
  
    @TargetApi(Build.VERSION_CODES.HONEYCOMB)  
    private static int getRowResourceId() {  
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {  
            return(android.R.layout.simple_list_item_activated_1);  
        }  
  
        return(android.R.layout.simple_list_item_1);  
    }  
}
```

The result is that our master list is a list of all installed packages, sorted by package name, with the detail TableLayout peeking out of the right edge when shown on a phone-sized screen:

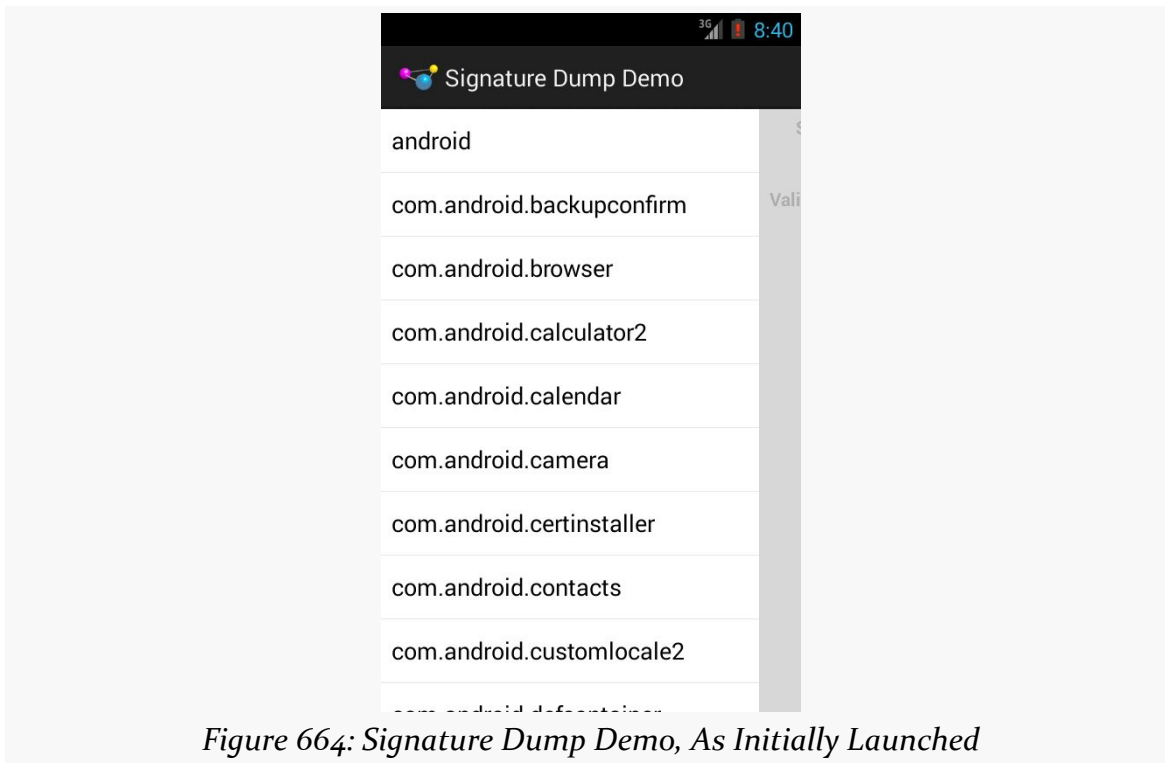

Figure 664: Signature Dump Demo, As Initially Launched

Dumping the Key

onListItemClick() of our PackagesFragment routes control to onPackageSelected() of the Contract interface, which in our case is MainActivity. There, we need to do some useful stuff based upon the fact that the user tapped on a particular package:

```
@Override
public void onPackageSelected(PackageInfo pkgInfo) {
    Signature[] signatures=pkgInfo.signatures;
    byte[] raw=signatures[0].toByteArray();

    sigDisplay.show(raw);
    panes.closePane();

    File output=
        new File(getExternalFilesDir(null),
            pkgInfo.packageName.replace('.', '_') + ".bin");

    new WriteThread(output, raw).start();
}
```

First, we get the Signature array from the PackageInfo object. While this is an array, usually an app will only be signed once. Signing more than once is not especially useful, as an upgraded app needs to match the count and contents of each signature. Hence, we will only pay attention to the first signature. If you are using these techniques as the basis for your client JAR checking the public key of your app for IPC protection purposes, *and* your app is signed with multiple keys, you will want to check all of those keys.

The public key itself is represented as a byte array in the Signature. onPackageSelected() does two things with this byte array:

- Writes it to a file on external storage using a background thread, with a filename based on the app's package name, with . characters replaced by _ characters
- Passes the byte array to the detail fragment (a SignatureFragment) and updates the SlidingPanelLayout to ensure that detail fragment is now visible

Decoding the Key

SignatureFragment is mostly comprised of the show() method that MainActivity uses to pass us the byte array of the “signature” to display:

```
package com.commonware.android.signature.dump;

import android.app.Fragment;
import android.os.Bundle;
import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;
import java.io.ByteArrayInputStream;
import java.security.cert.CertificateException;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.Locale;

public class SignatureFragment extends Fragment {
    DateFormat fmt=new SimpleDateFormat("yyyy-MM-dd HH:mm:ss", Locale.US);

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        return(inflater.inflate(R.layout.sig, container, false));
    }
}
```

```
}

void show(byte[] raw) {
    CertificateFactory cf=null;

    try {
        cf=CertificateFactory.getInstance("X509");
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting CertificateFactory", e);
        return;
    }

    X509Certificate c=null;
    ByteArrayInputStream bin=new ByteArrayInputStream(raw);

    try {
        c=(X509Certificate)cf.generateCertificate(bin);
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting X509Certificate", e);
        return;
    }

    TextView tv=(TextView)getView().findViewById(R.id.subject);

    tv.setText(c.getSubjectDN().toString());

    tv=(TextView)getView().findViewById(R.id.issuer);
    tv.setText(c.getIssuerDN().toString());

    tv=(TextView)getView().findViewById(R.id.valid);
    tv.setText(fmt.format(c.getNotBefore()) + " to "
        + fmt.format(c.getNotAfter()));
}
}
```

That byte array *really* represents an X509 certificate, serialized to a byte array. `show()` goes through the work to get the `X509Certificate` object representing that same data, assuming the byte array is not corrupted somehow. Then, `show()` populates some `TextView` widgets in our `TableLayout` with the:

- The subject of the signature
- The issuer of the signature
- The range of dates in which this signature is valid

A debug signing key output will resemble:

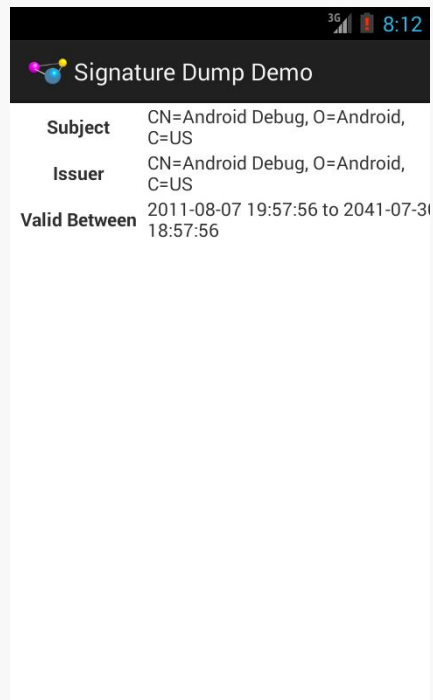

Figure 665: Signature Dump Demo, Showing Debug Signing Key

A self-signed production signing key will resemble:

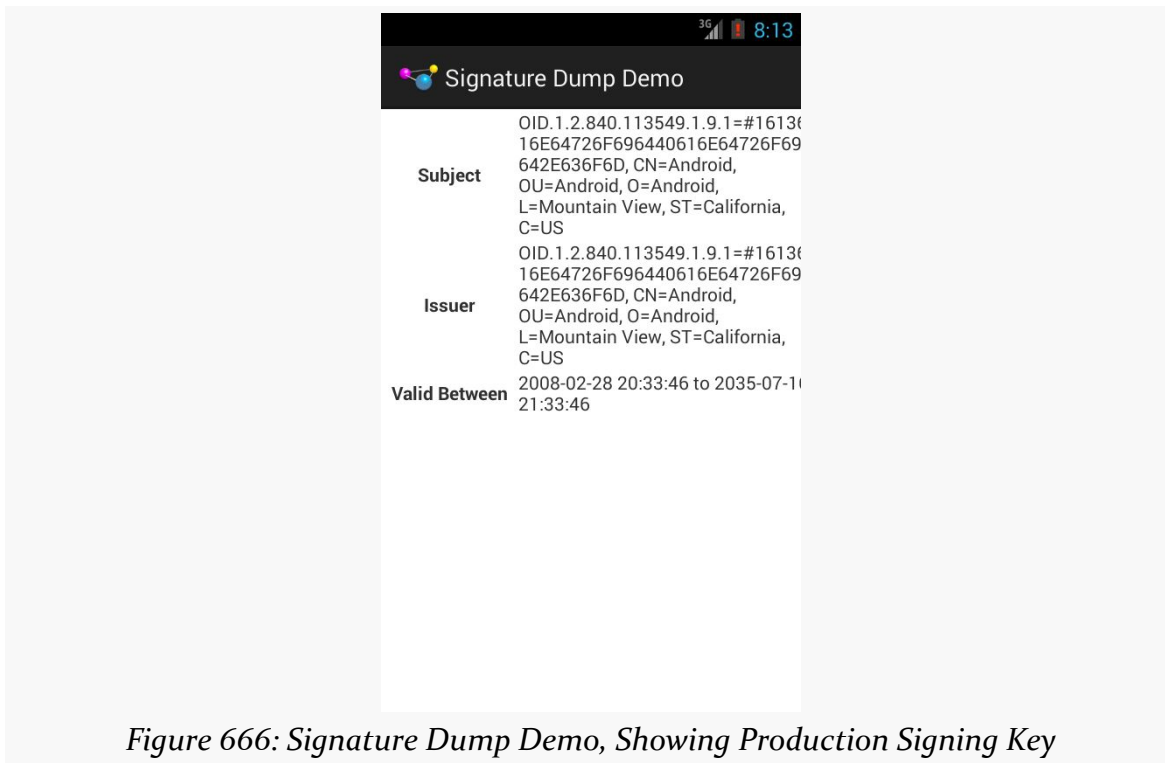

Figure 666: Signature Dump Demo, Showing Production Signing Key

A signing key created by some signing authority would have a subject that is distinct from its issuer.

Validating a Service's Public Key

Seeing these public keys is one thing — using them to help protect the user from man-in-the-middle attacks is another.

In this section, we will look at how to validate the public key of a service that is exporting some API that a client app will use, so the client app knows that it is talking to the right service implementation. There are three sample projects that make up this demonstration, all found in the [MiscSecurity/SecureServiceIPC](#) directory of the GitHub repository.

The Services

The demo contains two separate apps, each implementing a Service. The GoodService project has GoodService, which contains support for both the

command and binding patterns, where the only effective behavior for either of them is to log positive-sounding messages to LogCat:

```
package com.commonware.android.secsvc.demo1;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.os.RemoteException;
import android.util.Log;
import com.commonware.android.secsvc.SomethingUseful;

public class GoodService extends Service {

    @Override
    public IBinder onBind(Intent arg0) {
        return(new GoodBinder());
    }

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        Log.d(getClass().getSimpleName(), "It's all good");

        stopSelf();

        return(START_NOT_STICKY);
    }

    static class GoodBinder extends SomethingUseful.Stub {
        @Override
        public void hi() throws RemoteException {
            Log.d(getClass().getSimpleName(), "It's all good");
        }
    }
}
```

The BadService project has BadService, with the same implementation, except that the logging messages indicate that the service is, in fact, evil.

However, *both* projects have their services defined in the manifest with the same <intent-filter>, tying each of their services to the com.commonware.android.secsvc.SOMETHING custom action:

```
<service
    android:name="GoodService"
    tools:ignore="ExportedService">

    <intent-filter>
        <action android:name="com.commonware.android.secsvc.SOMETHING"/>
    </intent-filter>
</service>
```

The difference is that the BadService adds a high android:priority value, in an attempt to masquerade as the GoodService and convince clients to talk to it instead:

```
<service
  android:name="BadService"
  tools:ignore="ExportedService">
  <intent-filter android:priority="2147483647">
    <action android:name="com.commonware.android.secsvc.SOMETHING" />
  </intent-filter>
</service>
```

Using the Services

The third project in the demo, Client, has a MainActivity with a layout consisting of two Button widgets and a Switch:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  tools:context=".MainActivity">

  <Switch
    android:id="@+id/verify"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dip"
    android:text="@string/enable_verification"/>

  <Button
    android:id="@+id/command"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_margin="4dip"
    android:layout_weight="1"
    android:onClick="testCommand"
    android:text="@string/test_command"/>

  <Button
    android:id="@+id/binding"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_margin="4dip"
    android:layout_weight="1"
    android:onClick="testBinding"
    android:text="@string/test_binding"/>

</LinearLayout>
```

Not surprisingly, the “Test Command” button sends a command to the `com.commonware.android.secsvc.SOMETHING` service, while the “Test Binding” button will bind to the service, call the `hi()` method of the service’s AIDL-defined API, and then unbind from the service.

And, by default, the Intent used for sending the command or initiating the binding is simply one that identifies the `com.commonware.android.secsvc.SOMETHING` action string:

```
private static final String ACTION_SERVICE=
    "com.commonware.android.secsvc.SOMETHING";
private static final Intent INTENT_SERVICE=new Intent(ACTION_SERVICE);
```

Validating the Service

If the Switch is checked, though, we want to validate that the service is the right one for our activity to talk to.

The `buildServiceIntent()` method in `MainActivity` creates the Intent that we will use for sending the command or binding to the service. In there, if the `verify` Switch is checked, we iterate over all possible services that advertise that they support our custom action string:

```
Intent buildServiceIntent() {
    Intent result=null;

    if (verify.isChecked()) {
        PackageManager mgr=getPackageManager();

        for (ResolveInfo info : mgr.queryIntentServices(INTENT_SERVICE, 0)) {
            try {
                if (validate(info.serviceInfo.packageName,
                    R.raw.valid_signature)) {
                    result=new Intent(INTENT_SERVICE);
                    result.setComponent(new ComponentName(
                        info.serviceInfo.packageName,
                        info.serviceInfo.name));

                    break;
                }
            }
            catch (Exception e) {
                Log.e(getClass().getSimpleName(),
                    "Exception finding valid service", e);
            }
        }
    }
    else {
```

```
        result=INTENT_SERVICE;
    }

    return(result);
}
```

Probably `queryIntentServices()` will return a list of size 1. If it returns an empty list, `buildServiceIntent()` will return null, and the caller can know to avoid trying to work with the service. However, `buildServiceIntent()` will *also* return null if there is no valid service to talk to — even if `queryIntentServices()` indicates that there is a matching Service. That is because `buildServiceIntent()` calls `validate()` to compare the public key of the service with a known good edition of that key. Here, we package that “known good edition” as a raw resource, named `valid_signature`. This is the signature dumped by the SigDump sample application described earlier in this chapter.

`validate()`, in turn, finds the signature of the service’s package and compares it with the contents of the raw resource:

```
boolean validate(String pkg, int raw) throws NameNotFoundException,
                                           NotFoundException, IOException {
    PackageManager mgr=getPackageManager();
    PackageInfo pkgInfo=
        mgr.getPackageInfo(pkg, PackageManager.GET_SIGNATURES);
    Signature[] signatures=pkgInfo.signatures;
    byte[] local=signatures[0].toByteArray();

    return(isEqual(new ByteArrayInputStream(local),
                  getResources().openRawResource(raw)));
}
```

The `isEqual()` method is simply some code, found in a Stack Overflow answer, that compares the bytes of two streams, looking for a match:

```
// from http://stackoverflow.com/a/4245881/115145

private boolean isEqual(InputStream i1, InputStream i2)
    throws IOException {
    byte[] buf1=new byte[1024];
    byte[] buf2=new byte[1024];

    try {
        DataInputStream d2=new DataInputStream(i2);
        int len;
        while ((len=i1.read(buf1)) >= 0) {
            d2.readFully(buf2, 0, len);
            for (int i=0; i < len; i++)
                if (buf1[i] != buf2[i])
                    return false;
        }
    }
}
```

```
    }
    return d2.read() < 0; // is the end of the second file
                        // also.
}
catch (EOFException ioe) {
    return false;
}
finally {
    i1.close();
    i2.close();
}
}
```

The `buildServiceIntent()` method not only calls `validate()`, but then calls `setComponent()` on the `Intent` for the service with the matching public key. This ensures that we will *only* talk to this `Service` implementation, and not any others.

If you wish to test this behavior, you will need to have the `GoodService` and the `BadService` apps signed with different signing keys, and use the `SigDump` sample app to get the binary representation of that signing key to use in your client app.

What you will find is that if validation is enabled, the client app will only work with `GoodService`, even if `BadService` is installed. Without this validation, if `BadService` is installed along with `GoodService`, the client app will work with `BadService`, due to the higher `android:priority` on the `BadService`.

You might argue that, in this case, we could simply see if the package name is the right one, rather than fussing around with the public keys. That is true... in this case. The more likely attack, though, is that the service app is replaced by a modified version of the same service app, with a bit of additional code that makes use of the data flowing between client and service. In that case, the package name, and even the class name of the service, are likely to be unmodified. However, unless the real services' author lost control of their production signing key, the attacker's app would be signed by a *different* signing key, making the public key validation important.

Choosing Your Signing Keysize

[The documentation for app signing](#) contains a small side note about the `-keysize` parameter to `keytool`, the utility used to generate our signing keys:

The size of each generated key (bits). If not supplied, Keytool uses a default key size of 1024 bits. In general, we recommend using a key size of 2048 bits or higher.

The reason for the 2,048-bit key size recommendation is that 1,024-bit RSA (the `keytool` default) has been considered at risk for a few years.

The recent revelations about state-sponsored decryption research should be hammering this home. Even if today, forging a 1,024-bit digital signature is still impractical for all but the largest security agencies, it is well within reason that this will fall within the reach of large botnets in the not-too-distant future. Once signing keys can be cracked, apps will be able to be replaced with hacked editions, without tripping up the signature check, or signature-level permission checks might start passing due to forged signatures.

Switching to a larger keysize is not that hard... for new apps. Just specify `-keysize 4096` when creating your production signing key, and you should be good for a long time, barring a major decryption breakthrough for RSA signatures.

For existing apps with existing signing keys, though, you cannot change the key without breaking your ability to update the app.

Create a new, stronger production signing key, as a separate key from whatever you are using for production. Make note to use that new signing key for any new apps you create. And, if you have other reasons why you are migrating an existing user base to a new app (e.g., free app for which you are now offering a paid-app option), consider using the new signing key.

If you are a consultant, and you create unique signing keys per project, just cut over to using a stronger key for new clients and projects.

And if you are [creating apps for which security is paramount](#), you might consider whether it is worthwhile to move your user base to a new version of the app with a new signing key at some point, just for the added protection.

Avoiding Accidental APIs

One place where developers create their own security problems is with “accidental APIs”.

An API, of course, is where one code base exposes some interface that another code base can use. An accidental API is when one code base does not intend to expose an interface, but does anyway, possibly to the app’s detriment.

Bear in mind that if your app becomes popular, other developers will poke and prod at it, to see if they can connect to your app by one means or another. Perhaps they want to offer features that you have not gotten to yet. Perhaps they have more nefarious aims. Regardless, making sure that other code can only work with your app the way that *you* intend for such code to work with your app.

Export Only What's Necessary

A component of your app is only reachable by a third-party app if it is exported. Otherwise, it is inaccessible to third-party apps.

(Admittedly, content providers have an exception to this rule, which we will get to shortly)

You normally do not think about exporting components, except when it comes to content providers. However, your choices for how you implement your app may lead you to accidentally export things that you did not realize were exported.

Export Defaults

The official way to declare whether or not a component is exported is to have an `android:exported` attribute for that component in the manifest (e.g., on an `<activity>` element). However, many times, we do not have such an attribute, but instead rely on the default export behavior.

Activities, services, and broadcast receivers have a simple rule for the default: if the component has an `<intent-filter>`, it is exported by default. Otherwise, it is not exported by default.

This, in turn, leads to a fairly simple development rule: only use an `<intent-filter>` and implicit Intents for working with your components if you *also* want third party apps to work with those components. Otherwise, do not use `<intent-filter>`, and instead communicate with your components using explicit Intents (e.g., the kind that take a Java class as the second constructor parameter).

For example, the classic MAIN/LAUNCHER `<intent-filter>` on your launcher activity is specifically there because you *want* a third party app — the launcher — to be able to start your activity. Most, if not all, of your other activities probably do not need an `<intent-filter>`, as they are likely to be private to your app.

The Chooser Bug

Some developers choose to still use an `<intent-filter>` and implicit Intents for their own private activities, yet then use `android:exported` to enforce the privacy.

This is not a good plan.

The rest of the system, notably `PackageManager`, does not pay much attention to `android:exported` *until the time when the component is to be used*, such as when the activity is to be started. Then, and only then, does Android realize that the component is not exported, and it fails the request, usually with a cryptic `SecurityException`.

A classic example of where this can cause problem came to light in 2012, with the UPS Mobile app. The following is an excerpt from [the author's blog post on this incident](#):

The [UPS Mobile app](#) allows you to track packages and do a handful of other things that you might ordinarily do via the UPS Web site. It generally seems to be well-regarded, but it has an annoying flaw:

It claims to be Barcode Scanner, and does a lousy job at it.

[Barcode Scanner](#), from [ZXing](#), is a favorite among Android developers for its integration possibilities. However, some people do not like having a dependence upon the Barcode Scanner app, so they grab the open source code and attempt to blend it into their own apps. This is neither endorsed nor supported by the ZXing team, but since it is open source, it is also perfectly legitimate.

However, UPS (or whoever they hired to build the app) screwed up. They not only copied the source code, but they copied the manifest entry for the scanning activity. And, their activity has:

```
<intent-filter>
  <action android:name="com.google.zxing.client.android.SCAN" />
  <category android:name="android.intent.category.DEFAULT" />
</intent-filter>
```

This means that on any device that has UPS Mobile installed, they will be an option for handling Barcode Scanner Intents. What happened was that the person asking the question was manually invoking `startActivityForResult()` to bring up

Barcode Scanner, was getting a chooser with UPS Mobile in it, and then was crashing upon choosing UPS Mobile... because UPS Mobile declared this activity to be not exported.

Due to [this bug](#), Android will display non-exported activities in a chooser, despite the fact that they can never be successfully used by the user.

So, what should we learn from this?

First, UPS Mobile should not have used that `<intent-filter>`. As Dianne Hackborn has pointed out, your `<intent-filter>` mix [is effectively part of your app's API](#), and so you need to think long and hard about every `<intent-filter>` you publish. UPS Mobile is not Barcode Scanner and should not be advertising that they handle such Intents, despite the activity being not exported.

Second, UPS Mobile probably should not have had *any* `<intent-filter>` elements for this activity, if they intend to use it purely internally. They could just as easily use an explicit Intent to identify the activity and avoid all of this nonsense.

Third, the person who filed the SO question ideally would have been using ZXing's IntentIntegrator. As Sean Owen of the ZXing project noted in a comment on my answer, IntentIntegrator ensures that only Barcode Scanner or official brethren will handle any scan requests, so this problem would not have appeared.

Fourth, Android really should not be showing non-exported activities in a chooser, which means probably that PackageManager should be filtering out non-exported activities from methods like `queryIntentActivities()`, which I presume lies at the heart of the chooser.

In summary, if your component is truly private, do not have an `<intent-filter>` on it, lest you cause yourself, and your users, problems with other apps.

The ContentProvider Behavior Change

Content providers are a little different... in lots of ways. In the specific scenarios being covered here, there are two primary differences.

First, third-party apps *can* still access a provider that has `android:exported="false"`. However, they can only do so in response to some operation initiated by your application, using `android:grantUriPermissions` and

flags like `FLAG_GRANT_READ_URI_PERMISSION`. A third-party app will have no *independent* access to your non-exported provider.

Second, the default value for `android:exported` not only does not depend upon `<intent-filter>` (since few providers use one), but it has changed over the years:

- For apps with `android:minSdkVersion` *and* `android:targetSdkVersion` set to 16 or lower, the provider is exported by default
- All other apps, the provider is *not* exported by default

Lint will complain about your manifest having a `<provider>` without an `android:exported` attribute.

Sanitize Your Input Extras

If you do expose one or more of your components to third-party apps, and you are supporting certain Intent extras on any Intents used to talk to those components, make sure that the extras' values make sense.

Even Google makes this error, as was seen in [the PreferenceActivity bug](#). `PreferenceActivity` supports an extra, named `:android:show_fragment`, to indicate that the activity should immediately jump to a specific fragment, rather than start at the top level of the preference navigation. The problem is that `PreferenceActivity` did not — and, at the time, could not — validate that the fragment to be loaded is a fragment that is *supposed* to be loaded. This would allow attackers to force apps, like Settings, to load arbitrary fragments, including those not normally accessible to the current user. This is the reason why we now need to override `isValidFragment()` in our `PreferenceActivity` implementations, so we can declare whether or not a particular requested fragment is a legitimate choice or not.

The equivalent behavior for a `ContentProvider` is to sanitize the inputs to methods like `query()`, `update()`, `openFile()`, and so on, to make sure that you do not expose something that you should not. For example, blindly accepting paths to `openFile()` could get you in trouble, if the `Uri` contains relative paths (e.g., `content://your.authority.here/../../databases/your-private.db`), perhaps allowing third parties to get at files that you did not intend for them to access.

Secure Your Output Extras

Similarly, if you send broadcasts or otherwise use IPC to talk to third-party apps, bear in mind that others might be able to see some of that interaction, depending on the IPC in question.

The obvious case is with a broadcast Intent for an implicit Intent. Any app with a registered receiver will be able to “tune into” that broadcast and get whatever data is inside the Intent. In cases where you cannot use permissions to limit the scope of the broadcast, you need to make sure that there is nothing in the Intent that is private to the user.

Sometimes, though, non-obvious cases will emerge. For a few years, Intent extras on activities might be viewed by third-party apps that held the `GET_TASKS` permission, courtesy of the recent-tasks list. The Intent used to launch the task is available via `ActivityManager` and `getRecentTasks()`. While this specific problem was resolved in Android 4.1.1, there may be other similar scenarios lurking about.

Other Ways to Expose Data

Sometimes, we expose data to third-party apps by using standard Android APIs. We focus on the normal publisher and consumer of data using those APIs and forget about other apps that might be monitoring those communications. Or, we might not realize that one party in those communications may not have the user’s best interests at heart. This section outlines some examples.

App Widgets

Any data that is put into the widgets inside of your `RemoteViews` for an app widget is visible to the home screen, lockscreen, or other app widget host. Those apps are the ones actually converting the `RemoteViews` into a view hierarchy, and they can inspect those views, reading the text in your `TextViews`, and so forth.

As a result, be careful about exposing potentially sensitive data via an app widget.

Notifications

Custom notifications also use `RemoteViews` and therefore could suffer from the same problem.

On the surface, you might not be worried quite so much about this, because the Notification object goes to the NotificationManager, for display by the OS itself.

However, as of Android 4.3 (API Level 18), apps can register to listen to added and removed notifications via a NotificationListenerService. Not only can such a service read the text from your Notification, but it can also access your RemoteViews. This includes any RemoteViews that may be generated for you by the expanded notification classes (e.g., BigPictureStyle).

As a result, be careful about exposing potentially sensitive data via a Notification.

Clipboard

Any app can retrieve text off of the clipboard. After all, that's the point behind a clipboard.

However, this does mean that you need to be careful what you put on the clipboard in the first place. The quintessential problem case is a password manager: putting a password on the clipboard for easy pasting into an app's EditText password field will be popular, but it allows that password to be retrieved by other apps.

You can attempt to help reduce the window of risk by clearing the clipboard after a period of time. However, bear in mind that your process might be terminated before that occurs. Also, only clear the clipboard if the clipboard text is still yours — do not clear the clipboard if another app has already put its own contents there, lest you confuse and irritate the user in the middle of some other paste operation.

ServerSocket and Kin

If you open up any sort of server-style socket connection — TCP/IP, Bluetooth, etc. — bear in mind that the Android security framework may not be able to help you much. You cannot secure a ServerSocket with an android:permission attribute, for example. It is up to you to validate whether a particular request is expected and allowed, or not.

Trail: Hardware and System Services

Accessing Location-Based Services

A popular feature on current-era mobile devices is GPS capability, so the device can tell you where you are at any point in time. While the most popular use of GPS service is mapping and directions, there are other things you can do if you know your location. For example, you might set up a dynamic chat application where the people you can chat with are based on physical location, so you are chatting with those you are nearest. Or, you could automatically “geotag” posts to Twitter or similar services.

GPS is not the only way a mobile device can identify your location. Alternatives include:

1. Cell tower triangulation, where your position is determined based on signal strength to nearby cell towers
2. Proximity to public WiFi “hotspots” that have known geographic locations
3. GPS alternatives, such as [GLONASS](#) (Russia), [Galileo](#) (European Union, still under development), and [Compass](#) (China, still under development)

Android devices may have one or more of these services available to them. You, as a developer, can ask the device for your location, plus details on what providers are available. There are even ways for you to simulate your location in the emulator, for use in testing your location-enabled applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#).

Location Providers: They Know Where You're Hiding

Android devices can have access to several different means of determining your location. Some will have better accuracy than others. Some may be free, while others may have a cost associated with them. Some may be able to tell you more than just your current position, such as your elevation over sea level, or your current speed.

Android, therefore, has abstracted all this out into a set of `LocationProvider` objects. Your Android environment will have zero or more `LocationProvider` instances, one for each distinct locating service that is available on the device. Providers know not only your location, but also their own characteristics, in terms of accuracy, cost, etc.

You, as a developer, will use a `LocationManager`, which holds the `LocationProvider` set, to figure out which `LocationProvider` is right for your particular circumstance. You will also need a permission in your application, or the various location APIs will fail due to a security violation. Depending on which location providers you wish to use, you may need `ACCESS_COARSE_LOCATION`, `ACCESS_FINE_LOCATION`, or both. Note that `ACCESS_COARSE_LOCATION` may intentionally filter out location fixes that are “too good” (i.e., more accurate than a city block).

Finding Yourself

The obvious thing to do with a location service is to figure out where you are right now.

To do that, you need to get a `LocationManager` — call `getSystemService(LOCATION_SERVICE)` from your activity or service and cast it to be a `LocationManager`.

The next step to find out where you are is to get the name of the `LocationProvider` you want to use. Here, you have two main options:

- Ask the user to pick a provider
- Find the best-match provider based on a set of criteria

ACCESSING LOCATION-BASED SERVICES

If you want the user to pick a provider, calling `getProviders()` on the `LocationManager` will give you a `List` of providers, which you can then present to the user for selection.

Or, you can create and populate a `Criteria` object, stating the particulars of what you want out of a `LocationProvider`, such as:

1. `setAltitudeRequired()` to indicate if you need the current altitude or not
2. `setAccuracy()` to set a minimum level of accuracy, in meters, for the position
3. `setCostAllowed()` to control if the provider must be free or if it can incur a cost on behalf of the device user

Given a filled-in `Criteria` object, call `getBestProvider()` on your `LocationManager`, and Android will sift through the criteria and give you the best answer. Note that not all of your criteria may be met – all but the monetary cost criterion might be relaxed if nothing matches.

You are also welcome to hard-wire in a `LocationProvider` name (e.g., `GPS_PROVIDER`), perhaps just for testing purposes.

Once you know the name of the `LocationProvider`, you can call `getLastKnownLocation()` to find out where you were recently. However, unless something else is causing the desired provider to collect fixes (e.g., unless the GPS radio is on), `getLastKnownLocation()` will return `null`, indicating that there is no known position. On the other hand, `getLastKnownLocation()` incurs no monetary or power cost, since the provider does not need to be activated to get the value.

These methods return a `Location` object, which can give you the latitude and longitude of the device in degrees as a Java `double`. If the particular location provider offers other data, you can get at that as well:

1. For altitude, `hasAltitude()` will tell you if there is an altitude value, and `getAltitude()` will return the altitude in meters.
2. For bearing (i.e., compass-style direction), `hasBearing()` will tell you if there is a bearing available, and `getBearing()` will return it as degrees east of true north.
3. For speed, `hasSpeed()` will tell you if the speed is known and `getSpeed()` will return the speed in meters per second.

A more likely approach to getting the `Location` from a `LocationProvider`, though, is to register for updates, as described in the next section.

On the Move

Not all location providers are necessarily immediately responsive. GPS, for example, requires activating a radio and getting a fix from the satellites before you get a location. That is why Android does not offer a `getMeMyCurrentLocationNow()` method. Combine that with the fact that your users may well want their movements to be reflected in your application, and you are probably best off registering for location updates and using that as your means of getting the current location.

The [Internet/Weather](#) sample application shows how to register for updates — call `requestLocationUpdates()` on your `LocationManager` instance. This takes four parameters:

- The name of the location provider you wish to use
- How long, in milliseconds, *should* have elapsed before we might get a location update
- How far, in meters, must the device have moved before we might get a location update
- An implementation of the `LocationListener` interface that will be notified of key location-related events

`LocationListener` requires four methods, the big one being `onLocationChanged()`, where you will receive your `Location` object when an update is ready:

```
@Override
public void onLocationChanged(Location location) {
    FetchForecastTask task=new FetchForecastTask();

    task.execute(location);
}
```

Bear in mind that the time parameter is only a guide to help steer Android from a power consumption standpoint. You may get many more location updates than this. To get the maximum number of location updates, supply 0 for both the time and distance constraints.

When you no longer need the updates, call `removeUpdates()` with the `LocationListener` you registered. If you fail to do this, your application will

continue receiving location updates even after all activities and such are closed up, which will also prevent Android from reclaiming your application's memory.

There is another version of `requestLocationUpdates()` that takes a `PendingIntent` rather than a `LocationListener`. This is useful if you want to be notified of changes in your position even when your code is not running. For example, if you are logging movements, you could use a `PendingIntent` that triggers a `BroadcastReceiver` (`getBroadcast()`) and have the `BroadcastReceiver` add the entry to the log. This way, your code is only in memory when the position changes, so you do not tie up system resources while the device is not moving.

Are We There Yet? Are We There Yet? Are We There Yet?

Sometimes, you want to know not where you are now, or even when you move, but when you get to where you are going. This could be an end destination, or it could be getting to the next step on a set of directions, so you can give the user the next turn.

To accomplish this, `LocationManager` offers `addProximityAlert()`. This registers a `PendingIntent`, which will be fired off when the device gets within a certain distance of a certain location. The `addProximityAlert()` method takes, as parameters:

1. The latitude and longitude of the position that you are interested in
2. A radius, specifying how close you should be to that position for the Intent to be raised
3. A duration for the registration, in milliseconds — after this period, the registration automatically lapses. A value of -1 means the registration lasts until you manually remove it via `removeProximityAlert()`.
4. The `PendingIntent` to be raised when the device is within the “target zone” expressed by the position and radius

Note that it is not guaranteed that you will actually receive an Intent, if there is an interruption in location services, or if the device is not in the target zone during the period of time the proximity alert is active. For example, if the position is off by a bit, and the radius is a little too tight, the device might only skirt the edge of the target zone, or go by so quickly that the device's location isn't sampled while in the target zone.

It is up to you to arrange for an activity or receiver to respond to the Intent you register with the proximity alert. What you then do when the Intent arrives is up to you: set up a notification (e.g., vibrate the device), log the information to a content provider, post a message to a Web site, etc. Note that you will receive the Intent whenever the position is sampled and you are within the target zone – not just upon entering the zone. Hence, you will get the Intent several times, perhaps quite a few times depending on the size of the target zone and the speed of the device's movement.

Testing... Testing...

The Android emulator does not have the ability to get a fix from GPS, triangulate your position from cell towers, or identify your location by some nearby WiFi signal. So, if you want to simulate a moving device, you will need to have some means of providing mock location data to the emulator.

For whatever reason, this particular area has undergone significant changes as Android itself has evolved. It used to be that you could provide mock location data within your application, which was very handy for demonstration purposes. Alas, those options have all been removed as of Android 1.0.

One likely option for supplying mock location data is the Dalvik Debug Monitor Service (DDMS). This is an external program, separate from the emulator, where you can feed it single location points or full routes to traverse, in a few different formats, as is mentioned in [the chapter on DDMS](#).

You can also send location fixes via `telnet` to an emulator. The port number is in your emulator's title bar (usually 5554 for the first running emulator instance). You can then run:

```
telnet localhost 5554
```

to access the Android Console within the emulator. Running the `geo fix NNN NNN` command, where `NNN NNN` is your latitude and longitude, will have the emulator respond as if those coordinates came from GPS.

Alternative Flavors of Updates

There are more ways to get updates from `LocationManager` than the versions of `requestLocationUpdates()` we have seen so far. There are four major axes of difference:

1. Some versions of `requestLocationUpdates()` take a `Criteria` object, having Android give you fixes based on the best-available provider given the requirements stipulated in the `Criteria`
2. Some versions of `requestLocationUpdates()` take a `Looper` as a parameter, allowing you to receive updates on a background `HandlerThread` instead of the main application thread
3. Some versions of `requestLocationUpdates()` take a `PendingIntent` which will be executed, instead of calling your `LocationListener`
4. There are a few flavors of `getSingleUpdate()`, which, as the name suggests, gives you just one location fix, rather than a stream until you remove the request for updates

For the `Criteria`-flavored versions of `requestLocationUpdates()` and `requestSingleUpdate()`, bear in mind that your code will still crash if there are no possible providers for your `Criteria`. For example, even if you use an empty `Criteria` object (for maximum possible matches), but GPS is disabled and the device lacks telephony (e.g., a tablet), you can get a crash like this one:

```
02-09 13:29:21.549: E/AndroidRuntime(2236): FATAL EXCEPTION: main

Hence, you will still want to use `getProviders()` or `getBestProvider()` to ensure that your `Criteria` will resolve to *something* before you try using the `Criteria` to actually request fixes.

The Fused Option

Google Play Services — the proprietary API set supported by many Android devices – offers a fused location provider that simplifies location tracking. This capability is covered in [the next chapter](#).

The Fused Location Provider

At the 2013 Google I/O conference, Google announced an update to Google Play Services that offers a “fused location provider”, one that seamlessly uses all available location data to give you as accurate of a location as possible, as quickly as possible, with as little power consumption as possible. This serves as an adjunct to the traditional `LocationManager` approach for finding one’s position. The fused location provider has a different API, though one that is similar in some respects to the `LocationManager` API.

In this chapter, we will examine how to use the fused location provider.

Prerequisites

This chapter assumes that you have read the preceding chapter on [location-based services](#), along with that chapter’s prerequisites.

Why Use the Fused Location Provider?

The traditional recipes for using location providers are a bit complicated, if you want to maximize results. Simply asking for a GPS fix is not that hard, but:

- What if GPS is disabled?
- What if GPS signals are unavailable (e.g., the device is indoors)?
- What about the GPS power drain?

The fused location provider is designed to address these sorts of concerns. Its implementation will blend data from GPS, cell tower triangulation, and WiFi hotspot proximity to determine the device’s location, without your having to

manually set all of that up. The fused location provider will also take advantage of sensor data, so it does not try to update your location as frequently if the accelerometer indicates that you are not moving.

The net result is better location data, delivered more quickly, with (reportedly) less power consumption.

Why Not Use the Fused Location Provider?

The fused location provider is part of Google Play Services. Google Play Services is available on hundreds of millions of Android devices. However:

- It is closed source, and so we do not know what the Play Services all do, and whether anything that it does might be detrimental.
- It is proprietary, and so Play Services will not be available on the Kindle Fire series and other devices working solely from the Android open source project.
- Play Services is only available on devices that have the Play Store, as opposed to the old Android Market, and so older devices (e.g., Android 2.2 and older) are far less likely to have Play Services available.

If you are aiming to distribute your app solely through the Play Store, relying upon the Play Services framework is reasonable. If, however, you are distributing through other channels, you will either need to *conditionally* use the fused location provider on devices that offer it, or *avoid* the fused location provider entirely, falling back to the traditional `LocationManager` solution.

Finding Our Location, Once

The fused location provider requires a fair bit of setup, because of its dependence upon the Play Services framework. However, once that is established, the fused location provider is as easy to use, if not easier, than is `LocationManager`.

This section will review the [Location/Fused](#) sample application, which is a clone of the Internet/Weather sample application from [the previous chapter](#), revised to use the fused location provider to get a one-off weather forecast.

Installing and Attaching Google Play Services

If you have not done so already (e.g., for [Maps V2](#)), you will need to install the Play Services framework in your development environment.

Android Studio users should install the “Google Repository” entry in the SDK Manager. At that point, you can add a dependency upon the `com.google.android.gms:play-services-location` artifact for some appropriate version, such as `com.google.android.gms:play-services-location:6.5.87`.

Eclipse users will need to install the “Google Play services” entry in the SDK Manager, then add to your project a reference to the Android library project found in the `extras/google/google_play_services/libproject/google-play-services_lib/` directory in your Android SDK installation.

Checking for Google Play Services

At runtime, before we even start bothering to try the fused location provider, we need to confirm that Play Services is ready for use. As with the samples shown in [the chapter on Maps V2](#), our revised `WeatherDemo` activity uses a `readyToGo()` method to confirm that it is safe to start the fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new WeatherFragment()).commit();
        }
    }
}
```

In `readyToGo()`, we call the static `isGooglePlayServicesAvailable()` method on `GooglePlayServicesUtil`. This will return an integer indicating whether Play Services is available for our use or not:

```
protected boolean readyToGo() {
    int status=
        GooglePlayServicesUtil.isGooglePlayServicesAvailable(this);

    if (status == ConnectionResult.SUCCESS) {
        return(true);
    }
}
```

THE FUSED LOCATION PROVIDER

```
}  
else if (GooglePlayServicesUtil.isUserRecoverableError(status)) {  
    AlertDialogFragment.newInstance(status)  
        .show(getFragmentManager(),  
            TAG_ERROR_DIALOG_FRAGMENT);  
}  
else {  
    Toast.makeText(this, R.string.no_fused, Toast.LENGTH_LONG).show();  
    finish();  
}  
  
return(false);  
}
```

If the return value is `ConnectionResult.SUCCESS`, we return `true`, to indicate that we are indeed ready to go. But, what if `isGooglePlayServicesAvailable()` returns something else?

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling the static `isUserRecoverableError()` on `GooglePlayServicesUtil`, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return `true` if the user might be able to fix the problem, `false` otherwise.

In the false case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return `false`, so `WeatherDemo` skips over the rest of its work.

In the true case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on the `GooglePlayServicesUtil` class. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```
public static class ErrorDialogFragment extends DialogFragment {  
    static final String ARG_STATUS="status";  
  
    static ErrorDialogFragment newInstance(int status) {  
        Bundle args=new Bundle();  
  
        args.putInt(ARG_STATUS, status);  
    }  
}
```

```
ErrorDialogFragment result=new ErrorDialogFragment();
result.setArguments(args);
return(result);
}

@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    Bundle args=getArguments();

    return GooglePlayServicesUtil.getErrorDialog(args.getInt(ARG_STATUS),
                                                getActivity(), 0);
}

@Override
public void onDismiss(DialogInterface dlg) {
    if (getActivity() != null) {
        getActivity().finish();
    }
}
}
```

While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Play Services is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Play Services.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. This leads to unpleasant user experiences:

- If the device [lacks the Play Store](#), `isUserRecoverableError()` returns true, even though the user cannot recover from this situation (except perhaps via a firmware update)
- `getErrorDialog()` apparently [can return null](#) for cases where the error is supposedly user-recoverable

Permissions

To use the fused location provider, you still need the `ACCESS_FINE_LOCATION` or `ACCESS_COARSE_LOCATION` permissions. If you only hold `ACCESS_COARSE_LOCATION`, the data you get back will be limited to data that is sufficiently “fuzzy”. Typically, if

you are bothering using this provider, you will request `ACCESS_FINE_LOCATION` — if coarse location data is all you need, using `LocationManager` should be just as good and is compatible with more devices.

Clients, Connections, and Callbacks

Play Services runs in its own process, one that appears to be continuously monitoring the user's location. In order to get location data from this process, we need to establish some sort of IPC (inter-process communication) with it. The low-level implementation of this is handled by the Play Services Android library project. However, we do need to set some things up ourselves.

Specifically, we need to create and use an instance of `LocationClient`, our gateway to the Play Services fused location provider. In the sample app, we create this `GoogleApiClient` in `onCreate()` of our `WeatherFragment`, holding onto the object in a client data member:

```
public class WeatherFragment extends ListFragment implements
    GoogleApiClient.ConnectionCallbacks,
    GoogleApiClient.OnConnectionFailedListener,
    Runnable {
    private static final int REQUEST_ID=1337;
    private String template=null;
    private GoogleApiClient client=null;
```

We initialize the `GoogleApiClient` in `onAttach()`, as we now know that we have an activity to work with:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    client=new GoogleApiClient.Builder(host)
        .addApi(LocationServices.API)
        .addConnectionCallbacks(this)
        .addOnConnectionFailedListener(this)
        .build();
}
```

To create a `GoogleApiClient` instance, use a `GoogleApiClient.Builder`. As the class name suggests, `GoogleApiClient` is used as a client connection to many (but not all) Google Play Services APIs, and `GoogleApiClient.Builder` is a builder for building such a connection. In particular:

- We pass our Activity as our Context

THE FUSED LOCATION PROVIDER

- We call `addApi(LocationServices.API)` to indicate that we are interested in the fused locations API
- We call `addConnectionCallbacks()` to indicate that the fragment should be the one to be notified when our connection to the Play Services process is ready
- We call `addOnConnectionFailedListener()` to indicate that the fragment should be the one to be notified if we have a problem connecting to the Play Services process
- We call `build()` on the Builder to actually build the `GoogleApiClient`

Given that we have a `GoogleApiClient`, we need to `connect()` to it to be able to start requesting location data, then `disconnect()` from it when we no longer need that location data. In our case, we do that work in `onResume()` and `onPause()` of our `WeatherFragment`:

```
@Override
public void onResume() {
    super.onResume();

    client.connect();
}

@Override
public void onPause() {
    getListView().removeCallbacks(this);
    client.disconnect();

    super.onPause();
}
```

(the call to `removeCallbacks()` will be explained shortly)

These, in turn, will trigger calls to our `onConnected()` and `onDisconnected()` methods of the `GoogleApiClient.ConnectionCallbacks` interface, assuming all goes well. In `onConnected()`, we can start requesting location data, which we delegate to the `run()` method of the `WeatherFragment` (implemented as part of implementing the `Runnable` interface). Our fragment largely ignores `onConnectionSuspended()`, but if we needed to stop something else once we no longer were eligible for location data, we could stop that here.

```
@Override
public void onConnected(Bundle undocumented) {
    run();
}

@Override
```

```
public void onConnectionSuspended(int i) {
    Log.w(((Object)this).getClass().getSimpleName(),
        "onConnectionSuspended() called, whatever that means");
}
```

However, apparently it is possible for this connection attempt to fail. Exactly how and why it might fail is not well documented. If it fails, the `onConnectionFailed()` method from our `GoogleApiClient.OnConnectionFailedListener` implementation will be called. `onConnectionFailed()` is passed a `ConnectionResult` indicating what specifically went wrong.

It turns out that this `ConnectionResult` may contain a `PendingIntent` that can be used to try to help the user recover from whatever the problem was. The recipe that [we have been given](#) to try to use this is to call `hasResolution()` (to see if the `PendingIntent` exists) and to use `startResolutionForResult()` (to invoke the activity pointed to by the `PendingIntent`). Of course, `hasResolution()` may return false, and apparently the `PendingIntent` might be broken, so we have to handle those scenarios as well:

```
@Override
public void onConnectionFailed(ConnectionResult result) {
    boolean anyLuck=false;

    if (result.hasResolution()) {
        try {
            result.startResolutionForResult(getActivity(), REQUEST_ID);
            anyLuck=true;
        }
        catch (IntentSender.SendIntentException e) {
            Log.e(((Object)this).getClass().getSimpleName(),
                "Exception trying to startResolutionForResult()", e);
        }
    }

    if (!anyLuck) {
        Toast.makeText(getActivity(), R.string.no_fused,
            Toast.LENGTH_LONG).show();
        getActivity().finish();
    }
}
```

If we have a resolution and successfully start up the resolution activity, our fragment will be paused and later resumed, at which point we will wind up trying to `connect()` again naturally. If we do not have a resolution, or the resolution itself is broken, the sample just displays a `Toast` and finishes the activity, along the same lines as how we handle the case where Play Services is completely unavailable. A production-grade application would probably handle this case a bit more gracefully.

Finding the Current Location

Given all that setup, actually getting the location is almost anti-climactic.

To find the current location, given a connected `GoogleApiClient`, just call the static `getLastLocation()` method on `LocationServices.FusedLocationApi`, passing in the `GoogleApiClient` instance as a parameter. This usually will return a non-null `Location` object, using the same `Location` class that you would use with `LocationManager`.

In the sample, the `run()` method checks to see if `getLastLocation()` returns null or not. If the location is null, it schedules `run()` to be invoked again in one second, using `postDelayed()` on some suitable `View` (in this case, the `WebView` for displaying the results). If, however, we do have a valid location, `run()` invokes a `FetchForecastTask`, as did the original version of this sample:

```
@Override
public void run() {
    Location loc=LocationServices.FusedLocationApi
        .getLastLocation(client);

    if (loc == null) {
        getListView().postDelayed(this, 1000);
    }
    else {
        FetchForecastTask task=new FetchForecastTask();

        task.execute(loc);
    }
}
```

The fact that we are using `postDelayed()` here is why we use `removeCallbacks()` in `onPause()`, to stop polling for `getLastLocation()` when we are disconnecting from the `LocationClient`.

Note that the documentation for `getLastLocation()` states “If a location is not available, which should happen very rarely, null will be returned.” The “very rarely” part indicates that Play Services is constantly checking for the user’s location, [if it is able to do so](#).

The Rest of the Sample

The rest of the sample follows some examples from earlier in the book for fetching data and displaying it.

THE FUSED LOCATION PROVIDER

`run()`, once it gets a location from `getLastLocation()`, executes a `FetchForecastTask`, which is a subclass of `AsyncTask`. This task, in `doInBackground()`, calls `getForecastXML()`, which uses `URLConnection` to retrieve the weather forecast XML. The task also calls `buildForecasts()`, which parses that XML using the Java DOM and builds an `ArrayList` of `Forecast` objects, where each `Forecast` holds a time, the predicted temperature, and a code indicating the expected cloud cover and precipitation.

In the task's `onPostExecute()` method, it creates a `ForecastAdapter`, wrapped around our list of `Forecast` objects, and puts that adapter in the `ListView` for our `ListFragment`. `ForecastAdapter` follows the same pattern as was seen in [the Picasso sample](#), using Picasso to load in icons associated with each cloud cover/precipitation prediction and show those alongside the time and temperature.

The result looks like:

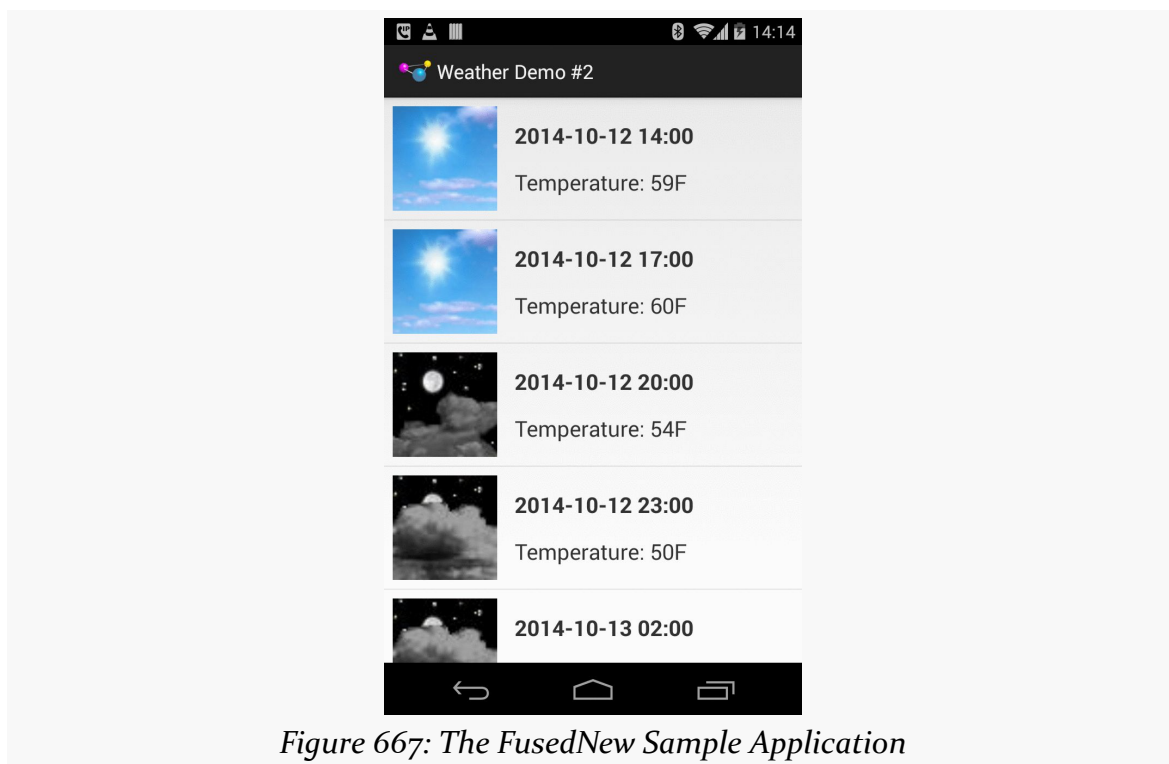

Figure 667: The FusedNew Sample Application

Requesting Location Updates

As with `LocationManager`, you can use `LocationClient` to be delivered location updates as the device moves, via `requestLocationUpdates()`. There are two major axes of control you have over these updates: the way the locations are delivered to you, and the `LocationRequest` that configures what updates you receive.

Delivery Options

A foreground application would use forms of `requestLocationUpdates()` that take a `LocationListener` as a parameter. Despite the class being named the same, this is a separate implementation of the `LocationListener` interface. The Play Services one (`com.google.android.gms.location.LocationListener`) only requires a single method: `onLocationChanged()`, which is handed a `Location` object representing a location fix.

A background application would use the `requestLocationUpdates()` that takes a `PendingIntent` instead of a `LocationListener`, where that `PendingIntent` can do whatever you wish (start an activity, start a service, send a broadcast). The location itself is delivered in the form of an `Intent` extra, keyed as `KEY_LOCATION_CHANGED`, with a value in the form of a `Location` object.

Request Options

All forms of `requestLocationUpdates()` take a `LocationRequest` object describing what you want in terms of updates. Unlike with `LocationManager`, you do not specify specific location technologies (e.g., GPS). You also lack the fine-grained control of the `Criteria` object (e.g., to require the location to have speed data). However, you do have some measure of control, via various setters on `LocationRequest`.

Frequency

Calling `setInterval()` indicates approximately how frequently you wish to receive location updates. The key word here is “approximately”, as you will receive updates more or less frequently than the number of milliseconds you specify as the desired interval. However, your requested interval is taken into account, and the longer of an interval you provide, the less power your app will consume.

To help prevent being flooded with location data, you can also call `setFastestInterval()`, which will throttle the actual updates to be no more frequent than the number of milliseconds that you state.

Priority

`setPriority()` allows you to control the accuracy and power consumption of your app's request, by specifying one of four possible priority levels:

- `PRIORITY_HIGH_ACCURACY` will tend to use GPS and therefore will consume more power
- `PRIORITY_BALANCED_POWER_ACCURACY` will try to consume somewhat less power
- `PRIORITY_LOW_POWER` will try to consume even less power
- `PRIORITY_NO_POWER` indicates that you want to consume no additional power over any other requests, but to get what you can (akin to the “passive provider” available with `LocationManager`)

Duration

You can proactively cancel receiving further updates by calling `removeUpdates()`, passing in your delivery option from `requestLocationUpdates()`:

- The same `LocationListener` as you used to request the updates, or
- An equivalent `PendingIntent` to the one that you used to request the updates

You can also automatically expire your requested updates by one of three means:

- `setNumUpdates()` indicates exactly how many location fixes that you want to receive (e.g., 1) and discontinues the updates after that number
- `setExpirationDuration()` indicates how long you wish to receive updates, expressed as a number of milliseconds from now
- `setExpirationTime()` indicates when you wish to discontinue updates, expressed in the form of the number of milliseconds since the device turned on (e.g., the same time base as is used by `elapsedRealtime()` on the `SystemClock` class)

For example, an improved version of the sample shown in this chapter would use a `LocationRequest` with `setNumUpdates(1)`, instead of the one-second polling of `getLastLocation()`.

Gaps in the Fused Location Provider

The fused location provider is governed by the user's enabled location providers (e.g., via the Settings app). Unfortunately, there is no way to interrogate `LocationClient` to find out whether it is even possible for you to get a location, such as if all providers are disabled. You just fail to get location data (e.g., `getLastLocation()` perpetually returns `null`). If you need to detect this case, you will also need to use `LocationManager` and methods like `isProviderEnabled()`.

Working with the Clipboard

Being able to copy and paste is something that mobile device users seem to want almost as much as their desktop brethren. Most of the time, we think of this as copying and pasting text, and for a long time that was all that was possible on Android. Android 3.0 added in new clipboard capabilities for more rich content, which application developers can choose to support as well. This section will cover both of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Using the Clipboard on Android 1.x/2.x

Android has a `ClipboardManager` that allows you to interact with the clipboard manually, in addition to built-in clipboard facilities for users (e.g., copy/paste context menus on `EditText`). `ClipboardManager`, like `AudioManager`, is obtained via a call to `getSystemService()`:

From there, you have three simple methods:

1. `getText()` to retrieve the current clipboard contents
2. `hasText()`, to determine if there are any clipboard contents, so you can react accordingly (e.g., disable “paste” menus when there is nothing to paste)
3. `setText()`, to put text on the clipboard

WORKING WITH THE CLIPBOARD

For example, the [SystemServices/ClipIP](#) sample project contains a little application that puts your current IP address on the clipboard, for pasting into some EditText of an application.

The IPClipper activity's onCreate() does the work of putting text onto the clipboard via setText() and notifying the user via a Toast:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        String addr=getLocalIPAddress();

        if (addr == null) {
            Toast.makeText(this,
                "IP address not available -- are you online?",
                Toast.LENGTH_LONG).show();
        }
        else {
            ClipboardManager cm=
                (ClipboardManager) getSystemService(CLIPBOARD_SERVICE);

            try {
                cm.setText(addr);

                Toast.makeText(this, "IP Address clipped!",
                    Toast.LENGTH_SHORT).show();
            }
            catch (Exception e) {
                Log.e(getClass().getSimpleName(), "Exception clipping IP", e);
                Toast.makeText(this, "Exception: " + e.getMessage(),
                    Toast.LENGTH_SHORT).show();
            }
        }
    }
    catch (Exception e) {
        Log.e("IPClipper", "Exception getting IP address", e);
        Toast.makeText(this, "Could not obtain IP address",
            Toast.LENGTH_LONG).show();
    }

    finish();
}
```

The work of figuring out what the IP address is can be found in the getLocalIPAddress() method:

```
public String getLocalIPAddress() throws SocketException {
    Enumeration<NetworkInterface> nics=
        NetworkInterface.getNetworkInterfaces();
```

```
while (nics.hasMoreElements()) {
    NetworkInterface intf=nics.nextElement();
    Enumeration<InetAddress> addrs=intf.getInetAddresses();

    while (addrs.hasMoreElements()) {
        InetAddress addr=addrs.nextElement();

        if (!addr.isLoopbackAddress()) {
            return(addr.getHostAddress().toString());
        }
    }
}

return(null);
}
```

This uses the `NetworkInterface` and `InetAddress` classes from the `java.net` package to loop through all network interfaces and find the first one that has a non-localhost (loopback) IP address. The emulator will return 10.0.2.15 all of the time; your device will return whatever IP address it has from WiFi, 3G, etc. If no such address is available, it returns `null`.

The activity itself has no UI, as the application uses `Theme.NoDisplay`. The activity avoids a call to `setContentView()`, and calls `finish()` when all the work is done in `onCreate()`. Hence after starting the activity, the user will hopefully see the “successful” Toast, and nothing else:

Figure 668: The IPClipper, shortly after launching

Then, if the user long-taps on an `EditText` and chooses Paste, the IP address is added to the `EditText` contents. Note that the clipboard is system-wide, not merely application-wide, which is why you can successfully paste the IP address into any application's fields.

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setText()` call wrapped in a try/catch block, even though `setText()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

Advanced Clipboard on Android 3.x and Higher

Android 3.0 added in new ways of working with `ClipboardManager` to clip things that transcend simple text. In part, this is expected to be used for advanced copy and paste features between applications. However, this also forms the foundation for a rich drag-and-drop model within an application.

Note that they also moved `ClipboardManager` to the `android.content` package. You can still refer to it via the `android.text` package, for backwards compatibility. However, if your project will be on API Level 11 or higher only, you might consider using the new `android.content` package edition of the class.

Copying Rich Data to the Clipboard

In addition to methods like `setText()` to put a piece of plain text on the clipboard, `ClipboardManager` (as of API Level 11) offers `setPrimaryClip()`, which allows you to put a `ClipData` object on the clipboard.

What's a `ClipData`? In some respects, it is whatever you want. It can hold:

1. plain text
2. a `Uri` (e.g., to a piece of music)
3. an `Intent`

The `Uri` means that you can put anything on the clipboard that can be referenced by a `Uri`... and if there is nothing in Android that lets you reference some data via a `Uri`, you can invent your own content provider to handle that chore for you.

Furthermore, a single `ClipData` can actually hold as many of these as you want, each represented as individual `ClipData.Item` objects. As such, the possibilities are endless.

There are static factory methods on `ClipData`, such as `newUri()`, that you can use to create your `ClipData` objects. In fact, that is what we use in the [SystemServices/ClipMusic](#) sample project and the `MusicClipper` activity.

`MusicClipper` has the classic two-big-button layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="Pick"
        android:onClick="pickMusic"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
```

WORKING WITH THE CLIPBOARD

```
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="Play"
        android:onClick="playMusic"
    />
</LinearLayout>
```

Figure 669: The Music Clipper main screen

In `onCreate()`, we get our hands on our `ClipboardManager` system service:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    clipboard=(ClipboardManager)getSystemService(CLIPBOARD_SERVICE);
}
```

Tapping the “Pick” button will let you pick a piece of music, courtesy of the `pickMusic()` method wired to that `Button` object:

```
public void pickMusic(View v) {
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);

    i.setType("audio/*");
```

WORKING WITH THE CLIPBOARD

```
startActivityForResult(i, PICK_REQUEST);  
}
```

Here, we tell Android to let us pick a piece of music from any available audio MIME type (audio/*). Fortunately, Android has an activity that lets us do that:

Figure 670: The XOOM tablet's music track picker

We get the result in `onActivityResult()`, since we used `startActivityForResult()` to pick the music. There, we package up the content:// Uri to the music into a `ClipData` object and put it on the clipboard:

```
@Override  
protected void onActivityResult(int requestCode, int resultCode,  
                                Intent data) {  
    if (requestCode == PICK_REQUEST) {  
        if (resultCode == RESULT_OK) {  
            ClipData clip=  
                ClipData.newUri(getContentResolver(), "Some music",  
                                data.getData());  
  
            try {  
                clipboard.setPrimaryClip(clip);  
            }  
            catch (Exception e) {  
                Log.e(getClass().getSimpleName(), "Exception clipping Uri", e);  
            }  
        }  
    }  
}
```

```
        Toast.makeText(this, "Exception: " + e.getMessage(),
                        Toast.LENGTH_SHORT).show();
    }
}
}
```

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setPrimaryClip()` call wrapped in a try/catch block, even though `setPrimaryClip()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

Pasting Rich Data from the Clipboard

The catch with rich data on the clipboard is that somebody has to know about the sort of information you are placing on the clipboard. Eventually, the Android development community will work out common practices in this area. Right now, though, you can certainly use it within your own application (e.g., clipping a note and pasting it into another folder).

Since putting `ClipData` onto the clipboard involves a call to `setPrimaryClip()`, it should not be surprising that the reverse operation — getting a `ClipData` from the clipboard — uses `getPrimaryClip()`. However, since you do not know where this clip came from, you need to validate that it has what you expect and to let the user know when the clipboard contents are not something you can leverage.

The “Play” button in our UI is wired to a `playMusic()` method. This will only work when we have pasted a `Uri` `ClipData` to the clipboard pointing to a piece of music. Since we cannot be sure that the user has done that, we have to sniff around:

```
public void playMusic(View v) {
    ClipData clip=clipboard.getPrimaryClip();

    if (clip == null) {
        Toast.makeText(this, "There is no clip!", Toast.LENGTH_LONG)
            .show();
    }
    else {
        ClipData.Item item=clip.getItemAt(0);
        Uri song=item.getUri();

        if (song != null
            && getContentResolver().getType(song).startsWith("audio/")) {
            startActivity(new Intent(Intent.ACTION_VIEW, song));
        }
    }
}
```

```
else {  
    Toast.makeText(this, "There is no song!", Toast.LENGTH_LONG)  
        .show();  
}  
}
```

First, there may be nothing on the clipboard, in which case the `ClipData` returned by `getPrimaryClip()` would be `null`. Or, there may be stuff on the clipboard, but it may not have a `Uri` associated with it (`getUri()` on `ClipData`). Even then, the `Uri` may point to something other than music, so even if we get a `Uri`, we need to use a `ContentResolver` to check the MIME type (`getContentResolver().getType()`) and make sure it seems like it is music (e.g., starts with `audio/`). Then, and only then, does it make sense to try to start an `ACTION_VIEW` activity on that `Uri` and hope that something useful happens. Assuming you clipped a piece of music with the “Pick” button, “Play” will kick off playback of that song.

ClipData and Drag-and-Drop

Android 3.0 also introduced Android’s first built-in drag-and-drop framework. One might expect that this would be related entirely to `View` and `ViewGroup` objects and have nothing to do with the clipboard. In reality, the drag-and-drop framework leverages `ClipData` to say what it is that is being dragged and dropped. You call `startDrag()` on a `View`, supplying a `ClipData` object, along with some objects to help render the “shadow” that is the visual representation of this drag operation. A `View` that can receive objects “dropped” via drag-and-drop needs to register an `OnDragListener` to receive drag events as the user slides the shadow over the top of the `View` in question. If the user lifts their finger, thereby dropping the shadow, the recipient `View` will get an `ACTION_DROP` drag event, and can get the `ClipData` out of the event.

Monitoring the Clipboard

Android 3.0 added the capability for an app to monitor what is put on the clipboard, including things put on the clipboard by other apps.

This is a somewhat esoteric feature, but one that perhaps has some valid use cases. Mostly, it would be used by something *not* in the foreground, since the foreground activity is probably what is adding material to the clipboard. A service, or perhaps an activity that has moved to the background, could use this feature to find out about new clipboard entries.

WORKING WITH THE CLIPBOARD

To monitor the clipboard, you simply call `addPrimaryClipChangedListener()` on `ClipboardMonitor`, passing an implementation of an `OnPrimaryClipChangedListener` interface. That object, in turn, will be called with `onPrimaryClipChanged()` whenever there is a new clipboard entry. Later on, you can call `removePrimaryClipChangedListener()` to stop being notified about new clipboard entries.

For example, here is `MainActivity` from the [SystemServices/ClipboardMonitor](#) sample project:

```
package com.commonware.android.clipmon;

import android.app.Activity;
import android.content.ClipboardManager;
import android.content.ClipboardManager.OnPrimaryClipChangedListener;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnPrimaryClipChangedListener {
    private ClipboardManager cm=null;
    private TextView lastClip=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        lastClip=(TextView)findViewById(R.id.last_clip);
        cm=(ClipboardManager)getSystemService(CLIPBOARD_SERVICE);
    }

    @Override
    public void onResume() {
        super.onResume();
        cm.addPrimaryClipChangedListener(this);
    }

    @Override
    public void onPause() {
        cm.removePrimaryClipChangedListener(this);
        super.onPause();
    }

    @Override
    public void onPrimaryClipChanged() {
        lastClip.setText(cm.getPrimaryClip().getItemAt(0)
            .coerceToText(this));
    }
}
```

Here, we:

- Retrieve the `ClipboardManager` in `onCreate()`
- Register for clipboard events via `addPrimaryClipChangedListener()` in `onResume()`
- Unregister from clipboard events via `removePrimaryClipChangedListener()` in `onPause()`
- Convert the first item (`getItemAt(0)`) of the primary clip (`getPrimaryClip()`) to text (`coerceToText(this)`), and stuff the results into a `TextView`

In theory, this activity will display new clipboard entries as they arrive. In practice, it will only do so while it is in the foreground, and so it would require something in the background to add something to the clipboard. That is not a particularly useful example... except to test the bug outlined in the next section.

The Android 4.3 Clipboard Bug

[AndroidPolice](#) reported on [a fairly unpleasant bug in Android 4.3](#). While this bug was fixed in Android 4.4, there is little evidence that Google will be releasing a fix for Android 4.3 devices, which means that this problem will plague developers into 2015 and perhaps beyond.

The bug stems from [the clipboard monitoring facility](#). If an app has used `addPrimaryClipChangedListener()`, *any other app* that tries to paste to the clipboard will crash.

The first crash will be a `SecurityException`:

```
java.lang.SecurityException: uid ... does not have
android.permission.UPDATE_APP_OPS_STATS
```

The second and subsequent times this occurs on the device, it will be an `IllegalStateException`:

```
java.lang.IllegalStateException: beginBroadcast() called while already
in a broadcast
```

The only resolution is to unregister the clipboard listener... and hope that the first crash has not occurred. If it has, a **full reboot of the device is required** to fix the broken system.

If Your App Monitors the Clipboard...

If you have a component, such as a long-running service, that is monitoring the clipboard, please ensure that the users have an easy way to stop that behavior, even if it means stopping your whole service. While this may mean that your app has seriously degraded functionality, the alternative is that the user has to keep rebooting their device while your app is installed.

If Your App Pastes to the Clipboard...

If you are pasting to the clipboard, with `setPrimaryClip()` or the older `setText()`, you will want to throw a try/catch block around those calls, so you catch the `RuntimeExceptions` that will be thrown.

However, you will need to tell your users that they are now fairly well screwed, needing to both find the clipboard-monitoring app and learn how to control it (or uninstall/disable it, if needed), plus reboot their device, in order to paste to the clipboard again.

Telephony

Many, if not most, Android devices will be phones. As such, not only will users be expecting to place and receive calls using Android, but you will have the opportunity to help them place calls, if you wish.

Why might you want to?

1. Maybe you are writing an Android interface to a sales management application (a la Salesforce.com) and you want to offer users the ability to call prospects with a single button click, and without them having to keep those contacts both in your application and in the phone's contacts application
2. Maybe you are writing a social networking application, and the roster of phone numbers that you can access shifts constantly, so rather than try to "sync" the social network contacts with the phone's contact database, you let people place calls directly from your application
3. Maybe you are creating an alternative interface to the existing contacts system, perhaps for users with reduced motor control (e.g., the elderly), sporting big buttons and the like to make it easier for them to place calls

Whatever the reason, Android has the means to let you manipulate the phone just like any other piece of the Android system.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on working with multiple activities](#).

Report To The Manager

To get at much of the phone API, you use the `TelephonyManager`. That class lets you do things like:

1. Determine if the phone is in use via `getCallState()`, with return values of `CALL_STATE_IDLE` (phone not in use), `CALL_STATE_RINGING` (call requested but still being connected), and `CALL_STATE_OFFHOOK` (call in progress)
2. Find out the SIM ID (IMSI) via `getSubscriberId()`
3. Find out the phone type (e.g., GSM) via `getPhoneType()` or find out the data connection type (e.g., GPRS, EDGE) via `getNetworkType()`

You Make the Call!

You can also initiate a call from your application, such as from a phone number you obtained through your own Web service. To do this, simply craft an `ACTION_DIAL` Intent with a `Uri` of the form `tel:NNNNN` (where `NNNNN` is the phone number to dial) and use that Intent with `startActivity()`. This will not actually dial the phone; rather, it activates the dialer activity, from which the user can then press a button to place the call.

For example, let's look at the [Phone/Dialer](#) sample application. Here's the crude-but-effective layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <LinearLayout
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        >
        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Number to dial:"
            />
        <EditText android:id="@+id/number"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:cursorVisible="true"
            android:editable="true"
```

```
        android:singleLine="true"
    />
</LinearLayout>
<Button android:id="@+id/dial"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:text="Dial It!"
        android:onClick="dial"
    />
</LinearLayout>
```

We have a labeled field for typing in a phone number, plus a button for dialing said number.

The Java code simply launches the dialer using the phone number from the field:

```
package com.commonware.android.dialer;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class DialerDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
    }

    public void dial(View v) {
        EditText number=(EditText)findViewById(R.id.number);
        String toDial="tel:"+number.getText().toString();

        startActivity(new Intent(Intent.ACTION_DIAL, Uri.parse(toDial)));
    }
}
```

The activity's own UI is not that impressive:

Figure 671: The DialerDemo sample application, as initially launched

However, the dialer you get from clicking the dial button is better, showing you the number you are about to dial:

Figure 672: The Android Dialer activity, as launched from DialerDemo

No, Really, You Make the Call!

The good news is that ACTION_DIAL works without any special permissions. The bad news is that it only takes the user to the Dialer – the user still has to take action (pressing the green call button) to actually place the phone call.

An alternative approach is to use ACTION_CALL instead of ACTION_DIAL. Calling `startActivity()` on an ACTION_CALL Intent will immediately place the phone call, without any other UI steps required. However, you need the CALL_PHONE [permission](#) in order to use ACTION_CALL.

Working With SMS

Oh, what a tangled web we weave

When first we practice to work with SMS on Android, Eve

(with apologies to [Sir Walter Scott](#))

Android devices have had SMS capability since Android 1.0. However, from a programming standpoint, for years, SMS and Android were intensely frustrating. When the Android SDK was developed, some aspects of working with SMS were put into the SDK, while others were held back. This, of course, did not stop many an intrepid developer from working with the undocumented, unsupported SMS APIs, with varying degrees of success.

After much wailing and gnashing of teeth by developers, Google finally formalized a more complete SMS API in Android 4.4. However, this too has its issues, where some apps that worked fine with the undocumented API will now fail outright, in irreparable fashion, on Android 4.4+.

This chapter starts with the one thing you can do reasonably reliably across Android device versions – [send an SMS](#), either directly or by invoking the user's choice of SMS client. The chapter then examines how to monitor or receive SMS messages (both pre-4.4 and 4.4+) and the SMS-related ContentProvider (both pre-4.4 and 4.4+).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#). One of the samples uses [the](#)

[ContactsContract.provider](#), so reading that chapter will help you understand that particular sample.

Sending Out an SOS, Give or Take a Letter

While much of Android's SMS capabilities are not in the SDK, sending an SMS is. You have two major choices for doing this:

- Invoke the user's choice of SMS client application, so they can compose a message, track its progress, and so forth using that tool
- Send the SMS directly yourself, bypassing any existing client

Which of these is best for you depends on what your desired user experience is. If you are composing the message totally within your application, you may want to just send it. However, as we will see, that comes at a price: an extra permission.

Sending Via the SMS Client

Sending an SMS via the user's choice of SMS client is very similar to the use of ACTION_SEND described [elsewhere in this book](#). You craft an appropriate Intent, then call startActivity() on that Intent to bring up an SMS client (or allow the user to choose between clients).

The Intent differs a bit from the ACTION_SEND example:

1. You use ACTION_SENDTO, rather than ACTION_SEND
2. Your Uri needs to begin with smsto:, followed by the mobile number you want to send the message to
3. Your text message goes in an sms_body extra on the Intent

For example, here is a snippet of code from the [SMS/Sender](#) sample project:

```
Intent sms=new Intent(Intent.ACTION_SENDTO,
                      Uri.parse("smsto:"+c.getString(2)));

sms.putExtra("sms_body", msg.getText().toString());

startActivity(sms);
```

Here, our phone number is coming out of the third column of a Cursor, and the text message is coming from an EditText — more on how this works later in this section, when we review the Sender sample more closely.

Sending SMS Directly

If you wish to bypass the UI and send an SMS directly, you can do so through the `SmsManager` class, in the `android.telephony` package. Unlike most Android classes ending in `Manager`, you obtain an `SmsManager` via a static `getDefault()` method on the `SmsManager` class. You can then call `sendTextMessage()`, supplying:

1. The phone number to send the text message to
2. The “service center” address — leave this `null` unless you know what you are doing
3. The actual text message
4. A pair of `PendingIntent` objects to be executed when the SMS has been sent and delivered, respectively

If you are concerned that your message may be too long, use `divideMessage()` on `SmsManager` to take your message and split it into individual pieces. Then, you can use `sendMultipartTextMessage()` to send the entire `ArrayList` of message pieces.

For this to work, your application needs to hold the `SEND_SMS` permission, via a child element of your `<manifest>` element in your `AndroidManifest.xml` file.

For example, here is code from `Sender` that uses `SmsManager` to send the same message that the previous section sent via the user’s choice of SMS client:

```
SmsManager
    .getDefault()
    .sendTextMessage(c.getString(2), null,
                    msg.getText().toString(),
                    null, null);
```

Inside the Sender Sample

The `Sender` example application is fairly straightforward, given the aforementioned techniques.

The manifest has both the `SEND_SMS` and `READ_CONTACTS` permissions, because we want to allow the user to pick a mobile phone number from their list of contacts, rather than type one in by hand:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
```

```
android:versionCode="1"
android:versionName="1.0">

<uses-permission android:name="android.permission.READ_CONTACTS"/>
<uses-permission android:name="android.permission.SEND_SMS"/>

<uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

<supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name="Sender"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

If you noticed the `android:installLocation` attribute in the root element, that is to allow this application to be installed onto external storage, such as an SD card.

The layout has a `Spinner` (for a drop-down of available mobile phone numbers), a pair of `RadioButton` widgets (to indicate which way to send the message), an `EditText` (for the text message), and a “Send” Button:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
    <Spinner android:id="@+id/spinner"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:drawSelectorOnTop="true"
    />
    <RadioGroup android:id="@+id/means"
        android:orientation="horizontal"
        android:layout_width="match_parent"
```

```
        android:layout_height="wrap_content"
    >
        <RadioButton android:id="@+id/client"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="Via Client" />
        <RadioButton android:id="@+id/direct"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Direct" />
    </RadioGroup>
    <EditText
        android:id="@+id/msg"
        android:layout_width="match_parent"
        android:layout_height="0px"
        android:layout_weight="1"
        android:singleline="false"
        android:gravity="top|left"
    />
    <Button
        android:id="@+id/send"
        android:text="Send!"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="sendMessage"
    />
</LinearLayout>
```

Sender uses the same technique for obtaining mobile phone numbers from our contacts as is seen in the [chapter on contacts](#). To support Android 1.x and Android 2.x devices, we implement an abstract class and two concrete implementations, one for the old API and one for the new. The abstract class then has a static method to get at an instance suitable for the device the code is running on:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.os.Build;
import android.widget.SpinnerAdapter;

abstract class ContactsAdapterBridge {
    abstract SpinnerAdapter buildPhonesAdapter(Activity a);

    public static final ContactsAdapterBridge INSTANCE=buildBridge();

    private static ContactsAdapterBridge buildBridge() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<5) {
            return(new OldContactsAdapterBridge());
        }
    }
}
```

```
        return(new NewContactsAdapterBridge());
    }
}
```

The Android 2.x edition uses ContactsContract to find just the mobile numbers:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.CommonDataKinds.Phone;
import android.widget.AdapterView;
import android.widget.SimpleCursorAdapter;

class NewContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts._ID,
                                           Contacts.DISPLAY_NAME,
                                           Phone.NUMBER
                                           };
        String[] ARGS={String.valueOf(Phone.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Phone.CONTENT_URI,
                                PROJECTION, Phone.TYPE+"=?",
                                ARGS, Contacts.DISPLAY_NAME);

        SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
                                                            android.R.layout.simple_spinner_item,
                                                            c,
                                                            new String[] {
                                                                Contacts.DISPLAY_NAME
                                                            },
                                                            new int[] {
                                                                android.R.id.text1
                                                            });

        adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

        return(adapter);
    }
}
```

... while the Android 1.x edition uses the older Contacts provider to find the mobile numbers:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.Contacts;
```

WORKING WITH SMS

```
import android.widget.SimpleCursorAdapter;
import android.widget.SpinnerAdapter;

@SuppressWarnings("deprecation")
class OldContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts.Phones._ID,
                                           Contacts.Phones.NAME,
                                           Contacts.Phones.NUMBER
                                           };
        String[] ARGS={String.valueOf(Contacts.Phones.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Contacts.Phones.CONTENT_URI,
                                PROJECTION,
                                Contacts.Phones.TYPE+"=?", ARGS,
                                Contacts.Phones.NAME);

        SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
                                                            android.R.layout.simple_spinner_item,
                                                            c,
                                                            new String[] {
                                                                Contacts.Phones.NAME
                                                            },
                                                            new int[] {
                                                                android.R.id.text1
                                                            });

        adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

        return(adapter);
    }
}
```

For more details on how those providers work, please see the [chapter on contacts](#).

The activity then loads up the Spinner with the appropriate list of contacts. When the user taps the Send button, the `sendMessage()` method is invoked (courtesy of the `android:onClick` attribute in the layout). That method looks at the radio buttons, sees which one is selected, and routes the text message accordingly:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.os.Bundle;
import android.telephony.SmsManager;
import android.view.View;
import android.widget.EditText;
import android.widget.RadioGroup;
import android.widget.Spinner;
```

```
public class Sender extends Activity {
    Spinner contacts=null;
    RadioGroup means=null;
    EditText msg=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        contacts=(Spinner)findViewById(R.id.spinner);

        contacts.setAdapter(new ContactsAdapterBridge
            .INSTANCE
            .buildPhonesAdapter(this));

        means=(RadioGroup)findViewById(R.id.means);
        msg=(EditText)findViewById(R.id.msg);
    }

    public void sendTheMessage(View v) {
        Cursor c=(Cursor)contacts.getSelectedItem();

        if (means.getCheckedRadioButtonId()==R.id.client) {
            Intent sms=new Intent(Intent.ACTION_SENDTO,
                Uri.parse("smsto:"+c.getString(2)));

            sms.putExtra("sms_body", msg.getText().toString());

            startActivity(sms);
        }
        else {
            SmsManager
                .getDefault()
                .sendTextMessage(c.getString(2), null,
                    msg.getText().toString(),
                    null, null);
        }
    }
}
```

SMS Sending Limitations

Apps running on Android 1.x and 2.x devices are limited to sending 100 SMS messages an hour, before the user starts getting prompted with each SMS message request to confirm that they do indeed wish to send it.

Apps running on Android 4.x devices, the limits are now 30 SMS messages in 30 minutes, [according to some source code analysis by Al Sutton](#).

Monitoring and Receiving SMS

For the purposes of this section, “monitoring” refers to the ability to inspect incoming SMS messages, including reading their contents. In contrast, “receiving” SMS messages is actually consuming the message and storing it somewhere for the user to use.

As it turns out, “monitoring” and “receiving” are much the same thing prior to Android 4.4, but are significantly different in the new API made available in Android 4.4

The Undocumented, Unsupported, Pre-Android 4.4 Way

It is possible for an application to monitor or receive an incoming SMS message... if you are willing to listen on the undocumented `android.provider.Telephony.SMS_RECEIVED` broadcast Intent. That is sent by Android whenever an SMS arrives, and it is up to an application to implement a `BroadcastReceiver` to respond to that Intent and do something with the message. The Android open source project has such an application — `Messaging` — and device manufacturers can replace it with something else.

Note that to listen for this broadcast, your app must hold the `RECEIVE_SMS` permission.

The `BroadcastReceiver` can then turn around and use the `SmsMessage` class, in the `android.telephony` package, to get at the message itself, through the following undocumented recipe:

1. Given the received Intent (`intent`), call `intent.getExtras().get("pdus")` to get an `Object` array representing the raw portions of the message
2. For each of those “pdus” objects, call `SmsMessage.createFromPdu()` to convert the `Object` into an `SmsMessage` — though to make this work, you need to cast the `Object` to a byte array as part of passing it to the `createFromPdu()` static method

The resulting `SmsMessage` object gets you access to the text of the message, the sending phone number, etc.

The `SMS_RECEIVED` broadcast Intent is broadcast a bit differently than most others in Android. It is an “ordered broadcast”, meaning the Intent will be delivered to one `BroadcastReceiver` at a time. This has two impacts of note:

- In your receiver’s `<intent-filter>` element, you can have an `android:priority` attribute. Higher priority values get access to the broadcast Intent earlier than will lower priority values. The standard Messaging application has the default priority (undocumented, appears to be 0 or 1), so you can arrange to get access to the SMS before the application does.
- Your `BroadcastReceiver` can call `abortBroadcast()` on itself to prevent the Intent from being broadcast to other receivers of lower priority. In effect, this causes your receiver to consume the SMS — the Messaging application will not receive it. So, aborting the broadcast means that your app chose to “receive” the SMS; not aborting the broadcast means that your app is merely “monitoring” the SMS messages that come in.

However, just because the Messaging application has the default priority does not mean all SMS clients will, and so you cannot reliably intercept SMS messages this way. That, plus the undocumented nature of all of this, means that applications you write to receive SMS messages are likely to be fragile in production, breaking on various devices due to device manufacturer-installed apps, third-party apps, or changes to Android itself... such as the changes that came about in Android 4.4.

The Android 4.4+ Way: Monitoring SMS

The code described above still works on Android 4.4, though the formerly-hidden `android.provider.Telephony` class is now part of the SDK.

The biggest difference, though, is that even if you call `abortBroadcast()`, the user’s chosen SMS messaging client will still receive the message. It is not possible for an app listening for `SMS_RECEIVED` broadcasts to prevent the user’s chosen SMS messaging client from receiving those same messages. This is a substantial change, one that will break or make obsolete many Android applications.

Regardless, if monitoring SMS fits your needs, `SMS_RECEIVED` can do it.

So, for example, the [SMS/Monitor](#) sample project implements a `BroadcastReceiver` for `SMS_RECEIVED`, one with slightly elevated priority:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.monitor"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-permission android:name="android.permission.RECEIVE_SMS"/>

    <uses-sdk
        android:minSdkVersion="3"
        android:targetSdkVersion="19"/>

    <application
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <receiver
            android:name="Monitor"
            android:permission="android.permission.BROADCAST_SMS">
            <intent-filter android:priority="2">
                <action android:name="android.provider.Telephony.SMS_RECEIVED"/>
            </intent-filter>
        </receiver>

        <activity
            android:name="BootstrapActivity"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

You will notice that the `BroadcastReceiver` not only has the slightly-elevated priority (`android:priority="2"`), but also a required permission (`android:permission="android.permission.BROADCAST_SMS"`). Only apps that hold this permission can send this broadcast in a way that will be picked up by the receiver. Since this permission can only be held by the device firmware, you are protected from “spoof” SMS messages from rogue apps on the device, sending the `SMS_RECEIVED` themselves.

The app also has a do-nothing activity, solely there to activate the manifest-registered BroadcastReceiver, which will not work until some component of the app is manually started.

The bulk of the business logic — what little there is of it — lies in the Monitor class that is the BroadcastReceiver:

```
package com.commonware.android.sms.monitor;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.telephony.SmsMessage;
import android.util.Log;

public class Monitor extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Object[] rawMsgs=(Object[])intent.getExtras().get("pdus");

        for (Object raw : rawMsgs) {
            SmsMessage msg=SmsMessage.createFromPdu((byte[])raw);

            if (msg.getMessageBody().toUpperCase().contains("SEKRIT")) {
                Log.w("SMS:"+msg.getOriginatingAddress(),
                    msg.getMessageBody());

                abortBroadcast();
            }
        }
    }
}
```

Here, we retrieve the raw messages from the Intent extra, iterate over them, and convert each to an SmsMessage. Those that have the magic word in their message body will result in the message being dumped to LogCat, plus the broadcast is aborted. On Android 4.3 and below, this will prevent lower-priority receivers from receiving the SMS. On Android 4.4, the abort request is ignored.

The Android 4.4+ Way: Receiving SMS

Receiving SMS messages, on Android 4.4+, means that you are implementing an SMS client application, one the user might be willing to set as their default SMS client application in Settings. There are other sorts of apps that may temporarily want to be the default SMS client, such as a backup/restore utility, as only the default SMS client will be able to work with the SMS ContentProvider suite, such as the inbox.

Receiving the Broadcasts

The default SMS client should be able to handle both SMS and MMS. This is a problem, as while supporting SMS is poorly documented, supporting MMS has almost no documentation whatsoever. However, unless the default SMS client handles MMS, nobody else can (at least, while saving MMS details to the ContentProvider suite).

Hence, Google is expecting you to have two BroadcastReceivers registered in the manifest: one for SMS and one for MMS. Unfortunately, these cannot readily be combined into a single receiver, because each has its own permission requirement:

- the SMS receiver should require senders to hold BROADCAST_SMS
- the MMS receiver should require senders to hold BROADCAST_WAP_PUSH

In practice, probably both are held by the OS component that is sending these broadcasts in response to incoming messages of either type. In principle, though, they could be separate, and an individual <receiver> can only specify one such permission.

[The Android documentation](#) illustrates the <receiver> elements that Google expects your SMS client application to have:

```
<!-- BroadcastReceiver that listens for incoming SMS messages -->
<receiver android:name=".SmsReceiver"
    android:permission="android.permission.BROADCAST_SMS">
    <intent-filter>
        <action android:name="android.provider.Telephony.SMS_DELIVER" />
    </intent-filter>
</receiver>

<!-- BroadcastReceiver that listens for incoming MMS messages -->
<receiver android:name=".MmsReceiver"
    android:permission="android.permission.BROADCAST_WAP_PUSH">
    <intent-filter>
        <action android:name="android.provider.Telephony.WAP_PUSH_DELIVER" />
        <data android:mimeType="application/vnd.wap.mms-message" />
    </intent-filter>
</receiver>
```

Notice that the MMS receiver has both an <action> and a <data> element in its <intent-filter>, which is rather unusual.

On the SMS side, the Intent you receive should be the same as the Intent you would receive for the SMS_RECEIVED broadcast, where you can decode the message(s) and deal with them as you see fit. On the MMS side... there is little documentation.

Other Expectations

Google expects the default SMS client to be able to handle ACTION_SEND and ACTION_SENDTO for relevant schemes:

```
<!-- Activity that allows the user to send new SMS/MMS messages -->
<activity android:name=".ComposeSmsActivity" >
    <intent-filter>
        <action android:name="android.intent.action.SEND" />
        <action android:name="android.intent.action.SENDTO" />
        <category android:name="android.intent.category.DEFAULT" />
        <category android:name="android.intent.category.BROWSABLE" />
        <data android:scheme="sms" />
        <data android:scheme="smsto" />
        <data android:scheme="mms" />
        <data android:scheme="mmsto" />
    </intent-filter>
</activity>
```

That may not be terribly surprising. What is surprising is that Google also expects you to have an exported service for handling “quick response” requests. These requests come when the user receives a phone call and taps on an icon to reply with a text message, rather than accept the call. In those cases, Android will invoke a service in the default SMS client, with an action of android.intent.action.RESPOND_VIA_MESSAGE. The Intent that you receive in onStartCommand() (or onHandleIntent(), if you elect to use an IntentService) will have an EXTRA_TEXT and optionally an EXTRA_SUBJECT as extras, representing the message to be sent. The Uri in the Intent will indicate the intended recipient of the message. Your job is to use SmsManager to actually send the message.

The Android documentation cites this as the relevant <service> element:

```
<!-- Service that delivers messages from the phone "quick response" -->
<service android:name=".HeadlessSmsSendService"
    android:permission="android.permission.SEND_RESPOND_VIA_MESSAGE"
    android:exported="true" >
    <intent-filter>
        <action android:name="android.intent.action.RESPOND_VIA_MESSAGE" />
        <category android:name="android.intent.category.DEFAULT" />
        <data android:scheme="sms" />
        <data android:scheme="smsto" />
        <data android:scheme="mms" />
        <data android:scheme="mmsto" />
    </intent-filter>
</service>
```

```
</intent-filter>  
</service>
```

Note:

- The `<service>` requires that the sender have the `SEND_RESPOND_VIA_MESSAGE` permission, to reduce spoofing
- The `android:exported="true"` shown in the sample should be superfluous, as since the `<service>` has an `<intent-filter>`, it should be exported by default
- The `<category>`, and possibly the `<data>`, elements may be erroneous... and since the author cannot find anything in the OS that uses `RESPOND_VIA_MESSAGE`, the author cannot validate that these elements should be here or represent copy-and-paste errors in the documentation

Handling Both Receive Options

If you want to support receiving SMS using both the legacy approach and the Android 4.4+ approach, you can have two `BroadcastReceiver` implementations, one for `android.provider.Telephony.SMS_RECEIVED` and one for `android.provider.Telephony.SMS_DELIVER`. However, you will only need the latter one on Android 4.4, and by default you would receive both broadcasts.

To handle that, you can define a boolean resource in the `res/values-v19/` directory (e.g., `isPreKitKat`) to be false, with a default definition in `res/values/` of true for the same resource. Then, in your manifest, you can have `android:enabled="@bool/isPreKitKat"` on your `SMS_RECEIVED` `<receiver>` element. This will only enable this component on API Level 18 and below, disabling it on API Level 19+.

You can also define a counterpart resource for the positive case (e.g., `@bool/isKitKat`), and use that to selectively enable the SMS and MMS receivers, if desired.

The SMS Inbox

Many users keep their text messages around, at least for a while. These are stored in an “inbox”, represented by a `ContentProvider`. How you work with this `ContentProvider` — or if you can work with it at all, varies upon whether you are running on Android 4.4+ or not.

The Undocumented, Unsupported, Pre-Android 4.4 Way

When perusing the Internet, you will find various blog posts and such referring to the SMS inbox `ContentProvider`, represented by the `content://sms/inbox` `Uri`.

This `ContentProvider` is undocumented and is not part of the Android SDK, because it is not part of the Android OS.

Rather, this `ContentProvider` is used by the aforementioned Messaging application, for storing saved SMS messages. And, as noted, this application may or may not exist on any given Android device. If a device manufacturer replaces Messaging with their own application, there may be nothing on that device that responds to that `Uri`, or the schemas may be totally different. Plus, Android may well change or even remove this `ContentProvider` in future editions of Android.

For all those reasons, developers should not be relying upon this `ContentProvider`.

The Android 4.4+ Way

Android 4.4 has exposed a series of `ContentProviders`, in the `android.provider.Telephony` namespace, for storing SMS and MMS messages. These include:

- the Inbox for received messages
- the Outbox for a log of sent messages
- the Draft for messages that were written but have not yet been sent
- etc.

Some are duplicated, such as separate providers for the SMS inbox versus the MMS inbox. Some are distinct, such as `Sms.Conversations` and `Mms.Rate`.

All are largely undocumented.

The user's chosen default SMS client can write to these providers. Apps with `READ_SMS` permission should be able to read from them.

Asking to Change the Default

There are many areas in Android where the user must do two things to use an app:

1. Install the app (from the Play Store or elsewhere)
2. Go into Settings (or sometimes elsewhere) and indicate that a certain capability of the newly-installed app should become active

You see this with app widgets, input method editors, device administrators, and many others.

On Android 4.4+, you also see this with SMS/MMS clients. Devices usually ship with one. If the user wants a replacement, the user must indicate in Settings that this new SMS/MMS client should be the default, so it can write to the SMS/MMS ContentProvider suite.

Your app can determine what the default client is by calling `getDefaultSmsPackage()` on the `Telephony.Sms` class. This will return the package name of the current default client.

If this is not your package, and you would like the user to make you the default, you can start an activity to request this change:

```
Intent i = new Intent(Sms.Intents.ACTION_CHANGE_DEFAULT);
i.putExtra(Sms.Intents.EXTRA_PACKAGE_NAME, getPackageName());
startActivity(i);
```

The `EXTRA_PACKAGE_NAME` will trigger the UI to ask the user if the user wishes to change the current default to your package (versus anything else on the device that might also be a possible SMS/MMS client).

Hence, the recommended flow for a backup/restore app is to:

- Make note of the current default, via `getDefaultSmsPackage()`
- Request to the user to make you the default, via `ACTION_CHANGE_DEFAULT`
- Confirm that they did this, via `getDefaultSmsPackage()`
- If they did, do your backup or restore work
- Request to the user to restore the original default, via `ACTION_CHANGE_DEFAULT`

SMS and the Emulator

The “Emulator Control” view in DDMS allows you to send fake SMS messages to a running emulator. This is very useful for light testing.

WORKING WITH SMS

You can also send fake SMS messages to an emulator via the emulator console. This can be accessed via `telnet`, where the console is available on `localhost` on your development machine, via the port number that appears in the title bar of your emulator window (e.g., 5554). In the `telnet` session, you can enter `sms send [sendingNumber> <txt>`, replacing `<sendingNumber>` with the phone number of the pretend sender of the SMS, and replacing `<txt>` with the text message itself.

NFC, courtesy of high-profile boosters like Google Wallet, is poised to be a significant new capability in Android devices. While at the time of this writing, only a handful of Android devices have NFC built in, other handsets are slated to be NFC-capable in the coming months. Google is hoping that developers will write NFC-aware applications to help further drive adoption of this technology by device manufacturers.

This, of course, raises the question: what is NFC? Besides being where the Green Bay Packers play, that is?

(For those of you from outside of the United States, that was an American football joke. We now return you to your regularly-scheduled chapter.)

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#) and [services](#).

What Is NFC?

NFC stands for Near-Field Communications. It is a wireless standard for data exchange, aimed at very short range transmissions — on the order of a couple of centimeters. NFC is in wide use today, for everything from credit cards to passports. Typically, the NFC data exchange is for simple data — contact information, URLs, and the like.

In particular, NFC tends to be widely used where one side of the communications channel is “passive”, or unpowered. The other side (the “initiator”) broadcasts a signal, which the passive side converts into power enough to send back its response. As such, NFC “tags” containing such passive targets can be made fairly small and can be embedded in a wide range of containers, from stickers to cards to hats.

The objective is “low friction” interaction — no pairing like with Bluetooth, no IP address shenanigans as with WiFi. The user just taps and goes.

... Compared to RFID?

NFC is often confused with or compared to RFID. It is simplest to think of RFID as being an umbrella term, under which NFC falls. Not every RFID technology is NFC, but many things that you hear of being “RFID” may actually be NFC-compliant devices or tags.

... Compared to QR Codes?

In many places, NFC will be used in ways you might consider using QR codes. For example, a restaurant could use either technology, or both, on a sign to lead patrons to the restaurant’s [Yelp](#) page, as a way of soliciting reviews. Somebody with a capable device could either tap the NFC tag on the sign to bring up Yelp or take a picture of the QR code and use that to bring up Yelp.

NFC’s primary advantage over QR codes is that it requires no user intervention beyond physically moving their device in close proximity to the tag. QR codes, on the other hand, require the user to launch a barcode scanning application, center the barcode in the viewfinder, and then get the results. The net effect is that NFC will be faster.

QR’s advantages include:

1. No need for any special hardware to generate the code, as opposed to needing a tag and something to write information into the tag for NFC
2. The ability to display QR codes in distant locations (e.g., via Web sites), whereas NFC requires physical proximity

To NDEF, Or Not to NDEF

RFID is a concept, not a standard. As such, different vendors created their own ways of structuring data on these tags or chips, making one vendor's tags incompatible with another vendor's readers or writers. While various standards bodies, like ISO, have gotten involved, it's still a bit of a rat's nest of conflicting formats and approaches.

The NFC offshoot of RFID has had somewhat greater success in establishing standards. NFC itself is an ISO and ECMA standard, covering things like transport protocols and transfer speeds. And a consortium called the NFC Forum created NDEF — the NFC Data Exchange Format — for specifying the content of tags.

However, not all NFC tags necessarily support NDEF. NDEF is much newer than NFC, and so lots of NFC tags are out in the wild that were distributed before NDEF even existed.

You can roughly divide NFC tags into three buckets:

- Those that support NDEF “out of the box”
- Those that can be “formatted” as NDEF
- Those that use other content schemes

Android has some support for non-NDEF tags, such as the MIFARE Classic. However, the hope and expectation going forward is that NFC tags will coalesce around NDEF.

NDEF, as it turns out, maps neatly to Android's Intent system, as you will see as we proceed through this chapter.

NDEF Modalities

Most developers interested in NFC will be interested in reading NFC tags and retrieving the NDEF data off of them. In Android, tapping an NDEF tag with an NFC-capable device will trigger an activity to be started, based on a certain `IntentFilter`.

Some developers will be interested in writing to NFC tags, putting URLs, vCards, or other information on them. This may or may not be possible for any given tag.

And while the “traditional” thinking around NFC has been that one side of the communication is a passive tag, Android will help promote the “peer-to-peer” approach — having two Android devices exchange data via NFC and NDEF. Basically, putting the two devices back-to-back will cause each to detect the other device’s “tag”, and each can read and write to the other via this means. This is referred to as “Android Beam” and will be discussed [later in this chapter](#).

Of course, all of these are only available on hardware. At the present time, there is no emulator for NFC, nor any means of accessing a USB NFC reader or writer from the emulator.

NDEF Structure and Android’s Translation

NDEF is made up of messages, themselves made up of a series of records. From Android’s standpoint, each tag consists of one such message.

Each record consists of a binary (byte array) payload plus metadata to describe the nature of the payload. The metadata primarily consists of a type and a subtype. There are quite a few combinations of these, but the big three for new Android NFC uses are:

- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_TEXT`, indicating that the payload is simply plain text
- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, indicating that the payload is a URI, such as a URL to a Web page
- A type of `TNF_MIME_MEDIA`, where the subtype is a standard MIME type, indicating that the payload is of that MIME type

When Android scans an NDEF tag, it will use this information to construct a suitable Intent to use with `startActivity()`. The action will be `android.nfc.action.NDEF_DISCOVERED`, to distinguish the scanned-tag case from, say, something simply asking to view some content. The MIME type in the Intent will be `text/plain` for the first scenario above or the supplied MIME type for the third scenario above. The data (`Uri`) in the Intent will be the supplied URI for the second scenario above. Once constructed, Android will invoke `startActivity()` on that Intent, bringing up an activity or an activity chooser, as appropriate.

NFC-capable Android devices have a Tags application pre-installed that will handle any NFC tag not handled by some other app. So, for example, an NDEF tag with an

HTTP URL will fire up the Tags application, which in turn will allow the user to open up a Web browser on that URL.

The Reality of NDEF

The enthusiasm that some have with regards to Android and NFC technology needs to be tempered by the reality of NDEF, NFC tags in general, and Android's support for NFC. It is easy to imagine all sorts of possibilities that may or may not be practical when current limitations are reached.

Some Tags are Read-Only

Some tags come “from the factory” read-only. Either you arrange for the distributor to write data onto them (e.g., blast a certain URL onto a bunch of NFC stickers to paste onto signs), or they come with some other pre-established data. Touchatag, for example, distributes NFC tags that have Touchatag URLs on them — they then help you set up redirects from their supplied URL to ones you supply.

While these tags will be of interest to consumers and businesses, they are unlikely to be of interest to Android developers, since their use cases are already established and typically do not need custom Android application support. Android developers seeking customizable tags will want ones that are read-write, or at least write-once.

Some Tags Can't Be Read-Only

Conversely, some tags lack any sort of read-only flag. An ideal tag for developers is one that is write-once: putting an NDEF message on the tag and flagging it read-only in one operation. Some tags do not support this, or making the tag read-only at any later point. The MIFARE Classic 1K tag is an example — while technically it can be made read-only, it requires a key known only to the tag manufacturer.

Some Tags Need to be Formatted

The MIFARE Classic 1K NFC tag is NDEF-capable, but must be “formatted” first, supplying the initial NDEF message contents. You have the option of formatting it read-write or read-only (turning the Classic 1K a write-once tag).

This is not a problem — in fact, the write-once option may be compelling. However, it is something to keep in mind.

Also, note that the MIFARE Classic 1K, while it can be formatted as NDEF, uses a proprietary protocol “under the covers”. Not all Android devices will support the Classic 1K, as the device manufacturers elect not to pay the licensing fee. Where possible, try to stick to tags that are natively NDEF-compliant (so-called “NFC Forum Tag Types 1–4”).

Tags Have Limited Storage

The “1K” in the name “MIFARE Classic 1K” refers to the amount of storage on the tag: 1 kilobyte of information.

And that’s far larger than other tags, such as the MIFARE Ultralight C, some of which have ~64 bytes of storage.

Clearly, you will not be writing an MP3 file or JPEG photo to these tags. Rather, the tags will tend to either be a “launcher” into something with richer communications (e.g., URL to a Web site) or will use the sorts of data you may be used to from QR codes, such as a vCard or iCalendar for contact and event data, respectively.

NDEF Data Structures Are Documented Elsewhere

The Android developer documentation is focused on the [Android classes](#) related to NFC and on [the Intent mechanism used for scanned tags](#). It does not focus on the actual structure of the payloads.

For TNF_MIME_MEDIA and RTD_TEXT, the payload is whatever you want. For RTD_URI, however, the byte array has a bit more structure to it, as the NDEF specification calls for a single byte to represent the URI prefix (e.g., http://www. versus http:// versus https://www.). The objective, presumably, is to support incrementally longer URLs on tags with minuscule storage. Hence, you will need to convert your URLs into this sort of byte array if you are writing them out to a tag.

Generally speaking, the rules surrounding the structure of NDEF messages and records is found at the [NFC Forum site](#).

Tag and Device Compatibility

Different devices will have different NFC chipsets. Not all NFC chipsets can read and write all tags. The expectation is that NDEF-formatted tags will work on all devices,

but if you wander away from that, things get dicier. For example, NXP's Mifare Classic tag can only be read and written by NXP's NFC chip.

This is increasingly a challenge for Android developers, as a Broadcom NFC chip is becoming significantly more popular. Many new major Android devices, such as the Samsung Galaxy S4, the Nexus 4, the Nexus 10, and the 2013/2nd generation version of the Nexus 7, all use the Broadcom chip. Those devices are incompatible with the Mifare tags, such as the popular Mifare Classic 1K.

That is because NXP is the maker of the Mifare Classic series, and those tags broke the NFC Forum's standards to create a tag that was NXP-specific.

Right now, NTAG203 and Topaz tags (like the Topaz 512), are likely candidate tags that will work across all NFC-capable Android devices, due to their adherence to NFC standard protocols.

Sources of Tags

NFC tags are not the sort of thing you will find on your grocer's shelves. In fact, few, if any, mainstream firms sell them today.

Here are some online sites from which you can order rewritable NFC tags, listed here in alphabetical order:

1. [Andytags](#)
2. [Buy NFC Stickers](#)
3. [Buy NFC Tags](#)
4. [Smartcard Focus](#)
5. [tagstand](#)

Note that not all may ship to your locale.

Writing to a Tag

So, let's see what it takes to write an NDEF message to a tag, formatting it if needed. The code samples shown in this chapter are from the [NFC/URLTagger](#) sample application. This application will set up an activity to respond to ACTION_SEND activity Intents, with an eye towards receiving a URL from a browser, then waiting for a tag and writing the URL to that tag. The idea is that this sort of application

could be used by non-technical people to populate tags containing URLs to their company's Web site, etc.

Getting a URL

First, we need to get a URL from the browser. As we saw in the chapter on integration, the standard Android browser uses ACTION_SEND of text/plain contents when the user chooses the “Share Page” menu. So, we have one activity, URLTagger, that will respond to such an Intent:

```
<activity
    android:name="URLTagger"
    android:label="@string/app_name">
    <intent-filter android:label="@string/app_name">
        <action android:name="android.intent.action.SEND"/>

        <data android:mimeType="text/plain"/>

        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
```

Of course, lots of other applications support ACTION_SEND of text/plain contents that are not URLs. A production-grade version of this application would want to validate the EXTRA_TEXT Intent extra to confirm that, indeed, this is a URL, before putting in an NDEF message claiming that it is a URL.

Detecting a Tag

When the user shares a URL with our application, our activity is launched. At that point, we need to go into “detect a tag” mode – the user should then tap their device to a tag, so we can write out the URL.

First, in onCreate(), we get access to the NfcAdapter, which is our gateway to much of the NFC functionality in Android:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    nfc=NfcAdapter.getDefaultAdapter(this);
}
```

We use a boolean data member — `inWriteMode` — to keep track of whether or not we are set up to write to a tag. Initially, of course, that is set to be false. Hence, when we are first launched, by the time we get to `onResume()`, we can go ahead and register our interest in future tags:

```
@Override
public void onResume() {
    super.onResume();

    if (!inWriteMode) {
        IntentFilter discovery=new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=new Intent(this, getClass())
            .addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP |
                Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

When an NDEF-capable tag is within signal range of the device, Android will invoke `startActivity()` for the `NfcAdapter.ACTION_TAG_DISCOVERED` Intent action. However, it can do this in one of two ways:

- Normally, it will use a chooser (via `Intent.createChooser()`) to allow the user to pick from any activities that claim to support this action.
- The foreground application can request via `enableForegroundDispatch()` for it to handle all tag events while it is in the foreground, superseding the normal `startActivity()` flow. In this case, while Android still will invoke an activity, it will be our activity, not any other one.

We want the second approach right now, so the next tag brought in range is the one we will try writing to.

To do that, we need to create an array of `IntentFilter` objects, identifying the NFC-related actions that we want to capture in the foreground. In this case, we only care about `ACTION_TAG_DISCOVERED` – if we were supporting non-NDEF NFC tags, we might also need to watch for `ACTION_TECH_DISCOVERED`.

We also need a `PendingIntent` identifying the activity that should be invoked when such a tag is encountered while we are in the foreground. Typically, this will be the current activity. By adding `FLAG_ACTIVITY_SINGLE_TOP` and

NFC

FLAG_ACTIVITY_CLEAR_TOP to the Intent as flags, we ensure that our current specific instance of the activity will be given control again via `onNewIntent()`.

Armed with those two values, we can call `enableForegroundDispatch()` on the `NfcAdapter` to register our request to process tags via the current activity instance.

In `onPause()`, if the activity is finishing, we call `disableForegroundDispatch()` to undo the work done in `onResume()`:

```
@Override
public void onPause() {
    if (isFinishing()) {
        nfc.disableForegroundDispatch(this);
        inWriteMode=false;
    }

    super.onPause();
}
```

We have to see if we are finishing, because even though our activity never leaves the screen, Android still calls `onPause()` and `onResume()` as part of delivering the Intent to `onNewIntent()`. Our approach, though, has flaws — if the user presses HOME, for example, we never disable the NFC dispatch logic. A production-grade application would need to handle this better.

For any of this code to work, we need to hold the NFC permission via an appropriate line in the manifest:

```
<uses-permission android:name="android.permission.NFC"/>
```

Also note that if you have several activities that the user can reach while you are trying to also capture NFC tag events, you will need to call `enableForegroundDispatch()` in each activity — it's a per-activity request, not a per-application request.

Reacting to a Tag

Once the user brings a tag in range, `onNewIntent()` will be invoked with the ACTION_TAG_DISCOVERED Intent action:

```
@Override
protected void onNewIntent(Intent intent) {
    if (inWriteMode &&
        NfcAdapter.ACTION_TAG_DISCOVERED.equals(intent.getAction())) {
        Tag tag=intent.getParcelableExtra(NfcAdapter.EXTRA_TAG);
    }
}
```

```
byte[] url=buildUrlBytes(getIntent().getStringExtra(Intent.EXTRA_TEXT));
NdefRecord record=new NdefRecord(NdefRecord.TNF_WELL_KNOWN,
                                NdefRecord.RTD_URI,
                                new byte[] {}, url);
NdefMessage msg=new NdefMessage(new NdefRecord[] {record});

new WriteTask(this, msg, tag).execute();
}
}
```

If we are in write mode and the delivered Intent is indeed an ACTION_TAG_DISCOVERED one, we can get at the Tag object associated with the user's NFC tag via the `NfcAdapter.EXTRA_TAG` Parcelable extra on the Intent.

Writing an NDEF message to the tag, therefore, is a matter of crafting the message and actually writing it. An NDEF message consists of one or more records (though, typically, only one record is used), with each record wrapping around a byte array of payload data.

Getting the Shared URL

We did not do anything to get the URL out of the Intent back in `onCreate()`, when our activity was first started up. Now, of course, we need that URL. You might think it is too late to get it, since our activity was effectively started again due to the tag and `onNewIntent()`.

However, `getIntent()` on an Activity always returns the Intent used to create the activity in the first place. The `getIntent()` value is not replaced when `onNewIntent()` is called.

Hence, as part of the `buildUrlBytes()` method to create the binary payload, we can go and call `getIntent().getStringExtra(Intent.EXTRA_TEXT)` to retrieve the URL.

Creating the Byte Array

Given the URL, we need to convert it into a byte array suitable for use in a TNF_WELL_KNOWN, RTD_URI NDEF record. Ordinarily, you would just call `toByteArray()` on the String and be done with it. However, the byte array we need uses a single byte to indicate the URL prefix, with the rest of the byte array for the characters after this prefix.

This is efficient. This is understandable. This is annoying.

First, we need the roster of prefixes, defined in URLTagger as a static data member cunningly named PREFIXES:

```
static private final String[] PREFIXES={"http://www.", "https://www.",
                                         "http://", "https://",
                                         "tel:", "mailto:",
                                         "ftp://anonymous:anonymous@",
                                         "ftp://ftp.", "ftps://",
                                         "sftp://", "smb://",
                                         "nfs://", "ftp://",
                                         "dav://", "news:",
                                         "telnet://", "imap:",
                                         "rtsp://", "urn:",
                                         "pop:", "sip:", "sips:",
                                         "tftp:", "btspp://",
                                         "bt12cap://", "btgoep://",
                                         "tcpobex://",
                                         "irdaobex://",
                                         "file://", "urn:epc:id:",
                                         "urn:epc:tag:",
                                         "urn:epc:pat:",
                                         "urn:epc:raw:",
                                         "urn:epc:", "urn:nfc:"};
```

Then, in buildUrlBytes(), we need to find the prefix (if any) and use it:

```
private byte[] buildUrlBytes(String url) {
    byte prefixByte=0;
    String subset=url;
    int bestPrefixLength=0;

    for (int i=0;i<PREFIXES.length;i++) {
        String prefix = PREFIXES[i];

        if (url.startsWith(prefix) && prefix.length() > bestPrefixLength) {
            prefixByte=(byte)(i+1);
            bestPrefixLength=prefix.length();
            subset=url.substring(bestPrefixLength);
        }
    }

    final byte[] subsetBytes = subset.getBytes();
    final byte[] result = new byte[subsetBytes.length+1];

    result[0]=prefixByte;
    System.arraycopy(subsetBytes, 0, result, 1, subsetBytes.length);

    return(result);
}
```

We iterate over the PREFIXES array and find a match, if any, and the best possible match if there is more than one. If there is a match, we record the NDEF value for

the first byte (our PREFIXES index plus one) and create a subset string containing the characters after the prefix. If there is no matching prefix, the prefix byte is 0 and we will include the full URL.

Given that, we construct a byte array containing our prefix byte in the first slot, and the rest taken up by the byte array of the subset of our URL.

Creating the NDEF Record and Message

Given the result of `buildUrlBytes()`, our `onNewIntent()` implementation creates a `TNF_WELL_KNOWN`, `RTD_URI` `NdefRecord` object, and pours that into an `NdefMessage` object.

The third parameter to the `NdefRecord` constructor is a byte array representing the optional “ID” of this record, which is not necessary here.

Finally, we delegate the actual writing to a `WriteTask` subclass of `AsyncTask`, as writing the `NdefMessage` to the Tag is... interesting.

Writing to a Tag

Here is the aforementioned `WriteTask` static inner class:

```
static class WriteTask extends AsyncTask<Void, Void, Void> {
    Activity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTask(Activity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }

    @Override
    protected Void doInBackground(Void... arg0) {
        int size=msg.toByteArray().length;

        try {
            Ndef ndef=Ndef.get(tag);

            if (ndef==null) {
                NdefFormatable formatable=NdefFormatable.get(tag);

                if (formatable!=null) {
```

```
        try {
            formatable.connect();

            try {
                formatable.format(msg);
            }
            catch (Exception e) {
                text="Tag refused to format";
            }
        }
        catch (Exception e) {
            text="Tag refused to connect";
        }
        finally {
            formatable.close();
        }
    }
    else {
        text="Tag does not support NDEF";
    }
}
else {
    ndef.connect();

    try {
        if (!ndef.isWritable()) {
            text="Tag is read-only";
        }
        else if (ndef.getMaxSize()<size) {
            text="Message is too big for tag";
        }
        else {
            ndef.writeNdefMessage(msg);
        }
    }
    catch (Exception e) {
        text="Tag refused to connect";
    }
    finally {
        ndef.close();
    }
}
}
catch (Exception e) {
    Log.e("URLTagger", "Exception when writing tag", e);
    text="General exception: "+e.getMessage();
}

return(null);
}

@Override
protected void onPostExecute(Void unused) {
    if (text!=null) {
```

```
        Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }

    host.finish();
}
```

In `doInBackground()`, after making note of how big the message is in bytes, we first try to get the Ndef aspect of the Tag object, by calling the static `get()` method on the Ndef class. If the tag is an NDEF tag, this should return an Ndef instance. If it does not, we try to get an NdefFormatable aspect by calling `get()` on the NdefFormatable class. If the tag is not NDEF now but can be formatted as NDEF, this should give us an NdefFormatable object. If both aspect attempts fail, we bail out, displaying a Toast to let the user know that while the tag they used is NFC, it is not NDEF-compliant.

If the tag turned out to be NdefFormatable, to put the NdefMessage on it, we first `connect()` to the tag, then `format()` it, supplying the message. NdefFormatable also supports `formatReadOnly()` for tags that support that mode — this will write the message on the tag, then block it from further updates. When we are done, we `close()` the connection.

If the tag turned out to be Ndef already, we `connect()` to it, then see if it is writable and has enough room. If it meets both of those criteria, we can emit the message via `writeNdefMessage()`, which overwrites the NDEF message that had already existed on the tag (if any). If the tag supported it, a call to `makeReadOnly()` would block further updates to the tag. Again, when we are done, we `close()` the connection.

All of the actual NFC I/O is performed in `doInBackground()`, because this I/O may take some time, and we do not want to block the main application thread while doing it.

Responding to a Tag

Writing to a tag is a bit complicated. Responding to an NDEF message on a tag is significantly easier.

If the foreground activity is not consuming NFC events — as `URLTagger` does in write mode — then Android will use normal Intent resolution with `startActivity()` to handle the tag. To respond to the tag, all you need to do is have an activity set up to watch for an `android.nfc.action.NDEF_DISCOVERED` Intent. To

get control ahead of the built-in Tags application, also have a `<data>` element that describes the sort of content or URL you are expecting to find on the tag.

For example, suppose you used the Android browser to visit [some page on the CommonsWare Web site](#), and you wrote that to a tag using URLTagger. The URLTagger application has another activity, URLHandler, that will respond when you tap the newly-written tag from the home screen or anywhere else. It accomplishes this via a suitable `<intent-filter>`:

```
<activity
    android:name="URLHandler"
    android:label="@string/app_name">
    <intent-filter android:label="@string/app_name">
        <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

        <data
            android:host="commonsware.com"
            android:scheme="http"/>

        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
```

The URLHandler activity can then use `getIntent()` to retrieve the key pieces of data from the tag itself, if needed. In particular, the `EXTRA_NDEF_MESSAGES` Parcelable array extra will return an array of `NdefMessage` objects. Typically, there will only be one of these. You can call `getRecords()` on the `NdefMessage` to get at the array of `NdefRecord` objects (again, typically only one). Methods like `getPayload()` will allow you to get at the individual portions of the record.

The nice thing is that the URL still works, even if URLTagger is not on the device. In that case, the Tags application would react to the tag, and the user could tap on it to bring up a browser on this URL. A production application might create a Web page that tells the user about this great and wonderful app she can install, and provide links to the Play Store (or elsewhere) to go get the app.

Expected Pattern: Bootstrap

Tags tend to have limited capacity. Even in peer-to-peer settings, the effective bandwidth of NFC is paltry compared to anything outside of dial-up Internet access.

As a result, NFC will be used infrequently as the complete communications solution between a publisher and a device. Sometimes it will, when the content is specifically small, such as a contact (vCard) or event (iCalendar). But, for anything bigger than

that, NFC will serve more as a convenient bootstrap for more conventional communications options:

1. Embedding a URL in a tag, as the previous sample showed, allows an installed application to run or a Web site to be browsed
2. Embedding a Play Store URL in a tag allows for easy access to some specialized app (e.g., menu for a restaurant)
3. A multi-player game might use peer-to-peer NFC to allow local participants to rapidly connect into the same shared game area, where the game is played over the Internet or Bluetooth
4. And so on.

Mobile Devices are Mobile

Reading and writing NFC tags is a relatively slow process, mostly due to low bandwidth. It may take a second or two to actually complete the operation.

Users, however, are not known for their patience.

If a user moves their device out of range of the tag while Android is attempting to read it, Android simply will skip the dispatch. If, however, the tag leaves the signal area of the device while you are writing to it, you will get an `IOException`. At this point, the state of the tag is unknown.

You may wish to incorporate something into your UI to let the user know that you are working with the tag, encouraging them to leave the phone in place until you are done.

Enabled and Disabled

There are two separate system settings that control NFC behavior:

- The user could have NFC disabled outright, which you would detect by calling `isEnabled()` on your `NfcAdapter`
- The user could have NFC enabled but have Android Beam disabled, which you would detect by calling `isNdefPushEnabled()` on your `NfcAdapter`

As with most enabled/disabled settings, you cannot change these values yourself. On newer Android SDK versions, though, you can try to bring up the relevant

Settings screens for the user to enable these features, by using the following activity action strings from the `android.provider.Settings` class:

- `ACTION_NFC_SETTINGS` for the main NFC settings screen (added in API Level 16)
- `ACTION_NFCSHARING_SETTINGS` for the Android Beam settings screen (added in API Level 14)

Android Beam

Android Beam is Google's moniker for peer-to-peer NFC messaging, with an emphasis — obviously — on Android apps. Rather than you tapping your NFC-capable Android device on a smart tag, you put it back-to-back with another NFC-capable Android device, and romance ensues.

Partially, this is simply one side of the exchange “pushing” an NDEF record, in a fashion that makes the other side of the exchange think that it is picking up a smart tag.

Partially, this is the concept of the “Android Application Record” (AAR), another NDEF record you can place in the NDEF message being pushed. This will identify the app you are trying to push the message to. If nothing on the device can handle the rest of the NDEF message, the AAR will lead Android to start up an app, or even lead the user to the Play Store to go download said app.

As the basis for explaining further how this all works, let's take a look at the [NFC/WebBeam](#) sample application. The UI consists of a `WebViewFragment`, in which we can browse to some Web page. Then, running this app on two NFC-capable devices, one app can “push” the URL of the currently-viewed Web page to the other app, which will respond by displaying that page. In this fashion, we are “sharing” a URL, without one side having to type it in by hand. And, while we are using this to share a URL, you could use Android Beam to share any sort of bootstrapping data, such as the user IDs of each person, for use in connecting to some common game server.

The Fragment

The fragment that implements our UI, `BeamFragment`, extends from `WebViewFragment`. In `onActivityCreated()`, we configure the `WebView`, load up Google's home page, and indicate that would like to participate in the action bar (via a call to `setHasOptionsMenu()`):

```
@SuppressWarnings("SetJavaScriptEnabled")
@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    getWebView().setWebViewClient(new BeamClient());
    getWebView().getSettings().setJavaScriptEnabled(true);
    loadUrl("http://google.com");
    setHasOptionsMenu(true);
}
```

To keep all links within the WebView, we attached a WebViewClient implementation, named BeamClient, that just loads all requested URLs back into the WebView:

```
class BeamClient extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView wv, String url) {
        wv.loadUrl(url);

        return(true);
    }
}
```

We add one item to the action bar: a toolbar button (R.id.beam) that will be used to indicate we wish to beam the URL in our WebView to another copy of this application running on another NFC-capable Android device:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    if (getContract().hasNFC()) {
        inflater.inflate(R.menu.actions, menu);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.beam) {
        getContract().enablePush();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

So, when the app is initially launched, it will look something like this:

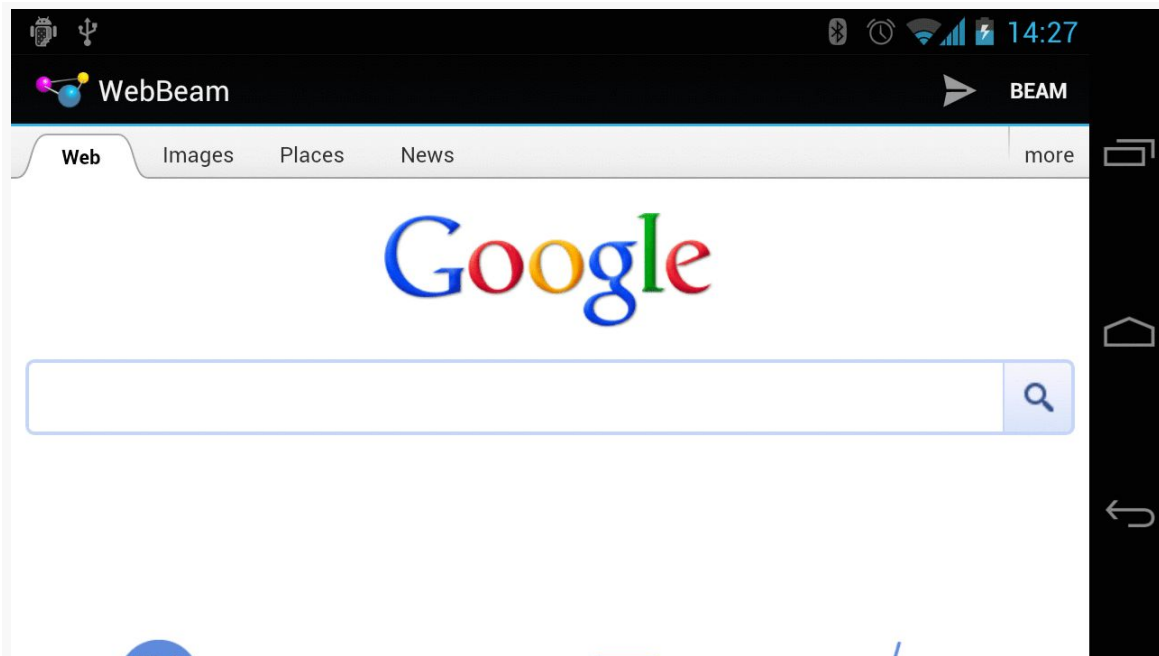

Figure 673: The WebBeam UI

The user can use Google to find a Web page worth beaming.

Requesting the Beam

Our hosting activity, `WebBeamActivity`, gets access to our `NfcAdapter`, as we did in the previous example:

```
adapter=NfcAdapter.getDefaultAdapter(this);
```

When the user taps on our action bar item, the fragment calls `enablePush()` on the activity. `WebBeamActivity`, in turn, calls `setNdefPushMessageCallback()` on the `NfcAdapter`, supplying two parameters:

1. An implementation of the `NfcAdapter.CreateNdefMessageCallback` interface, used to let us know when another device is in range for us to beam to (in our case, `WebBeamActivity` implements this interface)
2. Our activity that is participating in this push

If something else comes to the foreground, `onStop()` will call a corresponding `disablePush()`, which also calls `setNdefPushMessageCallback()`, specifying a null first parameter, to turn off our request to beam:

```
void enablePush() {
    adapter.setNdefPushMessageCallback(this, this);
}

void disablePush() {
    adapter.setNdefPushMessageCallback(null, this);
}
```

In between the calls to `enablePush()` and `disablePush()`, if another NFC device comes in range that supports the NDEF push protocols, we're beamin'.

Sending the Beam

When our beam-enabled device encounters another beam-capable device, our `NfcAdapter.CreateNdefMessageCallback` is called with `createNdefMessage()`, where we need to prepare the `NfcMessage` to beam to the other party:

```
@Override
public NdefMessage createNdefMessage(NfcEvent arg0) {
    NdefRecord uriRecord=
        new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
            MIME_TYPE.getBytes(Charset.forName("US-ASCII")),
            new byte[0],
            beamFragment.getUrl()
                .getBytes(Charset.forName("US-ASCII")));

    NdefMessage msg=
        new NdefMessage(
            new NdefRecord[] {
                uriRecord,
            },
            NdefRecord.createApplicationRecord("com.commonware.android.webbeam") );

    return(msg);
}
```

We first create a typical `NfcRecord`, in this case of `TNF_MIME_MEDIA`, with a MIME type defined in a static data member and payload consisting of the URL from our `WebView`:

```
private static final String MIME_TYPE=
    "application/vnd.commonware.sample.webbeam";
```

You might wonder why we are using `TNF_MIME_MEDIA`, instead of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, since our payload is a URL. The reason is that we need to have a unique MIME type for our message for the whole beam process to work properly, and `TNF_WELL_KNOWN` does not support MIME types. This is also why the

MIME type is something distinctive, and not just text/plain — it has to be something only we will pick up.

Our `NfcMessage` then consists of *two* `NfcRecord` objects: the one we just created, and one created via the static `createApplicationRecord()` method on `NfcRecord`. This helper method creates an AAR record, identifying our application by its Android package name. This record must go last – Android will try to find an app to work with based on the other records first, before “failing over” to use the AAR.

Receiving the Beam

To receive our beam, our `WebBeamActivity` must be configured in the manifest to respond to `NDEF_DISCOVERED` actions with our unique MIME type:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.webbeam"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET"/>
    <uses-permission android:name="android.permission.NFC"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".WebBeamActivity"
            android:label="@string/app_name"
            android:launchMode="singleTask"
            android:screenOrientation="landscape">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

                <category android:name="android.intent.category.DEFAULT"/>

                <data android:mimeType="application/vnd.commonware.sample.webbeam"/>
            </intent-filter>
        </activity>
    </application>
```

```
</manifest>
```

You will also notice that we set `android:launchMode="singleTask"` on this activity. That is so we will only have one instance of this activity, regardless of whether it is in the foreground or not. Otherwise, if we already have an instance of this activity, and we receive a beam, Android will create a *second* instance of this activity — when the user later presses BACK, they return to our first instance, and wonder why our app is broken.

If we receive the beam, we will get the Intent for the NDEF_DISCOVERED action *either* in `onCreate()` (if we were not already running) or `onNewIntent()` (if we were). In either case, we want to handle it the same way: pass the URL from the first record's payload to our BeamFragment. However, we cannot do that from `onCreate()` — the fragment will not have created the WebView yet. So, we use a trick: calling `post()` with a Runnable puts that Runnable on the *end* of the work queue for the main application thread. We can delay our processing of the Intent by this mechanism, so we can safely assume the WebView exists.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    beamFragment=
(BeamFragment)getFragmentManager().findFragmentById(android.R.id.content);

    if (beamFragment == null) {
        beamFragment=new BeamFragment();

        getFragmentManager().beginTransaction()
                                .add(android.R.id.content, beamFragment)
                                .commit();
    }

    adapter=NfcAdapter.getDefaultAdapter(this);

    findViewById(android.R.id.content).post(new Runnable() {
        public void run() {
            handleIntent(getIntent());
        }
    });
}

@Override
public void onNewIntent(Intent i) {
    handleIntent(i);
}
```

```
private void handleIntent(Intent i) {
    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
        Parcelable[] rawMsgs=
            i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);
        NdefMessage msg=(NdefMessage)rawMsgs[0];
        String url=new String(msg.getRecords()[0].getPayload());

        beamFragment.loadUrl(url);
    }
}
```

The Scenarios

There are three possible scenarios, when we try beaming from one device to another:

1. The other device has our application installed, and it is running. In that case, our activity is brought to the foreground and the Intent is delivered to it, courtesy of our NDEF_DISCOVERED <intent-filter> with our unique MIME type.
2. The other device has our application installed, but it is not running. Android's Intent system handles this in the same general fashion as the first scenario, though it starts up a process for us and creates our activity instance anew in this case.
3. The other device does not have our application installed. Since nothing (hopefully) claims to support our unique MIME type, the AAR takes effect, and the user is led to the Play Store to go download our app (or, in this case, display an error message, as WebBeam is not in the Play Store).

Beaming Files

Android 4.1 (a.k.a., Jelly Bean) added in a far simpler facility for an app to beam a file to another device using the Android Beam system. You can use `setBeamPushUri()` or `setBeamPushUriCallback()` on an `NfcAdapter` to hand Android one or more `Uri` objects representing files to be transferred. While the initial connection will be made via NFC and Android Beam, the actual data transfer will be via Bluetooth or WiFi, much more suitable than NFC for bulk data.

The difference between the two approaches is mostly when you provide the array of `Uri` objects. With `setBeamPushUri()`, you initiate the beam operation and supply the `Uri` values immediately. With `setBeamPushUriCallback()`, you initiate the

beam but do not supply the `Uri` values until the beam connection is established with the peer app.

The [NFC/FileBeam](#) sample application shows file-based beaming in action.

In our activity (`MainActivity`), in `onCreate()`, we check to make sure that Android Beam is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`. If it is, then we use `ACTION_GET_CONTENT` to retrieve some file from the user (MIME type wildcard of `*/*`):

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    adapter=NfcAdapter.getDefaultAdapter(this);

    if (!adapter.isNdefPushEnabled()) {
        Toast.makeText(this, R.string.sorry, Toast.LENGTH_LONG).show();
        finish();
    }
    else {
        Intent i=new Intent(Intent.ACTION_GET_CONTENT);

        i.setType("*/*");
        startActivityForResult(i, 0);
    }
}
```

In `onActivityResult()`, if we actually got a file (e.g., the result is `ACTION_OK`), we turn around and call `setBeamPushUri()` to pass that file to some peer device. We also set up a `Button` as our UI — clicking the `Button` will `finish()` the activity:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==0 && resultCode==RESULT_OK) {
        adapter.setBeamPushUri(new Uri[] {data.getData()}, this);

        Button btn=new Button(this);

        btn.setText(R.string.over);
        btn.setOnClickListener(this);
        setContentView(btn);
    }
}
```

That is all there is to it. If you run this app and pick a file, then hold the device up to another Android 4.1+ device, you will be prompted to “Touch to Beam” — doing so will kick off the transfer. Once the transfer is shown on the receiving device, you can

pull the devices apart a bit, as the transfer will be proceeding over Bluetooth or WiFi. However, while Bluetooth ranges are much longer than NFC, you still need to keep the devices within a handful of meters of one another.

Note that the receiving device is not running our app. The OS handles the receipt of the transferred file, not our code. Similarly, the OS on the sending device is really the one responsible for the file transfer, so our app does not need the `INTERNET` or `BLUETOOTH` permissions. The downside is that we have no control over anything on the receiving side — the file is stored wherever the OS elects to put it, and the Notification it displays when complete will simply launch `ACTION_VIEW` on the pushed file.

Another Sample: SecretAgentMan

To provide another take on using these features of `NfcAdapter`, let's examine the [NFC/SecretAgentMan](#) sample application, originally written for a presentation at the 2012 droidcon UK conference. This combines writing to tags, directly beaming text to another device, and using `Uri`-based beaming, all in one app.

The UI of the app is a large `EditText` widget with an action bar:

Figure 674: The SecretAgentMan UI

There are three action bar items, one each for the three operations: writing to a tag, directly beaming to another device, and beaming a file (represented via a `Uri`).

Configuration and Initialization

Our app is comprised of a single activity, named `MainActivity`. As part of our manifest setup, we request the NFC permission. And, since the app needs NFC to be useful, we also have a `<uses-feature>` element, stipulating that the device needs to have NFC, otherwise the app should not be shown in the Play Store:

```
<uses-permission android:name="android.permission.NFC"/>

<uses-feature
    android:name="android.hardware.nfc"
    android:required="true"/>
```

In `onCreate()` of `MainActivity`, we can then safely get access to an `NfcAdapter`, since the NFC hardware should exist and we have rights to use NFC:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    nfc=NfcAdapter.getDefaultAdapter(this);
    secretMessage=(EditText)findViewById(R.id.secretMessage);

    nfc.setOnNdefPushCompleteCallback(this, this);

    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(getIntent().getAction())) {
        readFromTag(getIntent());
    }
}
```

We also get our hands on the `EditText` widget, storing a reference to it in a data member named `secretMessage`. We will cover the rest of the initialization work in `onCreate()` later in this section, as we cover the code that needs that initialization.

Writing to the Tag

If the user chooses the “Write to Tag” action bar item, we call a `setUpWriteMode()` method from `onOptionsItemSelected()` of `MainActivity`. We maintain an `inWriteMode` boolean data member to track whether or not we are already trying to write to an NFC tag. If `inWriteMode` is false, we go ahead and take control over the NFC hardware to attempt to write to the next tag we see:

```
void setUpWriteMode() {
    if (!inWriteMode) {
        IntentFilter discovery=
            new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=
            new Intent(this, getClass()).addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP
                | Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

To do that, we:

- Create an IntentFilter for ACTION_TAG_DISCOVERED
- Create a PendingIntent for an Intent pointing back to this same activity instance (using getClass() to identify the instance, plus FLAG_ACTIVITY_SINGLE_TOP and FLAG_ACTIVITY_CLEAR_TOP to route control back to our running instance)
- Call enableForegroundDispatch() on our NfcAdapter, to route newly-discovered tags to us, with the IntentFilter identifying the tag-related events we are interested in, and the PendingIntent identifying what to do when such a tag is encountered

Once our activity is finishing (e.g., the user presses BACK), we need to clean up our write-to-tag logic. This is kicked off in onPause() of MainActivity:

```
@Override
public void onPause() {
    if (isFinishing()) {
        cleanUpWritingToTag();
    }

    super.onPause();
}
```

All we do in cleanUpWritingToTag() is discontinue our foreground control over the NFC hardware:

```
void cleanUpWritingToTag() {
    nfc.disableForegroundDispatch(this);
    inWriteMode=false;
}
```

If, before that occurs, the device is tapped on a tag, our activity should regain control in `onNewIntent()` as a result of our `PendingIntent` having been executed:

```
@Override
protected void onNewIntent(Intent i) {
    if (inWriteMode
        && NfcAdapter.ACTION_TAG_DISCOVERED.equals(i.getAction())) {
        writeToTag(i);
    }
    else if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
        readFromTag(i);
    }
}
```

If we are in write mode, and if the `Intent` that was just used with `startActivity()` was `ACTION_TAG_DISCOVERED`, we call our `writeToTag()` method to actually start writing information to the tag:

```
void writeToTag(Intent i) {
    Tag tag=i.getParcelableExtra(NfcAdapter.EXTRA_TAG);
    NdefMessage msg=
        new NdefMessage(new NdefRecord[] { buildNdefRecord() });

    new WriteTagTask(this, msg, tag).execute();
}
```

To write to the tag, we get our `Tag` out of its `Intent` extra (keyed by `EXTRA_TAG`). Then, we build an `NfcMessage` to write to the tag, getting its `NfcRecord` from `buildNdefRecord()`:

```
NdefRecord buildNdefRecord() {
    return(new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
        MIME_TYPE.getBytes(), new byte[] {},
        secretMessage.getText().toString().getBytes()));
}
```

Our NDEF record will be of a specific MIME type, represented by a static data member named `MIME_TYPE`:

```
private static final String MIME_TYPE="vnd.secret/agent.man";
```

The payload of the NDEF record is our “secret message” from the `secretMessage` `EditText` widget.

The `writeToTag()` method then kicks off the same `WriteTagTask` that we used earlier in this chapter:

NFC

```
package com.commonware.android.jimmyb;

import android.nfc.NdefMessage;
import android.nfc.Tag;
import android.nfc.tech.Ndef;
import android.nfc.tech.NdefFormatable;
import android.os.AsyncTask;
import android.util.Log;
import android.widget.Toast;

class WriteTagTask extends AsyncTask<Void, Void, Void> {
    MainActivity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTagTask(MainActivity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }

    @Override
    protected Void doInBackground(Void... arg0) {
        int size=msg.toByteArray().length;

        try {
            Ndef ndef=Ndef.get(tag);

            if (ndef == null) {
                NdefFormatable formatable=NdefFormatable.get(tag);

                if (formatable != null) {
                    try {
                        formatable.connect();

                        try {
                            formatable.format(msg);
                        }
                        catch (Exception e) {
                            text=host.getString(R.string.tag_refused_to_format);
                        }
                    }
                    catch (Exception e) {
                        text=host.getString(R.string.tag_refused_to_connect);
                    }
                    finally {
                        formatable.close();
                    }
                }
            }
            else {
                text=host.getString(R.string.tag_does_not_support_ndef);
            }
        }
    }
}
```

```
else {
    ndef.connect();

    try {
        if (!ndef.isWritable()) {
            text=host.getString(R.string.tag_is_read_only);
        }
        else if (ndef.getMaxSize() < size) {
            text=host.getString(R.string.message_is_too_big_for_tag);
        }
        else {
            ndef.writeNdefMessage(msg);
            text=host.getString(R.string.success);
        }
    }
    catch (Exception e) {
        text=host.getString(R.string.tag_refused_to_connect);
    }
    finally {
        ndef.close();
    }
}

catch (Exception e) {
    Log.e("URLTagger", "Exception when writing tag", e);
    text=host.getString(R.string.general_exception) + e.getMessage();
}

return(null);
}

@Override
protected void onPostExecute(Void unused) {
    host.cleanUpWritingToTag();

    if (text != null) {
        Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }
}
}
```

The net result is that if the user taps the “Write to Tag” action bar item, then taps and holds the device to a tag, we will write a message to the tag and display a Toast when we are done.

And, yes, this is a surprising amount of code for what really should be a simple operation...

Reading from the Tag

We can set up MainActivity to respond to tags similar to the one we wrote — ones that have the desired MIME Type — via an `android.nfc.action.NDEF_DISCOVERED` `<intent-filter>`:

```
<intent-filter android:label="@string/app_name">
  <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

  <data android:mimeType="vnd.secret/agent.man"/>

  <category android:name="android.intent.category.DEFAULT"/>
</intent-filter>
```

In both `onCreate()` and `onNewIntent()`, if the Intent that started our activity is an `NDEF_DISCOVERED` Intent, we route control to a `readFromTag()` method:

```
void readFromTag(Intent i) {
    Parcelable[] msgs=
        (Parcelable[])i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);

    if (msgs.length > 0) {
        NdefMessage msg=(NdefMessage)msgs[0];

        if (msg.getRecords().length > 0) {
            NdefRecord rec=msg.getRecords()[0];

            secretMessage.setText(new String(rec.getPayload(), US_ASCII));
        }
    }
}
```

In principle, there could be several NDEF messages on the tag, but we only pay attention to the first element, if any, of the `EXTRA_NDEF_MESSAGES` array of `Parcelable` objects on the Intent. Similarly, in principle, there could be several NDEF records in the first message, but we only examine the first element out of the array of `NdefRecord` objects contained in the `NdefMessage`. From there, we extract our secret message and display it by means of putting it in the `EditText` widget.

Beaming the Text

This sample only supports beaming — whether of NDEF messages directly or of a file — if we are on API Level 16 or higher. Hence, in `onCreateOptionsMenu()`, we check our version and only enable our default-disabled beam action bar items if:

- We are on API Level 16 or higher, and

NFC

- NDEF push mode is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`:

```
@TargetApi(16)
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_main, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN) {
        menu.findItem(R.id.simple_beam)
            .setEnabled(nfc.isNdefPushEnabled());
        menu.findItem(R.id.file_beam).setEnabled(nfc.isNdefPushEnabled());
    }

    return(super.onCreateOptionsMenu(menu));
}
```

If the user taps on the “Beam” action bar item, we call an `enablePush()` method from `onOptionsItemSelected()`, which simply enables push mode:

```
void enablePush() {
    nfc.setNdefPushMessageCallback(this, this);
}
```

We arrange for the activity itself to be the `CreateNdefMessageCallback` necessary for push mode. That requires us to implement `createNdefMessage()`, which will be called if we are in push mode and a push-compliant device comes within range:

```
@Override
public NdefMessage createNdefMessage(NfcEvent event) {
    return(new NdefMessage(
        new NdefRecord[] {
            buildNdefRecord(),
            NdefRecord.createApplicationRecord("com.commonware.android.jimmyb") }));
}
```

Here, we create an `NdefMessage` similar to the one we wrote to the tag earlier in this sample. However, we also attach an Android Application Record (AAR), by means of the static `createApplicationRecord()` method on `NdefRecord`. This, in theory, will help route the push to our app on the other device, including downloading it from the Play Store if needed (and, of course, if it actually existed on the Play Store, which it does not).

Back up in `onCreate()`, we call `setOnNdefPushCompleteCallback()`, to be notified of when a push operation is completed. Once again, we set up `MainActivity` to be the callback, this time by implementing the `OnNdefPushCompleteCallback` interface.

That, in turn, requires us to implement `onNdefPushComplete()`, where we disable push mode via a call to `setNdefPushMessageCallback()` with a null listener:

```
@Override
public void onNdefPushComplete(NfcEvent event) {
    nfc.setNdefPushMessageCallback(null, this);
}
```

To receive the beam, we only need our existing logic to read from the tag, as on the receiving side, a push is indistinguishable from reading a tag, and we are using the same MIME type for both the message written to the tag and the message we are pushing.

Beaming the File

If the user taps the “Beam File” action bar item, we find some file to beam, by means of an `ACTION_GET_CONTENT` request and `startActivityForResult()`:

```
case R.id.file_beam:
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);

    i.setType("*/*");
    startActivityForResult(i, 0);
    return(true);
```

In `onActivityResult()`, if the request succeeded, we use `setBeamPushUri()` to tell Android to beam the selected file to another device. Nothing more is needed on our side, and the receipt of the file is handled entirely by the OS, not our application code, so there is nothing to be written for that.

This code assumes the NFC adapter is enabled. We could check that via a call to `isEnabled()` on our `NfcAdapter`. If it is not enabled, we could — on user request — bring up the Settings activity for configuring NFC, via `startActivity(new Intent(Settings.ACTION_NFC_SETTINGS))`. However, oddly, this Intent action is only available on Android 4.1 (API Level 16) and higher, despite NFC having been available for some time previously.

This code ignores the possibility of doing the simple beam (not the file-based beam) on Android 4.0.x devices. That is because the `isNdefPushEnabled()` method was not added until Android 4.1, and therefore we do not know whether or not we can actually do a beam.

If `isNdefPushEnabled()` returns `false`, we simply disable some action bar items. Alternatively, we could use `startActivity(new Intent(Settings.ACTION_NFCSHARING_SETTINGS))`, on API Level 14 and higher, to bring up the beam screen in Settings, to allow the user to toggle beam support on.

Additional Resources

To help make sense of the tags that you are trying to use with your app, you may wish to grab the [NFC TagInfo](#) application off of the Google Play Store. This application simply scans a tag and allows you to peruse all the details of that tag, including the supported technologies (e.g., does it support NDEF? is it `NdefFormatable?`), the NDEF records, and so on.

To learn more about NFC on Android — beyond this chapter or the Android developer documentation — [this Google I/O 2011 presentation](#) is recommended.

Device Administration

Balding authors of Android books often point out that enterprises and malware authors have the same interests: they want to take control of a device away from the person that is holding it and give that control to some other party. Android, being a consumer operating system, is designed to defend against malware, and so enterprises can run into issues.

However, Android does have a growing area of device administration APIs, that allow carefully-constructed and installed applications to exert some degree of control over the device, how it is configured, and how it operates.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on [broadcast Intents](#).

Objectives and Scope

One might read the phrase “device administration” and assume that somebody, using these APIs, could do anything they want on the device.

That’s not quite what “device administration” means in this case.

Rather, the device administration APIs serve three main roles:

1. They allow an application to dictate how well a device is secured, from the password required in the OS lock screen to whether the device should have full-disk encryption

2. They allow an application to find out when security issues might arise, notably failed password attempts
3. They allow an application to lock the device, disable its cameras, or even perform a “wipe” (i.e., factory reset)

The user, however, has to agree to enable a device administration app. It does not magically get all these powers simply by being installed. What the user gets from agreeing to this is access to something that otherwise would be denied (e.g., to use Enterprise App X, you must agree to allow it to be a device administrator).

Defining and Registering an Admin Component

There are four pieces for defining and registering a device administration app: creating the metadata, adding the `<receiver>` to the manifest, implementing that `BroadcastReceiver`, and telling Android to ask the user to agree to allow the app to a device administrator.

Here, we will take a peek at the [DeviceAdmin/LockMeNow](#) sample application.

The Feature

Apps implementing device administrators should add a `<uses-feature>` element with a name of `android.software.device_admin`, indicating whether or not they require this device feature to exist. This can be used by the Play Store to filter your app from being available on devices that, for one reason or another, do not offer this capability.

The Metadata

As with [app widgets](#) and other Android facilities, you will need to define a metadata file as an XML resource, describing in greater detail what your device administration app wishes to do. This information will determine what you will be allowed to do once the user approves your app, and what you list here will be displayed to the user when you request such approval.

The `DeviceAdminInfo` class has a series of static data members (e.g., `USES_ENCRYPTED_STORAGE`) that represent specific policies that your device administrator app could use. The documentation for each of those static data members lists the corresponding element that goes in this XML metadata file (e.g., `<encrypted-storage>`). These elements are wrapped in a `<uses-policies>` element,

which itself is wrapped in a `<device-admin>` element. The range of possible policies is shown in the following sample XML metadata file:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-camera />
    <encrypted-storage />
    <expire-password />
    <force-lock />
    <limit-password />
    <reset-password />
    <watch-login />
    <wipe-data />
  </uses-policies>
</device-admin>
```

Here, we:

- Intend to disable the cameras, if needed
- Will ask the user to encrypt their device storage, if it has not been done already
- Will set an expiration time for the user's password, after which they will need to set up a new one
- Intend to lock the device, if needed
- Will set criteria for password quality, such as minimum length
- Intend to forcibly reset the user's password, if needed
- Intend to monitor for failed and successful login attempts
- Intend to wipe the device, if needed

Choose which of those policies you need — the fewer you request, the more likely it is the user will not wonder about your intentions. In your project's `res/xml/` directory, create a file that looks like the above with the policies you wish. You can name this file whatever you want (e.g., `device_admin.xml`), within standard Android resource naming rules.

The Manifest

In the manifest, you will need to declare a `<receiver>` element for the `DeviceAdminReceiver` component that you will write. This component not only is the embodiment of the device admin capabilities of your app, but it will be the one notified of failed logins and other events.

For example, here is the `<receiver>` element from the `LockMeNow` sample app:

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin"/>

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
  </intent-filter>
</receiver>
```

There are three things distinctive about this element compared to your usual `<receiver>` element:

1. It requires that whoever sends broadcasts to it hold the `BIND_DEVICE_ADMIN` permission. Since that permission is protected and can only be held by apps signed with the firmware's signing key, you can be reasonably assured that any events sent to you are real.
2. It has the `<meta-data>` child element pointing to our device administration metadata from the previous section.
3. It registers for `android.app.action.DEVICE_ADMIN_ENABLED` broadcasts via its `<intent-filter>` — this is the broadcast that will be used to notify you about failed logins or other events.

The Receiver

The `DeviceAdminReceiver` itself needs to exist as a component in your app, registered in the manifest as shown above. At minimum, though, it does not need to override any methods, such as the implementation from the `LockMeNow` sample app:

```
package com.commonware.android.lockme;

import android.app.admin.DeviceAdminReceiver;

public class AdminReceiver extends DeviceAdminReceiver {
}
```

By requesting the `DEVICE_ADMIN_ENABLED` broadcasts, we could get control when we are enabled by overriding an `onEnabled()` method. We could also register for other broadcasts (e.g., `ACTION_PASSWORD_FAILED`) and implement the corresponding callback method on our `DeviceAdminReceiver` (e.g., `onPasswordFailed()`).

The Demand for Device Domination

Simply having this component in our manifest, though, is insufficient. The user must proactively agree to allow us to administer their device. And, since this is potentially very dangerous, a simple permission was deemed to also be insufficient. Instead, we need to ask the user to approve us as a device administrator from our app, typically from an activity.

In the case of LockMeNow, the UI is just a really big button, tied to a `lockMeNow()` method on our `LockMeNowActivity`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/Button1"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:onClick="lockMeNow"
        android:text="@string/lock_me"
        android:textColor="#FFFF0000"
        android:textSize="40sp"
        android:textStyle="bold"/>

</LinearLayout>
```

In `onCreate()` of the activity, in addition to loading up the UI via `setContentView()`, we create a `ComponentName` object identifying our `AdminReceiver` component. We also request access to the `DevicePolicyManager`, via a call to `getSystemService()`. `DevicePolicyManager` is our gateway for making direct requests for device administration operations, such as locking the device:

```
package com.commonware.android.lockme;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class LockMeNowActivity extends Activity {
    private DevicePolicyManager mgr=null;
    private ComponentName cn=null;
```

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.main);
    cn=new ComponentName(this, AdminReceiver.class);
    mgr=(DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);
}

public void lockMeNow(View v) {
    if (mgr.isAdminActive(cn)) {
        mgr.lockNow();
    }
    else {
        Intent intent=
            new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
        intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
        intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
            getString(R.string.device_admin_explanation));
        startActivity(intent);
    }
}
```

In `lockMeNow()`, we ask the `DevicePolicyManager` if we have already been registered as a device administrator, by calling `isAdminActive()`, supplying the `ComponentName` of our `DeviceAdminReceiver` that should be so registered. If that returns false, then the user has not approved us as a device administrator yet, so we need to ask them to do so. To do that, you:

- Create an Intent for the `DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN` action
- Add the `ComponentName` of our `DeviceAdminReceiver` as an extra, keyed as `DevicePolicyManager.EXTRA_DEVICE_ADMIN`
- Add another extra, `DevicePolicyManager.EXTRA_ADD_EXPLANATION`, which is some text to show the user as part of the authorization screen, to explain why we need to be a device admin
- Start up an activity using that Intent, via `startActivity()`

If you run this on a device, then tap the button, the first time you do so the user will be prompted to agree to making the app be a device administrator:

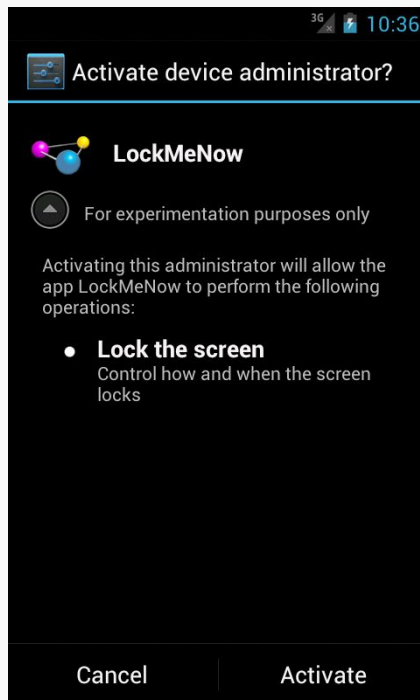

Figure 675: The Activate Device Administrator Screen

The “For experimentation purposes only” is the value of our `DevicePolicyManager.EXTRA_ADD_EXPLANATION` extra, loaded from a string resource.

If the user clicks “Activate”, and you override `onEnabled()` in your `DeviceAdminReceiver`, that will be called to let you know that you have been approved and can perform device administration functions. Your component will also appear in the list of device administrators in the Settings app:

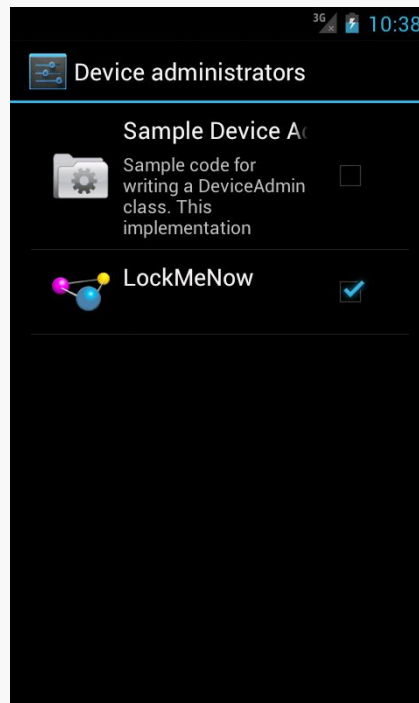

Figure 676: The Device Administrator List

The user can, at any time, uncheck you in this list and disable you. You can find out about this by having your `DeviceAdminReceiver` listen for `ACTION_DEVICE_ADMIN_DISABLE_REQUESTED` broadcasts and overriding the `onDisableRequested()` method, where you can return the text of a message to be displayed to the user confirming that they do indeed wish to go ahead with the disable operation. To find out if they go through with it, your `DeviceAdminReceiver` can listen for `ACTION_DEVICE_ADMIN_DISABLED` broadcasts and override `onDisabled()`.

Going Into Lockdown

Given that the user has approved your device administration request, and given that you requested `<force-lock>` in your metadata, you can call `lockNow()` on a `DevicePolicyManager`. That will immediately lock the device and (generally) turn off the screen. It is as if the user pressed the `POWER` button on the device.

The `LockItNow` sample app does this if, when the user clicks the really big button, it detects that it is already a device administrator. If you test this on a device, it will

behave as though the user pressed POWER; on an emulator, you will need to press the HOME button to “power on” the screen and be able to re-enter your emulator.

You can also call:

- `setCameraDisabled()` to disable all cameras, if you requested `<disable-camera>` in the metadata. Note that this disables all cameras; there is no provision at this time to disable individual cameras separately.
- `wipeData()`, which performs what amounts to a factory reset — it leaves external storage alone but wipes the contents of internal storage as part of a reboot. This requires the `<wipe-data>` policy in the metadata.
- `setKeyguardDisabledFeatures()`, to control whether or not the lockscreen allows direct access to the camera and/or app widgets (lockscreen app widgets are described in [the chapter on app widgets](#))

For example, the latter feature, while available in the Android SDK, is not built into the Settings app of Android 4.2. As a result, users need a third-party app to toggle on or off lockscreen access to the camera and app widgets. One such third-party app is [LockscreenLocker](#), released as open source by the author of this book.

Basically, the app presents you with two Switch widgets to control the camera and app widgets on the lock screen. First, though, it shows you a message and a Button, if the app is not set up as a device administrator:

DEVICE ADMINISTRATION

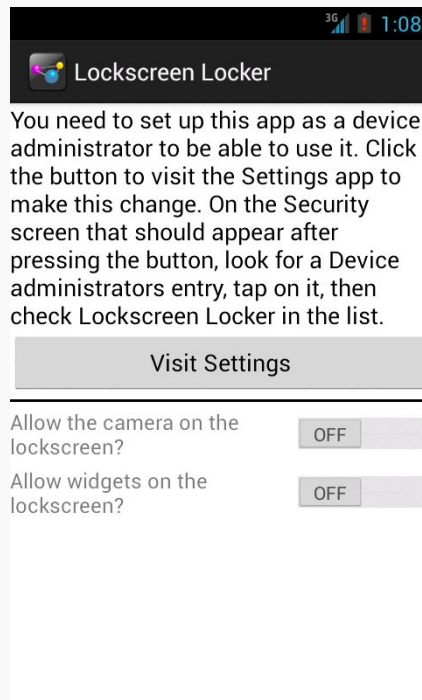

Figure 677: LockscreenLocker, On Initial Run

Once that is complete, the Switch widgets become enabled and usable:

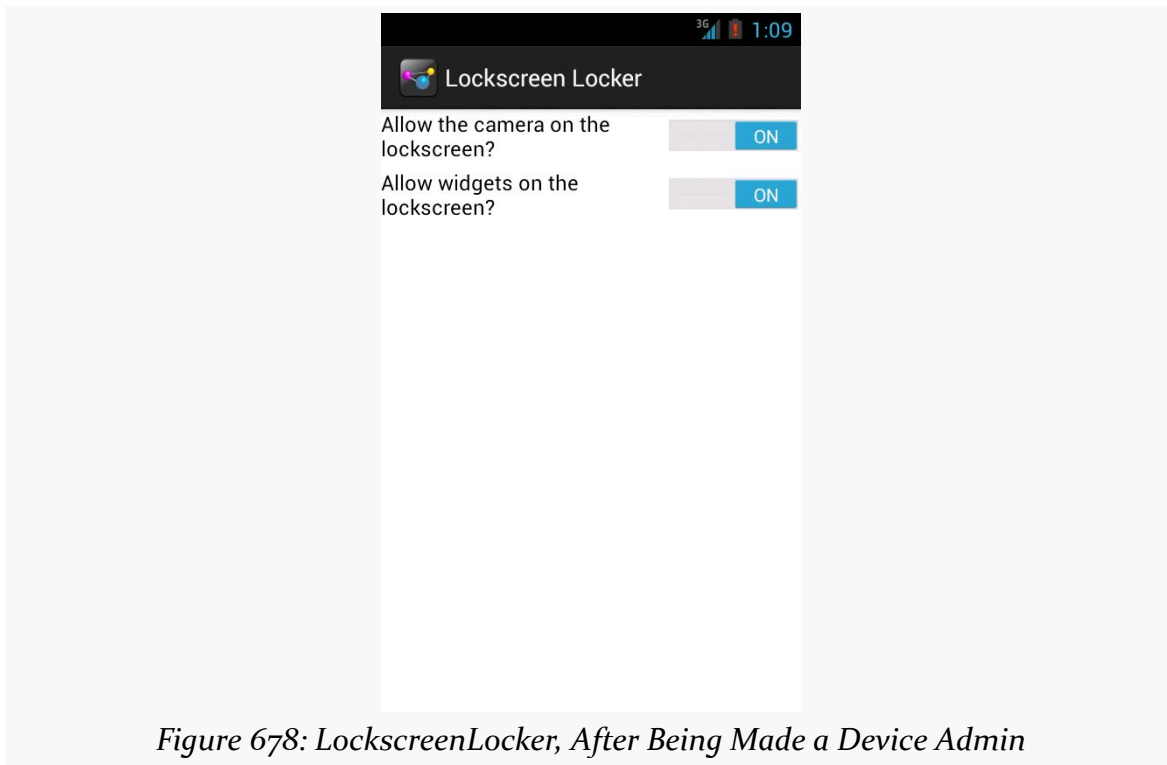

Figure 678: LockscreenLocker, After Being Made a Device Admin

The device admin metadata for this app specifies that we want to control keyguard features:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-keyguard-features/>
  </uses-policies>
</device-admin>
```

Note that, at the time of this writing, there is a flaw in the Android developer documentation — the correct element to have in the metadata is `<disable-keyguard-features/>`, not `<disable-keyguard-widgets>`. You can track [this issue](#) to see when this documentation bug has been repaired.

Our device admin component, `LockscreenAdminReceiver`, is empty, because there are no events that we are trying to listen to:

```
public class LockscreenAdminReceiver extends DeviceAdminReceiver {
}
```

However, we still need the `LockscreenAdminReceiver`, as it is the component that is tied to our device admin metadata and indicates to the system that we should be an option in Settings for available device administrators.

Our activity layout contains all the requisite widgets: a `TextView` for the message, a `Button` to jump to the Settings app, a `View` to serve as a divider, and a pair of `Switch` widgets to manage the lockscreen settings:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <TextView
        android:id="@+id/setupMessage"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/setup_message"
        android:textAppearance="?android:attr/textAppearanceMedium"
        android:visibility="gone"/>

    <Button
        android:id="@+id/setup"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showSettings"
        android:text="@string/visit_settings"
        android:visibility="gone"/>

    <View
        android:id="@+id/divider"
        android:layout_width="match_parent"
        android:layout_height="2dip"
        android:layout_marginBottom="4dip"
        android:layout_marginTop="4dip"
        android:background="#FF000000"
        android:visibility="gone"/>

    <Switch
        android:id="@+id/camera"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/allow_camera"/>

    <Switch
        android:id="@+id/widgets"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="4dip"
        android:text="@string/allow_widgets"/>
```

```
</LinearLayout>
```

In `onCreate()` of our activity (`MainActivity`), we request a `DevicePolicyManager`, set up a `ComponentName` identifying our `DeviceAdminReceiver` implementation (`LockscreenAdminReceiver`), and hook up the activity to know about changes in the state of the Switch widgets:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);
    cn=new ComponentName(this, LockscreenAdminReceiver.class);

    camera=(CompoundButton)findViewById(R.id.camera);
    camera.setOnCheckedChangeListener(this);

    widgets=(CompoundButton)findViewById(R.id.widgets);
    widgets.setOnCheckedChangeListener(this);
}
```

In `onResume()`, we check to see if our `DeviceAdminReceiver` is active — in other words, whether the user has set us up as being a device administrator or not:

```
@Override
public void onResume() {
    super.onResume();

    if (mgr.isAdminActive(cn)) {
        toggleWidgets(true);

        int status=mgr.getKeyguardDisabledFeatures(cn);

        camera.setChecked(!((status &
DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA) ==
DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA));
        widgets.setChecked(!((status &
DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL) ==
DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL));
    }
    else {
        toggleWidgets(false);
    }
}
```

We toggle the visibility and enabled settings of our widgets based upon whether we are a device administrator or not, in a `toggleWidgets()` private method:

```
private void toggleWidgets(boolean enable) {
    int visibility=(enable ? View.GONE : View.VISIBLE);

    camera.setEnabled(enable);
    widgets.setEnabled(enable);

    findViewById(R.id.divider).setVisibility(visibility);
    findViewById(R.id.setup).setVisibility(visibility);
    findViewById(R.id.setupMessage).setVisibility(visibility);
}
```

onResume() also sets the state of our Switch widgets based upon the current state of the keyguard features, by calling getKeyguardDisabledFeatures() on the DevicePolicyManager. This returns a bit set of which features are disabled, with DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA and/or DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL possibly being set.

At the outset, after being installed, we will not be a device administrator, so the Switch widgets will be disabled and the Button will be visible. We simply send the user to the security screen in the Settings app if they click that button:

```
public void showSettings(View v) {
    startActivity(new Intent(Settings.ACTION_SECURITY_SETTINGS));
}
```

When the user toggles a Switch, our activity will be called with onCheckedChanged(). There, we need to call setKeyguardDisabledFeatures() with a new bit set, toggling on or off a bit based on the user's chosen values in the UI:

```
@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    int status=mgr.getKeyguardDisabledFeatures(cn);

    if (buttonView == camera) {
        if (isChecked) {
            mgr.setKeyguardDisabledFeatures(cn, status
                & ~DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
        }
        else {
            mgr.setKeyguardDisabledFeatures(cn, status
                | DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
        }
    }
    else {
        if (isChecked) {
            mgr.setKeyguardDisabledFeatures(cn, status
                & ~DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
        }
    }
}
```

```
else {  
    mgr.setKeyguardDisabledFeatures(cn, status  
        | DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);  
}  
}  
}
```

Note that we have the Switch widgets set up for positive statements (e.g., “enable the camera”), while the bit set uses negative statements (e.g., “disable the camera”). That makes toggling the bit set a “bit” more complicated, to ensure that we are applying the user’s choices correctly.

Passwords and Device Administration

One popular facet of the device administration APIs is for an app to mandate a certain degree of password quality. The app might then fail to operate if the current password does not meet the requested quality standard.

Mandating Quality of Security

You can call various setters on `DevicePolicyManager` to dictate your minimum requirements for the password that the user uses to get past the lock screen. Examples include:

- `setPasswordMinimumLength()`
- `setPasswordQuality()` (with an integer flag describing the type of “quality” you seek, such as `PASSWORD_QUALITY_NUMERIC` if a PIN is OK, or `PASSWORD_QUALITY_COMPLEX` if you require mixed case and numbers and such)
- `setPasswordMinimumLowerCase()` (indicating how many lowercase letters are required at minimum in the user’s password)

All of these require the `<limit-password>` policy be requested in the metadata.

Then, you can call `isActivePasswordSufficient()` to determine if the current password meets your requirements. If it does not, you might elect to disable certain functionality. Or, if you requested the `<reset-password>` policy in the metadata, you can call `resetPassword()` to force the user to come up with a password meeting your requirements.

Similarly, you can also call `getStorageEncryptionStatus()` on `DevicePolicyManager` to find out whether full-disk encryption is active, inactive, or

unavailable on this particular device. If it is inactive, and you requested the <encrypted-storage> policy in your metadata, you can call `setStorageEncryption()` to demand it, and start the encryption process via starting the `ACTION_START_ENCRYPTION` activity.

Establishing Password Requirements

To see password quality enforcement in action, let us examine the [DeviceAdmin/PasswordEnforcer](#) sample application.

The activity (`MainActivity`) is fairly short, and much of its code is based off of the earlier `LockMeNow` sample:

```
package com.commonware.android.pwenforce;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        ComponentName cn=new ComponentName(this, AdminReceiver.class);
        DevicePolicyManager mgr=
            (DevicePolicyManager) getSystemService(DEVICE_POLICY_SERVICE);

        if (mgr.isAdminActive(cn)) {
            int msgId;

            if (mgr.isActivePasswordSufficient()) {
                msgId=R.string.compliant;
            }
            else {
                msgId=R.string.not_compliant;
            }

            Toast.makeText(this, msgId, Toast.LENGTH_LONG).show();
        }
        else {
            Intent intent=
                new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
            intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
            intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
                getString(R.string.device_admin_explanation));
            startActivity(intent);
        }
    }
}
```

```
    }  
    finish();  
  }  
}
```

In `onCreate()`, after obtaining a `DevicePolicyManager`, we see if our app has been designated by the user as a device administrator. If not — which will be the case when the app is first installed — we use an `ACTION_ADD_DEVICE_ADMIN` Intent and `startActivity()` to steer the user towards making our app be a device administrator.

If the user does make our app be a device administrator, our `AdminReceiver` will get control in `onEnabled()`, as we have registered it for `DEVICE_ADMIN_ENABLED` broadcasts in the manifest. In `onEnabled()`, we mandate that the password for the device must be alphanumeric, via a call to `setPasswordQuality()` on the `DevicePolicyManager`:

```
@Override  
public void onEnabled(Context ctxt, Intent intent) {  
    ComponentName cn=new ComponentName(ctxt, AdminReceiver.class);  
    DevicePolicyManager mgr=  
(DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);  
  
    mgr.setPasswordQuality(cn,  
                           DevicePolicyManager.PASSWORD_QUALITY_ALPHANUMERIC);  
  
    onPasswordChanged(ctxt, intent);  
}
```

We will see the role of the `onPasswordChanged()` method, called late in `onEnabled()`, later in this chapter.

Back in `onCreate()` of our `MainActivity`, if we *are* a device administrator, then we know that the `setPasswordQuality()` call has been made, and so we can check to see if the current password meets our standards via a call to `isActivePasswordSufficient()` on the `DevicePolicyManager`. The app displays a Toast showing whether the password is or is not currently “sufficient”.

Password-Related Events

Via appropriate actions in our `<intent-filter>` for our `DeviceAdminReceiver`, and associated callback methods, we can find out other things that go on with respect to the password:

DEVICE ADMINISTRATION

- ACTION_PASSWORD_CHANGED informs us when the user has changed her password
- ACTION_PASSWORD_FAILED informs us when somebody tries to enter a password, and the password was incorrect
- ACTION_PASSWORD_SUCCEEDED informs us when the user has successfully entered the password and unlocked the device... after an attempt had previously failed

The PasswordEnforcer sample registers for all of these in the manifest:

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin"/>

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_CHANGED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_FAILED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_SUCCEEDED"/>
  </intent-filter>
</receiver>
```

The implementations of the corresponding onPasswordChanged(), onPasswordFailed(), and onPasswordSucceeded() methods simply display Toast messages about those events:

```
@Override
public void onPasswordChanged(Context ctxt, Intent intent) {
    DevicePolicyManager mgr=
(DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);
    int msgId;

    if (mgr.isActivePasswordSufficient()) {
        msgId=R.string.compliant;
    }
    else {
        msgId=R.string.not_compliant;
    }

    Toast.makeText(ctxt, msgId, Toast.LENGTH_LONG).show();
}

@Override
public void onPasswordFailed(Context ctxt, Intent intent) {
    Toast.makeText(ctxt, R.string.password_failed, Toast.LENGTH_LONG)
        .show();
}
```

```
}  
  
@Override  
public void onPasswordSucceeded(Context ctxt, Intent intent) {  
    Toast.makeText(ctxt, R.string.password_success, Toast.LENGTH_LONG)  
        .show();  
}
```

However, these will illustrate some quirks in the behavior of the device administration APIs:

- `onPasswordSucceeded()` is not called on *every* successful password entry, only those that come after a prior `onPasswordFailed()` call. One imagines that perhaps `onPasswordSucceededAfterItHadFailedBefore()` was deemed to be too wordy.
- `isActivePasswordSufficient()` will return a value based on the *previous* password in `onPasswordChanged()`, not the newly-changed password. Since the system will prevent the user from entering a new password that is insufficient, you should not need to call `isActivePasswordSufficient()` from `onPasswordChanged()`.
- A Toast cannot display over the lockscreen, and so the `onPasswordFailed()` Toast will never be seen.

Getting Along with Others

Bear in mind that you might not be the only device administrator on any given device. If there are multiple administrators, the most secure requirements are in force. So, for example, if Admin A requests a minimum password length of 7, and Admin B requests a minimum password length of 10, the user will have to supply a password that is at least 10 characters long, to meet both device administrators' requirements.

This also means that certain requests you make may fail. For example, if you decide to say that you do *not* need encryption (`setStorageEncryption()` with a value of `false`), if something *else* needs encryption, the user will still need to encrypt their device.

PowerManager and WakeLocks

There are going to be times when you want the device to keep running, even though it ordinarily would go into a sleep mode, with the CPU powered down and the screen turned off. Sometimes, that will be based upon user interactions, or the lack thereof, such as keeping the screen on while playing back a video. Sometimes, that will be to allow background scheduled work to run to completion, as was introduced in the chapter on `AlarmManager`.

This chapter looks a bit more at the details of this sort of power management, including coverage of how `AlarmManager` works.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on `AlarmManager`](#).

Keeping the Screen On, UI-Style

If your objective is to keep the screen (and CPU) on while your activity is in the foreground, the simplest solution is to add `android:keepScreenOn="true"` to something in the activity's layout. So long as that widget or container is visible, the screen will stay on.

If you wish to do this conditionally, `setKeepScreenOn()` allows you to toggle this setting at runtime.

Once your activity is no longer in the foreground, or the widget or container is no longer visible, the effect lapses, and screen operation returns to normal.

The Role of the WakeLock

Most of the time in Android, you are developing code that will run while the user is actually using the device. Activities, for example, only really make sense when the device is fully awake and the user is tapping on the screen or keyboard.

Particularly with scheduled background tasks, though, you need to bear in mind that the device will eventually “go to sleep”. In full sleep mode, the display, main CPU, and keyboard are all powered off, to maximize battery life. Only on a low-level system event, like an incoming phone call, will anything wake up the device.

Another thing that will partially wake up the phone is an Intent raised by the AlarmManager. So long as broadcast receivers are processing that Intent, the AlarmManager ensures the CPU will be running (though the screen and keyboard are still off). Once the broadcast receivers are done, the AlarmManager lets the device go back to sleep.

You can achieve the same effect in your code via a WakeLock.

One of the changes that the core Android team made to the Linux kernel was to introduce the concept of the “wakelock”. In simple terms, a wakelock allows a Linux userland application — such as our Android SDK apps — to control whether or not the CPU can be powered down as part of a sleep mode. While a wakelock is in force, the CPU will remain on and processing instructions from the processes and threads that are on the device.

From the SDK, to access a wakelock, you use a WakeLock object, obtained from the PowerManager system service. When you call `acquire()` on that WakeLock, the CPU will remain on; when you call `release()` on that WakeLock, the CPU can fall back asleep, if there are no other outstanding WakeLocks from SDK apps or the operating system itself.

There are four types of WakeLock objects. All will keep the CPU on. They vary in their effects on the screen (leave it off, have it display with dim backlight, have it display with normal backlight) and any physical keys (ignore or accept). You will pass a flag into `newWakeLock()` on the PowerManager system service to indicate what type of WakeLock you want. The most common is the `PARTIAL_WAKE_LOCK`, which keeps the CPU on but leaves the screen and keyboard off — ideal for periodic background work triggered by an AlarmManager event.

What WakefulIntentService Does

For a `_WAKEUP` alarm, the `AlarmManager` will arrange for the device to stay awake, via a `WakeLock`, for as long as the `BroadcastReceiver`'s `onReceive()` method is executing. For some situations, that may be all that is needed. However, `onReceive()` is called on the main application thread, and Android will kill off the receiver if it takes too long.

Your natural inclination in this case is to have the `BroadcastReceiver` arrange for a `Service` to do the long-running work on a background thread, since `BroadcastReceiver` objects should not be starting their own threads. Perhaps you would use an `IntentService`, which packages up this “start a `Service` to do some work in the background” pattern. And, given the preceding section, you might try acquiring a partial `WakeLock` at the beginning of the work and release it at the end of the work, so the CPU will keep running while your `IntentService` does its thing.

This strategy will work... some of the time.

The problem is that there is a gap in `WakeLock` coverage, as depicted in the following diagram:

Figure 679: The WakeLock Gap

The `BroadcastReceiver` will call `startService()` to send work to the `IntentService`, but that service will not start up until after `onReceive()` ends. As a result, there is a window of time between the end of `onReceive()` and when your `IntentService` can acquire its own `WakeLock`. During that window, the device might fall back asleep. Sometimes it will, sometimes it will not.

What you need to do, instead, is arrange for overlapping `WakeLock` instances. You need to acquire a `WakeLock` in your `BroadcastReceiver`, during the `onReceive()`

execution, and hold onto that WakeLock until the work is completed by the IntentService:

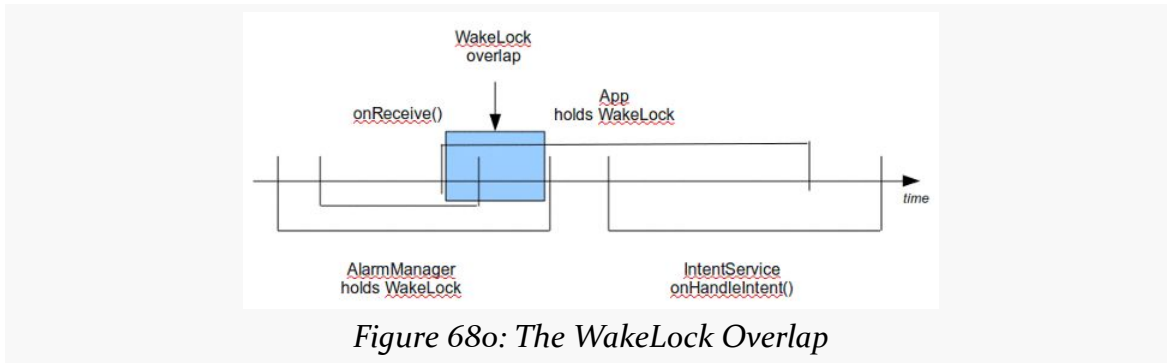

Figure 680: The WakeLock Overlap

Then you are assured that the device will stay awake as long as the work remains to be done.

The WakefulIntentService recipe described in [its chapter](#) does not have you manage your own WakeLock. That is because WakefulIntentService handles it for you. One reason why WakefulIntentService exists is to manage that WakeLock, because WakeLocks suffer from one major problem: they are not Parcelable, and therefore cannot be passed in an Intent extra. Hence, for our BroadcastReceiver and our WakefulIntentService to use the same WakeLock, they have to be shared via a static data member... which is icky. WakefulIntentService is designed to hide this icky part from you, so you do not have to worry about it.

WakefulIntentService also handles various edge and corner cases, such as:

- What happens if Android elects to get rid of your process due to low memory conditions?
- What happens if your `doWakefulWork()` crashes, so we do not leak the acquired WakeLock?
- What if your UI also sends commands to the WakefulIntentService, or your processing takes longer than your polling period in AlarmManager, so that we have more than one piece of work outstanding at a point in time?

The one requirement related to a WakeLock that WakefulIntentService imposes upon you is the `WAKE_LOCK` permission. Any code in your process that is directly manipulating WakeLock objects needs this permission, even if that code is from a third-party JAR like WakefulIntentService.

JobScheduler

AlarmManager was our original solution for doing work on a periodic basis. However, AlarmManager can readily be misused, in ways that impact the battery — this is why API Level 19 put renewed emphasis on “inexact” alarm schedules. Worse, AlarmManager will give us control at points in time that may be useless to us, such as giving us control when there is no Internet access, when the point of the scheduled work is to transfer some data over the Internet.

Android 5.0 introduced JobScheduler, which offers a more sophisticated API for handling these sorts of scenarios. This chapter will explore how to set up JobScheduler and use it for one-off and periodic work.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on AlarmManager](#). Also, you should have read [the chapter on PowerManager and wakelocks](#).

The Limitations of AlarmManager

AlarmManager does its job, and frequently does it well. However, it is far from perfect:

- It does not persist its alarm schedule across reboots, forcing us to implement an ACTION_BOOT_COMPLETED BroadcastReceiver to re-establish our alarms
- It does not keep the device awake after waking it up with a _WAKEUP alarm, forcing us to use tools like WakefulBroadcastReceiver to make sure that we can get our work done without the device falling back asleep

- It gives us control even if the work we want to do is not possible, such as wanting to download material from the Internet but being woken up at points in time when we lack a working Internet connection (e.g., a WiFi-only tablet in a location for which it does not recognize any access points)
- In cases where the criteria we want cannot be met, we cannot readily implement any sort of back-off policy, except by doing the calculations ourselves and perhaps abandoning the convenient “repeating” API outright

And so on. `AlarmManager` is nice, but it would be better to have another solution.

Enter the JobScheduler

`JobScheduler` was designed to handle those four problems outlined above:

- It persists its roster of jobs and will re-establish them automatically after a reboot. Note, though, that you still have to hold the `ACTION_BOOT_COMPLETED` permission for this to work. Also note that you do not *have* to have jobs be persisted — this is an opt-in capability of `JobScheduler`.
- It handles “wakefulness” for us, via its own `WakeLock`, so we do not have to worry about it ourselves.
- It offers an API where we can specify criteria to be satisfied before we should be given control, notably a criteria indicating that we need a working network connection.
- If our criteria cannot be met, `JobScheduler` implements a configurable back-off policy, so we can slow down our attempts to get control when those attempts are regularly failing.

Employing JobScheduler

The [JobScheduler/PowerHungry](#) sample project demonstrates the use of `JobScheduler`, by way of comparing its use to that of `AlarmManager`.

The UI for `JobScheduler` allows you to pick from three types of event schedules: exact alarm, inexact alarm, and `JobScheduler`. You can also choose from one of four polling periods: 1 minute, 15 minutes, 30 minutes, and 60 minutes:

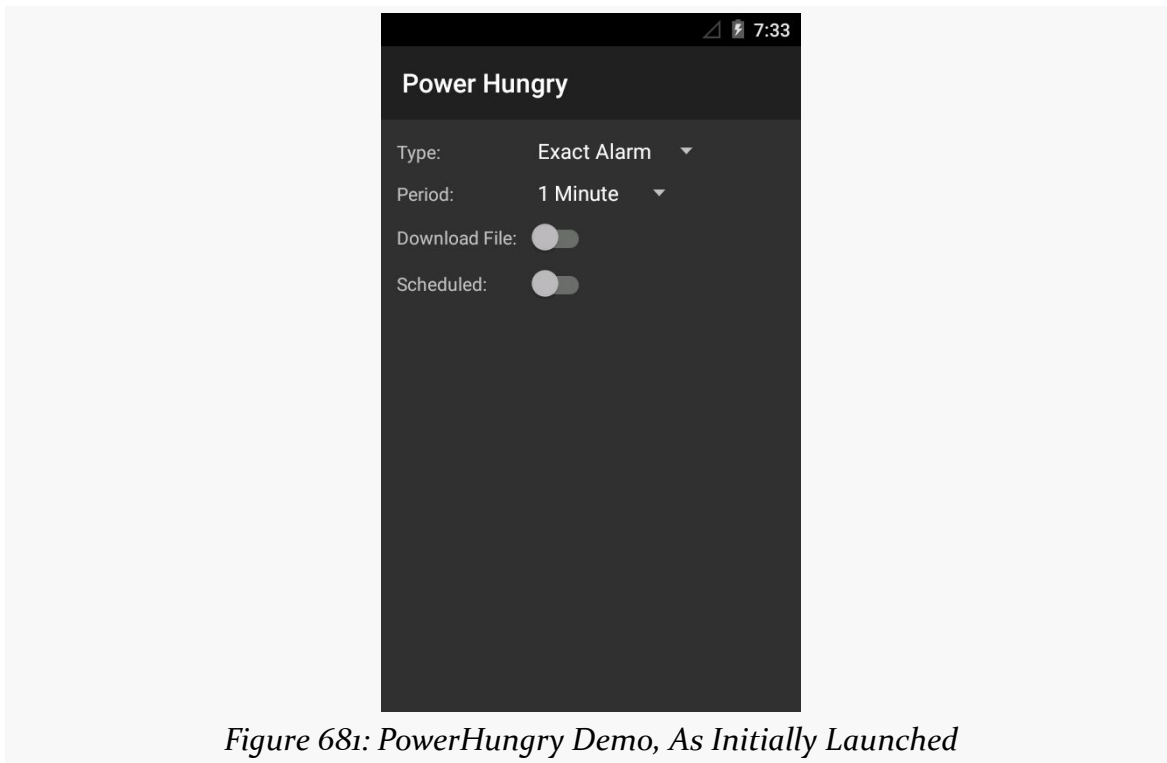

Figure 681: PowerHungry Demo, As Initially Launched

A `Switch` (in its `Theme.Material` styling) allows you to determine whether you are simply getting control at those points in time to just log to `LogCat`, or whether you are going to try to do some work at those points in time. Specifically, the “work” is to download a file, using `URLConnection`.

The bottom `Switch` toggles on and off the event schedules. When the event schedules are toggled on, you cannot manipulate the rest of the UI — you need to turn off the events in order to change the event configuration.

Note that none of this information is persisted. This is a lightweight demo; it is expected that you are keeping this UI in the foreground while a test is running.

Defining and Scheduling the Job

The “job” is defined as an instance of `JobInfo`, typically created using an instance of `JobInfo.Builder` to configure a `JobInfo` using a fluent builder-style API. We teach the `JobInfo` the work to do and when to do it, then use a `JobScheduler` to actually schedule the job.

In the sample app, this work is mostly accomplished via a `manageJobScheduler()` method on the `MainActivity` class:

```
private void manageJobScheduler(boolean start) {
    if (start) {
        JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
            new ComponentName(this, DemoJobService.class));
        PersistableBundle pb=new PersistableBundle();

        if (download.isChecked()) {
            pb.putInt(KEY_DOWNLOAD_AS_AN_INT, 1);
            b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
        } else {
            b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
        }

        b.setPeriodic(getPeriod()).setPersisted(false)
            .setRequiresCharging(false).setRequiresDeviceIdle(true);

        jobs.schedule(b.build());
    }
    else {
        jobs.cancel(JOB_ID);
    }
}
```

The `start` parameter to `manageJobScheduler()` is driven by the bottom `Switch` widget. A `start` value of `true` means that we should start up the job; a value of `false` means that we should cancel any existing job.

If `start` is `true`, we begin by creating a `JobInfo.Builder`, supplying two key pieces of data:

- an `int` that will serve as the job ID, which needs to be unique to our app but does not have to be unique for the whole device
- a `ComponentName` identifying the `JobService` that will actually implement the work of the job itself

The primary way of passing data from the scheduling code (our activity) and the job-implementing code (`JobService`) is by means of a `PersistableBundle` – a `Bundle`-like object that can be persisted to disk. What we would like to do is pass a `boolean` in this `PersistableBundle` to indicate whether we should be downloading a file or not, based on the first `Switch` widget. Alas, for inexplicable reasons, [PersistableBundle does not offer accessors for a boolean](#). So, we settle for an `int`, where a non-zero value indicates that we want to download a file. Our `PersistableBundle` can have more data than just this one extra, though that is all

we need in this case. We attach the `PersistableBundle` to the `JobInfo` via the `setExtras()` method on the `JobInfo.Builder`.

We can also call methods on the `JobInfo.Builder` to configure the criteria that should be satisfied before giving us control. In our case, one criterion that we need is to have a network connection, but only if we are supposed to be downloading a file. So, we call `setRequiredNetworkType()` in either case, indicating that we either want ANY type of network connection (metered or unmetered) or NONE.

Other criteria-defining methods that we invoke include `setRequiresCharging()` (set to false to indicate we want control even if we are on battery) and `setRequiresDeviceIdle()` (set to true to indicate that we want control only if the user is not using it).

In the case of this sample, we want to do this work every so often, based upon the period chosen by the user in the bottom Spinner and retrieved via the `getPeriod()` method. So, we call `setPeriodic()` on the `JobInfo.Builder` to request getting control with that frequency, bearing in mind that this is merely a hint, not a requirement, and we may get control more or less frequently than this.

We also call `setPersisted(false)` to indicate that we do not need for this job to be persisted, so it will be lost on a reboot. If we instead called `setPersisted(true)`, the manifest would need to request the `RECEIVE_BOOT_COMPLETED` permission to have the job be re-created at boot time.

Finally, we call `schedule()` on a `JobScheduler` instance named `jobs` to schedule the job.

The `jobs` data member is populated up in `onCreate()` of the activity:

```
jobs=(JobScheduler)getSystemService(JOB_SCHEDULER_SERVICE);
```

While this may look like an ordinary request for a system service, it has one issue: your version of Android Studio may not know anything about it. In that case, this code will fail a Lint check, complaining that the service is not recognized. [This is a bug](#) that should be fixed in Android Studio 0.8.14. The workaround is to add `@SuppressWarnings("ResourceType")` to the method where you are making this `getSystemService()` call to suppress this Lint check.

If the start parameter to `manageJobScheduler()` is false, we call `cancel()` on the `JobScheduler`, passing in our unique job ID (`JOB_ID`) to indicate what job to cancel.

Or, we could have called `cancelAll()`, which would cancel all jobs scheduled by our application.

Implementing the Job

The work for the job itself is handled by a `JobService`. This is a subclass of `Service` that we, in turn, extend ourselves, overriding two job-specific callback methods to actually do the work: `onStartJob()` and `onStopJob()`.

The `JobService` in our sample app is `DemoJobService`:

```
package com.commonware.android.job;

import android.app.job.JobParameters;
import android.app.job.JobService;
import android.os.PersistableBundle;
import android.util.Log;

public class DemoJobService extends JobService {
    private volatile Thread job=null;

    @Override
    public boolean onStartJob(JobParameters params) {
        PersistableBundle pb=params.getExtras();

        if (pb.getInt(MainActivity.KEY_DOWNLOAD_AS_AN_INT, 0)==1) {
            job=new DownloadThread(params);
            job.start();

            return(true);
        }

        Log.d(getClass().getSimpleName(), "job invoked");

        return(false);
    }

    @Override
    synchronized public boolean onStopJob(JobParameters params) {
        if (job!=null) {
            Log.d(getClass().getSimpleName(), "job interrupted");
            job.interrupt();
        }

        return(false);
    }

    synchronized private void clearJob() {
        job=null;
    }
}
```

```
private class DownloadThread extends Thread {
    private final JobParameters params;

    DownloadThread(JobParameters params) {
        this.params=params;
    }

    @Override
    public void run() {
        Log.d(getClass().getSimpleName(), "job begins");
        new DownloadJob().run();
        Log.d(getClass().getSimpleName(), "job ends");
        clearJob();
        jobFinished(params, false);
    }
}
```

onStartJob() is passed a JobParameters. This serves both as a “handle” identifying a particular job invocation and giving us access to the job ID (getJobId()) and PersistableBundle of extras (getExtras()) that were set up by our JobInfo when we scheduled the job.

onStartJob() needs to return true if we have successfully forked a background thread to do the work, or false if no work needs to be done. In our case, this is determined by whether or not we want to try to download a file. In a production-grade app, this may be determined by whether there is any work to be done (e.g., “do we have entries in the upload queue?”).

In onStartJob(), we check the PersistableBundle to see if we are supposed to download a file. If we are, we fork a DownloadThread to do that work, then return true. Otherwise, we return false.

Because this sample app illustrates the difference in behavior between JobScheduler and AlarmService, we want to isolate the actual download-the-file logic into a common implementation that can be used from either code path. That takes the form of a DownloadJob, which implements Runnable and does the download work when it is run():

```
package com.commonware.android.job;

import android.net.Uri;
import android.os.Environment;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
```

```
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

class DownloadJob implements Runnable {
    static final Uri TO_DOWNLOAD=
        Uri.parse("https://commonsware.com/Android/excerpt.pdf");

    @Override
    public void run() {
        try {
            File root=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, TO_DOWNLOAD.getLastPathSegment());

            if (output.exists()) {
                output.delete();
            }

            URL url=new URL(TO_DOWNLOAD.toString());
            HttpURLConnection c=(HttpURLConnection)url.openConnection();

            FileOutputStream fos=new FileOutputStream(output.getPath());
            BufferedOutputStream out=new BufferedOutputStream(fos);

            try {
                InputStream in=c.getInputStream();
                byte[] buffer=new byte[8192];
                int len=0;

                while ((len=in.read(buffer)) >= 0) {
                    out.write(buffer, 0, len);
                }

                out.flush();
            }
            finally {
                fos.getFD().sync();
                out.close();
                c.disconnect();
            }
        }
        catch (IOException e2) {
            Log.e("DownloadJob", "Exception in download", e2);
        }
    }
}
```

DownloadThread delegates to DownloadJob to do the actual work. However, when the work is complete, it then calls `jobFinished()` on the `DemoJobService`.

`jobFinished()`, as the name suggests, tells the framework that we are finished doing the work associated with this job. If the job succeeded, we pass `false` as the second parameter, to indicate that this job does not need to be rescheduled. If, on the other hand, we were unable to actually do the work (e.g., we cannot connect to the desired server, perhaps due to server maintenance), we would pass `true` as the second parameter, to request that this job be rescheduled to be invoked again shortly, so that we can retry the operation.

Our `onStopJob()` method will be called by Android if environmental conditions have changed and we should stop the background work that we are doing. For example, we asked to do this work when the device was idle — if the user picks up the device and starts using it, we should stop our background work. In this case, if the job thread is still outstanding, we `cancel()` it. `onStopJob()` should return `true` if this job is still needed and should be retried, or `false` otherwise. Most short-period periodic jobs should return `false`, to just worry about the next job in the next period, and that is what `onStopJob()` does here. One-time jobs, or jobs with long periods (e.g., a day), may wish to return `true` to ensure that they will get another chance to do the desired work. We will cover more about this issue [later in this chapter](#).

Wiring in the Job Service

Since a `JobService` is a `Service`, we need the corresponding `<service>` element in the manifest. For a `JobService`, the `<service>` element is perfectly normal... with one exception:

```
<service
    android:name=".DemoJobService"
    android:permission="android.permission.BIND_JOB_SERVICE"
/>
```

You need to defend the service with the `BIND_JOB_SERVICE` permission. This only allows code that holds the `BIND_JOB_SERVICE` permission to start or bind to this service, which should limit it to the OS itself.

The Rest of the Sample

As noted earlier, the UI for our activity is a pair of `Spinner` widgets, along with a pair of `Switch` widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:useDefaultMargins="true">

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/type_label"
        android:layout_row="0"
        android:layout_column="0"/>

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/type"
        android:layout_row="0"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/period_label"
        android:layout_row="1"
        android:layout_column="0"/>

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/period"
        android:layout_row="1"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/download_label"
        android:layout_row="2"
        android:layout_column="0"/>

    <Switch
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/download"
        android:layout_row="2"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
```

```
        android:text="@string/scheduled_label"
        android:layout_row="3"
        android:layout_column="0"/>

        <Switch
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:id="@+id/scheduled"
            android:layout_row="3"
            android:layout_column="1"/>
    </GridLayout>
```

onCreate() of MainActivity sets up the UI, including populating the two Spinner widgets based on <string-array> resources and hooking up the activity to respond to changes in the checked state of the scheduled Switch widget:

```
@SuppressWarnings("ResourceType")
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.main);
    type=(Spinner)findViewById(R.id.type);

    ArrayAdapter<String> types=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.types));

    types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    type.setAdapter(types);

    period=(Spinner)findViewById(R.id.period);

    ArrayAdapter<String> periods=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.periods));

    periods.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    period.setAdapter(periods);

    download=(Switch)findViewById(R.id.download);
    scheduled=(Switch)findViewById(R.id.scheduled);
    scheduled.setOnCheckedChangeListener(this);

    alarms=(AlarmManager) getSystemService(ALARM_SERVICE);
    jobs=(JobScheduler) getSystemService(JOB_SCHEDULER_SERVICE);
}
```

When the user toggles the scheduled Switch widget, we examine the type Spinner and route control to a method dedicated for handling that particular type of periodic request, such as the `manageJobScheduler()` method we saw earlier in this chapter:

```
@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    toggleWidgets(!isChecked);

    switch(type.getSelectedItemPosition()) {
        case 0:
            manageExact(isChecked);
            break;

        case 1:
            manageInexact(isChecked);
            break;

        case 2:
            manageJobScheduler(isChecked);
            break;
    }
}
```

Our `onCheckedChanged()` for the schedule Switch also calls a `toggleWidgets()` method that enables or disables the other widgets, depending upon whether the schedule Switch is checked or unchecked:

```
private void toggleWidgets(boolean enable) {
    type.setEnabled(enable);
    period.setEnabled(enable);
    download.setEnabled(enable);
}
```

If the user had chosen an exact alarm, `onCheckedChanged()` routes control to `manageExact()`:

```
private void manageExact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleExactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}
```

It, in turn, routes control over to a PollReceiver, a WakefulBroadcastReceiver that is set up for handling our alarms:

```
package com.commonware.android.job;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;

public class PollReceiver extends WakefulBroadcastReceiver {
    static final String EXTRA_PERIOD="period";
    static final String EXTRA_IS_DOWNLOAD="isDownload";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        boolean isDownload=i.getBooleanExtra(EXTRA_IS_DOWNLOAD, false);
        startWakefulService(ctxt,
            new Intent(ctxt, DemoScheduledService.class)
                .putExtra(EXTRA_IS_DOWNLOAD, isDownload));

        long period=i.getLongExtra(EXTRA_PERIOD, -1);

        if (period>0) {
            scheduleExactAlarm(ctxt,
                (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE),
                period, isDownload);
        }
    }

    static void scheduleExactAlarm(Context ctxt, AlarmManager alarms,
                                   long period, boolean isDownload) {
        Intent i=new Intent(ctxt, PollReceiver.class)
            .putExtra(EXTRA_PERIOD, period)
            .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        alarms.setExact(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime()+period, pi);
    }

    static void scheduleInexactAlarm(Context ctxt, AlarmManager alarms,
                                     long period, boolean isDownload) {
        Intent i=new Intent(ctxt, PollReceiver.class)
            .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        alarms.setInexactRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime()+period, period, pi);
    }
}
```

```
static void cancelAlarm(Context ctxt, AlarmManager alarms) {  
    Intent i=new Intent(ctxt, PollReceiver.class);  
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);  
  
    alarms.cancel(pi);  
}  
}
```

This sample app has a `targetSdkVersion` of 21. Hence, on Android 5.0 devices — the ones that have `JobScheduler`, we cannot set up exact repeating alarms. Our only option is to handle the repeating work ourselves.

Hence, `scheduleExactAlarm()` creates a broadcast `PendingIntent`, on an `Intent` pointing at our `PollReceiver`, with a pair of extras indicating the polling period and whether or not we should be downloading a file. It then uses `setExact()` on an `AlarmManager` to schedule a *one-off* event to occur one polling period from now.

That, in turn, will trigger `onReceive()` of the `PollReceiver`. Here, we call `startWakefulService()` to have our work be done by a `DemoScheduledService`. In addition, if we have a polling period, that means that this is an exact alarm, and we call `scheduleExactAlarm()` to set up the next occurrence of this “repeating” event.

`DemoScheduledService` is simply an `IntentService` wrapper around the `DownloadJob` that we used with `DemoJobService`, logging the fact that it ran and calling `completeWakefulIntent()` to indicate that the work initiated by the `WakefulBroadcastReceiver` was done.

`cancelAlarm()` on `PollReceiver` — called by `manageExact()` when we are stopping the repeating event — creates an equivalent `PendingIntent` to the ones used for the `AlarmManager` events, and uses that with `cancel()` on `AlarmManager` to cancel those events.

If the user had chosen an exact alarm, `onCheckedChanged()` routes control to `manageInexact()`:

```
private void manageInexact(boolean start) {  
    if (start) {  
        long period=getPeriod();  
  
        PollReceiver.scheduleInexactAlarm(this, alarms, period,  
            download.isChecked());  
    }  
    else {  
        PollReceiver.cancelAlarm(this, alarms);  
    }  
}
```

```
}  
}
```

It uses the same recipe as `manageExact()`, except that it calls `scheduleInexactAlarm()` on `PollReceiver`. `scheduleInexactAlarm()`, in turn, uses `setInexactRepeating()` on `AlarmManager` to arrange to get control every so often.

Pondering Backoff Criteria

Sometimes, even with the Internet-availability checks offered by `JobScheduler`, you find that you cannot actually do the job you scheduled. Perhaps the server is down for maintenance, or has been replaced by [a honeycomb frame](#), or something. In this case, while you failed to do the job now, you may want to try again later.

Sometimes, “later” can just be handled by your existing `JobScheduler` setup. If the job in question is a periodic job, and missing a whole period is not a big problem, you might just continue on normally.

However, sometimes you will want the job to be retried, either because:

- it was a one-shot job, not a periodic one, or
- the period of the job is fairly long (e.g., once per day) and you want to retry well before the job is scheduled to happen again

Requesting that a job be retried is handled by the boolean parameter to `jobFinished()` or the boolean return value from `onStopJob()`. `true` means that you want the job to be rescheduled; `false` means that it is OK to skip the job entirely.

Given that you use `true` for either `jobFinished()` or `onStopJob()`, there are three possible options for how to request and retry a failed job:

- What happens for a job which you requested only run when the device is idle
- What happens for other jobs by default
- How you can influence the timing of when the job is retried, known as the “backoff criteria”

Idle Jobs

If you requested idle-only jobs, if the user wakes up the device while the job is going on, you will be called with `onStopJob()`. Ideally, you then stop the background work

and return true or false from `onStopJob()` to determine if the job should be rescheduled.

If you request a job be rescheduled, when that job is set up to only run when the device is idle, the job is simply “put back in the queue” to be tried again during the next idle window.

Default Behavior

If, for a non-idle-only job, you use true for `jobFinished()` or `onStopJob()`, the next time to try will be calculated using the default backoff criteria, which has a time of 30 seconds and a policy of `BACKOFF_POLICY_EXPONENTIAL`.

What this means is that the first time you use true, your job will be tried again 30 seconds later. If you use true again for that job, it will be tried again 60 seconds later. If you use true again, it would be tried 120 seconds later — in other words, each job failure will reschedule using the formula $2^{(n-1)} \cdot t$, where n is the number of failures and t is 30 seconds.

However, there is a cap of 18,000,000 milliseconds, or what normal people would refer to as “5 hours”. That is the most your job will be delayed, regardless of how many failures you have.

Custom Backoff Criteria

You can change the backoff criteria for non-idle-only jobs via a call to `setBackoffCriteria()` on your `JobInfo.Builder`, where you provide your own time (measured in milliseconds) and policy (`BACKOFF_POLICY_EXPONENTIAL` or `BACKOFF_POLICY_LINEAR`).

As noted above, the formula for exponential backoff rescheduling is $2^{[sup>n-1</sup]}t$, where n is the number of failures and t is your chosen time.

The formula for linear backoff rescheduling is $n \cdot t$, where n is the number of failures and t is your chosen time.

Other JobScheduler Features

There are a few other options for scheduling jobs that may be of use to you in select circumstances:

- `JobInfo.Builder` has `setOverrideDeadline()`, which indicates a maximum delay for this job before it will be executed even if other criteria (e.g., idleness) have been met. Note that this is only available on one-shot jobs, not periodic jobs.
- The `JobParameters` passed to `onStartJob()` has an `isOverrideDeadlineExpired()` method. This will return `true` if the job was executed early due to a `setOverrideDeadline()` value being met. This will indicate to you that your requirements may not be met (e.g., Internet access) and you will need to double-check those things yourself.
- `JobInfo.Builder` has `setMinimumLatency()` which sets a minimum delay time; the job will not be considered until at least this amount of time has elapsed. Note that this is only available on one-shot jobs, not periodic jobs.

Also, `JobScheduler` has a `getAllPendingJobs()` method, that returns a `List` of `JobInfo` objects representing “the jobs registered by this package that have not yet been executed”. Presumably, this includes the next occurrence of any periodic jobs and any jobs that are blocked pending a backoff delay, though the documentation is unclear on this point.

Push Notifications with GCM

[Google Cloud Messaging](#) – GCM for short — is Google’s current framework for asynchronously delivering notifications from the Internet (“cloud”) to Android devices. Rather than the device waking up and polling on a regular basis at the behest of your app, your app can register for notifications and then wait for them to arrive. GCM is engineered with power savings in mind, aiming to minimize the length of time 3G radios are exchanging data.

The proper use of GCM means better battery life for your users. It can also reduce the amount of time your code runs, which helps you stay out of sight of users looking to pounce on background tasks and eradicate them with task killers.

GCM replaces C2DM (“cloud to device messaging”) as Google’s push framework for Android. While C2DM is still in operation, it is accepting no new developer registrations. New development should use GCM; apps already using C2DM should plan to cut over to GCM as soon as is practical.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- [broadcast Intents](#)
- [service theory](#)
- [AlarmManager](#) (though mostly for the discussion of `WakefulIntentService`)

The Precursor: C2DM

C2DM debuted in 2010 as a way for apps to receive “push” messages: messages sent to it from “the cloud” by the app developer’s server. It quickly became popular, for everything from triggering near-real-time data synchronization (e.g., Remember the Milk to-do list updates) to lightweight coordination between multiple players in a game.

However, C2DM was a Google Labs product and in perpetual beta form. When Google Labs was shut down, C2DM was in limbo: not canceled, but not converted into an actual product. Most likely, that was because while they knew the concept was sound, they wanted to tweak the implementation and APIs and were not ready with its replacement just yet.

The Replacement: GCM

GCM replaced C2DM in 2012, with C2DM moving into a deprecated state, continuing to function but accepting no new applications.

GCM follows the same basic structure as C2DM, with the app registering for messages, and the developer’s server sending messages to the app via a Google-supplied Web service interface. Hence, apps written to use C2DM should migrate over to GCM without significant architectural changes.

GCM raises the 1KB limit for the message to 4KB. It also simplifies the server side, by replacing a fairly clunky authentication model with a “Simple API Key” and lifting quotas that had hamstrung popular C2DM-enabled apps. Also, if the same message needs to be delivered to multiple devices, GCM can send to up to 1,000 at a time, whereas C2DM was limited to a one-device-per-Web-service-call model.

As a result, GCM provides the benefits of C2DM without some of the annoying limitations. That being said, GCM is not perfect, and we will examine some of the limitations that remain [later in this chapter](#).

The Re-Replacement: GCM 2013

At Google I/O 2013, Google debuted a substantial update to GCM. The update enables a handful of new features, most notably an upstream messaging option, so devices can “push” messages to servers just as servers can push messages to clients.

Along the way, Google:

- Added a dependency to the Play Services SDK library project
- Deprecated a JAR containing code that you need, in one form or fashion, to write GCM-enabled apps, forcing you to basically rewrite lots of that JAR from scratch or “forward-port” the old implementation
- Further weakened their documentation, including all but eliminating any discussion of actual server implementations

The Pieces of Push

There are many components that you will need to work with in order to enable GCM in your app, both inside the app itself and in your app server (or other off-app environment) where you are trying to push messages to the app.

A Suitable Android Environment

GCM is part of Play Services. That means that you probably want to test your app on hardware that legitimately has the Play Store on it. Some emulator images, offering “Google APIs”, may have a copy of Play Services on it, though this can sometimes be out of date or otherwise buggy.

API Key

Since GCM is a Google service, you need a Google API key to use it. To get one of these:

1. Log into <https://cloud.google.com/console> with your Google account
2. In the navigation on the left, go into “APIs & auth > APIs”
3. Find “Google Cloud Messaging for Android” and click the “OFF” button next to it (note: this might involve then agreeing to additional terms of service)
4. In the navigation on the left, go into “APIs & auth > Registered apps”
5. Click the red REGISTER APP button.
6. Give the app a name and choose Web Application, then click Register
7. Click the “Server Key” section for your server key

To confirm that your API key works, if you have [the curl program](#), the `gcmtest` script in the [Push/GCMClient](#) sample project will help you confirm that the API key works. Run `gcmtest`, with your API key as a parameter. If you get something like the following, your API key is good:

```
{ "multicast_id":7932441338082226994,  
  "success":0,  
  "failure":1,  
  "canonical_ids":0,  
  "results":[{"error":"InvalidRegistration"}]}
```

If, instead, you get an HTTP 401 error, then your API key is flawed in some way.

Play Services Framework

In the initial incarnation of GCM, the scaffolding for your client-side code came in the form of a JAR, accompanied by source code, shipped as part of the “Google Cloud Messaging for Android Library” entry in the SDK Manager.

The 2013 update to GCM officially deprecated that JAR, in favor of a new `GoogleCloudMessaging` object from the Play Services SDK.

Android Studio users should install the “Google Repository” entry in the SDK Manager. At that point, you can add a dependency upon the `com.google.android.gms:play-services-base` artifact for some appropriate version, such as `com.google.android.gms:play-services-base:6.5.87`.

Eclipse users will need to install the “Google Play services” entry in the SDK Manager, then add to your project a reference to the Android library project found in the `extras/google/google_play_services/libproject/google-play-services_lib/` directory in your Android SDK installation.

You will find reference to an older “Google Cloud Messaging for Android Library” in the SDK Manager. Nowadays, it will only appear there if you have the “Obsolete” checkbox checked. This is the original, pre-Play Services library for accessing GCM. The sample GCM client app profiled in this book demonstrates how some of that old code can be blended in with some of the new Google-supplied GCM samples to create a framework that minimizes the amount of GCM-specific code needed in your app. However, since the sample project contains all of the forked code, you do not need this library, unless you are maintaining some legacy GCM code that still uses it.

Android App

Beyond the aforementioned library, your application using GCM has several requirements that you must meet, outlined in the following sections.

Custom Permission

Your application needs to define a custom permission, whose name is your application's package name with `.permission.C2D_MESSAGE` appended to the end. So, for an app residing in the `com.commonware.android.gcm.client` package, the permission to be defined is:

```
<permission
  android:name="com.commonware.android.gcm.client.permission.C2D_MESSAGE"
  android:protectionLevel="signature"/>
```

You also need the corresponding `<uses-permission>` element:

```
<uses-permission
  android:name="com.commonware.android.gcm.client.permission.C2D_MESSAGE"/>
```

This is all rather odd, considering that nothing else in your project seems to refer to this permission. Also, it is not required if you are only supporting API Level 16 and higher (i.e., your `android:minSdkVersion` is set to at least 16).

Additional Permissions

There are several other permissions that you need to hold:

```
<uses-permission android:name="com.google.android.c2dm.permission.RECEIVE"/>
<uses-permission android:name="android.permission.INTERNET"/>
<uses-permission android:name="android.permission.GET_ACCOUNTS"/>
<uses-permission android:name="android.permission.WAKE_LOCK"/>
```

The first allows you to receive messages from GCM, though it uses `c2dm` in the name for backwards compatibility with C2DM. The second allows your GCM library to access the Internet, while the third allows your GCM library to access information about your Google account. The last permission allows you to hold a `WakeLock` to keep the device awake for a bit — we will use this with a `WakefulIntentService` to process incoming messages.

Your Registration Code

Your app will need to use the static `register()` method on the `GoogleCloudMessaging` class supplied by the Play Services SDK to register with GCM and create a registration ID. That ID, in turn, will be used by your server code to uniquely identify a copy of your app running on a specific device. Messages sent by your server to that registration ID will be delivered to your app on that device.

`register()` is a blocking call, doing network I/O, so you will want to register on a background thread, such as an `AsyncTask`.

You will need to send that registration ID to your server — or whatever else will be pushing messages — by some means. A typical implementation would have your app call some Web service of yours to hand over the registration ID, perhaps tying it to some user account on your Web server. This sort of network I/O also should be done in a background thread.

Your registration ID is good until you update your app to a new version, as determined via its `android:versionCode` in the manifest. Since `register()` will generate a new registration ID each time, you will want to cache the registration ID until such time as you ship a new version of the app, at which time you will need to generate a fresh ID. Google's [sample code in their documentation](#) demonstrates this.

Google's sample code also deals with the scenario in which your server somehow loses the registration ID, generating a fresh registration ID every week. Whether this is truly necessary, or whether you want to do something else to deal with this use case, is up to you.

You can place this code wherever makes sense, such as your launcher activity.

Of course, pretty much all of this used to be handled for us by Google's GCM client library. They deprecated that library and failed to replace it in the 2013 updates to GCM. The sample app, presented later in this chapter, will show some replacement code for that library, synthesized from the old library source code and the newer GCM samples.

GCM BroadcastReceiver

You will need to implement a `BroadcastReceiver` that will get control when messages are received that have been pushed to the device. Specifically:

- The receiver should be registered in the manifest, as push messages can be delivered at any point in time
- The receiver must have an `<intent-filter>` with an `<action>` of `com.google.android.c2dm.intent.RECEIVE` and a `<category>` whose value is the package name of your app
- The receiver should require the `com.google.android.c2dm.permission.SEND` permission, to prevent other apps from spoofing push messages

You will wind up with a `<receiver>` element reminiscent of the following:

```
android:theme="@style/AppTheme">
<activity android:name=".MainActivity">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

The Intent that comes into your receiver's `onReceive()` method will represent a push message from your server, or possibly a system message. You can call `getMessageType()` on a `GoogleCloudMessaging` instance to help decipher what sort of event occurred:

- `GoogleCloudMessaging.MESSAGE_TYPE_SEND_ERROR` means that some error occurred
- `GoogleCloudMessaging.MESSAGE_TYPE_DELETED` means that too many messages had been queued up for your app on this device (e.g., due to a protracted period of being in airplane mode), and some were deleted
- `GoogleCloudMessaging.MESSAGE_TYPE_MESSAGE` means that the Intent is an actual push message from the server

The extras Bundle that is part of the Intent (retrieved via `getExtras()`) will have name-value pairs supplied by your server, representing whatever data the server wanted to push to your app on this device.

It is up to you to do something useful with these events. However, `onReceive()` of a manifest-registered `BroadcastReceiver` is a precarious place:

- You are running on the main application thread, so you cannot take much time
- You cannot do much of anything that lives beyond the end of `onReceive()`, such as forking a thread, as Android can terminate your process at will once `onReceive()` returns

Hence, a typical pattern is for the receiver to delegate the message to an `IntentService` for actual processing. And, once again, this used to be done for you by the GCM client library, which supplied a stock `BroadcastReceiver` and a base `IntentService` class that you could use. The sample app profiled in this chapter includes replacements for those now-lost classes.

Your Server (a.k.a., the Thing Doing the Pushing)

Something, outside of your app, is going to be pushing messages to devices that are running your app and registered for such messages. In the GCM documentation, this is referred to as your “server”.

Technically speaking, this does not have to be a “server”: something running constantly with some sort of inbound socket connection. To actually push messages, you will need Internet access to Google’s servers, but whether you push the message from a true server, or a desktop app, or a command-line program, is really up to you.

The classic mode for sending push messages to the device involves your server using HTTP and a REST protocol to hand the messages to Google’s servers, which in turn forward the messages to devices. There is also a new Cloud Connection Service option that uses XMPP instead of HTTP, to avoid creating and tearing down sockets quite so frequently. Cloud Connection Service will be discussed [later in this chapter](#).

GCM supplies a “server” JAR file that handles the REST protocol and gives you Java objects for building and sending the message. This JAR file has an undocumented dependency on the `json-simple` library. If your desired “server” environment is not in Java, you could re-implement the REST protocol library in some other programming language (e.g., Ruby) if desired. The GCM documentation [describes the request and response formats](#) that your library would need to handle.

For simplicity, the sample app for this chapter will demonstrate a crude command-line Java client, based upon the GCM “server” JAR, rather than expecting you to run some Java-capable Web server just to experiment with GCM.

Google’s Server and the Google Services Framework

One piece of the environment that you do not control is Google’s GCM server farm. When you send a message to the clients, you do not do so directly, but rather you send your message to Google by means of a REST-style Web service (or XMPP using the Cloud Connection Service). Google, in turn, forwards your messages along to the clients. Google supplies a JAR file that you can use on your server, or you could implement the REST-style interface in other ways, using anything from `curl` to a Ruby gem, if you so choose.

Each device maintains a long-running persistent socket connection to Google’s GCM server farm. When your server sends a message, it passes the message to Google’s GCM server farm, which finds the connection to the client(s) and sends along the

message. If a client is unavailable for some reason, the GCM servers will cache your message for a period of time in hopes of being able to deliver it shortly.

The fact that Google servers have your message for any length of time introduces some privacy and security issues, which we will examine [later in this chapter](#).

A Simple Push

With all this in mind, we can walk through an example of implementing GCM. This sample comes in two parts:

1. An app that runs on the Android device that uses GCM
2. A command-line Java app that can send messages via GCM, useful for light testing

The Client

Our client-side Android app can be found in the [Push/GCMClient2](#) sample project. |

Our manifest has all the things outlined earlier in this chapter, including the custom permission, all those other permission elements, and a suitably-configured BroadcastReceiver:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.gcm.client"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="13"
        android:targetSdkVersion="17"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"
        android:xlargeScreens="true"/>

    <!--
    <permission
        android:name="com.commonware.android.gcm.client.permission.C2D_MESSAGE"
        android:protectionLevel="signature"/>

    <uses-permission
        android:name="com.commonware.android.gcm.client.permission.C2D_MESSAGE"/>
    -->
```

```
<permission
  android:name="${applicationId}.permission.C2D_MESSAGE"
  android:protectionLevel="signature" />
<uses-permission
  android:name="${applicationId}.permission.C2D_MESSAGE" />

<uses-permission android:name="com.google.android.c2dm.permission.RECEIVE"/>
<uses-permission android:name="android.permission.INTERNET"/>
<uses-permission android:name="android.permission.GET_ACCOUNTS"/>
<uses-permission android:name="android.permission.WAKE_LOCK"/>

<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme">
  <activity android:name=".MainActivity">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>

  <receiver
    android:name="GCMBroadcastReceiverCompat"
    android:permission="com.google.android.c2dm.permission.SEND">
    <intent-filter>
      <action android:name="com.google.android.c2dm.intent.RECEIVE"/>

      <category android:name="${applicationId}" />
    </intent-filter>
  </receiver>

  <service android:name=".GCMIntentService"/>

  <meta-data
    android:name="com.google.android.gms.version"
    android:value="@integer/google_play_services_version"/>
</application>

</manifest>
```

The rest of the app is made up of an activity (MainActivity) and an IntentService (GCMIntentService) that represent the app’s “business logic”, plus three additional classes that represent a partial replacement for the code from the deprecated GCM client JAR.

The Activity

MainActivity has a highly sophisticated user interface, consisting of one really large “Register me!” button. The objective of the UI is simply to register the app with GCM, so that you can test sending messages to your app on the test device.

To do this, MainActivity has GCM-related hooks in onCreate() and the onClick() handler being used for the Button:

```
package com.commonsware.android.gcm.client;

import android.app.Activity;
import android.content.Context;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.Toast;

public class MainActivity extends Activity {
    static final String SENDER_ID="this is so fake"; // change
                                                    // me!

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        GCMRegistrarCompat.checkDevice(this);

        if (BuildConfig.DEBUG) {
            GCMRegistrarCompat.checkManifest(this);
        }
    }

    public void onClick(View v) {
        final String regId=GCMRegistrarCompat.getRegistrationId(this);

        if (regId.length() == 0) {
            new RegisterTask(this).execute(SENDER_ID);
        }
        else {
            Log.d(getClass().getSimpleName(), "Existing registration: "
                + regId);
            Toast.makeText(this, regId, Toast.LENGTH_LONG).show();
        }
    }

    private static class RegisterTask extends
        GCMRegistrarCompat.BaseRegisterTask {

        RegisterTask(Context context) {
```

PUSH NOTIFICATIONS WITH GCM

```
    super(context);  
}  
  
@Override  
public void onPostExecute(String regid) {  
    Log.d(getClass().getSimpleName(), "registered as: " + regid);  
    Toast.makeText(context, regid, Toast.LENGTH_LONG).show();  
}  
}
```

Specifically:

- onCreate() calls checkDevice() and checkManifest() static methods on a GCMRegistrarCompat class
- onClick() tries to retrieve the current registration ID via a call to the static getRegistrationId() method on GCMRegistrarCompat, then kicks off a RegisterTask subclass of GCMRegistrarCompat.BaseRegisterTask if we do not have a current valid registration ID

The SENDER_ID value, as is noted in the code comment, needs to be replaced with *your* sender ID. This is referred to as the “project number” in the Google Developers Console:

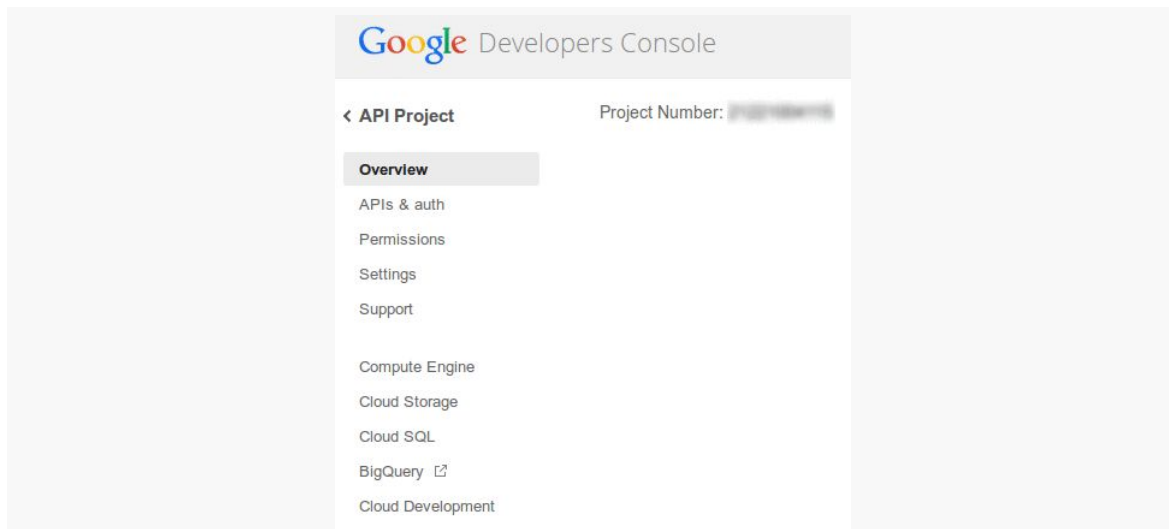

Figure 682: Google Developers Console, Showing Project Number (a.k.a., Sender ID)

GCMRegistrarCompat

The deprecated GCM client JAR contained a class named GCMRegistrar that handled:

- the communication to the GCM servers for the actual registration process, and
- caching the registration ID on the device, until such time as it was known to be invalid (e.g., after an app version upgrade)

Since that JAR is deprecated, but we still need to do this work, this project contains GCMRegistrarCompat, which incorporates some of the original GCMRegistrar logic, updated to use the new GoogleCloudMessaging interface. And, as one might expect, the resulting code is a bit nasty.

The checkDevice() method is simple enough, simply throwing an UnsupportedOperationException if the device is not running at least API Level 8:

```
public static void checkDevice(Context context) {
    int version=Build.VERSION.SDK_INT;
    if (version < 8) {
        throw new UnsupportedOperationException(
            "Device must be at least "
            + "API Level 8 (instead of "
            + version + ")");
    }
}
```

The checkManifest() method makes heavy use of PackageManager to validate:

- That you have defined the custom permission
- That there is a receiver listening for GCM broadcasts and requiring the GCM permission

```
public static void checkManifest(Context context) {
    PackageManager packageManager=context.getPackageManager();
    String packageName=context.getPackageName();
    String permissionName=packageName + ".permission.C2D_MESSAGE";
    // check permission
    try {
        packageManager.getPermissionInfo(permissionName,
            PackageManager.GET_PERMISSIONS);
    }
    catch (NameNotFoundException e) {
        throw new IllegalStateException(
            "Application does not define permission "
            + permissionName);
    }
}
```

```
}
// check receivers
PackageInfo receiversInfo;
try {
    receiversInfo=
        packageManager.getPackageInfo(packageName,
                                      PackageManager.GET_RECEIVERS);
}
catch (NameNotFoundException e) {
    throw new IllegalStateException(
        "Could not get receivers for package "
        + packageName);
}
ActivityInfo[] receivers=receiversInfo.receivers;
if (receivers == null || receivers.length == 0) {
    throw new IllegalStateException("No receiver for package "
        + packageName);
}
if (Log.isLoggable(TAG, Log.VERBOSE)) {
    Log.v(TAG, "number of receivers for " + packageName + ": "
        + receivers.length);
}
Set<String> allowedReceivers=new HashSet<String>();
for (ActivityInfo receiver : receivers) {
    if (PERMISSION_GCM_INTENTS.equals(receiver.permission)) {
        allowedReceivers.add(receiver.name);
    }
}
if (allowedReceivers.isEmpty()) {
    throw new IllegalStateException("No receiver allowed to receive "
        + PERMISSION_GCM_INTENTS);
}
checkReceiver(context, allowedReceivers, INTENT_FROM_GCM_MESSAGE);
}

private static void checkReceiver(Context context,
                                  Set<String> allowedReceivers,
                                  String action) {
    PackageManager pm=context.getPackageManager();
    String packageName=context.getPackageName();
    Intent intent=new Intent(action);
    intent.setPackage(packageName);
    List<ResolveInfo> receivers=
        pm.queryBroadcastReceivers(intent,
                                   PackageManager.GET_INTENT_FILTERS);
    if (receivers.isEmpty()) {
        throw new IllegalStateException("No receivers for action "
            + action);
    }
    if (Log.isLoggable(TAG, Log.VERBOSE)) {
        Log.v(TAG, "Found " + receivers.size() + " receivers for action "
            + action);
    }
}
// make sure receivers match
```

PUSH NOTIFICATIONS WITH GCM

```
for (ResolveInfo receiver : receivers) {
    String name=receiver.activityInfo.name;
    if (!allowedReceivers.contains(name)) {
        throw new IllegalStateException("Receiver " + name
            + " is not set with permission " + PERMISSION_GCM_INTENTS);
    }
}
```

GCMRegistrarCompat offers three public methods for working with the registration ID:

- `getRegistrationId()` will return the registration ID saved in `SharedPreferences`, if it exists, if the app version is the same as before, and if the registration is not expired
- `clearRegistrationId()` simply wipes out the saved registration ID, if there is one
- `setRegistrationId()` updates `SharedPreferences` with a newly-retrieved registration ID, also saving the app version

```
public static String getRegistrationId(Context context) {
    final SharedPreferences prefs=getGCMPreferences(context);
    String registrationId=prefs.getString(PROPERTY_REG_ID, "");
    // check if app was updated; if so, it must clear
    // registration id to
    // avoid a race condition if GCM sends a message
    int oldVersion=
        prefs.getInt(PROPERTY_APP_VERSION, Integer.MIN_VALUE);
    int newVersion=getAppVersion(context);
    if (oldVersion != Integer.MIN_VALUE && oldVersion != newVersion) {
        Log.v(TAG, "App version changed from " + oldVersion + " to "
            + newVersion + "; resetting registration id");
        clearRegistrationId(context);
        registrationId="";
    }
    else if (isRegistrationExpired(context)) {
        Log.v(TAG, "Registration expired; resetting registration id");
        clearRegistrationId(context);
        registrationId="";
    }
    return registrationId;
}

public static String clearRegistrationId(Context context) {
    return setRegistrationId(context, "");
}

private static String setRegistrationId(Context context, String regId) {
    final SharedPreferences prefs=getGCMPreferences(context);
    String oldRegistrationId=prefs.getString(PROPERTY_REG_ID, "");
    int appVersion=getAppVersion(context);
```

PUSH NOTIFICATIONS WITH GCM

```
long expirationTime=
    System.currentTimeMillis() + REGISTRATION_EXPIRY_TIME_MS;
Editor editor=prefs.edit();

editor.putString(PROPERTY_REG_ID, regId);
editor.putInt(PROPERTY_APP_VERSION, appVersion);
editor.putLong(PROPERTY_ON_SERVER_EXPIRATION_TIME, expirationTime);
editor.commit();

return oldRegistrationId;
}

private static int getAppVersion(Context context) {
    try {
        PackageInfo packageInfo=
            context.getPackageManager()
                .getPackageInfo(context.getPackageName(), 0);
        return packageInfo.versionCode;
    }
    catch (NameNotFoundException e) {
        // should never happen
        throw new RuntimeException("Could not get package name: " + e);
    }
}

private static boolean isRegistrationExpired(Context context) {
    final SharedPreferences prefs=getGCMPreferences(context);
    // checks if the information is not stale
    long expirationTime=
        prefs.getLong(PROPERTY_ON_SERVER_EXPIRATION_TIME, -1);
    return System.currentTimeMillis() > expirationTime;
}

private static SharedPreferences getGCMPreferences(Context context) {
    return context.getSharedPreferences(PREFERENCES,
        Context.MODE_PRIVATE);
}
```

GCMRegistrarCompat also has a public static inner class, BaseRegisterTask, that handles calling register() on a GoogleCloudMessaging instance on a background thread, calling setRegistrationId() to save the resulting value for later use, plus calling sendRegistrationIdToServer() on that same background thread:

```
static public class BaseRegisterTask extends
    AsyncTask<String, Void, String> {
    protected Context context=null;

    BaseRegisterTask(Context context) {
        this.context=context;
    }

    @Override
```

PUSH NOTIFICATIONS WITH GCM

```
protected String doInBackground(String... params) {
    GoogleCloudMessaging gcm=
        GoogleCloudMessaging.getInstance(context);
    String regid=null;

    try {
        regid=gcm.register(params[0]);
        setRegistrationId(context, regid);
        sendRegistrationIdToServer(regid);
    }
    catch (IOException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    }

    return(regid);
}

protected void sendRegistrationIdToServer(String regid) {
    // no-op -- subclasses should override and send
    // registration id to server by some means
}

// override this to do something more, note that it
// is called on a background thread!

protected void onError(IOException e) {
    Log.e(getClass().getSimpleName(),
        "Exception registering for GCM", e);
}
}
```

You can elect to override `sendRegistrationIdToServer()` to actually send the registration ID to your Web service or other source of push messages, by whatever means you feel is appropriate. As it is called on a background thread, you will be able to do network I/O without freezing the UI. There is also an `onError()` method that you can elect to override, if desired, to handle any unexpected `IOExceptions` that may be raised while trying to contact the GCM server.

GCMBroadcastReceiverCompat

The `BroadcastReceiver` that we have receiving GCM broadcasts, named `GCMBroadcastReceiverCompat`, serves in a role similar to `GCMBroadcastReceiver` from the original GCM client JAR. It forwards the received broadcasts along to a service for processing, so that work can more easily be done in a background thread.

Since we have no guarantee that the device is going to stay awake very long, this is a fine use case for the `WakefulIntentService` profiled [earlier in the book](#):

PUSH NOTIFICATIONS WITH GCM

```
package com.commonware.android.gcm.client;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class GCMBroadcastReceiverCompat extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        intent.setClass(context, GCMIntentService.class);

        WakefulIntentService.sendWakefulWork(context, intent);
    }
}
```

To get the broadcasted Intent over to the service, we simply call `setClass()` on the Intent, identifying our service (`GCMIntentService`). This way, it does not matter what action is on the Intent, as we are specifying the component that this Intent should be delivered to.

If your app is going to do something fairly cheap when a message comes in, though, you are welcome to just do it in the `BroadcastReceiver` itself. Here, “fairly cheap” means “can be done in just a few milliseconds”, and so disk or network I/O should be delegated to a service with a background thread.

GCMBaseIntentServiceCompat

The deprecated GCM client JAR offered a `GCMBaseIntentService` class that you could extend, where `GCMBaseIntentService` would call dedicated methods on your subclass, like `onMessage()`, for the different sorts of events that could arrive via the forwarded broadcast. `GCMBaseIntentServiceCompat` is a `WakefulIntentService` that offers similar behavior:

```
package com.commonware.android.gcm.client;

import android.content.Intent;
import com.commonware.cwac.wakeful.WakefulIntentService;
import com.google.android.gms.gcm.GoogleCloudMessaging;

abstract public class GCMBaseIntentServiceCompat extends
    WakefulIntentService {
    abstract protected void onMessage(Intent message);

    abstract protected void onError(Intent message);

    abstract protected void onDeleted(Intent message);
}
```

```
public GCMBaseIntentServiceCompat(String name) {
    super(name);
}

@Override
protected void doWakefulWork(Intent i) {
    GoogleCloudMessaging gcm=GoogleCloudMessaging.getInstance(this);
    String messageType=gcm.getMessageType(i);

    if (GoogleCloudMessaging.MESSAGE_TYPE_SEND_ERROR.equals(messageType)) {
        onError(i);
    }
    else if (GoogleCloudMessaging.MESSAGE_TYPE_DELETED.equals(messageType)) {
        onDeleted(i);
    }
    else {
        onMessage(i);
    }
}
}
```

Inside of `doWakefulWork()`, we use a `GoogleCloudMessaging` instance to examine the message type of the received broadcast. Depending upon whether it is `MESSAGE_TYPE_SEND_ERROR`, `MESSAGE_TYPE_DELETED`, or a regular message, drives calls to the abstract `onError()`, `onDeleted()`, and `onMessage()` methods, respectively.

The Service

Our service, named `GCMIntentService`, extends `GCMBaseIntentServiceCompat` and overrides the three abstract methods (`onMessage()`, `onError()`, `onDeleted()`):

```
package com.commonware.android.gcm.client;

import android.content.Intent;
import android.os.Bundle;
import android.util.Log;

public class GCMIntentService extends GCMBaseIntentServiceCompat {
    public GCMIntentService() {
        super("GCMIntentService");
    }

    @Override
    protected void onMessage(Intent message) {
        dumpEvent("onMessage", message);
    }

    @Override
    protected void onError(Intent message) {
        dumpEvent("onError", message);
    }
}
```

```
}

@Override
protected void onDeleted(Intent message) {
    dumpEvent("onDeleted", message);
}

private void dumpEvent(String event, Intent message) {
    Bundle extras=message.getExtras();

    for (String key : extras.keySet()) {
        Log.d(getClass().getSimpleName(),
            String.format("%s: %s=%s", event, key,
                extras.getString(key)));
    }
}
}
```

Each simply passes the supplied Intent along to a `dumpEvent()` private method that iterates over all of the extras and writes them out to LogCat. This way, when we send a push message, we will be able to see in LogCat what information makes it over to the service.

The “Server”

Our command-line Java app for sending messages can be found in the [Push/GCMCommand](#) sample project. Note that this is a plain Java project, not an Android project, as this is designed to run on your desktop or server, not on your device. Also note that four total JARs are needed to run this app:

1. The project’s own JAR
2. `gcm-server.jar`, from the GCM portion of your SDK’s `extras/` area
3. `json-simple-1.1.jar`, a compatible implementation of the `json-simple` library used by the GCM JAR
4. `commons-cli-1.2.jar`, which is used for command-line argument processing for this app

From a GCM standpoint, the GCM class in this sample project has a static `sendMessage()` method that does the work of sending a message to one or more devices:

```
private static void sendMessage(String apiKey, List<String> devices,
    Properties data) throws Exception {
    Sender sender=new Sender(apiKey);
    Message.Builder builder=new Message.Builder();
```

```
for (Object o : data.keySet()) {
    String key=o.toString();

    builder.addData(key, data.getProperty(key));
}

MulticastResult mcResult=sender.send(builder.build(), devices, 5);

for (int i=0; i < mcResult.getTotal(); i++) {
    Result result=mcResult.getResults().get(i);

    if (result.getMessageId() != null) {
        String canonicalRegId=result.getCanonicalRegistrationId();

        if (canonicalRegId != null) {
            System.err.println(String.format("%s canonical ID = %s",
                                              devices.get(i),
                                              canonicalRegId));
        }
        else {
            System.out.println(String.format("%s success", devices.get(i)));
        }
    }
    else {
        String error=result.getErrorCodeName();

        if (Constants.ERROR_NOT_REGISTERED.equals(error)) {
            System.err.println(String.format("%s is unregistered",
                                              devices.get(i)));
        }
        else if (error != null) {
            System.err.println(String.format("%s error = %s",
                                              devices.get(i), error));
        }
    }
}
}
```

The pieces of information we need to send a message are:

- Our GCM API key
- A list of the device registration IDs to which GCM should deliver our message
- The key/value pairs of data that form our message payload

The [Apache Commons CLI](#) logic in this class' static main() method will extract these values from the command line and give them to sendMessage() for processing.

To send the message, sendMessage() first creates a GCM Sender object, supplying our API key to the constructor. Then, it creates a Message.Builder, which is a

PUSH NOTIFICATIONS WITH GCM

builder for constructing a GCM message to be sent by that Sender. We use `addData()` on the builder to attach our key/value pairs, extracted from the `java.util.Properties` object that Apache Commons CLI used to give us the key/value pairs specified on the command line.

Actually sending the message then is a matter of calling `send()` on the Sender, supplying the Message built by the builder, the list of device registration IDs, and the number of retries in case there are issues in delivering the message (e.g., the server farm is swamped). We get back a `MulticastResult` object, containing details of what happened for each device in our list of devices.

`MulticastResult` is really a collection of individual `Result` objects, one per device. Each `Result` will tell us what happened, with four major possibilities:

1. Our request to enqueue the message succeeded, and the device should receive it momentarily if it is online and connected to Google.
2. Our request succeeded, but Google would like us to use a different registration ID in the future. We are given the revised ID via `getCanonicalRegistrationId()`. In a production app, we would have some sort of database of registered devices; we would replace the old registration ID with the new canonical one in that database when this result occurs.
3. Our request failed, because the device is no longer registered (e.g., the app was uninstalled). In a production app, we should remove this device from our database.
4. Our request failed for some other reason (e.g., our request was attacked by ninjas). We get an error message as a string indicating the reason for the failure; a production app would log this somewhere.

In the case of this sample command-line client, these are simply logged to `stdout` or `stderr`.

The sample project has a Linux shell script that wraps up building Java command line:

```
java -cp libs/commons-cli-1.2.jar:libs/gcm-server.jar:libs/
json_simple-1.1.jar:dist/gcm-cmd.jar \
com.commonware.android.gcm.cmd.GCM "$@"
```

(note: once again, the trailing `\` on the first line indicates that this should be all on one line)

PUSH NOTIFICATIONS WITH GCM

To use the script, switch to the GCMCommand directory, run `./gcm`, supplying the following command-line switches:

- `-a` or `--apiKey` with the value of your API key (note: **not** your sender ID!)
- `-d` or `--device` with the value of a device's registration ID (can have one or several of these switches)
- `-D` or `--data`, with the key=value pair of some data to send to a device (can have one or several of these switches)

For example, this command would send `foo=bar` to a device:

```
./gcm -a your-api-key-here -D foo=bar -d your-device-reg-id-here
```

The results will be printed to standard output, one line per `-d` switch, in the order of the `-d` switches (e.g., first registration ID in the command maps to the first line in the output).

Message Options and Advanced Features

Most of what you get out of GCM comes just from the code we have implemented so far. However, there are other things you can configure with your message to tailor delivery behavior. These come in the form of special key/value pairs added to the message payload itself, serving in the role of metadata. Note that since they elected to blend the metadata in with your data, you cannot yourself have data with the same keys as are used by Google for metadata. And, unfortunately, they did not elect to namespace their keys — even with something as trivial as a leading underscore — to help prevent collisions.

Collapse Keys

Google is not considering GCM to be a guaranteed store-and-forward queue system. In particular, Google reserves the right to try to coalesce messages, in part to reduce storage demands, but also so as not to flood the device when a connection is re-established.

Key to this is the `collapse_key` key on the message request. If a device is unavailable, and during that time you send two or more messages with the same `collapse_key`, the GCM servers may elect to only send one of those messages — typically the last one, though not necessarily. You can use this to your advantage, to minimize processing you need to do on the client. For example, if your use of GCM

is to alert your custom email application that “you’ve got mail”, you can use a consistent `collapse_key` with messages telling the client how many unread emails are in their inbox. That can be used by the client to update a `Notification` and, eventually, cajole the user into actually reading her mail. In this case, you do not need the device to receive two messages in a short timespan to raise this `Notification`, so collapsing those into a single message is good for everyone.

For example, using the `gcm` script, `-D collapse_key=inbox` would set the `collapse_key` of the request to `inbox`, coalescing it with any other messages that you have sent to this device, with the same `collapse_key`, that have not yet been delivered.

A related optional parameter you can include in your messages is `delay_while_idle`. If you specify this key with a value of `true`, that will indicate to the GCM servers that, while you want the message to be delivered, it is not important enough to wake up the device. GCM will hold onto the message (or the last one if several are sent with the same `collapse_key`), but it will not push it to the device until it knows the device is awake (perhaps due to another GCM message for that device lacking this parameter). You can think of this as being akin to choosing an `AlarmManager` alarm type lacking the `_WAKEUP` suffix. The goal is to minimize battery consumption.

Note that if you eschew `collapse_key`, and you send a lot of messages without the device receiving them (e.g., it is powered down), you will run into problems. Right now, there is a limit of 100 queued messages. If you hit that limit, all queued messages are dumped, and the device will be sent “a special message indicating that the limit was reached”. It will be up to your app to handle this scenario, typically by assuming that your data from the server is very stale and needs to be completely reloaded. Note that the structure of this “special message” is, alas, undocumented.

The `Message.Builder` in the GCM server JAR has dedicated `collapseKey()` and `delayWhileIdle()` methods to set these values.

Time-To-Live

If you are using `collapse_key`, you can also control how long the message will remain cached on the server, via a `time_to_live` value specified in seconds. The default is four weeks. But if you know the message is useless after a shorter period of time (e.g., after some real-world event has occurred), specifying a `time_to_live` can purge this message and prevent the app on the device from displaying something useless to the user.

The `Message.Builder` in the GCM server JAR has a dedicated `timeToLive()` method to set this value.

Re-Registration

In an ideal world, we would have our apps generate a registration ID once and be done with it for any given device. However, there are scenarios in which our app will need to re-register and supply a revised registration ID to the server:

- if the user uninstalls and reinstalls our app
- if the user taps the “Clear Data” button in the Settings app, to wipe out our app’s internal storage (where the registration ID is held)
- when we upgrade our app (i.e., ship an app with a different `android:versionCode` in the manifest)

While the first two might not be terribly surprising, the latter one might be. The source code for `GCMRegistrar`, as of the time of this writing, has the following comment in `getRegistrationId()`:

```
// check if app was updated; if so, it must clear registration id to  
// avoid a race condition if GCM sends a message
```

`GCMRegistrar` keeps our app’s `versionCode` in the same custom `SharedPreferences` that it uses for the registration ID. Whenever registration occurs, it saves our `versionCode`. But, the next time we go to retrieve the registration ID, if our `versionCode` is different than the one that was saved, GCM clears our saved registration ID, forcing us to get a new one.

Since this behavior seems to be undocumented, it is possible that in the future they will find some other solution and perhaps reduce the number of re-registrations that may be required.

Additional Features

There are a few other options available to you with GCM that go beyond basic push messaging.

Cloud Connection Services

“Cloud Connection Services” (CCS) is Google’s branding for an XMPP connection from your server to Google’s GCM server farm, replacing (or operating alongside) the classic HTTP/REST interface for sending messages.

Partly, the XMPP support is there for performance. Using HTTP as a protocol results in blocking I/O (send a message, wait to find out if it was sent), typically on a new socket each time. XMPP, unlike HTTP, uses a long-lived socket connection to the server, avoiding the socket churn. And XMPP is itself a messaging interface, originally designed for use with instant messaging clients, and so it specializes in asynchronous delivery. Hence, your server can send messages as fast as it wants along a single socket, finding out asynchronously the status of those messages.

Partly, the XMPP support is used as part of the mechanism behind [upstream messages](#), described a bit later in this chapter.

At this time, Google is not providing any particular client library to assist with GCM over CCS, saying that “you can use most XMPP libraries to interact with CCS” without specifics.

You can learn more about CCS by visiting [the CCS page in the GCM documentation](#).

Upstream Messages

If you are using CCS, you can implement support for upstream messages: “push” messages originating with the client, delivered to your server.

You might wonder: why bother?

The big reason is battery. Upstream messages are delivered asynchronously, as part of existing GCM operations. There are no new sockets, and GCM takes steps to make the most efficient use of the mobile radio. For non-real-time delivery of information via a one-way (device->server) channel, upstream messages has its benefits.

The `GoogleCloudMessaging` object has a `send()` method where you can indicate what server to send messages to (appending `@gcm.googleapis.com` to the server’s sender ID), the locally-unique ID for the message, and the message itself, in the form of a `Bundle`. The server, in turn, will receive XMPP messages containing a JSON

payload with the key/value pairs from the Bundle, plus metadata (sending app's package and registration ID, plus the ID value included in the `send()` call).

User Notifications

Upstream messaging, in turn, enables support for what Google refers to as “user notifications”.

As tablets become more popular, it is increasingly likely that a user of your app will have that app on multiple devices, such as both a phone and a tablet. A sufficiently-savvy server could track multiple GCM app registration IDs per user account and then send GCM messages to *all* the user's devices, so no matter which one happens to be in use at the moment, the message is delivered to it.

Many times, the end UI result of the GCM message is a Notification, to let the user know about some event (e.g., “we updated your records”). However, if you are sending the GCM message to all the user's devices, you would show the Notification on all those devices as well. By default, the user would need to manually dismiss that Notification from all those devices.

Once again, a sufficiently-savvy server and app could deal with this, by telling the server that the user dismissed the Notification from a certain device, and the server sending follow-on messages to the other devices that cause the app to dismiss the Notification programmatically.

GCM's “user notifications” attempts to simplify this somewhat.

The server can create a “registration key” representing the collection of devices for a user, then send GCM messages to that key instead of to the individual registration IDs. GCM automatically will fan out that message and deliver it to all of the devices.

Furthermore, a device can send an *upstream* message to that registration key, which will then be delivered by GCM to all of the other devices associated with that key. An app could use this to notify copies of that app on the user's other devices that a Notification was dismissed, so the app can dismiss the Notification on those other devices. The server does not need to get involved.

Considering Encryption

GCM uses encryption over the air. This includes both your server communicating with Google's server via HTTPS and Google's server communicating with your device.

However, there is still one party who has access to that data besides you and your user: Google. Google also knows the identity of your users, since their devices are the ones registering for GCM messages, and therefore those messages can be traced back to their devices. The fact that Android 4.1 and beyond eschew the need for a Google account to use GCM will help privacy somewhat.

Here are two ways of dealing with this, beyond ignoring the issue:

1. Encrypt your payload. Since GCM is expecting key/value pairs, that means that you would either encrypt each value (and their keys, if the keys might somehow be leaking data), or creating your own encrypted payload, encoding it in Base64, and using that as a single value in your GCM message. This, of course, implies that the client will be capable of decrypting your messages.
2. Have your payload be a URL pointing to some other resource that your client can access but not Google (at least not readily). In this mode, you are using GCM purely as a "tickle" to tell the client to go download some data via another secured means earlier than it might ordinarily do such a download (e.g., via a daily poll).

Issues with GCM

GCM, of course, is not perfect. As with its C2DM predecessor, it has a variety of issues, many of which will not be a problem for you, though some might be more troublesome.

Requires Play Services Framework

GCM only works on devices that have the Play Services Framework. For all intents and purposes, this means it only works on devices that have the Play Store. While most Android devices do have the Play Store, some notable ones do not, including the Kindle Fire.

If you are planning to distribute your app to devices by means other than the Play Store, you will need to consider a fallback plan.

Requires API Level 8

GCM only works on devices with API Level 8 or higher — the point in time when the Google Services Framework was formally established and C2DM was added to the ecosystem.

Since the vast majority of Android devices run API Level 8 or higher, this should only be an issue for developers specifically aiming to support older devices (e.g., still have significant customers for the older app).

No SLA

Google does not offer a service level agreement (SLA) for GCM. In other words, what they offer is a “best efforts” service, but if they fail to deliver your messages for one reason or another, you have no legal recourse.

For many situations, this is less a legal problem and more of a usage problem. The fact that GCM can fail means that, from time to time, it likely *will* fail. Apps should not rely upon GCM as their sole means of getting data from a server. Instead, use GCM as an optimization, to get data faster than some slow poll (e.g., once every 24 hours) would accomplish. That way, even if GCM hiccups and loses a message or two, the data will still make it down to your users, albeit not as quickly.

Applications that need some sort of guaranteed delivery will need to seek some alternative solution where the provider offers an SLA.

4K Message Limit

C2DM had a 1K message payload limit. GCM raises that to 4K. This is still relatively small. The theory behind the increase is that it is more likely that everything you need to hand the client would be included in the GCM message versus needing additional network I/O. However, due to the fact that Google has access to GCM messages, you might need additional network I/O for privacy reasons, regardless of message size.

Amazon Simple Notification Service and GCM

Amazon has had the [Simple Notification Service](#) (SNS) as part of their Amazon Web Services (AWS) portfolio for some time. SNS has long had support for sending notification messages to SMS, email, Amazon's own Simple Queue Service (SQS), or some form of HTTP endpoint (e.g., for Web hook implementations).

In the summer of 2013, Amazon extended SNS to support GCM, as well as Apple's equivalent push notification service, so that you can use a single Web service API to deliver notifications via any of these means. This competes with other services (e.g., PushIO, PushWoosh) for cross-platform mobile push options.

Basic Use of Sensors

“Sensors” is Android’s overall term for ways that Android can detect elements of the physical world around it, from magnetic flux to the movement of the device. Not all devices will have all possible sensors, and other sensors are likely to be added over time. In this chapter, we will explore the general concept of Android sensors and how to receive data from them.

Note, however, that this chapter will not get into details of detecting movement via the accelerometer, etc.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#). Having experience with other system-service-and-listener patterns, such as [fetching locations with LocationManager](#), is helpful but not strictly required.

The Sensor Abstraction Model

When fetching locations from `LocationManager`, you do not have dedicated APIs per location-finding technology (e.g., GPS vs. WiFi hotspot proximity vs. cell-tower triangulation vs. ...). Instead, you work with a `LocationManager` system service, asking for locations using a single API, where location technologies are identified by name (e.g., `GPS_PROVIDER`).

Similarly, when working with sensors, you do not have dedicated APIs to get sensor readings from each sensor. Instead, you work with a `SensorManager` system service,

asking for sensor events using a single API, where sensors are identified by name (e.g., `TYPE_LINEAR_ACCELERATION`).

Note, though, that there are some dedicated methods on `SensorManager` to help you *interpret* some of the sensors, particularly the accelerometer. However, those are merely helper methods; getting at the actual accelerometer data uses the same APIs that you would use to, say, access the barometer for atmospheric pressure.

Considering Rates

Usually, when working with sensors, you want to find out about changes in the sensor reading over a period of time. For example, in a driving game, where the user holds their device like a steering wheel and uses it to “turn” their virtual car, you need to know information about acceleration and positioning so long as game play is going on.

Hence, when you request a feed of sensor readings from `SensorManager`, you will specify a desired rate at which you should receive those readings. You do that by specifying an amount of delay in between readings; Android will drop sensor readings that arrive before the delay period has elapsed.

There are four standard delay periods, defined as constants on the `SensorManager` class:

1. `SENSOR_DELAY_NORMAL`, which is what most apps would use for broad changes, such as detecting a screen rotating from portrait to landscape
2. `SENSOR_DELAY_UI`, for non-game cases where you want to update the UI continuously based upon sensor readings
3. `SENSOR_DELAY_GAME`, which is faster (less delay) than `SENSOR_DELAY_UI`, to try to drive a higher frame rate
4. `SENSOR_DELAY_FASTEST`, which is the “firehose” of sensor readings, without delay

The more sensor readings you get, the faster your code has to be for using those readings, lest you take too long and starve your thread of time to do anything else. This is particularly important given that you receive these sensor events on the main application thread, and therefore the time you spend processing these events is time unavailable for screen updates. Hence, choose the slowest rate that you can that will give you acceptable granularity of output.

Reading Sensors

Sensors are event-driven. You cannot ask Android for the value of a sensor at a point in time. Rather, you register a listener for a sensor, then process the sensor events as they come in. You can unregister the listener when you are done, either because you have the reading that you need, or the user has done something (like move to another activity) that indicates that you no longer need the sensor events.

To demonstrate this, we will examine the [Sensor/Monitor](#) sample application, which will list all of the available sensors, plus show the incoming readings from a selected sensor.

Obtaining a SensorManager

The gateway to the sensor roster on the device is the SensorManager system service. You obtain one of these by calling `getSystemService()` on any Context, asking for the `SENSOR_SERVICE`, and casting the result to be a SensorManager, as seen in the `onCreate()` method of our MainActivity:

```
mgr=(SensorManager)getSystemService(Context.SENSOR_SERVICE);
```

Identifying a Sensor of Interest

There are sensor types, and then there are sensors.

You might think that there would be a one-to-one mapping between these. In truth, there might be more than one sensor for a given type, the way the SensorManager API is set up. Regardless, somewhere along the line, you will need to identify the Sensor that you want to work with.

The most common pattern, if you know the type of sensor that you want, is to call `getDefaultSensor()` on SensorManager, supplying the type of the sensor (e.g., `TYPE_ACCELEROMETER`, `TYPE_GYROSCOPE`), where the type names are constants defined on the Sensor class. If there is more than one possible Sensor for that type, Android will give you the “default” one, which is usually a reasonable choice.

Another approach, and the one used by this sample application, is to call `getSensorList()` on SensorManager, which returns a List of all Sensor objects available on this device. The sample’s MainActivity has a `getSensorList()` that returns this list, after a bit of manipulation:

BASIC USE OF SENSORS

```
@Override
public List<Sensor> getSensorList() {
    List<Sensor> unfiltered=
        new ArrayList<Sensor>(mgr.getSensorList(Sensor.TYPE_ALL));
    List<Sensor> result=new ArrayList<Sensor>();

    for (Sensor s : unfiltered) {
        if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT
            || !isTriggerSensor(s)) {
            result.add(s);
        }
    }

    Collections.sort(result, new Comparator<Sensor>() {
        @Override
        public int compare(final Sensor a, final Sensor b) {
            return(a.toString().compareTo(b.toString()));
        }
    });

    return(result);
}
```

Android 4.4 started introducing some “trigger sensors”, ones that are designed to deliver a single reading, then automatically become unregistered. This sample app is designed to display results from more traditional sensors that provide ongoing readings. So, `getSensorList()` calls an `isTriggerSensor()` method on API Level 19+ devices, and throws out sensors that are trigger sensors. The `isTriggerSensor()` method simply checks the sensor type against a list of trigger sensors:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isTriggerSensor(Sensor s) {
    int[] triggers=
        { Sensor.TYPE_SIGNIFICANT_MOTION, Sensor.TYPE_STEP_DETECTOR,
          Sensor.TYPE_STEP_COUNTER };

    return(Arrays.binarySearch(triggers, s.getType()) >= 0);
}
```

The reason for isolating `isTriggerSensor()` into a separate method, and not having the array of sensor types as a static final array, is because these sensor types are not available in all Android versions. Having the array of sensor types as a static final data member would require putting the `@TargetApi` annotation on the entire class, which is unwise if the class will be used on older devices. This way, we can isolate the new-target code into a dedicated method, with a more locally-scoped `@TargetApi` annotation.

Getting Sensor Events

To get sensor events, you need a `SensorEventListener`. This is an interface, calling for two method implementations:

1. `onAccuracyChanged()`, where you are informed about a significant change in the accuracy of the readings that you are going to get from the sensor
2. `onSensorChanged()`, where you are passed a `SensorEvent` representing one of those readings

To receive events for a given `Sensor`, you call `registerListener()` on the `SensorManager`, supplying the `Sensor`, the `SensorEventListener`, and one of the `SENSOR_DELAY_*` values to control the rate of events. Later on, you need to call `unregisterListener()`, supplying the same `SensorEventListener`, to break the connection. **Failing to unregister the listener is bad.** The sensor subsystem is oblivious to things like activity lifecycles, and so if you leak a listener, not only will you perhaps leak the component that registered the listener, but you will continue to get sensor events until the process is terminated. As active sensors do consume power, users will not appreciate the battery drain your leaked listener will incur.

The List of `Sensor` objects from that `getSensorList()` method shown previously will be used to populate a `ListView`. When the user taps on a `Sensor` in the list, an `onSensorSelected()` method is called on the `MainActivity`. Here, we unregister our listener (a `SensorLogFragment` that we will discuss more in a bit), in case we were registered for a prior `Sensor` choice, before registering for the newly-selected `Sensor`:

```
@Override
public void onSensorSelected(Sensor s) {
    mgr.unregisterListener(log);
    mgr.registerListener(log, s, SensorManager.SENSOR_DELAY_NORMAL);
    log.init(isXYZ(s));
    panes.closePane();
}
```

We will discuss the remainder of the `onSensorSelected()` method a bit later in this chapter.

Since `SensorLogFragment` implements `SensorEventListener` — so we can use it with `registerListener()` — we need to implement `onAccuracyChanged()` and `onSensorChanged()`:

```
@Override
public void onAccuracyChanged(Sensor sensor, int accuracy) {
```

```
// unused
}

@Override
public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values[1];
    values[2]=e.values[2];

    adapter.add(values);
}
```

Once again, we will get into the implementation of `onSensorChanged()` a bit later in this chapter.

The big thing to note now about `onSensorChanged()`, though, is that **the `SensorEvent` object comes from an object pool and gets recycled**. It is not safe for you to hold onto this `SensorEvent` object past the call to `onSensorChanged()`. Hence, you need to do something with the data in the `SensorEvent`, then let go of the `SensorEvent` itself, so that instance can be used again later. This is to help prevent excessive garbage collection, particularly for low-delay requests for sensor readings (e.g., `SENSOR_DELAY_FASTEST`).

Interpreting Sensor Events

The key piece of data in the `SensorEvent` object is `values`. This is a six-element float array containing the actual sensor reading. What those values *mean* will vary by sensor. For example:

- For accelerometer readings (e.g., `TYPE_ACCELEROMETER`), the first three elements of the array represent the reported acceleration, in m/s^2 , along the X, Y, and Z axes respectively (X = out the right side of the device, Y = out the top edge of the device, Z = out the screen towards the user's eyes)
- `TYPE_PRESSURE` uses the first element of the `values` array to report the barometric pressure in millibars
- `TYPE_LIGHT` uses the first element of the `values` array to report the light level in lux

And so on.

The `SensorEvent` documentation contains instructions on how to interpret these events on a per-sensor-type basis.

That being said, sensors can be roughly divided into two groups:

1. Sensors whose readings take into account three axes (X/Y/Z). These include TYPE_ACCELEROMETER, TYPE_GRAVITY, TYPE_GYROSCOPE, TYPE_LINEAR_ACCELERATION, and TYPE_MAGNETIC_FIELD.
2. Sensors that have simple single-value readings, such as TYPE_PRESSURE and TYPE_LIGHT

The `isXYZ()` method on `MainActivity` simply returns a boolean indicating whether or not this particular `Sensor` is one that uses all three axes (`true`) or not (`false`). As the roster of sensors has changed over the years, it also does some checks based on API level:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isXYZ(Sensor s) {
    switch (s.getType()) {
        case Sensor.TYPE_ACCELEROMETER:
        case Sensor.TYPE_GRAVITY:
        case Sensor.TYPE_GYROSCOPE:
        case Sensor.TYPE_LINEAR_ACCELERATION:
        case Sensor.TYPE_MAGNETIC_FIELD:
        case Sensor.TYPE_ROTATION_VECTOR:
            return(true);
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR2) {
        if (s.getType() == Sensor.TYPE_GAME_ROTATION_VECTOR
            || s.getType() == Sensor.TYPE_GYROSCOPE_UNCALIBRATED
            || s.getType() == Sensor.TYPE_MAGNETIC_FIELD_UNCALIBRATED) {
            return(true);
        }
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        if (s.getType() == Sensor.TYPE_GEOMAGNETIC_ROTATION_VECTOR) {
            return(true);
        }
    }

    return(false);
}
```

Wiring Together the Sample

Overall, this sample app uses the `SlidingPaneLayout` first seen back in [the chapter on large-screen support](#). We have two fragments, in a master-detail pattern, where the “master” will be a list of all available sensors, and the “detail” will be a log of sensor readings from a selected sensor.

BASIC USE OF SENSORS

Our layout (res/layout/activity_main.xml) wires in a SensorsFragment (master) and SensorLogFragment (detail) in a SlidingPanelLayout:

```
<android.support.v4.widget.SlidingPanelLayout
xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/sensors"
        android:name="com.commonware.android.sensor.monitor.SensorsFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent"/>

    <fragment
        android:id="@+id/log"
        android:name="com.commonware.android.sensor.monitor.SensorLogFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

</android.support.v4.widget.SlidingPanelLayout>
```

The SensorsFragment is reminiscent of CountriesFragment from the SlidingPanelLayout variant of the EU4You sample. The biggest differences are that we use a SensorListAdapter for representing the list of sensors, that we use getSensorList() on our SensorsFragment.Contract class to retrieve the model data, and that we call onSensorSelected() on the contract to report of selections:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Bundle;
import android.view.View;
import android.widget.ListView;
import java.util.List;

public class SensorsFragment extends
    ContractListFragment<SensorsFragment.Contract> {
    static private final String STATE_CHECKED=
        "com.commonware.android.sensor.monitor.STATE_CHECKED";
    private SensorListAdapter adapter=null;

    @Override
    public void onActivityCreated(Bundle state) {
        super.onActivityCreated(state);

        adapter=new SensorListAdapter(this);
        getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
        setListAdapter(adapter);
    }
}
```

```
    if (state != null) {
        int position=state.getInt(STATE_CHECKED, -1);

        if (position > -1) {
            getListView().setItemChecked(position, true);
            getContract().onSensorSelected(adapter.getItem(position));
        }
    }

    @Override
    public void onItemClick(ListView l, View v, int position, long id) {
        l.setItemChecked(position, true);

        getContract().onSensorSelected(adapter.getItem(position));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        super.onSaveInstanceState(state);

        state.putInt(STATE_CHECKED, getListView().getCheckedItemPosition());
    }

    interface Contract {
        void onSensorSelected(Sensor s);

        List<Sensor> getSensorList();
    }
}
```

SensorListAdapter illustrates another approach for handling the difference in “activated” row support. The EU4You samples used an activated style to apply the “activated” support on Android 3.0 and higher. Here, our custom ArrayAdapter subclass dynamically chooses between android.R.layout.simple_list_item_activated_1 (an activated-capable built-in row layout) and the classic android.R.layout.simple_list_item_1 based upon API level:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;

class SensorListAdapter extends ArrayAdapter<Sensor> {
    SensorListAdapter(SensorsFragment sensorsFragment) {
```

BASIC USE OF SENSORS

```
        super(sensorsFragment.getActivity(), getRowResourceId(),
              sensorsFragment.getContract().getSensorList());
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        ((TextView)result).setText(getItem(position).getName());

        return(result);
    }

    private static int getRowResourceId() {
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
            return(android.R.layout.simple_list_item_activated_1);
        }

        return(android.R.layout.simple_list_item_1);
    }
}
```

We also have to override `getView()`, as our model is `Sensor`, whose `toString()` is not what we want, so we have to manually populate the list row with `getName()` instead.

`SensorLogFragment` is another `ListFragment`. In particular, though, we set it up for `TRANSCRIPT_MODE_NORMAL`, which means that Android will automatically scroll the `ListView` to the bottom if we add new rows to the list *and* the user has not scrolled up in the list to view past data:

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);
}
```

However, we do not initialize our `ListAdapter` in `onActivityCreated()`, as we might normally do. Instead, we have a dedicated `init()` method, to be called by `MainActivity`, where we set up the `SensorLogAdapter` and keep track of whether the `Sensor` that we are logging is designed to report three-dimensional values (`isXYZ` is true) or not:

```
void init(boolean isXYZ) {
    this.isXYZ=isXYZ;
    adapter=new SensorLogAdapter(this);
    setListAdapter(adapter);
}
```

BASIC USE OF SENSORS

The `init()` method, in turn, was called by `onSensorSelected()` of `MainActivity`. Hence, whenever the user taps on a sensor, we set up a fresh log. `init()` can do this because `MainActivity` retrieved our `SensorLogFragment` up in `onCreate()`, stashing it in a log data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    log=
        (SensorLogFragment)getFragmentManager().findFragmentById(R.id.log);

    panes=(SlidingPanelLayout)findViewById(R.id.panes);
    panes.openPane();
}
```

Our `onSensorChanged()` method in `SensorLogFragment` copies the values from the `SensorEvent` into a separate `Float` array that is our list's model data:

```
@Override
public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values[1];
    values[2]=e.values[2];

    adapter.add(values);
}
```

`SensorLogAdapter` uses the `isXYZ` value to determine how it should format the rows:

- For single-value sensors, we just show the first `Float` from the array
- For three-dimensional sensors, we show all three dimensions, plus the “net” (square root of the sum of the squares), separated by slashes

```
class SensorLogAdapter extends ArrayAdapter<Float[]> {
    public SensorLogAdapter(SensorLogFragment sensorLogFragment) {
        super(sensorLogFragment.getActivity(),
            android.R.layout.simple_list_item_1,
            new ArrayList<Float[]>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
```

BASIC USE OF SENSORS

```
(TextView)super.getView(position, convertView, parent);
String content=null;
Float[] values=getItem(position);

if (isXYZ) {
    content=
        String.format("%7.3f / %7.3f / %7.3f / %7.3f",
            values[0],
            values[1],
            values[2],
            Math.sqrt(values[0] * values[0] + values[1]
                * values[1] + values[2] * values[2]));
}
else {
    content=String.format("%7.3f", values[0]);
}

row.setText(content);

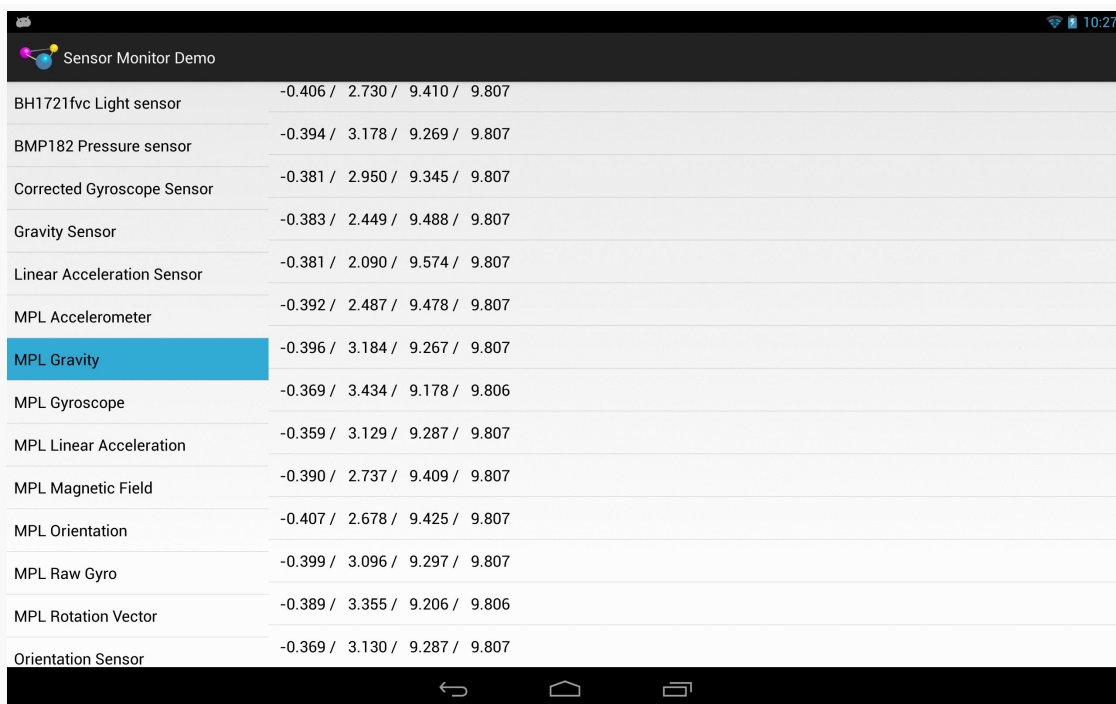

return(row);
}
```

The rest of MainActivity simply manages the SlidingPaneLayout, much like the EU4YouSlidingPane sample did.

The Results

When the user taps on a sensor in the list, we get a log of readings:

BASIC USE OF SENSORS

Sensor	Reading
BH1721fvc Light sensor	-0.406 / 2.730 / 9.410 / 9.807
BMP182 Pressure sensor	-0.394 / 3.178 / 9.269 / 9.807
Corrected Gyroscope Sensor	-0.381 / 2.950 / 9.345 / 9.807
Gravity Sensor	-0.383 / 2.449 / 9.488 / 9.807
Linear Acceleration Sensor	-0.381 / 2.090 / 9.574 / 9.807
MPL Accelerometer	-0.392 / 2.487 / 9.478 / 9.807
MPL Gravity	-0.396 / 3.184 / 9.267 / 9.807
MPL Gyroscope	-0.369 / 3.434 / 9.178 / 9.806
MPL Linear Acceleration	-0.359 / 3.129 / 9.287 / 9.807
MPL Magnetic Field	-0.390 / 2.737 / 9.409 / 9.807
MPL Orientation	-0.407 / 2.678 / 9.425 / 9.807
MPL Raw Gyro	-0.399 / 3.096 / 9.297 / 9.807
MPL Rotation Vector	-0.389 / 3.355 / 9.206 / 9.806
Orientation Sensor	-0.369 / 3.130 / 9.287 / 9.807

Batching Sensor Readings

API Level 19 (Android 4.4) added a new feature to the sensor subsystem: batched sensor events. Now, `registerListener()` can take a batch period in microseconds, and Android may elect to deliver events to you delayed by up to that amount of time. The objective will be to reduce the power draw of the sensors, for sensor hardware that supports this sort of batching behavior. Not all hardware will, in which case your requested batch latency will be ignored.

Printing and Document Generation

Mobile devices are continuing to close the gap on capabilities that had formerly been the sole province of desktop systems or servers. After all, if the vision is that people should be able to use phones and tablets *instead of* desktops and notebooks, phones and tablets need to do whatever it is that those people need to have done.

One such capability is the ability to print to networked printers. While various third-party printing options have been available for some time, it is only with the Android 4.4 release that the OS and framework itself has support for printing. In the fullness of time, a preponderance of Android devices will be natively capable of printing, and so users will be more likely to expect that your app supports such printing.

As it turns out, the print engine in Android is centered upon the PDF document format, and Android supports converting HTML into PDF, albeit on a somewhat limited basis.

The API seems simple and clean. It actually *is* simple and clean... so long as you are printing very simple contents (bitmaps or HTML). Once you get into anything more complicated than that, the threading alone starts to make things rather messy.

This chapter describes how to use the Android 4.4 print system, including how to print HTML and PDF files. It will also cover how to generate HTML and PDF files, whether for printing or for other purposes (e.g., reports to be emailed or uploaded somewhere).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on [advanced uses of WebView](#).

The Android Print System

Writing programs that print on desktop operating systems historically has been tedious. The fine-grained control that is needed for high-quality output makes the APIs complicated, and these tend to be only partially masked by high-level wrappers to simplify common scenarios.

Android's print system is no different.

Starting with Android 4.4, you can request access to a `PrintManager` system service (via `getSystemService()`, called on any `Context`). It offers a `print()` method that lets you describe what should be printed, in the form of a `PrintAttributes` (e.g., what size paper are you looking for?) and a `PrintDocumentAdapter`. The latter is responsible for working with Android to actually create the content to be printed.

`print()` returns a `PrintJob`, which you can use to examine the status of the print request. `PrintManager` also offers a `getPrintJobs()` method that returns all of *your* outstanding print requests. Note that you cannot access print jobs from other applications.

Hence, the real complexity of printing lies in the `PrintDocumentAdapter` implementation. This class is responsible for generating a PDF that represents the content to be printed. This leads to four basic ways of working with a `PrintDocumentAdapter`:

1. Have one created for you, such as via a `WebView` for printing HTML content
2. Create one that takes a PDF generated elsewhere and uses it for the output
3. Create one that uses Android's Canvas-based PDF generation class, called `PrintedPdfDocument`
4. Use APIs that avoid all of this entirely, such as `printBitmap()` on `PrintHelper`

About the Sample App

The [Printing/PrintManager](#) sample project demonstrates all but the Canvas option.

The UI is just a large EditText, designed for you to type in a message.

The action bar overflow contains four options:

- “Bitmap”, to print an image from your device or emulator
- “Web Page”, to print [the Web page for this book](#)
- “TPS Report”, which prints a report containing the message from the EditText
- “PDF”, which prints a copy of the cover of Version 5.8 of this book, which is packaged in the app as an asset

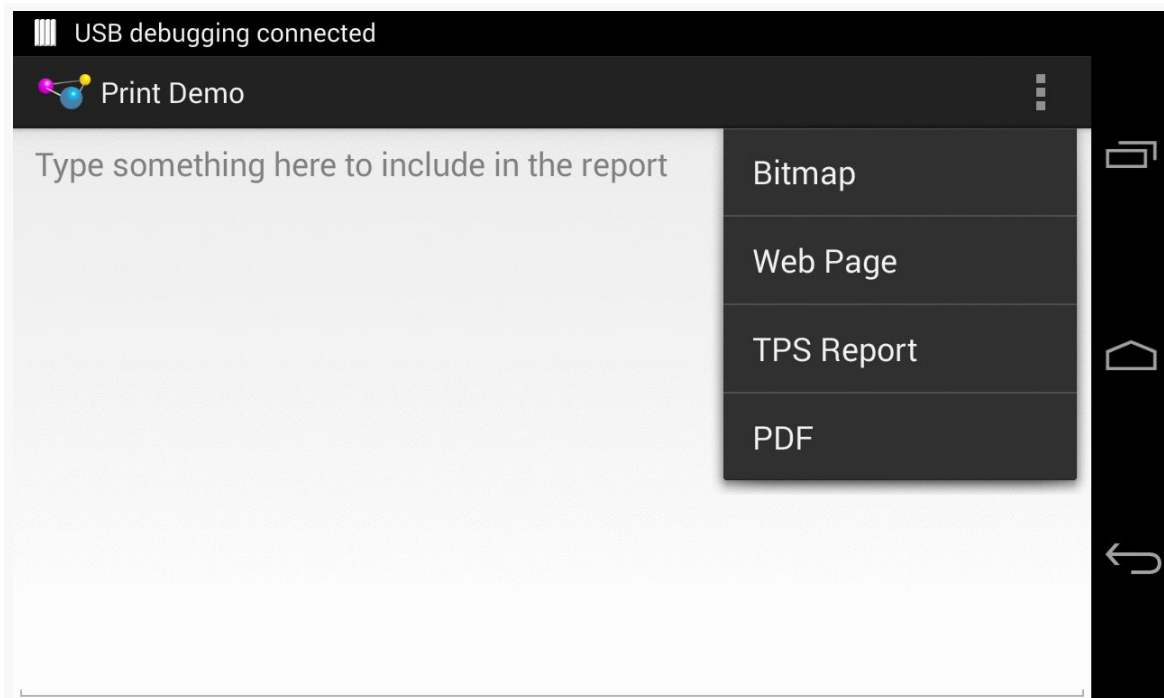

Figure 684: Print Demo App, Showing Overflow

Printing a Bitmap

Google helpfully supplies a `PrintHelper` class in the Android Support package that makes it trivially easy to print a bitmap. Just call `printBitmap()` on the `PrintHelper`, after some minor configuration, and it takes over from there.

In `onOptionsItemSelected()` of the sample app's `MainActivity`, when the user chooses the “Bitmap” item, we call `startActivityForResult()` on an `ACTION_GET_CONTENT` Intent, to allow the user to pick an image from the device or emulator:

```
Intent i=
    new Intent(Intent.ACTION_GET_CONTENT).setType("image/*");

startActivityForResult(i, IMAGE_REQUEST_ID);
```

This, in turn, will trigger a call to `onActivityResult()`, once the user has (presumably) chosen an image:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == IMAGE_REQUEST_ID
        && resultCode == Activity.RESULT_OK) {
        try {
            PrintHelper help=new PrintHelper(this);

            help.setScaleMode(PrintHelper.SCALE_MODE_FIT);
            help.printBitmap("Photo!", data.getData());
        }
        catch (FileNotFoundException e) {
            Log.e(getClass().getSimpleName(), "Exception printing bitmap",
                e);
        }
    }
}
```

If the user did indeed choose an image, we create an instance of `PrintHelper`, call `setScaleMode()` to tell it fit the image to the page, and then call `printBitmap()` to print the image.

`setScaleMode()` takes one of two values:

1. `SCALE_MODE_FIT` will show the entire image, blown up as big as possible

2. `SCALE_MODE_FILL` will fill the entire page, at the cost of cropping the image along one axis, if the image's aspect ratio does not match the paper's aspect ratio

`printBitmap()` takes the name of the print job (so the user, when reviewing the outstanding print jobs, knows what it is) and either a `Uri` or a `Bitmap` for the image itself. In the case of a `Uri`, the `Uri` could be malformed, in which case the `FileNotFoundException` may be thrown, which is why we catch it.

What the user sees, after choosing an image to print (and a printer, if the user has more than one available), is a print configuration dialog appear, much like those you might see in a desktop OS:

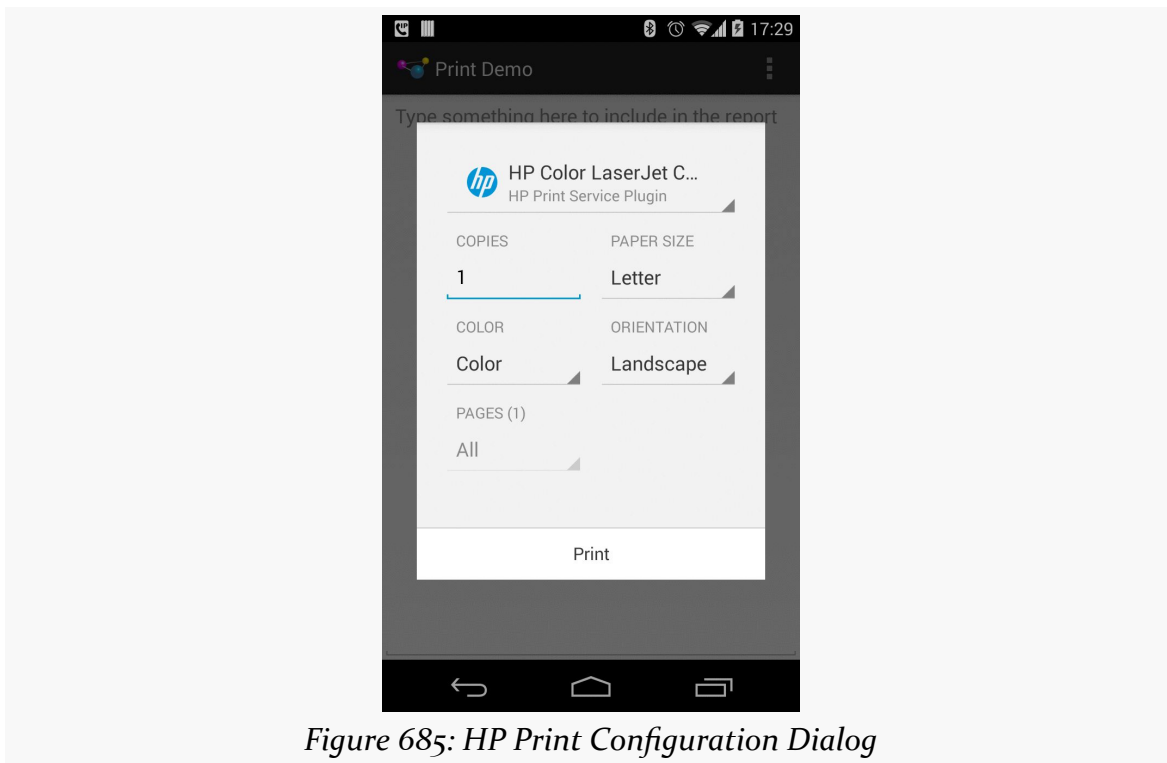

Figure 685: HP Print Configuration Dialog

The dialog itself is provided by Android; the contents of the dialog is provided by a `PrintService` that is responsible for taking our print job and actually dispatching it to the printer.

Here, the user can make typical changes, like portrait/landscape printing and the number of copies, before pressing the “Print” button. At that point, the user’s chosen image will be printed.

Note that, in Android 4.4, the print dialog does not work especially well in landscape on smaller screen sizes, forcing the user to scroll to get to all of the widgets, including the “Print” button.

Printing an HTML Document

Printing a bitmap is nice. It is not especially useful, as it implies that we have a bitmap worth printing... and printing by itself. That is certainly possible, but it is unlikely. Even in the case where we want to print a photo, there is a very good chance that we will need to print some additional information along with the photo (caption, date when photo was taken, etc.).

Being able to print something over which we have greater control of the rendering would be more useful. The easiest way to do that is to print some HTML. [Later in this chapter](#) we will cover how to generate some dynamic HTML representing what you want to print. For the moment, though, let’s focus on the printing itself.

Printing and WebView

Starting in API Level 19, `WebView` is capable of participating in the print process. You can load up a `WebView` with your desired content, then print that content.

Some apps will already be using a `WebView` as part of the UI, and that `WebView` will contain what needs to be printed. For example, a Web browser can easily add a “Print” action bar overflow item that would print the contents of the active `WebView` in the browser.

For cases where you want to print something, but you are not using the `WebView` for anything but printing, you do *not* need to add the `WebView` to the UI. You can create a `WebView` instance via its constructor, passing in your Activity as the Context required by that constructor. You can then populate that `WebView` with what needs to be printed, then print it. That is the technique that the sample application demonstrates, in part because it is likely to be the more common scenario — only so many apps use a `WebView` in the UI, and more are likely to need to print.

Printing a URL

The sample app’s “Web Page” action bar overflow item is tied to an `R.id.web MenuItem`. When that is tapped by the user, `onOptionsItemSelected()` calls `printWebPage()` to print a Web page loaded from a URL:

```
private void printWebPage() {
    WebView print=prepPrintWebView(getString(R.string.web_page));

    print.loadUrl("http://commonsware.com/Android");
}
```

Here, `getString(R.string.web_page)` is returning a string resource that will be used for the name of a print job. `prepPrintWebView()` returns the `WebView` that will be used for printing. `loadUrl()` is the standard `WebView` method for populating the `WebView` from a URL. Note that this causes the sample app to need the `INTERNET` permission, since we are downloading a Web page and its related assets (CSS, images) from the Internet.

You will notice that we are not actually printing anything directly in `printWebPage()`, which may seem a bit odd given the name of the method. That is because we cannot print anything until the page is loaded — after all, it is only then that we have what we want to print.

The job of `prepPrintWebView()` is to arrange to get control when the page is loaded and actually print the desired page:

```
private WebView prepPrintWebView(final String name) {
    WebView result=getWebView();

    result.setWebViewClient(new WebViewClient() {
        @Override
        public void onPageFinished(WebView view, String url) {
            print(name, view.createPrintDocumentAdapter(),
                new PrintAttributes.Builder().build());
        }
    });

    return(result);
}
```

`getWebView()` is just a lazy-initialization method, populating a `wv` data member of the activity with a `WebView`. This way, we avoid creating the `WebView` up front, as if the user does not elect to print any HTML, we do not need the `WebView`, and a `WebView` is expensive to initialize:

```
private WebView getWebView() {
    if (wv == null) {
        wv=new WebView(this);
    }

    return(wv);
}
```

We are holding onto the `WebView` in a data member to ensure that it will not be garbage-collected. A `WebView` that is part of our UI is being strongly held by its parent in the View hierarchy, so we do not normally need to worry about this. However, in this case, we are creating a `WebView` dynamically and are *not* adding it to the UI, so we are responsible for holding onto it, at least as long as is needed. In this sample, we just hold onto it for the rest of the life of the activity.

Back in `prepPrintWebView()`, we call `setWebViewClient()`, to attach an anonymous inner class extending `WebViewClient` to the `WebView`. Back in [the chapter introducing `WebView`](#), we saw `WebViewClient` in the context of `shouldOverrideUrlLoading()`. Another popular method to override on a `WebViewClient` is `onPageFinished()`. This is called when the HTML and related assets (CSS, images, etc.) have been loaded and rendered within the `WebView`. At this point, for the particular URL we are loading, it is safe to print the page.

In `onPageFinished()`, we call a `print()` method on `MainActivity` itself:

```
private PrintJob print(String name, PrintDocumentAdapter adapter,
    PrintAttributes attrs) {
    startService(new Intent(this, PrintJobMonitorService.class));

    return(mgr.print(name, adapter, attrs));
}
```

The first line of `print()` calls `startService()` to start a `PrintJobMonitorService`. We will see more about why we are doing that [later in this chapter](#). For the moment, take it on faith that this service will help ensure that our process stays around long enough for our print job to finish.

The second line of `print()` calls a `print()` method on a `mgr` data member. Here, `mgr` is a `PrintManager`, initialized up in `onCreate()` of the activity, by calling `getSystemService()`, asking for the `PRINT_SERVICE`, and casting the result to be a `PrintManager`.

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
    prose=(EditText)findViewById(R.id.prose);
    mgr=(PrintManager)getSystemService(PRINT_SERVICE);
}
```

The `print()` method tells the `PrintManager` to go print something. `print()` takes three parameters:

1. The name of the print job, which is kept along with the print job itself in case something (e.g., the print driver) wishes to show the user a roster of print jobs. In our case, this is that string resource passed in as the name parameter to `prepPrintWebView()`. That parameter is marked `final`, so the call to `setWebViewClient()` will include the value of that parameter in the anonymous inner class' implementation of `onPageFinished()`.
2. A `PrintDocumentAdapter`. For the case of printing HTML, we get one of those by calling `createPrintDocumentAdapter()` on our populated `WebView`.
3. A `PrintAttributes` object, describing any particular requirements that you have for the printed output (e.g., media size, margins, color/monochrome). If you will let the user control all of that via the print dialog, an empty `PrintAttributes` is fine to use with `print()`. You typically create a `PrintAttributes` by creating a `PrintAttributes.Builder`, calling setters on the Builder to configure the `PrintAttributes`, and getting the resulting `PrintAttributes` via a call to `build()`.

And that's it. Android — in particular, `WebView` and its `PrintDocumentAdapter` — takes over from here and prints the Web page.

Limitations and Concerns

Alas, we do not have infinite flexibility with printing HTML from a `WebView`. Here are some limitations and potential problem areas that you will encounter:

- While you can use JavaScript in the loaded HTML, it cannot trigger the print itself using any standard DOM methods.
- Also, if your JavaScript is going to fire off some asynchronous operations, like an AJAX request, bear in mind that `onPageFinished()` does *not* take those operations into account. You will need to use `addJavascriptInterface()` to inject a Java object into the JavaScript realm, then have your asynchronous work arrange to call some method on that Java object, to signal to you that the document is ready for printing.
- Print CSS rules, like headers, footers, page numbers, landscape properties, and the like are ignored at present.
- A `WebView` can only do one print job at a time. Printing occurs asynchronously, and so you have to be careful that you do not accidentally start off a second print job while an earlier one is in process. The `print()` method returns a `PrintJob` that you can use to monitor the print job status, and this object will be covered in a bit more detail [later in this chapter](#). You may wish to set up a `WebView` pool, where you reuse an existing `WebView` only if its associated `PrintJob` is completed, creating a new `WebView` instance if

there is no available `WebView` at the moment. Or, you might disable printing options in the UI until the `PrintJob` is done, so you can reuse the `WebView`. The sample app does none of this, to keep things simpler.

- Printing HTML is “an all-or-nothing affair”. You cannot print a subset of the HTML, whether denoted by HTML constructs (e.g., `<div>` IDs) or by page numbers. Hence, you need to load into the `WebView` *exactly* what you want to print, no more, no less.

Also, any direct use of `PrintManager` will only work on API Level 19. You will need to ensure that you only try using it on API Level 19+ devices, using Java version guard blocks. You will also need to set your build target to at least API Level 19 to be able to reference the `PrintManager` and related classes.

Finally, while loading and printing HTML are both intrinsically asynchronous, *generating* HTML locally is not. We will discuss this issue a bit more [later in this chapter](#).

Printing a PDF File

As will be seen in [the next section](#), even if we “hand-roll” our printed output using a `Canvas`, the result seems to be a PDF file. Hence, you would think that the printing framework would provide convenience code to print a PDF file that we obtained by other means.

Alas, [that is not the case](#).

The sample app contains some code demonstrating how this is possible, inspired by [this Stack Overflow answer](#), though it may cut a few corners that Google would prefer not be cut. However, it also illustrates how to create your own `PrintDocumentHandler`, which you will need for any print job not involving a bitmap or HTML.

The `PrintDocumentAdapter` Protocol

We supply a `PrintDocumentAdapter` to the `print()` method on `PrintManager`. In the HTML case, we got a `PrintDocumentAdapter` from the `WebView`, and so it is Google’s job to implement that adapter. Similarly, `PrintHelper` has its own internal implementation of a `PrintDocumentAdapter` that it uses for printing the bitmap.

For anything else, you need to create your own `PrintDocumentAdapter`, or find a third-party implementation that you can perhaps reuse.

`PrintDocumentAdapter`'s job is to supply the `PrintManager` with the content to be printed, in the form of a PDF file. To do that, there are four callback methods that `PrintManager` (and related classes) will call on the `PrintDocumentAdapter`:

1. `onStart()` is called first. If you are planning on using the same `PrintDocumentAdapter` instance for multiple print jobs, this would be a spot to initialize the work for a new job. Otherwise, if you were only planning on using a `PrintDocumentAdapter` instance once, you may as well just put your initialization logic in the constructor.
2. `onLayout()` is called next. Here is where you do enough work to determine what the resulting output will be later on as printing continues. In particular, if you want to provide an accurate page count, this is where you will need to perform the necessary calculations to determine that.
3. `onWrite()` is called next, asking you to write one or more PDF pages out to a supplied `ParcelFileDescriptor` (on which you can create an `OutputStream`).
4. `onFinish()` is called last, when the printing request is completed, so you can free up any necessary resources.

Introducing `ThreadedPrintDocumentAdapter`

All four of those callback methods are called on the main application thread. Your `onStart()` and `onFinish()` methods need to be fast enough to complete their work on that thread, and that may not be a problem. The work that `onLayout()` and `onWrite()` do may take a while, though, and so the protocol is designed to allow you to do that work on a background thread. Both methods are passed a callback object that you use to pass along the results of your work, and both are passed a `CancellationSignal` to indicate if the user cancels the print job while you are doing the work.

What `PrintDocumentAdapter` does *not* do is actually give you a thread to use.

So, the sample app contains a `ThreadedPrintDocumentAdapter` that moves the `onLayout()` and `onFinish()` work to a background thread:

```
package com.commonware.android.print;

import android.content.Context;
import android.os.Bundle;
import android.os.CancellationSignal;
```

```
import android.os.ParcelFileDescriptor;
import android.print.PageRange;
import android.print.PrintAttributes;
import android.print.PrintDocumentAdapter;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;

abstract class ThreadedPrintDocumentAdapter extends
    PrintDocumentAdapter {
    abstract LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                                      PrintAttributes newAttributes,
                                      CancellationSignal cancellationSignal,
                                      LayoutResultCallback callback,
                                      Bundle extras);

    abstract WriteJob buildWriteJob(PageRange[] pages,
                                     ParcelFileDescriptor destination,
                                     CancellationSignal cancellationSignal,
                                     WriteResultCallback callback,
                                     Context ctxt);

    private Context ctxt=null;
    private ExecutorService threadPool=Executors.newFixedThreadPool(1);

    ThreadedPrintDocumentAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public void onLayout(PrintAttributes oldAttributes,
                        PrintAttributes newAttributes,
                        CancellationSignal cancellationSignal,
                        LayoutResultCallback callback, Bundle extras) {
        threadPool.submit(buildLayoutJob(oldAttributes, newAttributes,
                                          cancellationSignal, callback,
                                          extras));
    }

    @Override
    public void onWrite(PageRange[] pages,
                       ParcelFileDescriptor destination,
                       CancellationSignal cancellationSignal,
                       WriteResultCallback callback) {
        threadPool.submit(buildWriteJob(pages, destination,
                                         cancellationSignal, callback, ctxt));
    }

    @Override
    public void onFinish() {
        threadPool.shutdown();

        super.onFinish();
    }
}
```

```
protected abstract static class LayoutJob implements Runnable {
    PrintAttributes oldAttributes;
    PrintAttributes newAttributes;
    CancellationSignal cancellationSignal;
    LayoutResultCallback callback;
    Bundle extras;

    LayoutJob(PrintAttributes oldAttributes,
              PrintAttributes newAttributes,
              CancellationSignal cancellationSignal,
              LayoutResultCallback callback, Bundle extras) {
        this.oldAttributes=oldAttributes;
        this.newAttributes=newAttributes;
        this.cancellationSignal=cancellationSignal;
        this.callback=callback;
        this.extras=extras;
    }
}

protected abstract static class WriteJob implements Runnable {
    PageRange[] pages;
    ParcelFileDescriptor destination;
    CancellationSignal cancellationSignal;
    WriteResultCallback callback;
    Context ctxt;

    WriteJob(PageRange[] pages, ParcelFileDescriptor destination,
             CancellationSignal cancellationSignal,
             WriteResultCallback callback, Context ctxt) {
        this.pages=pages;
        this.destination=destination;
        this.cancellationSignal=cancellationSignal;
        this.callback=callback;
        this.ctxt=ctxt;
    }
}
```

This class uses a single-thread thread pool, managed by an `ExecutorService`. In principle, a well-written `PrintDocumentAdapter` could handle multiple print jobs in parallel — if you attempt this and are using `ThreadedPrintDocumentAdapter` for inspiration, simply increase the size of the thread pool.

The `onLayout()` and `onWrite()` methods package up their parameters (described in [the next section](#)) into job objects. Those objects implement `Runnable`, and they are then handed to the `ExecutorService` to be run on the next-available thread. `onFinish()` shuts down the `ExecutorService`, though if you wanted to use the `ThreadedPrintDocumentAdapter` for multiple print jobs, you would come up with some other logic to clean up the `ExecutorService` when you were done with *all* of the jobs.

Subclasses of `ThreadedPrintDocumentAdapter` need to:

- Create subclasses of the `LayoutJob` and `WriteJob` static inner classes, implementing their respective `run()` methods, to do the work required of `onLayout()` and `onWrite()`
- Implement `buildLayoutJob()` and `buildWriteJob()` methods that return instances of those custom subclasses

(fans of dependency injection no doubt can find better solutions for wiring up a `ThreadedPrintDocumentAdapter`)

A PdfDocumentAdapter

However, we still need to actually be able to print a PDF, which `ThreadedPrintDocumentAdapter` does not do on its own. The sample app also has a `PdfDocumentAdapter`, which extends `ThreadedPrintDocumentAdapter` and demonstrates a crude way of printing a PDF through the `PrintDocumentAdapter` protocol.

`PdfDocumentAdapter` does not use `onStart()` or `onFinish()`. And, since the `onLayout()` and `onWrite()` methods are handled by `ThreadedPrintDocumentAdapter`, `PdfDocumentAdapter` does not have those either.

It does, however, have the `buildLayoutJob()` and `buildWriteJob()` methods required by `ThreadedPrintDocumentAdapter`. These return instances of a `PdfLayoutJob` and `PdfWriteJob`, respectively:

```
@Override
LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                        PrintAttributes newAttributes,
                        CancellationSignal cancellationSignal,
                        LayoutResultCallback callback, Bundle extras) {
    return(new PdfLayoutJob(oldAttributes, newAttributes,
                           cancellationSignal, callback, extras));
}

@Override
WriteJob buildWriteJob(PageRange[] pages,
                      ParcelFileDescriptor destination,
                      CancellationSignal cancellationSignal,
                      WriteResultCallback callback, Context ctxt) {
    return(new PdfWriteJob(pages, destination, cancellationSignal,
                           callback, ctxt));
}
```

PdfLayoutJob needs to fulfill the bulk of the onLayout() contract:

- Monitor the CancellationSignal and call onLayoutCancelled() on the supplied LayoutResultCallback if the job has been canceled
- Populate a PrintDocumentInfo object to provide metadata about the document to be printed, and pass that to onLayoutFinished() on the LayoutResultCallback

```
private static class PdfLayoutJob extends LayoutJob {
    PdfLayoutJob(PrintAttributes oldAttributes,
                  PrintAttributes newAttributes,
                  CancellationSignal cancellationSignal,
                  LayoutResultCallback callback, Bundle extras) {
        super(oldAttributes, newAttributes, cancellationSignal, callback,
              extras);
    }

    @Override
    public void run() {
        if (cancellationSignal.isCanceled()) {
            callback.onLayoutCancelled();
        }
        else {
            PrintDocumentInfo.Builder builder=
                new PrintDocumentInfo.Builder("CHANGE ME PLEASE");

            builder.setContentType(PrintDocumentInfo.CONTENT_TYPE_DOCUMENT)
                .setPageCount(PrintDocumentInfo.PAGE_COUNT_UNKNOWN)
                .build();

            callback.onLayoutFinished(builder.build(),
                                     !newAttributes.equals(oldAttributes));
        }
    }
}
```

PdfLayoutJob also has access to two PrintAttributes objects, the “old” attributes and the “new” attributes. In principle, onLayout() could be called a couple of times, perhaps based upon changes the user makes in the print dialog. These PrintAttributes objects describe the nature of the output, including things like page size and margins. PdfLayoutJob totally ignores these, because the PDF is a packaged asset in this case and cannot be changed. If you are dynamically generating a PDF file, you may wish to pay attention to the new PrintAttributes and take them into account.

PdfLayoutJob also has access to a Bundle of “extras”, not unlike the “extras” associated with an Intent. At the present time, there is only one semi-documented “extra”, EXTRA_PRINT_PREVIEW, which will be true if onLayout() is being called to

generate a print preview of the printed output, false otherwise. There is no obvious way to trigger a print preview, from code or the print dialog, and so PdfLayoutJob ignores this as well.

What PdfLayoutJob does do is create a PrintDocumentInfo.Builder to set up a PrintDocumentInfo object indicating that:

- The output is a “document” (CONTENT_TYPE_DOCUMENT) versus a “photo” (CONTENT_TYPE_PHOTO) or “unknown” (CONTENT_TYPE_UNKNOWN). This information is passed to the PrintService that functions as a bridge between PrintManager and the printer, and the PrintService might optimize output based upon this setting (e.g., lower quality print output for a “document” instead of a “photo”).
- The page count of the output is unknown (PAGE_COUNT_UNKNOWN). In principle, the page count is known, insofar as the PDF that will be printed is an asset baked into the app, and so we could hard-code the page count in addition to hard-coding other details (like the asset’s filename).

The boolean second parameter to onLayoutFinished() is supposed to be true if the layout changed, false otherwise. In practice, the value does not seem to matter on the first onLayout() call. The implementation here compares the two PrintAttributes objects using equals().

The last piece is the PdfWriteJob, which performs the work required of the onWrite() callback:

```
private static class PdfWriteJob extends WriteJob {
    PdfWriteJob(PageRange[] pages, ParcelFileDescriptor destination,
                CancellationSignal cancellationSignal,
                WriteResultCallback callback, Context ctxt) {
        super(pages, destination, cancellationSignal, callback, ctxt);
    }

    @Override
    public void run() {
        InputStream in=null;
        OutputStream out=null;

        try {
            in=ctxt.getAssets().open("cover.pdf");
            out=new FileOutputStream(destination.getFileDescriptor());

            byte[] buf=new byte[16384];
            int size;

            while ((size=in.read(buf)) >= 0
```

```
        && !cancellationSignal.isCanceled()) {
            out.write(buf, 0, size);
        }

        if (cancellationSignal.isCanceled()) {
            callback.onWriteCancelled();
        }
        else {
            callback.onWriteFinished(new PageRange[] { PageRange.ALL_PAGES });
        }
    }
    catch (Exception e) {
        callback.onWriteFailed(e.getMessage());
        Log.e(getClass().getSimpleName(), "Exception printing PDF", e);
    }
    finally {
        try {
            in.close();
            out.close();
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                "Exception cleaning up from printing PDF", e);
        }
    }
}
```

At its core, PdfWriteJob simply writes our PDF (culled from a cover .pdf asset) to an OutputStream. The OutputStream is built from the ParcelFileDescriptor, indicating where the PDF content should be written to.

The InputStream-to-OutputStream “bucket brigade” is augmented with checks on the CancellationSignal, to abandon the loop if the print job was canceled by the user. At the end, we call one of three methods on the WriteResultCallback:

- onWriteCancelled() if the CancellationSignal indicates that the job was canceled
- onWriteFinished() if everything succeeded
- onWriteFailed() (with an error message) if there was some problem, such as failed I/O

PdfWriteJob has access to a PageRange array, representing the particular pages out of a larger document to be printed. The parameter to onWriteFinished() is another PageRange array that should indicate what pages were printed. Once again, since the PDF is fixed, PdfWriteJob ignores the input PageRange array, and it indicates that we wrote all pages (PageRange.ALL_PAGES) in the output. In principle, if you have more control over your environment, you should only print the requested pages, in which

case the output parameter to `onWriteFinished()` might be the same array as was passed into `onWrite()`.

Using PdfDocumentAdapter

Back in `MainActivity`, the “PDF” action bar overflow item triggers a call to `print()` on the `PrintManager`, supplying our `PdfDocumentAdapter` and another empty `PrintAttributes`:

```
print("Test PDF",
      new PdfDocumentAdapter(getApplicationContext()),
      new PrintAttributes.Builder().build());
```

The `PdfDocumentAdapter` needs a `Context`, in order to access the `cover.pdf` asset. If your PDF file is being generated, or is saved as a file on external storage, you would not need this. Since it is theoretically possible that our activity could be destroyed while the printing is going on in background threads, rather than briefly leak an `Activity`, we provide the `Application Context` to `PdfDocumentAdapter`, as that is a singleton and cannot be leaked.

The result of all of this is that when the user chooses the “PDF” action bar overflow item, the book cover copy is printed.

Printing Using a Canvas

What Google *really* wants you to do — if bitmaps and HTML are insufficient — is to create PDF documents using `PdfPrintedDocument` and a `Canvas`.

The concept is simple:

- Create a `PrintedPdfDocument` instance, given a `PrintAttributes` that describes the page size, margins, etc.
- Call `startPage()` to add a page to the document, which returns a `PdfDocument.Page`
- Call `getCanvas()` on the `Page` and use the standard Android 2D drawing APIs to draw lines, text, shaded areas, and so forth
- Call `finishPage()` on the `PdfPrintedDocument` when you are done rendering that page
- Repeat the preceding three steps for all needed pages

- Call `writeTo()` on the `PrintedPdfDocument` to write the PDF to an `OutputStream`, such as the one you get from the `ParcelFileDescriptor` in the `onWrite()` callback of your `PrintDocumentAdapter`
- Call `close()` on the `PrintedPdfDocument` when you are done

For example, let's look at the `onWrite()` implementation used by `PrintHelper` to print a bitmap:

```
@Override
public void onWrite(PageRange[] pageRanges, ParcelFileDescriptor fileDescriptor,
                    CancellationSignal cancellationSignal,
                    WriteResultCallback writeResultCallback) {
    PrintedPdfDocument pdfDocument = new PrintedPdfDocument(mContext,
        mAttributes);
    try {
        Page page = pdfDocument.startPage(1);
        RectF content = new RectF(page.getInfo().getContentRect());

        // Compute and apply scale to fill the page.
        Matrix matrix = getMatrix(mBitmap.getWidth(), mBitmap.getHeight(),
            content, fittingMode);

        // Draw the bitmap.
        page.getCanvas().drawBitmap(mBitmap, matrix, null);

        // Finish the page.
        pdfDocument.finishPage(page);

        try {
            // Write the document.
            pdfDocument.writeTo(new FileOutputStream(
                fileDescriptor.getFileDescriptor()));
            // Done.
            writeResultCallback.onWriteFinished(
                new PageRange[]{PageRange.ALL_PAGES});
        } catch (IOException ioe) {
            // Failed.
            Log.e(LOG_TAG, "Error writing printed content", ioe);
            writeResultCallback.onWriteFailed(null);
        }
    } finally {
        if (pdfDocument != null) {
            pdfDocument.close();
        }
        if (fileDescriptor != null) {
            try {
                fileDescriptor.close();
            } catch (IOException ioe) {
                /* ignore */
            }
        }
    }
}
```

```
}  
}
```

(note: the preceding code snippet is Copyright (C) 2013 The Android Open Source Project)

Here, they:

- Create the `PrintedPdfDocument`
- Add a page using `startPage()`
- Calculate a scaling `Matrix` based upon the image size, the page size, and the scale type (`FIT` or `FILL`)
- Draw the bitmap on the `Canvas` using that `Matrix`
- Finish the page
- Write the result to an `OutputStream` for the supplied `ParcelFileDescriptor`
- Close the document

Curiously, they do not do this work in a background thread, though the `onLayout()` implementation does use a background thread (since the image `Uri` may require an Internet download).

If you are comfortable with the `Canvas` API, writing PDF pages is much the same as drawing to your custom `View`. On the other hand, Android's `Canvas` API is not the same as any other drawing system's API, so there will be distinct differences from any other 2D drawing API that you might have used previously.

Print Jobs

The `print()` method that we have been calling on `PrintManager` returns a `PrintJob`, representing the print job. This object has a number of status inquiry methods, including (in rough order of when the events occur):

- `isStarted()`
- `isQueued()` (i.e., waiting for the print system to process it)
- `isBlocked()` (i.e., permanently stuck, but needs to be canceled)
- `isCompleted()`
- `isFailed()`
- `isCancelled()`

It also has a `cancel()` method that you can call to cancel the print job (e.g., based on user request). `PrintJob` also offers a `restart()` method that you can use to re-try a failed (but not canceled) print job.

What `PrintJob` does not have is a listener interface to be proactively notified when the job changes state.

`PrintManager` also has `getPrintJobs()`, which will return a list of the `PrintJob` objects representing the jobs you have requested in this process, rather than having to keep track of all of those yourself.

Printing, Threads, and Services

If you are going to create a report in HTML, you will want to consider doing that work in an `AsyncTask`'s `doInBackground()` method, so the I/O involved in creating the report happens in the background. However, `PrintManager` requires that `print()` be called on the main application thread, so you would call `print()` from `onPostExecute()` of the `AsyncTask`.

Similarly, if you are creating your own `PrintDocumentAdapter`, you will want to consider moving the `onLayout()` and `onWrite()` work into background threads, such as is illustrated in the sample app via `ThreadedPrintDocumentAdapter`.

The problem with bare threads or an `AsyncTask` is that they do not indicate to Android that your process is still doing some work. It is possible that the user could request that you print something, then switch to another app (e.g., HOME, recent-tasks list). Android might consider your process to be relatively low priority and could terminate it before your print job completes.

The obvious solution is to involve a service, perhaps even a foreground service, to indicate to Android that your process is doing work that the user will notice if it does not complete. You could start the service when you do the print job, and then stop the service when the print job is completed, to return your process to normal priority.

However, actually having a service do the printing is a serious pain:

- `WebView`'s `PrintDocumentAdapter` really wants the `Context` that created the `WebView` to be an `Activity`

- The key parameters to `onLayout()` and `onWrite()` are not `Parcelable` and so cannot be passed in `Intent` extras via `startService()` to the service

One possibility would be to create a `PrintJobMonitorService`, which is what the sample app does. `PrintJobMonitorService` takes advantage of that `listPrintJobs()` method on `PrintManager` to keep tabs on all of our requested print jobs. So long as there is one or more print jobs in an active state, the service keeps running. Otherwise, the service stops. Hence, while the service is not actually doing the printing, it is running while the printing is going on, flagging to the OS to leave our process alone during this critical juncture.

```
package com.commonware.android.print;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.os.SystemClock;
import android.print.PrintJob;
import android.print.PrintJobInfo;
import android.print.PrintManager;
import java.util.concurrent.Executors;
import java.util.concurrent.ScheduledExecutorService;
import java.util.concurrent.TimeUnit;

public class PrintJobMonitorService extends Service implements Runnable {
    private static final int POLL_PERIOD=3;
    private PrintManager mgr=null;
    private ScheduledExecutorService executor=
        Executors.newSingleThreadScheduledExecutor();
    private long lastPrintJobTime=SystemClock.elapsedRealtime();

    @Override
    public void onCreate() {
        super.onCreate();

        mgr=(PrintManager)getSystemService(PRINT_SERVICE);
        executor.scheduleAtFixedRate(this, POLL_PERIOD, POLL_PERIOD,
            TimeUnit.SECONDS);
    }

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        return(super.onStartCommand(intent, flags, startId));
    }

    @Override
    public void onDestroy() {
        executor.shutdown();

        super.onDestroy();
    }
}
```

```
@Override
public void run() {
    for (PrintJob job : mgr.getPrintJobs()) {
        if (job.getInfo().getState() == PrintJobInfo.STATE_CREATED
            || job.isQueued() || job.isStarted()) {
            lastPrintJobTime=SystemClock.elapsedRealtime();
        }
    }

    long delta=SystemClock.elapsedRealtime() - lastPrintJobTime;

    if (delta > POLL_PERIOD * 2) {
        stopSelf();
    }
}

@Override
public IBinder onBind(Intent intent) {
    return(null);
}
}
```

PrintJobMonitorService uses a single-thread ScheduledExecutorService, to get control every three seconds in its run() method. The run() method iterates over the PrintJob objects associated with our app and looks for any that are in one of three states:

- “started”, meaning that printing has begun
- “queued”, meaning that the user has accepted the print dialog values, but printing has not yet started
- “created”, meaning that the job has been created, but it is not yet considered queued, such as when the print dialog is up on the screen

The first two states have simple test methods on PrintJob (isStarted() and isQueued()). The “created” state does not, for some reason, so we have to get the underlying PrintJobInfo object and manually check its state (getState()) to see if it is started (PrintJobInfo.STATE_STARTED).

PrintJobMonitorService tracks the last time we saw an in-progress print job. If we have gone through two three-second polling periods without any in-progress print jobs, the service assumes that it is no longer needed and calls stopSelf().

Printing Prior to Android 4.4

Before Android 4.4, printing in Android was limited and clunky.

The primary approach was to use Google Cloud Print. In effect, Google Cloud Print is a Web-managed print server. You would teach Google how to talk to your printers, and then any authorized device could print to those printers. By sharing your content (particularly PDFs) via `ACTION_SEND`, the user could choose Google Cloud Print as an option if they had Google Cloud Print set up for their device and printer. Note that the Android 4.4 printing framework includes a `PrintService` that works with Google Cloud Print, so users who have set up Google Cloud Print can still use it even with the new printing framework.

Various printer manufacturers or third parties also created their own apps that would fill a similar role, albeit perhaps working with printers on the local network. Or, you could write your own low-level code to talk to a network printer via relevant printing protocols like IPP, though this would be unpleasant at best.

HTML Generation

[Earlier in this chapter](#), we saw how to print HTML. However, the HTML we printed was loaded from a URL. That is fine, but, as with printing bitmaps, it may not be a very popular scenario. What will be more likely is that you want to print some sort of report, generated on the device. And, since printing using the Canvas is a bit complicated, creating the report via HTML may be an easier route to take.

The typical approach for this involves creating an HTML template that sets up the basic page (e.g., references to CSS), then uses some sort of “macros” in the template to indicate portions that should be replaced dynamically with something from outside of the template.

This approach has been used since the early days of the original “dot-com revolution” of the 1990’s, pioneered by tools like Cold Fusion. In Java, there are any number of [available template engines](#).

However, for HTML, it is reasonably likely that a Web designer is going to want to get involved, to style the report. Ideally, you choose a template engine that is either something the designer is already using, or is one that is something the designer might wish to use elsewhere in the future. Forcing the designer to learn some new template syntax, just for the purposes of creating these reports, may not be the best use of the designer’s time (or your time, for answering all of the designer’s questions).

One of the more popular template structures used today use braces (a.k.a., curly brackets) as the macro delimiters (e.g., `{{ something }}`). In particular, the macro syntax popularized by [mustache](#) is used by many template engine implementations. There is a very good chance that your Web designer already has used mustache-style templates, or at least has heard about them.

And, conveniently enough, there is a Java implementation – [jmustache](#) — that is Android-friendly. The sample app in this chapter implements a [“TPS Report”](#) that is generated from a mustache template using `jmustache`.

Adding jmustache To Your App

The [“Get It” section of the jmustache documentation](#) contains up-to-date instructions for adding it to a project.

Developers using Gradle for Android — including Android Studio users – should reference the Maven Central artifact (`com.samskivert:jmustache`) from `build.gradle`.

Developers using Eclipse or Ant can download the JAR file and add it to their project’s `libs/` directory.

Writing the Report Template

A report template for `jmustache` can be a `String` or a `Reader`, with the latter allowing you to pull in files, assets, or raw resources (the latter two via an `InputStreamReader`).

In the case of the sample app, the template is small, and is packaged as a string resource. However, since the template involves HTML tags, we have to use `CDATA` notation to allow those tags to be left alone within the XML of the string resource:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of this week\'s TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
```

Figure 686: TPS Report Mustache Template

The template contains {{reportDate}} and {{message}} variables to be replaced at runtime with dynamic data from our app. Also note that, despite the CDATA, we still need to escape the apostrophe with a leading backslash (\').

Creating a Report Context

What will fill in the {{reportDate}} and {{message}} variables will be values from a “context”. Here, “context” is not referring to Context, but rather an object that we pass to jmustache to serve as the source of data to blend into the report.

jmustache has fairly flexible rules for how it can resolve template variables, including calling Java getter methods based on the variable names. Hence, we can create a “context” that has getReportDate() and getMessage() methods, such as the TpsReportContext class in the sample app:

```
private static class TpsReportContext {
    private static final SimpleDateFormat fmt=
        new SimpleDateFormat("yyyy-MM-dd", Locale.US);
    String msg;

    TpsReportContext(String msg) {
        this.msg=msg;
    }

    @SuppressWarnings("unused")
    String getReportDate() {
        return(fmt.format(new Date()));
    }

    @SuppressWarnings("unused")
    String getMessage() {
        return(msg);
    }
}
```

```
}  
}
```

Printing the Report

The “TPS Report” action bar overflow item eventually routes to a `printReport()` method on `MainActivity`:

```
private void printReport() {  
    Template tpl=  
        Mustache.compiler().compile(getString(R.string.report_body));  
    WebView print=prepPrintWebView(getString(R.string.tps_report));  
  
    print.loadData(tpl.execute(new TpsReportContext(prose.getText()  
                                                    .toString())),  
                  "text/html", "UTF-8");  
}
```

The first statement creates a `jmustache Template` object representing the report template. This is created by getting the singleton `compiler()` from `Mustache`, and calling `compile()` on it to interpret the string resource. Note that since this `Template` only depends upon the string resource, we could cache the `Template`, rebuilding it only on configuration changes, if desired.

Note that we load the template on the main application thread, as `printReport()` is called from `onOptionsItemSelected()`. For a small string resource, that is OK. If you are loading a more complex report template, you will want to do that in a background thread.

The second statement mirrors one from printing the Web page from before, where we call `prepPrintWebView()` to lazy-create our `WebView` and set it up to print when the page is loaded. Here, we use a different print job name than before, one reflecting the fact that this is a TPS report.

Finally, we use `execute()` on the `Template` to generate our HTML for printing, then pass that HTML to the `loadData()` method on `WebView`. `execute()` takes our “context” Object, which in this case is an instance of our `TpsReportContext` class, with the value typed into the `EditText` widget in our UI as the “message” to go into the report.

Note that we `execute()` the `Template` on the main application thread as well as having loaded it on that thread in the first place. Once again, the more complex the report, the more likely it is that you will want to move this logic into a background

thread. However, remember that `print()` needs to be called on the main application thread.

The result is that the user gets a printed TPS report, containing today's date and whatever message they typed into the `EditText`.

PDF Generation Options

Perhaps you feel that generating HTML does not give you enough control, yet using the Canvas options directly was *too* much control. Perhaps you then think that generating a PDF to print, using something other than `PdfDocument`, is the right answer. Or perhaps you are generating a PDF for other reasons, such as to use with `ACTION_SEND` as output from your app.

You have two basic options for getting this PDF: generate it on the device, or offload the generation to a server.

There are various [open source and commercial libraries](#) for generating PDF on Android. The best-known open source Java PDF library – `iText` — has as dedicated Android version (`iTextG`), though the AGPL license may make it unsuitable for your use case. The commercial libraries range from fixed-price to per-device licenses. How much advantage these have over using `PrintedPdfDocument` from the Android SDK depends upon your needs.

If the bulk of the data needed for generating the PDF resides on a server, rather than downloading that data and using an underpowered Android device to create the PDF, you could upload the device-specific data to the server, have it create the PDF, and download the result from the server. There are plenty of server-side PDF generation tools, ranging from open source (e.g., [wkhtmltopdf](#), [unoconv](#), [prawn](#)) to commercial (e.g., [Prince](#), used to generate the PDF edition of this book). You also get to work in your preferred programming language, in case that is not Java, and perhaps leverage the PDF generation logic for other uses (e.g., generate reports from your Web app).

Other System Settings and Services

Android offers a number of system services, usually obtained by `getSystemService()` from your Activity, Service, or other Context. These are your gateway to all sorts of capabilities, from settings to volume to WiFi. Throughout the course of this book, we have seen several of these system services. In this chapter, we will take a look at others that may be of value to you in building compelling Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Setting Expectations

If you have an Android device, you probably have spent some time in the Settings application, tweaking your device to work how you want – ringtones, WiFi settings, USB debugging, etc. Many of those settings are also available via Settings class (in the `android.provider` package), and particularly the `Settings.System` and `Settings.Secure` public inner classes.

Basic Settings

`Settings.System` allows you to get and, with the `WRITE_SETTINGS` permission, alter these settings. As one might expect, there are a series of typed getter and setter methods on `Settings.System`, each taking a key as a parameter. The keys are class constants, such as:

OTHER SYSTEM SETTINGS AND SERVICES

1. `INSTALL_NON_MARKET_APPS` to control whether you can install applications on a device from outside of the Play Store
2. `HAPTIC_MODE_ENABLED` to control whether the user receives “haptic feedback” (vibrations) from things like the MENU button
3. `ACCELEROMETER_ROTATION` to control whether the screen orientation will change based on the position of the device

The [SystemServices/Settings](#) sample project has a `SettingsSetter` sample application that displays a checklist:

```
<?xml version="1.0" encoding="utf-8"?>
<ListView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

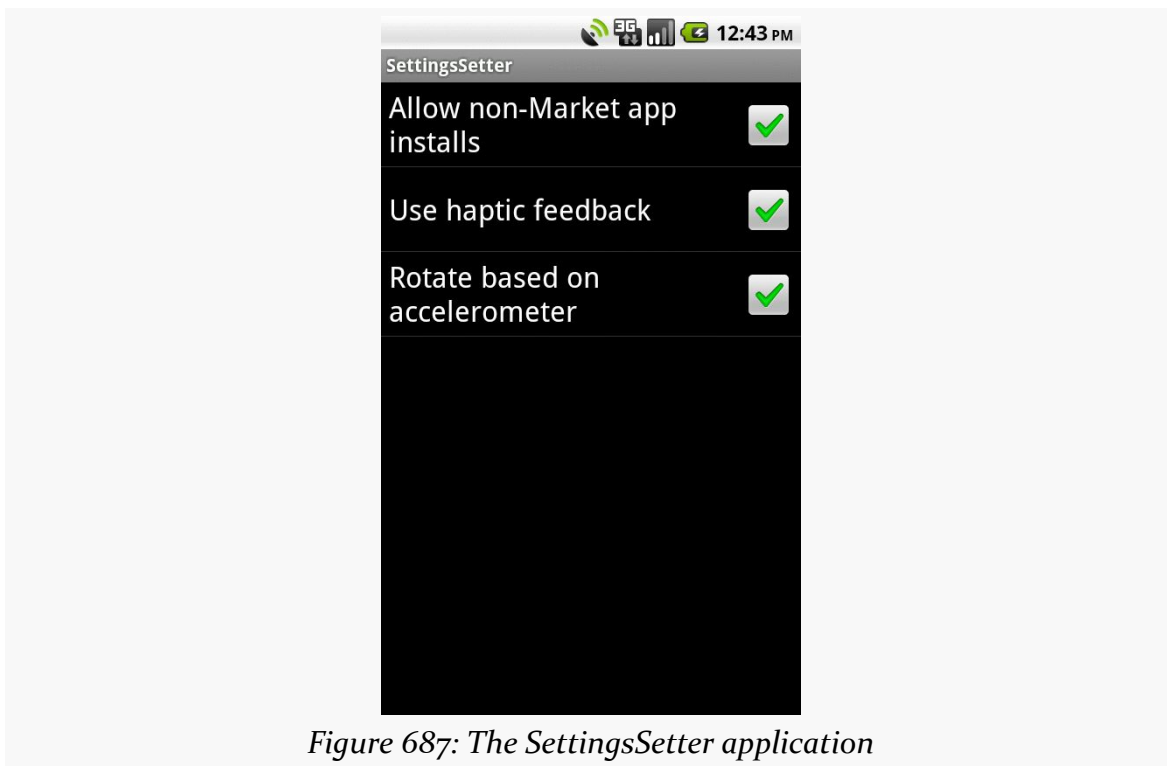

Figure 687: The `SettingsSetter` application

The checklist itself is filled with a few `BooleanSetting` objects, which map a display name with a `Settings.System` key:

```
static class BooleanSetting {
    String key;
```

```
String displayName;
boolean isSecure=false;

BooleanSetting(String key, String displayName) {
    this(key, displayName, false);
}

BooleanSetting(String key, String displayName,
    boolean isSecure) {
    this.key=key;
    this.displayName=displayName;
    this.isSecure=isSecure;
}

@Override
public String toString() {
    return(displayName);
}

boolean isChecked(ContentResolver cr) {
    try {
        int value=0;

        if (isSecure) {
            value=Settings.Secure.getInt(cr, key);
        }
        else {
            value=Settings.System.getInt(cr, key);
        }

        return(value!=0);
    }
    catch (Settings.SettingNotFoundException e) {
        Log.e("SettingsSetter", e.getMessage());
    }

    return(false);
}

void setChecked(ContentResolver cr, boolean value) {
    try {
        if (isSecure) {
            Settings.Secure.putInt(cr, key, (value ? 1 : 0));
        }
        else {
            Settings.System.putInt(cr, key, (value ? 1 : 0));
        }
    }
    catch (Throwable t) {
        Log.e("SettingsSetter", "Exception in setChecked()", t);
    }
}
}
```

Three such settings are put in the list:

```
settings.add(new BooleanSetting(Settings.System.INSTALL_NON_MARKET_APPS,
                                "Allow non-Market app installs",
                                true));
settings.add(new BooleanSetting(Settings.System.HAPTIC_FEEDBACK_ENABLED,
                                "Use haptic feedback",
                                false));
settings.add(new BooleanSetting(Settings.System.ACCELEROMETER_ROTATION,
                                "Rotate based on accelerometer",
                                false));
```

As the checkboxes are checked and unchecked, the values are passed along to the settings themselves:

```
@Override
protected void onListItemClick(ListView l, View v,
                                int position, long id) {
    super.onListItemClick(l, v, position, id);

    BooleanSetting s=settings.get(position);

    s.setChecked(getContentResolver(),
                 l.isItemChecked(position));
}
```

The SettingsSetter activity also has an option menu containing four items:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+id/app"
          android:title="Application"
          android:icon="@android:drawable/ic_menu_manage" />
    <item android:id="@+id/security"
          android:title="Security"
          android:icon="@android:drawable/ic_menu_close_clear_cancel" />
    <item android:id="@+id/wireless"
          android:title="Wireless"
          android:icon="@android:drawable/ic_menu_set_as" />
    <item android:id="@+id/all"
          android:title="All Settings"
          android:icon="@android:drawable/ic_menu_preferences" />
</menu>
```

These items correspond to four activity Intent values identified by the Settings class:

```
menuActivities.put(R.id.app,
                   Settings.ACTION_APPLICATION_SETTINGS);
menuActivities.put(R.id.security,
```

```
        Settings.ACTION_SECURITY_SETTINGS);
menuActivities.put(R.id.wireless,
        Settings.ACTION_WIRELESS_SETTINGS);
menuActivities.put(R.id.all,
        Settings.ACTION_SETTINGS);
```

When an option menu is chosen, the corresponding activity is launched:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    String activity=menuActivities.get(item.getItemId());

    if (activity!=null) {
        startActivity(new Intent(activity));

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

This way, you have your choice of either directly manipulating the settings or merely making it easier for users to get to the Android-supplied activity for manipulating those settings.

Secure Settings

You will notice that if you use the above code and try changing the Play Store setting, it does not seem to take effect. And, if you look at the LogCat output, you will see complaints.

Once upon a time, you could modify this setting, and others like it.

Now, though, these settings are ones that Android deems “secure”. The constants have been moved from `Settings.System` to `Settings.Secure`, though the old constants are still there, flagged as deprecated.

These so-called “secure” settings are ones that Android does not allow applications to change. While theoretically the `WRITE_SECURE_SETTINGS` permission resolves this problem, ordinary SDK applications cannot hold that permission. The only option is to display the official Settings activity and let the user change the setting.

API Level 17 takes things one step further, moving a number of settings out of `Settings.System` and `Settings.Secure` and placing them in a new `Settings.Global`. Like `Settings.Secure`, ordinary SDK apps cannot modify these

settings, as they are secured by `WRITE_SECURE_SETTINGS`. The distinction between `Settings.Secure` and `Settings.Global` comes with respect to scope: `Settings.Secure` is on a per-user basis (for devices set up with multiple users), and `Settings.Global` is device-wide.

Can You Hear Me Now? OK, How About Now?

The fancier the device, the more complicated controlling sound volume becomes.

On a simple MP3 player, there is usually only one volume control. That is because there is only one source of sound: the music itself, played through speakers or headphones.

In Android, though, there are several sources of sounds:

1. Ringing, to signify an incoming call
2. Voice calls
3. Alarms, such as those raised by the Alarm Clock application
4. System sounds (error beeps, USB connection signal, etc.)
5. Music, as might come from the MP3 player

Android allows the user to configure each of these volume levels separately. Usually, the user does this via the volume rocker buttons on the device, in the context of whatever sound is being played (e.g., when on a call, the volume buttons change the voice call volume). Also, there is a screen in the Android Settings application that allows you to configure various volume levels.

The `AudioService` in Android allows you, the developer, to also control these volume levels, for all five “streams” (i.e., sources of sound). In the [SystemServices/Volume](#) sample project, we create a `Volumizer` application that displays and modifies all five volume levels.

Attaching SeekBars to Volume Streams

The standard widget for allowing choice along a range of integer values is the `SeekBar`, a close cousin of the `ProgressBar`. `SeekBar` has a thumb that the user can slide to choose a value between 0 and some maximum that you set. So, we will use a set of five `SeekBar` widgets to control our five volume levels.

First, we need to create a layout with a `SeekBar` per stream:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">

    <TableRow
        android:paddingBottom="20px"
        android:paddingTop="10px">

        <TextView android:text="Alarm:"/>

        <SeekBar
            android:id="@+id/alarm"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow android:paddingBottom="20px">

        <TextView android:text="Music:"/>

        <SeekBar
            android:id="@+id/music"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow android:paddingBottom="20px">

        <TextView android:text="Ring:"/>

        <SeekBar
            android:id="@+id/ring"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow android:paddingBottom="20px">

        <TextView android:text="System:"/>

        <SeekBar
            android:id="@+id/system"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

        <TextView android:text="Voice:"/>

        <SeekBar
            android:id="@+id/voice"
```

```
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>
    </TableRow>
</TableLayout>
```

Then, we need to wire up each of those bars in the `onCreate()` for `Volumizer`, calling an `initBar()` method for each of the five bars:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(AudioManager)getSystemService(Context.AUDIO_SERVICE);

    alarm=(SeekBar)findViewById(R.id.alarm);
    music=(SeekBar)findViewById(R.id.music);
    ring=(SeekBar)findViewById(R.id.ring);
    system=(SeekBar)findViewById(R.id.system);
    voice=(SeekBar)findViewById(R.id.voice);

    initBar(alarm, AudioManager.STREAM_ALARM);
    initBar(music, AudioManager.STREAM_MUSIC);
    initBar(ring, AudioManager.STREAM_RING);
    initBar(system, AudioManager.STREAM_SYSTEM);
    initBar(voice, AudioManager.STREAM_VOICE_CALL);
}
```

In `initBar()`, we set the appropriate size for the `SeekBar` bar via `setMax()`, set the initial value via `setProgress()`, and hook up an `OnSeekBarChangeListener` to find out when the user slides the bar, so we can set the volume on the stream via the `VolumeManager`.

The net result is that when the user slides a `SeekBar`, it adjusts the stream to match:

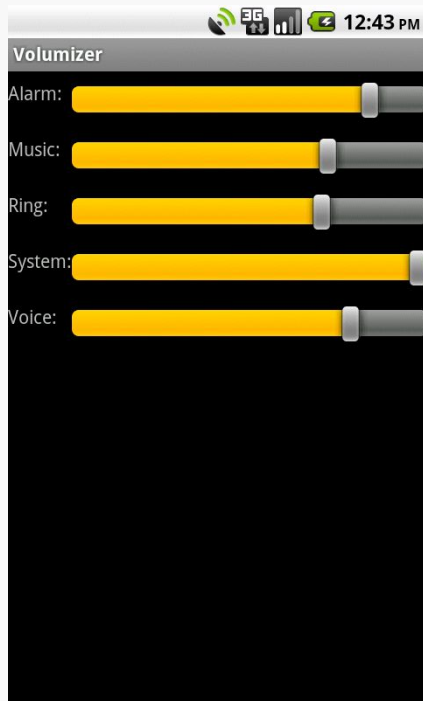

Figure 688: The Volumizer application

The Rest of the Gang

There are quite a few system services you can get from `getSystemService()`. Beyond the ones profiled in this chapter, you have access to:

1. `AccessibilityManager`, for being notified of key system events (e.g., activities starting) that might be relayed to users via haptic feedback, audio prompts, or other non-visual cues
2. `AccountManager`, for working with Android's system of user accounts and synchronization
3. `ActivityManager`, for getting more information about what processes and components are presently running on the device
4. `AlarmManager`, for scheduled tasks (a.k.a., “cron jobs”), covered [elsewhere in this book](#)
5. `ConnectivityManager`, for a high-level look as to what sort of network the device is connected to for data (e.g., WiFi, 3G)
6. `DevicePolicyManager`, for accessing device administration capabilities, such as wiping the device

7. DownloadManager, for downloading large files on behalf of the user, covered in [the chapter on Intents](#)
8. DropBoxManager, for maintaining your own ring buffers of logging information akin to LogCat
9. InputMethodManager, for working with input method editors
10. KeyguardManager, for locking and unlocking the keyguard, where possible
11. LayoutInflater, for inflating layout XML files into Views, covered elsewhere in this book
12. LocationManager, for determining the device's location (e.g., GPS), covered in [the chapter on location tracking](#)
13. NotificationManager, for putting icons in the status bar and otherwise alerting users to things that have occurred asynchronously, covered in [the chapter on Notification](#)
14. PowerManager, for obtaining WakeLock objects and such, covered [elsewhere in this book](#)
15. SearchManager, for interacting with the global search system – search in general is covered [elsewhere in this book](#)
16. SensorManager, for accessing data about sensors, such as the accelerometer
17. TelephonyManager, for finding out about the state of the phone and related data (e.g., SIM card details)
18. UiModeManager, for dealing with different “UI modes”, such as being docked in a car or desk dock
19. Vibrator, for shaking the phone (e.g., haptic feedback)
20. WifiManager, for getting more details about the active or available WiFi networks
21. WindowManager, mostly for accessing details about the default display for the device

Dealing with Different Hardware

While a lot of focus is placed on screen sizes, there are many other possible hardware differences among different Android devices. For example, some have telephony features, while others do not.

There is a three-phase plan for dealing with these variations:

1. **Filter** out devices that cannot possibly run your app successfully, so your app will not appear to them in the Play Store and they will be unable to install your app if obtained by other means
2. **React** to varying hardware that you can support, but perhaps might support differently (e.g., choosing a particular flash mode for a device having a camera with a flash)
3. **Cope** with device bugs or regressions that impact your application

This chapter will go through each of these topics.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Filtering Out Devices

Elsewhere in the book, we discussed a few manifest entries that will serve to filter out devices that cannot run your app:

- [android:minSdkVersion in the <uses-sdk> element](#), to stipulate that devices must run a certain version of Android (or higher)
- [<supports-screens> and <compatible-screens>](#), which indicate which screens sizes and densities you are capable of supporting

This section outlines other “advertisements” that you can put in the manifest to restrict which devices run your app.

uses-feature

The `<uses-feature>` element restricts your app to devices that have certain hardware features. For each element, you supply the name of a feature (e.g., `android.hardware.telephony`) and whether or not it is required:

```
<uses-feature
  android:name="android.hardware.camera"
  android:required="false" />
```

By default, `android:required` is set to `true`, so typically you will only see it in a manifest when it is set to `false`.

You might wonder why we would bother ever setting `android:required` to `false`. After all, that should have the same effect as not listing it at all. In practice, though, it has two major uses.

First, markets like the Play Store might highlight the fact that you *can* use a particular hardware capability, even though you do not strictly require it.

More importantly, you can use `android:required="false"` to *undo* a *requirement* that Android infers from your permissions. Requesting some permissions causes Android to assume — for backwards-compatibility reasons — that your app needs the affiliated hardware. For example, requesting the `CAMERA` permission causes Android to assume that you need a camera (`android.hardware.camera`) *and* that the camera support auto-focus (`android.hardware.camera.autofocus`). If, however, you are requesting the permission because you would like to use the hardware if available, but can live without it, you need to expressly add a `<uses-feature>` element declaring that the hardware feature is not required.

For example, in February 2010, the Motorola XOOM tablet was released. This was the first Android device that had the Play Store on it and truly had no telephony capability. As such, the XOOM would be filtered out of the then-Android Market (now Play Store) for any app that required permissions like `SEND_SMS`. Many

developers requested this permission, even though their apps could survive without SMS-sending capability. However, their apps were still filtered out if they did not have the `<uses-feature>` element declaring that telephony was not required.

You can find a table listing Android permissions and assumed hardware feature requirements in [the Android developer documentation](#).

uses-configuration

The `<uses-configuration>` element is very reminiscent of `<uses-feature>`: it dictates hardware requirements. The difference is two-fold:

1. It focuses on hardware elements that represent different device configurations, meaning that you might use different resources for them
2. It allows you to specify *combinations* of capabilities that you need

There are three capabilities that you can require via `<uses-configuration>`:

1. The existence of a five-way navigation control, whether a specific type (D-pad, trackball, etc.) or any such control
2. The existence of a physical keyboard, whether a specific type (QWERTY, 12-key numeric keypad, etc.) or any such keyboard
3. A touchscreen

You can have as many `<uses-configuration>` elements as you need – any device that matches at least one such configuration will be eligible to install your app.

For example, the following `<uses-configuration>` element restricts your app to devices that have some sort of navigation control but do not necessarily have a touchscreen, such as an Android TV device:

```
<uses-configuration
  android:reqFiveWayNav="true"
  android:reqTouchScreen="notouch" />
```

uses-library

The `<uses-library>` element tells Android that your application wishes to use a particular *firmware*-supplied library. The most common case for this was Maps V1, which is shipped in the form of an SDK add-on and firmware library. This, however, has been deprecated for quite some time.

However, there are other firmware libraries that you might need. These will typically be manufacturer-specific libraries, allowing your application to take advantage of particular beyond-the-Android-SDK capabilities of a particular device. For example, several Motorola Mobility devices ship with an [“Enterprise Device Management” firmware library](#), as an extension of Android’s own device admin APIs.

The Google Play Store will filter out your application from devices that lack a firmware library that you require via `<uses-library>`. If the user tries installing your app by some other means (e.g., download from a Web site), your app will fail to install on devices that lack the firmware library.

If you conditionally want the firmware library — you will use it if available but can cope if it is not — you can add `android:required="false"` to your `<uses-library>` element. That will allow your app to install and run on devices missing the library in question. Detecting whether or not the library exists in your process at runtime is a matter of using `Class.forName()` to see if you have access to some class from that library, where a `ClassNotFoundException` means that you do not have the library.

Runtime Capability Detection

Reacting to device capabilities is the second phase of dealing with different devices. Some features you might want (e.g., telephony for sending SMSes) but can live without. Other features may have subtle variations that you cannot filter against and therefore need to adapt to at runtime (e.g., possible picture resolutions off of a camera).

This section will cover various techniques for determining what a device can do, at runtime, so you can react accordingly.

Features

Any feature you do not make required via `<uses-feature>` can be detected at runtime by calling `hasSystemFeature()` on `PackageManager`. For example, if you would like to send SMS messages, but only on telephony-capable devices, you could have the following `<uses-feature>` element:

```
<uses-feature
  android:name="android.hardware.telephony"
  android:required="false" />
```

Then, at runtime, you can call `hasSystemFeature("android.hardware.telephony")` on a `PackageManager` instance to find out if, indeed, the device has telephony capability and sending SMSes should work.

Other Capabilities

Various subsystems have their own means of helping you determine what is possible or not:

- The [Camera class](#), via `Camera.Parameters`, can let you know the capabilities of a camera (e.g., whether or not it has a flash, and what specific flash modes are supported).
- The [LocationManager](#) will help you determine what location providers are available that meet your `Criteria`.
- The sensor subsystem lets you find out what sensors are installed, either overall or for a particular type (e.g., accelerometer).

Dealing with Device Bugs

Alas, devices are not perfect. Even though [the Compatibility Test Suite](#) attempts to ensure that all Android devices legitimately running the Play Store faithfully implement the Android SDK, some device manufacturers make changes that introduce bugs.

Just as Web developers can “sniff” on the User-Agent HTTP header to determine what sort of browser is requesting a page, you can use the `Build` class to determine what sort of device is running your app. If you encounter problems with a specific device, you may be able to use `Build` to identify that device at runtime and “route around the damage”.

Trail: Integration and Introspection

Responding to URLs

You may have noticed that Android supports a `market:` URL scheme. Web pages can use such URLs so that, if they are viewed on an Android device's browser, the user can be transported to a Play Store page, perhaps for a specific app or a list of apps for a publisher.

Fortunately, that mechanism is not limited to Android's code — you can get control for various other types of links as well. You do this by adding certain entries to an activity's `<intent-filter>` for an `ACTION_VIEW` Intent.

However, be forewarned that this capability is browser-specific. What works on the original Android “Browser” app and Google's Chrome may not necessarily work on Firefox for Android or other browsers.

Prerequisites

Understanding this chapter requires that you have read the chapter on [Intent filters](#).

Manifest Modifications

First, any `<intent-filter>` designed to respond to browser links will need to have a `<category>` element with a name of `android.intent.category.BROWSABLE`. Just as the `LAUNCHER` category indicates an activity that should get an icon in the launcher, the `BROWSABLE` category indicates an activity that wishes to respond to browser links.

You will then need to further refine which links you wish to respond to, via a `<data>` element. This lets you describe the URL and/or MIME type that you wish to respond

to. For example, here is the `AndroidManifest.xml` file from the [Introspection/URLHandler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.urlhandler"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity
            android:name="URLHandler"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data android:mimeType="application/pdf"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data
                    android:host="www.this-so-does-not-exist.com"
                    android:path="/something"
                    android:scheme="http"/>
            </intent-filter>
            <intent-filter>
                <action android:name="com.commonware.android.MY_ACTION"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>
            </intent-filter>
        </activity>
    </application>
```

```
</manifest>
```

Here, we have four `<intent-filter>` elements for our one activity:

- The first is a standard “put an icon for me in the launcher, please” filter, with the LAUNCHABLE category
- The second claims that we handle PDF files (MIME type of `application/pdf`), and that we will respond to browser links (BROWSABLE category)
- The third claims that we will handle any HTTP request (scheme of `"http"`) for a certain Web site (host of `"www.this-so-does-not-exist.com"` and path of `/something`), and that we will respond to browser links (BROWSABLE category)
- The last is a custom action, for which we will generate a URL that Android will honor, and that we will respond to browser links (BROWSABLE category) — we will examine this more closely in [the next section](#)

What happens for the first two links varies based on browser.

The original Android “Browser” app, and Google Chrome, will do the following:

- Tapping the link to the PDF, on Android 2.3+, will trigger a download of the PDF. When the user taps on the downloaded file (e.g., from the Notification in the status bar), the user will have URLHandler as one of the options in the chooser to view the PDF file.
- Tapping the link to `http://www.this-so-does-not-exist.com/something` will bring up a chooser showing all available Web browser, plus URLHandler, as expected

Firefox for Android will treat the PDF link the same way. However, Firefox for Android does not check the URL for the second link to see if there is anything else supporting ACTION_VIEW for the URL, and so it always loads up the Web page. You see this effect with the link to Barcode Scanner as well — even though a device has Barcode Scanner installed, Firefox never offers that as an option.

Creating a Custom URL

Responding to MIME types makes complete sense... if we implement something designed to handle such a MIME type.

Responding to certain schemes, hosts, paths, or file extensions is certainly usable, but other than perhaps the file extension approach, it makes your application a bit fragile. If the site changes domain names (even a sub-domain) or reorganizes its site with different URL structures, your code will break.

If the goal is simply for you to be able to trigger your own application from your own Web pages, though, the safest approach is to use an `intent: URL`. These can be generated from an `Intent` object by calling `toUri(Intent.URI_INTENT_SCHEME)` on a properly-configured `Intent`, then calling `toString()` on the resulting `Uri`.

For example, the `intent: URL` for the fourth `<intent-filter>` from above is:

```
intent:#Intent;action=com.commonware.android.MY_ACTION;end
```

This is not an official URL scheme, any more than `market:` is, but it works for Android devices. When the Android built-in Browser encounters this URL, it will create an `Intent` out of the URL-serialized form and call `startActivity()` on it, thereby starting your activity. Chrome also supports this URL structure. Firefox for Android does not, indicating instead that it cannot recognize the URL.

Reacting to the Link

Your activity can then examine the `Intent` that launched it to determine what to do. In particular, you will probably be interested in the `Uri` corresponding to the link — this is available via the `getData()` method. For example, here is the `URLHandler` activity for this sample project:

```
package com.commonware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        TextView uri=(TextView)findViewById(R.id.uri);
```

RESPONDING TO URLS

```
if (Intent.ACTION_MAIN.equals(getIntent().getAction())) {
    String intentUri=(new Intent("com.commonware.android.MY_ACTION"))
        .toUri(Intent.URI_INTENT_SCHEME)
        .toString();

    uri.setText(intentUri);
    Log.w("URLHandler", intentUri);
}
else {
    Uri data=getIntent().getData();

    if (data==null) {
        uri.setText("Got com.commonware.android.MY_ACTION Intent");
    }
    else {
        uri.setText(getIntent().getData().toString());
    }
}

public void visitSample(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse("http://commonware.com/sample")));
}
```

This activity's layout has a `TextView` (`uri`) for showing a `Uri` and a `Button` to launch a page of links, found on the CommonsWare site (<http://commonware.com/sample>). The `Button` is wired to call `visitSample()`, which just calls `startActivity()` on the aforementioned URL to display it in the Browser.

When the activity starts up, though, it first loads up the `TextView`. What goes in there depends on how the activity was launched:

1. If it was launched via the launcher (e.g., the action is `MAIN`), then we display in the `TextView` the intent: URL shown in the previous section, generated from an `Intent` object designed to trigger our fourth `<intent-filter>`. This also gets dumped to LogCat, and is how the author got this URL in the first place to put on the sample Web page of links.
2. If it was not launched via the launcher, it was launched from a Web link. If the `Uri` from the launching `Intent` is `null`, though, that means the activity was launched via the custom intent: URL (which only has an action string), so we put a message in the `TextView` to match.
3. Otherwise, the `Uri` from the launching `Intent` will have something we can use to process the link request. For the PDF file, it will be the local path to the downloaded PDF, so we can open it. For the

RESPONDING TO URLS

`www.this-so-does-not-exist.com` URL, it will be the URL itself, so we can process it our own way.

Note that for the PDF case, clicking the PDF link in the Browser will download the file in the background, with a Notification indicating when it is complete. Tapping on the entry in the notification drawer will then trigger the `URLHandler` activity.

Also, bear in mind that the device may have multiple handlers for some URLs. For example, a device with a real PDF viewer will give the user a choice of whether to launch the downloaded PDF in the real view or `URLHandler`.

Plugin Patterns

Plugins have historically been a popular model for extending the functionality of a base application. Browsers, for example, have long used plugins for everything from playing Flash animations to displaying calendars.

While Android does not have a specific “plugin framework”, many techniques exist in Android to create plugins. Which of these patterns is appropriate for you will depend upon the nature of the host application and, more importantly, on the nature of the plugin. This chapter will explore some of these plugin patterns.

Prerequisites

Having read the chapters on [app widgets](#) (to be exposed to RemoteViews) and [the Loader framework](#) would be useful, though neither is essential for grasping the core concepts presented in this chapter. Similarly, this chapter has a case study that covers a [lockscreen widget](#), so knowing a bit about those will help, but is not absolutely essential. Another sample involves the use of custom permissions, which are subject to a [vulnerability covered in another chapter](#).

Definitions, Scenarios, and Scope

For the purposes of this chapter, a “plugin model” refers to an app (the plugin “host”) that is being extended by other apps (the “plugins”) that are largely dedicated to that job.

Certainly, there are plenty of ways that apps can work together without one being a plugin to another. The user’s Web browser is not a plugin of your app when you call `startActivity()` to view a Web page, for example.

By contrast, the [Locale app](#) can be extended via plugins, written either by two forty four a.m. (the authors of Locale) or third parties. These plugins have no real value to the user other than by how they improve what Locale itself can do. This sort of structure, therefore, qualifies as a plugin model.

In particular, this chapter will focus on two general scenarios for wanting a plugin model, though others certainly exist:

1. You want to allow third parties to extend the capability of your app, much as two forty four a.m. wanted with Locale, or
2. You want to reduce the number of permissions in your core app by delegating some permissions to plugins, so users can “opt into” those permissions

The Keys to Any Plugin System

There are four essential ingredients for any plugin model:

1. Somehow, the user has to be able to find, download, and install plugins for the host.
2. Somehow, the host app has to know what plugins are installed and available for use.
3. Somehow, the host app and the plugin need to communicate, usually through one form or another of inter-process communication (IPC)
4. All of this needs to be done without compromising the user’s privacy or security

Depending upon the nature of the host app and plugin system, there may need to be additional ingredients (e.g., allowing users to configure the behavior of plugins).

Discovery... By the User

A popular thought experiment is:

If a tree falls in a forest and no one is around to hear it, does it make a sound?

The analog to plugins is:

If an app offers a plugin model, and the user cannot find any plugins, is there really a plugin model?

Somehow, users need to know about available plugins, and frequently that means that *you* will need to help steer them towards those plugins.

If you are focused solely on distributing through the Play Store, you could invite all of your plugin authors to use some particular keyword or phrase, likely to be unique for your plugins, then use `market://search?q=...&c=apps` (with ... replaced by your keyword or phrase) as a `Uri` for an `ACTION_VIEW` Intent passed to `startActivity()`. This will show the user a list of all apps on the Play Store with that keyword or phrase. For example, SONY suggested that developers writing extensions for the SONY SmartWatch use “smartwatch” as a keyword.

Of course, you are welcome to maintain your own roster of available plugins, where your app can download that roster as needed and display the candidates to your users. For example, you might have a JSON file on your Web server at a well-known URL that contains the current lineup of available plugins.

Or, you are welcome to simply offer this sort of information via your Web site, not from within your app. Depending upon how frequently users will be visiting your Web site, this may or may not be helpful to them, but it may be simpler than doing something custom built into your app. For example, you could maintain a simple static Web page with links to the plugins.

Discovery... By Your App

Once a user installs one or more plugins, your plugin host app needs to know that they are there. Continuing with the thought experiments:

If an app offers a plugin model, but fails to recognize any plugins, is there really a plugin model?

Conversely, once a user *removes* a plugin, your host app needs to know about that as well, so that you do not try to use a plugin that no longer exists.

There are any number of possible strategies for finding available plugins; the following sections outline a few candidates.

Broadcast-and-Response

One approach is to send a custom broadcast Intent, at relevant points in time, that is an advertisement to plugins, saying “Hey! Tell me that you exist!”. Plugins, as part of your instructions for writing a plugin, are obligated to respond to that broadcast by doing something to let you know about them, such as:

- Sending their own broadcast back to your host app, providing details about the plugin
- Inserting or updating an entry in a host-published ContentProvider
- Sending a command to a host-supplied IntentService
- Etc.

Any previously-existing plugins that do not respond within some specific period of time are considered “gone”, possibly with the host app using PackageManager and getPackageInfo() to confirm that it is gone.

This is fairly easy to set up, but suffers from non-deterministic timing of broadcasts. The host app can only guess when the broadcast has had enough time to reach all of the plugins and gather responses. It also forces all of those plugin apps to run (to respond to the broadcast), which will cause Android to eject other apps from memory, possibly irritating the user.

Another limitation is that a newly-installed plugin will not respond to a broadcast, on Android 3.1+, until something manually runs one of that plugin’s components, such as the user tapping on the plugin’s activity in the launcher. Not only does this require the plugin to have such an activity (which might not otherwise be needed), but it means that the plugin is useless until this happens. We will discuss this issue a bit more [later in this chapter](#).

Scanning with PackageManager

You could skip the broadcast and directly use PackageManager to find plugins. The benefit here is that the timing is deterministic — you know precisely when you are done with PackageManager. However, somehow, you will need to know what is and is not a plugin, in a way that you can determine by information returned from PackageManager.

If you happen to know the complete list of possible plugins, you could iterate over that list and use getPackageInfo() to see which ones exist and do not exist.

However, this reduces your flexibility, as it requires you to know up front the package names of all possible plugins.

Or, you could use `queryIntentActivities()`, `queryIntentServices()`, or `queryBroadcastReceivers()`, providing an `Intent` that identifies some operation a plugin is obligated to implement, to see what matches are found.

There is also a `queryContentProviders()`, but as it does not take an `Intent`, you would have to iterate over each returned `ProviderInfo` to try to determine if it is a `ContentProvider` representing a plugin.

Alternatively, you could call `getInstalledPackages()` on `PackageManager`, to find out about *everything* that is installed, then iterate over them looking for something.

Watching Package-Related Broadcasts

If using `PackageManager` to examine all possible plugins is still too slow, you could optimize things a bit by watching for `ACTION_PACKAGE_ADDED`, `ACTION_PACKAGE_REPLACED`, and `ACTION_PACKAGE_REMOVED` broadcasts, to monitor *changes* to the mix of installed packages. If a known plugin is removed, you can remove it from your roster of installed plugins. When packages are added or replaced, you could use `PackageManager` and `getPackageInfo()` to learn about that specific package, to determine if it represents one of your plugins.

This, however, increases the complexity of your app, as now you need to monitor these broadcasts and maintain your own roster of available plugins somewhere.

Discovery and Usage of the IPC Endpoints

Given that you know that you have a certain number of plugins, represented by a certain set of packages, you can work on actually communicating with them, using any of the available IPC mechanisms. Also, for static data, you have the option of using manifest metadata or well-known resources to publish that data.

No matter what you settle upon, though, you need to consider the impacts of changes to your host app, that might require changes to your interaction with plugins. Everything in this section qualifies as an API that your host app offers to plugins; changes to that API will require you to consider versioning and backwards compatibility.

Component IPC Options

Your plugin could:

- Have an activity, supporting an agreed-upon Intent structure, that your app opens as needed
- Have a service, supporting an agreed-upon Intent structure, that your app sends commands to or binds to as needed
- Have a BroadcastReceiver, supporting an agreed-upon Intent structure, that your app can send broadcasts to as needed

For any of those, you would use `setComponentName()` as part of the Intent, to specifically identify the plugin that you are talking to.

Your plugin could also have a `ContentProvider` that your host communicates with. That, however, requires that you somehow find out the appropriate authority to use. That authority might be obtained by an agreed-upon algorithm based upon the package name (e.g., the authority is the plugin's package name plus `.PROVIDER`). Or, that authority might be determined by some static data, techniques for which are described in the next section.

In any of these cases, your host's plugin model would document the expectations the host would have of the plugins:

- What Intent extras are supported, what their meanings are, and what the data types are for the extras' keys
- What the schema is for the `ContentProvider`
- Etc.

Your host could also be publishing activities, services, receivers, or providers for the plugin to use. So, for example, your host could send a command to a plugin's `IntentService`, that turns around and modifies data in your host's exported `ContentProvider`.

What data is transferred between the host and plugin, of course, is up to you. Bear in mind, though, that IPC cannot handle arbitrary objects. You will need to stick to primitives and basic collections, framework-supplied `Parcelable` classes (e.g., `Bundle`), or your own custom `Parcelable` classes.

Static Data Options

Some information that you might need about the plugin is static. In those cases, you do not need to use IPC to get the data, thereby saving the cost of loading the plugin into memory just to invoke some component inside of it.

One option for static data is to use manifest metadata. Any `<activity>`, `<service>`, or `<receiver>` element can have one or more child `<meta-data>` elements. These can hold static data that your host app can read in. There are two major flavors of `<meta-data>` elements:

- A simple key/value pair, where the key is provided by `android:name` and the value is provided by `android:value`
- A key pointing to a resource ID to some other resource, frequently an XML resource (i.e., file in `res/xml/`), providing more details, where the key is in `android:name` and the resource ID is `android:resource`

You will see this approach used in places like app widgets, which use a `<meta-data>` element to point to the app widget metadata, which resides in a separate XML resource.

Your app reads in these values — as literals or identifiers to resources — by retrieving an `ActivityInfo` or `ServiceInfo` object from `PackageManager` for the component (e.g., `getActivityInfo()`, `getReceiverInfo()`, `getServiceInfo()`), then examining the `Bundle` in the `metaData` field of that `...Info` object.

There is nothing stopping you from requiring your plugins implement certain resources or assets in agreed-upon paths. You could then access those resources — or ones from `android:resource` in a `<meta-data>` element — via a `Context` created from `createPackageContext()`. `createPackageContext()` is available on any `Context`, such as an `Activity` or `Service`. Given the package name of your plugin, it gives you a `Context` object that you can use to retrieve resources (`getResources()`) or assets (`getAssets()`) much as you do with one of your own contexts.

Versioning

Any time you are providing programmatic access to your app to others, or any time you are expecting others to provide programmatic access to their apps based upon your specification, you need to bear in mind that your needs may change over time. You may want additional extras, or new bits of static data, or new `Intent` actions. And while you can change your app to take into account your new requirements:

- You have no means of forcing third-party developers to update their apps in lock-step with yours
- You have no means of forcing users to update their plugins and such in lock-step with updating your host app

Hence, you are going to need to deal with versioning your plugin API and supporting older API versions, to offer backwards compatibility for not-yet-updated plugins.

A `<meta-data>` element is perhaps the easiest way to have plugins declare what API version they support. This way, you can find out what “language” the plugin speaks before you try talking to it.

When you then communicate via IPC to the plugins, you will need to take into account what API version the plugin speaks, and adjust your communications accordingly. For example, if you are binding to a plugin’s service, you would need to make sure that you are using the right AIDL, to get the right client-side proxy object, one that has the methods and parameters that the plugin supports.

Conversely, if you are providing ways for plugins to initiate communications back to you, you will have to take into account that plugins could be using any outstanding API version. You might elect to use different Intent actions or provider authorities to help distinguish the API versions. For example, the plugin sending a command to your service might use `com.suchandso.app.ACTION_PLUGIN.V1` or `com.suchandso.app.ACTION_PLUGIN.V2` in its Intent, so you have the flexibility of having a single Service handle both of those operations, or splitting them into separate Service classes if you feel that will help improve maintainability.

On the whole:

- Be careful in what you send to the plugins. If you claim that certain extras are of certain data types, stick with that, trying to avoid sending other data types that the plugins might not expect.
- Be generous in what you accept from the plugins, particularly where you are changing what you accept from version to version of your API. If you declared that an extra sent to you was originally an `int` and now is a `String`, ideally your new-version code would accept *either* an `int` or a `String`, to help ease the transition.
- Be slow to discontinue support for old API versions. You might use analytics or other data collection mechanisms to get a sense for how many devices are using plugins that speak a particular API version, to give you an idea of how

much grief you will get from users if you drop support for that API version and therefore disable certain plugins in an upgrade to your app.

Security

Any time you have inter-process communication, you open up security risks. Hence, intentionally doing IPC means that you intentionally have to consider how best to secure that IPC, to reduce those risks.

Here are three areas of security for you to consider with your plugin model:

User Safe from Permission Leakage

Your plugins, and perhaps the plugin host, may hold various Android permissions, like `READ_CONTACTS` or `INTERNET`. It is incumbent upon you to make sure that either:

- You do not expose information tied to such permissions through your plugin model API (either the host talking to a plugin or vice versa) in a way that other apps could intercept, or
- You ensure that the other party holds the same permission, so that the user knows that the secured information is moving from point to point

For example, suppose that your host app does not hold `READ_CONTACTS`, but a plugin does, specifically to allow the host app to get access to contact information. You need to make sure that, while the host app can get this contact information from the plugin, nobody else can.

Ideally, a plugin developer can be confident that, when the plugin sends information via IPC to the host app, that it is *really* the host app that the plugin is talking to. If some other app can pretend to be the host app, and intercept that information, that other app could potentially use that information to nefarious ends.

Partially, this is an extension of the permission leakage issue described above. It's bad enough that a plugin might leak data to a host app that is not authorized for that data; it is worse if some other app can intercept that data as well.

However, it may be that the data being transferred is not covered by an explicit Android permission, yet might represent information that the user is expecting to keep secure. A financial planner host app using plugins to collect a user's financial data from various banks and brokerages should be taking steps to ensure that the plugin data *only* flows back to the host app, and not to any other apps. This comes

despite the fact that Android does not have an `ACCESS_FINANCIAL_DATA` permission as part of the core operating system.

Mostly, this involves having the plugin explicitly state the component that it is communicating with via IPC, rather than relying upon Android derive that information via Intent resolution or similar approaches. So, for example, rather than calling `startService()` with just an Intent action identifying the host, also set the `ComponentName` on the Intent to specifically direct the command to the host app, not to something else advertising that same Intent action.

If the host and all its plugins are written by the same firm, you can also use [signature-level permissions](#) to restrict access, limiting the IPC to only apps signed by the same signing key.

Host Safe from Trojans

Conversely, if the host app supplies information to the plugins that might represent private or secure data, we need to make sure that the user is comfortable with that data being transferred.

Partially, this involves creating a [custom permission](#) that plugins must hold, letting the user know at the time of installing the plugin that this data will be transferred.

Partially, this is making sure that this data is only delivered to the plugins (and, if possible, only to the plugins that specifically need this data). Hence, rather than broadcast Intents — even ones where you require a specific permission be held by the receiver — consider using other IPC options that are more “point-to-point”, such as sending commands to a specific service identified by its `ComponentName`.

Case Study: DashClock

A Googler’s take on an app with a plugin model can be found in [DashClock](#), written by Roman Nurik. DashClock is [open source](#), making it easy to see how he elected to implement his plugin model.

What is DashClock?

Android 4.2 added the notion of [lockscreen widgets](#), app widgets that can go on the lockscreen. DashClock is one such lockscreen widget, designed to replace the standard clock. But, more importantly, it offers a plugin model, so third-party apps

can provide dynamic data to be displayed by DashClock, without themselves having to have a lockscreen widget. Similarly, the user can just add DashClock to the lockscreen, not a whole bunch of individual lockscreen widgets.

Discovery... By the User

DashClock helps users find extensions by linking to the Play Store via the following URL: <http://play.google.com/store/search?q=DashClock+Extension&c=apps>.

Anyone publishing a DashClock extension merely needs to describe their app as having (or being) a DashClock extension, and they will automatically show up when the user requests to get more extensions from within DashClock's configuration activity.

DashClock extensions do not *have* to be installed via the Play Store, but DashClock will not directly help improve the “findability” of extensions distributed by other means.

Discovery... By Your App

At its core, DashClock finds extensions by scanning via `PackageManager`. Each extension is obligated to implement a service that advertises an `<action>` of `com.google.android.apps.dashclock.Extension`. DashClock then uses `queryIntentServices()` on `PackageManager` to find these services.

DashClock, however, has the notion of installed versus active extensions. Just because a user installed some app that happens to implement a DashClock extension does not necessarily mean that the user *wants* that app's content cluttering up her DashClock lockscreen widget. Instead, the user not only has to install the app, but tell DashClock to activate that extension. Hence, DashClock has an activity that shows a list of all installed extensions and allows the user to toggle them between active and inactive states (plus order them, etc.).

It is conceivable that the user installs a DashClock extension while this extension-configuration activity is running. Hence, while this activity is running, DashClock registers a `BroadcastReceiver`, via `registerReceiver()`, for the package-management broadcasts (e.g., `ACTION_PACKAGE_ADDED`). Upon receipt of the broadcast, DashClock goes through the original logic to scan using `PackageManager` to find available extensions, then updates the list to match any changes (added extensions, removed extensions, etc.).

DashClock also monitors for the many of the same broadcasts via a manifest-registered receiver, so it knows when extensions are replaced or removed. In those cases, DashClock needs to determine whether the extension had been active, and if so, what is now required (e.g., removing the extension from the lockscreen widget once it is uninstalled).

Discovery and Usage of the IPC Endpoints

The DashClock app, serving as the plugin host, communicates with its plugins in three main ways:

- Via the aforementioned service, usually implemented as a `DashClockExtension`, which allows DashClock to proactively request that plugins publish updates to their data
- Via an optional “settings activity”, which DashClock links to from the extension list, so users can configure the behavior of this specific extension
- Via metadata in the `<service>` element for the `DashClockExtension`

One of the key pieces of metadata is the `protocolVersion`, which tells DashClock what version of the DashClock plugin API the plugin supports.

The plugin turns around and communicates back to DashClock via a service, exported by DashClock under an agreed-upon action. The extension uses this service to publish updates to the data that should be shown for this extension in DashClock’s lockscreen widget, much along the lines of how an `AppWidgetProvider` tells the `AppWidgetManager` to update an app widget.

Security

DashClock defines a custom `READ_EXTENSION_DATA` permission. Extensions protect their services by requiring this permission (`android.permission = "com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA"`), so that the user knows about apps seeking to communicate with the extension. Such apps need to hold the `READ_EXTENSION_DATA` permission, meaning that the user will be informed at installation time about the app wishing to speak with DashClock extensions.

Other Plugin Examples

DashClock shows one way of implementing a plugin model, but it is certainly not the only possible implementation. The following sections review some other approaches, to contrast with DashClock's approach.

Plugins by Remote

The biggest challenge with plugins comes at the UI level. While there are many ways to integrate applications for background work (remote services, broadcast Intents, etc.), blending user interfaces is a problem. It is unsafe to have an application execute some plugin's code in its own process, as the plugin may be malicious in nature. Yet, the plugin cannot directly add widgets to the host app's activities any other way.

The key word in that last sentence, of course, is “directly”.

There is an indirect way of having one app supply UI components to another app, in the form of the RemoteViews object. This is used by app widgets and custom Notifications, covered elsewhere in this book.

The plugin can create a RemoteViews structure describing the desired UI and deliver that RemoteViews to the host app, which can then render that RemoteViews wherever it is needed.

This section will outline some of the mechanics behind creating such a UI-centric plugin mechanism.

RemoteViews, Beyond App Widgets

RemoteViews are used in a few other places besides app widgets, such as custom Notification views. However, you can use RemoteViews yourself easily enough. You create one as you would for any other circumstance, like an app widget. To display one, you can use the `apply()` method on the RemoteViews object. The `apply()` method takes two parameters:

1. Your Context, typically your Activity
2. The container into which the contents of the RemoteViews will eventually reside

The `apply()` method returns the `View` specified by the rules poured into the `RemoteViews` object... but it does not add it to the container specified in that second parameter. Hence, `apply()` is a bit like calling the three-parameter `inflate()` on a `LayoutInflater` and passing `false` for the third parameter — you are still responsible for actually adding the `View` to the parent when appropriate.

And that's pretty much it.

Since a `RemoteViews` object implements the `Parcelable` interface, you can store a `RemoteViews` in an `Intent` extra, a `Bundle`, or anything else that works with `Parcelable` (e.g., AIDL-defined remote service interfaces). This is what makes `RemoteViews` so valuable – you can pass one to another process, which can `apply()` it to its own UI.

As a result, `RemoteViews` are a secure way for a plugin to contribute to some host activity's UI. In fact, you can think of an app widget as being a “plugin” for the UI of the home screen.

Thinking About Plugins

So, what does our plugin implementation need?

You have one application (the host) that will be able to display the `RemoteViews` supplied by other applications (the plugins). Somehow, the host will need to know:

1. What plugins are installed
2. How to get `RemoteViews` from the plugins to the host
3. Whether there are plugins that are installed that the user does not want (e.g., app widgets not added to the home screen) or if the user wants to see multiple `RemoteViews` from the same plugin (e.g., multiple instances of an app widget)

As is discussed earlier in this chapter, there are any number of ways of implementing these. The sample shown below will use a broadcast `Intent` to find plugins and another broadcast `Intent` to retrieve `RemoteViews` on demand, while assuming that each plugin will deliver exactly one `RemoteViews`.

Similarly, the plugin will need to know:

1. How it will be activated by the host

2. How it is supposed to deliver RemoteViews to the host (broadcast Intent? remote service API? something else?)
3. When it is supposed to deliver RemoteViews to the host (pulled by the host? pushed to the host? both?)
4. How many distinct instances of the plugin does the user want (e.g., multiple instances of the app widget), and what is the configuration data for each instance that makes one distinct from the next?

Let's take a look at the [RemoteViews/Host](#) and [RemoteViews/Plugin](#) sample applications. These are two apps, each in their own package, implementing a host/plugin relationship, with RemoteViews being generated by the plugin and displayed by the host.

In this sample, the plugin will respond to a broadcast Intent from the host with a broadcast of its own, signaling that it wishes to serve as a plugin. When the host sends a broadcast to retrieve the RemoteViews, the plugin will send a broadcast in response that contains the RemoteViews. And, to keep things simple, each plugin will only have one instance (and we will only have one plugin).

Finding Available Plugins

Our host is a simple activity containing a TextView as its only content. The expectation is that when the user chooses a Refresh options menu item, we will pull a RemoteViews from the plugin and display it.

That, of course, assumes that we have a plugin.

To find plugins, we will send a broadcast, with a custom action, ACTION_CALL_FOR_PLUGINS. Any plugin implementation would need a BroadcastReceiver set up in the manifest to respond to such an action.

To keep things simple, the host will only have one plugin. The plugin itself will be represented by a ComponentName object, identifying the implementation of the plugin, held in a pluginCN data member:

```
private ComponentName pluginCN=null;
```

In onResume(), if we do not have a plugin yet, we send the broadcast to try to find one:

```
@Override  
public void onResume() {
```

```
super.onResume();

IntentFilter pluginFilter=new IntentFilter();

pluginFilter.addAction(ACTION_REGISTER_PLUGIN);
pluginFilter.addAction(ACTION_DELIVER_CONTENT);

registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);

if (pluginCN == null) {
    sendBroadcast(new Intent(ACTION_CALL_FOR_PLUGINS));
}
}
```

Responding to the Call for Plugins

Over in our plugin implementation, we do indeed have a BroadcastReceiver — cunningly named Plugin — with a manifest entry set up to respond to our ACTION_CALL_FOR_PLUGINS broadcast.

What the host wants in response is to receive a broadcast from the plugin, with an action of ACTION_REGISTER_PLUGIN, and an extra of EXTRA_COMPONENT, containing the ComponentName of the BroadcastReceiver that is the plugin implementation. So, when Plugin receives an ACTION_CALL_FOR_PLUGINS broadcast, it does just that:

```
package com.commonware.android.rv.plugin;

import android.content.BroadcastReceiver;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class Plugin extends BroadcastReceiver {
    public static final String ACTION_CALL_FOR_PLUGINS=
        "com.commonware.android.rv.host.CALL_FOR_PLUGINS";
    public static final String ACTION_REGISTER_PLUGIN=
        "com.commonware.android.rv.host.REGISTER_PLUGIN";
    public static final String ACTION_CALL_FOR_CONTENT=
        "com.commonware.android.rv.host.CALL_FOR_CONTENT";
    public static final String ACTION_DELIVER_CONTENT=
        "com.commonware.android.rv.host.DELIVER_CONTENT";
    public static final String EXTRA_COMPONENT="component";
    public static final String EXTRA_CONTENT="content";
    private static final String HOST_PACKAGE="com.commonware.android.rv.host";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (ACTION_CALL_FOR_PLUGINS.equals(i.getAction())) {
            Intent registration=new Intent(ACTION_REGISTER_PLUGIN);
```

```
registration.setPackage(HOST_PACKAGE);
registration.putExtra(EXTRA_COMPONENT,
    new ComponentName(ctxt, getClass()));

ctxt.sendBroadcast(registration);
}
else if (ACTION_CALL_FOR_CONTENT.equals(i.getAction())) {
    RemoteViews rv=
        new RemoteViews(ctxt.getPackageName(), R.layout.plugin);
    Intent update=new Intent(ACTION_DELIVER_CONTENT);

    update.setPackage(HOST_PACKAGE);
    update.putExtra(EXTRA_CONTENT, rv);
    ctxt.sendBroadcast(update);
}
}
```

For added security, we use `setPackage()` in the plugin, so the `ACTION_REGISTER_PLUGIN` broadcast can only be received by the host.

The host activity needs to receive `ACTION_REGISTER_PLUGIN` broadcasts. Hence, it has a `BroadcastReceiver` implementation, in the plugin data member, that it registers for `ACTION_REGISTER_PLUGIN` in `onResume()`. The plugin `BroadcastReceiver`, upon receiving an `ACTION_REGISTER_PLUGIN` broadcast, grabs the `ComponentName` out of the `EXTRA_COMPONENT` extra and stores it in `pluginCN`:

```
private BroadcastReceiver plugin=new BroadcastReceiver() {
    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (ACTION_REGISTER_PLUGIN.equals(i.getAction())) {
            pluginCN=(ComponentName)i.getParcelableExtra(EXTRA_COMPONENT);
        }
        else if (ACTION_DELIVER_CONTENT.equals(i.getAction())) {
            RemoteViews rv=(RemoteViews)i.getParcelableExtra(EXTRA_CONTENT);
            ViewGroup frame=(ViewGroup)findViewById(android.R.id.content);

            frame.removeAllViews();

            View pluginView=rv.apply(RemoteViewsHostActivity.this, frame);

            frame.addView(pluginView);
        }
    }
};
```

At this point, we wait for the user to click the Refresh options menu item.

Requesting RemoteViews

When the user does indeed choose Refresh, we call a `refreshPlugin()` method on the host activity:

```
private void refreshPlugin() {  
    Intent call=new Intent(ACTION_CALL_FOR_CONTENT);  
  
    call.setComponent(pluginCN);  
    sendBroadcast(call);  
}
```

Here, we send an `ACTION_CALL_FOR_CONTENT` broadcast, with the target component set to be the plugin implementation, as identified by its `ComponentName`. This ensures that this broadcast will only go to that plugin app and nobody else.

Responding with RemoteViews

Our `Plugin` is also registered in the manifest to respond to `ACTION_CALL_FOR_CONTENT`. So, when that broadcast arrives, it can create the `RemoteViews` in response, sending it out via an `ACTION_DELIVER_CONTENT` broadcast back to the host. Once again, we use `setPackage()` to restrict the broadcast to be the host's package. The broadcast also has the `RemoteViews` tucked in an `EXTRA_CONTENT` extra.

Our host activity registered the plugin `BroadcastReceiver` for `ACTION_DELIVER_CONTENT` as well. So, when that broadcast arrives, it can utilize the `RemoteViews`. We find the `ViewGroup` that is the root of our content (`android.R.id.content`), wipe out whatever is in it now, `apply()` the `RemoteViews` to that `ViewGroup`, and add the resulting `View` to the `ViewGroup`. This has the net effect of getting rid of our original `TextView` content, replacing it with whatever the plugin poured into the `RemoteViews`. Or, if the user chooses Refresh again, the older `RemoteViews`-generated content is replaced with fresh content.

Dealing with Android 3.1+

To test this, install the Host application, followed by the Plugin application. On Android 3.0 and older, running the Host and choosing the Refresh options menu item will change the display from its original state to the one with the plugin's `RemoteViews`.

However, that will not work right away on Android 3.1 and higher.

PLUGIN PATTERNS

On these versions of Android, applications are installed into a “stopped” state, where no BroadcastReceiver in the manifest will work, until the user manually runs the application. The simplest way to do that is via an activity. So, the Plugin project has a trivial activity that just displays a Toast and exits:

```
package com.commonware.android.rv.plugin;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class PluginActivationActivity extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

You will need to run this activity on Android 3.1 and higher first, then run the Host project’s activity, to get the plugin to work.

If you happen to install these on an Android 3.0 or older device, though, you may wonder if the author has lost his marbles. That is because you will not see any activity associated with the Plugin application.

Since the author has not owned marbles in a few decades, clearly there must be some other answer. In this case, we use a variation of a trick pointed out by Daniel Lew.

Our <activity> element in the manifest has an android:enabled attribute. A disabled activity does not show up in the launcher. But rather than have android:enabled specifically tied to true or false in the manifest, it references a boolean resource:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.rv.plugin"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk android:minSdkVersion="7"/>

    <uses-permission android:name="com.commonware.android.rv.host.ACT_AS_PLUGIN"/>
```

```
<application
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name">
  <receiver
    android:name="Plugin"
    android:permission="com.commonware.android.rv.host.ACT_AS_HOST">
    <intent-filter>
      <action android:name="com.commonware.android.rv.host.CALL_FOR_PLUGINS"/>
      <action android:name="com.commonware.android.rv.host.CALL_FOR_CONTENT"/>
    </intent-filter>
  </receiver>

  <activity
    android:name="PluginActivationActivity"
    android:enabled="@bool/i_has_needs_activity"
    android:excludeFromRecents="true"
    android:theme="@android:style/Theme.NoDisplay">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>
</manifest>
```

In `res/values/bools.xml`, we define that boolean resource to be false, meaning the activity will not appear in the launcher:

```
<resources>

  <bool name="i_has_needs_activity">false</bool>
</resources>
```

But, in `res/values-v12/bools.xml`, we define that boolean resource to be true, causing the activity to appear on Android 3.1 and higher:

```
<resources>

  <bool name="i_has_needs_activity">true</bool>
</resources>
```

This way, our extraneous activity does not clutter up older devices where it is not needed. [Mr. Lew's blog post](#) on this subject points out that this trick can be used to have different implementations of an app widget for different Android versions (e.g., one that uses a `ListView` for API Level 11 and higher, plus one that does not for older devices).

The Permission Scheme

Another thing that these sample projects use are custom permissions, to help with security.

To serve as a plugin host, you must hold the ACTS_AS_HOST permission. To serve as a plugin implementation, you must hold the ACTS_AS_PLUGIN permission. These are defined in the Host project's manifest:

```
<permission
  android:name="com.commonware.android.rv.host.ACTS_AS_HOST"
  android:description="@string/host_desc"
  android:label="@string/host_label">
</permission>
<permission
  android:name="com.commonware.android.rv.host.ACTS_AS_PLUGIN"
  android:description="@string/plugin_desc"
  android:label="@string/plugin_label">
</permission>
```

Each application then has its appropriate <uses-permission> element for the role that it plays, such as the Plugin holding the ACTS_AS_PLUGIN permission:

```
<uses-permission android:name="com.commonware.android.rv.host.ACTS_AS_PLUGIN"/>
```

The BroadcastReceiver defined by the Plugin project has, in its <receiver> element, the android:permission attribute, indicating that whoever sends a broadcast to this receiver must hold ACTS_AS_HOST:

```
<receiver
  android:name="Plugin"
  android:permission="com.commonware.android.rv.host.ACTS_AS_HOST">
  <intent-filter>
    <action android:name="com.commonware.android.rv.host.CALL_FOR_PLUGINS"/>
    <action android:name="com.commonware.android.rv.host.CALL_FOR_CONTENT"/>
  </intent-filter>
</receiver>
```

Similarly, the BroadcastReceiver defined dynamically by the host activity uses a version of registerReceiver() that takes the permission the sender must hold:

```
registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);
```

That permission is defined in a static data member:

```
public static final String PERM_ACT_AS_PLUGIN=
    "com.commonware.android.rv.host.ACTS_AS_PLUGIN";
```

This way, the user is informed about the host/plugin relationship and can make appropriate decisions when they install plugins.

Note, though, that for this to work, the host application must be installed first, to define the custom permissions. If a plugin is installed before the host, there is no error, but the plugin will not be granted the as-yet-undefined custom permissions, and so the plugin will not work. The user would have to uninstall and reinstall the plugin after installing the host to fix this problem.

Other Plugin Features and Issues

It is possible for the `apply()` method on `RemoteViews` to throw a `RuntimeException`. For example, the `RemoteViews` might contain a reference to a widget ID that does not exist within the inflated views of the `RemoteViews` itself. Since `apply()` does not throw a checked exception, it is easy to do what we did in the sample app and assume `apply()` will succeed, but it very well may not. A robust implementation of this plugin system would wrap the `apply()` call in an exception handler that would do something useful if the plugin's `RemoteViews` has a bug.

You need to be a bit careful to make sure that a plugin can only update itself. The sample app assumes that the only thing that will send an `ACTION_DELIVER_CONTENT` broadcast to it will be the plugin, but that is not necessarily the case. In principle, anything that holds the `ACTS_AS_PLUGIN` permission could send an `ACTION_DELIVER_CONTENT` to the host, and thereby specify what the `RemoteViews` are. A robust plugin system would have some sort of shared secret, such as an identifier, between the host and the plugin, so another component cannot readily masquerade as being the plugin itself.

ContentProvider Plugins

Another way to extend your application at runtime is via plugins implemented via the `ContentProvider` framework. You could create new `ContentProvider` implementations that offer up data, perhaps using a consistent schema. Then, you could find those providers via a naming convention (e.g., for a main application with a package of `com.foo.abc`, your plugin apps would be `com.foo.abc.plugin.*`) and `PackageManager`, perhaps using a provider `Uri` naming convention to allow the host to know how to query the plugin.

However, there are other ways of employing a `ContentProvider` to help as a plugin, and this section explores one specific scenario: reducing the host app's permission requirements.

The Problem: Permission Creep

At the moment, for standard versions of Android, apps cannot request “conditional” or “optional” permissions, that the user could elect to opt out of. Instead, apps must request in their manifest all possible permissions that they could need. This is considered by many to be a significant limitation, but Google has stated repeatedly that they are not considering alternative strategies.

The net effect, though, is that an app often times needs a lot of permissions, or needs to add new permissions (requiring existing users to agree to the new permission list). Such lists of permissions can dissuade potential users from installing the app in the first place.

However, even though Android does not provide a simple and clean way for users to opt into (or out of) certain permissions for certain apps, plugins can offer a similar model. The base app can require some permissions for some features, with other features (and their respective permissions) added via plugins. Users can elect to install the plugins and agree to those permissions, or abandon or never install the plugins in the first place.

The hassle, of course, is in implementing the plugin APK and connecting to it from the main app. The plugin needs to have all the functionality that must directly use classes and methods secured by the permission. This can increase the complexity in maintaining the overall app.

A Solution: `ContentProvider` Proxies

Some permissions exist primarily to protect a `ContentProvider`, such as `READ_CONTACTS` and `WRITE_CONTACTS` for the `ContactsContract` provider.

The nice thing about the `ContentProvider` framework is that it is simply a contract. You use a `ContentResolver` and some magic values (`Uri`, “projection” of columns to return, etc.), and you get results. In fact, you can even change some of those magic values – any `Uri` supporting the same columns could be used with all the same client Java code, just by changing the `Uri` itself.

That allows us to create a proxy for `ContentProvider`. The proxy APK will hold the permission and call the real `ContentProvider` as needed. The proxy APK will expose its own `ContentProvider`, with a different `Uri`. Done properly — such that only the host app can use the proxy — the proxy will isolate the permission(s) for the real `ContentProvider` in the plugin. A `ContactsContract` proxy, for example, could hold `READ_CONTACTS` and `WRITE_CONTACTS`, proxying requests on behalf of a main app that lacks those permissions.

To secure the proxy, we need to ensure that only our apps can use the proxy, not anyone else's apps. Otherwise, those third-party apps could get at, say, contacts without the `READ_CONTACTS` permission.

The simplest way to accomplish this is to use a signature-level custom permission.

Any app can declare a new permission via the `<permission>` element in the manifest. Normally, any app can request to hold this permission via `<uses-permission>`, and the user will be able to grant or deny this request at install time, just like any system-defined permission.

However, it is possible to add an `android:protectionLevel="signature"` attribute to the `<permission>` element. In this case, only apps signed by the same signing key will be able to request the permission — everyone else is automatically denied. Furthermore, apps signed by the same signing key will automatically get the permission without the user having to approve it.

So, you can have the proxy require a signature-level custom permission, thereby limiting possible consumers of the proxy to be signed by the same signing key.

Let's look at a pair of projects that create and consume a proxy for the `CallLog` `ContentProvider`. These projects are located in the `Introspection/CppProxy` directory and are named [Provider](#) and [Consumer](#), respectively.

Note that this sample works only on API Level 11 and higher, due to the consumer's use of the native implementation of the `Loader` framework.

Provider

Most of the logic for our provider proxy can be found in the `AbstractCppProxy` base class. It implements the mandatory methods for the `ContentProvider` contract — such as `insert()` — and simply turns around and forwards those requests along to another provider:

```
@Override
public Cursor query(Uri uri, String[] projection, String selection,
                    String[] selectionArgs, String sortOrder) {
    checkTainted();

    Cursor result=
        getContext().getContentResolver().query(convertUri(uri),
                                                projection, selection,
                                                selectionArgs,
                                                sortOrder);

    return(new CrossProcessCursorWrapper(result));
}

@Override
public Uri insert(Uri uri, ContentValues values) {
    checkTainted();

    return(getContext().getContentResolver().insert(convertUri(uri),
                                                    values));
}

@Override
public int update(Uri uri, ContentValues values, String selection,
                  String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().update(convertUri(uri),
                                                    values, selection,
                                                    selectionArgs));
}

@Override
public int delete(Uri uri, String selection, String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().delete(convertUri(uri),
                                                    selection,
                                                    selectionArgs));
}

@Override
public String getType(Uri uri) {
    checkTainted();

    return(getContext().getContentResolver().getType(convertUri(uri)));
}
```

The `checkTainted()` calls are part of our confirming that our custom permission is OK, and that is covered in [the chapter on advanced permissions](#). For the purposes of this chapter, just ignore them (along with the `onCreate()` method not shown here).

It is up to a subclass of `AbstractCProxy` to implement the `convertUri()` method, which takes the `Uri` supplied by the consumer and transforms it into the proper `Uri` to use for making the real request. In this case, our subclass is `CallLogProxy`:

```
package com.commonware.android.cproxy.provider;

import android.content.ContentUris;
import android.net.Uri;
import android.provider.CallLog;

public class CallLogProxy extends AbstractCProxy {
    protected Uri convertUri(Uri uri) {
        long id=ContentUris.parseId(uri);

        if (id >= 0) {
            return(ContentUris.withAppendedId(CallLog.Calls.CONTENT_URI, id));
        }

        return(CallLog.Calls.CONTENT_URI);
    }
}
```

Here, we grab the instance ID off the end of the `Uri` (if it exists) and generate a new `Uri` based on `CallLog.CONTENT_URI`, indicating that we want to forward our requests to the `CallLog`.

The biggest complexity of the standard CRUD `ContentProvider` methods comes with `query()`. The `Cursor` returned by `query()` must implement the `CrossProcessCursor` interface. The `SQLiteCursor` implementation supports this interface, which is why typical providers do not worry about this requirement. However, the `Cursor` returned by `query()` on `ContentResolver` is not necessarily a `CrossProcessCursor`. Hence, we need to wrap it in a `CursorWrapper` that does implement `CrossProcessCursor`:

```
private static final String PREFS_TAINTED="tainted";
private boolean tainted=false;

public AbstractCProxy() {
    super();
}

@Override
public boolean onCreate() {
    SharedPreferences prefs=
        PreferenceManager.getDefaultSharedPreferences(getContext());
```

The resulting `CrossProcessCursorWrapper`, as originally shown in [a Stack Overflow answer](#), looks like this:

```
checkTainted();

Cursor result=
    getContext().getContentResolver().query(convertUri(uri),
                                             projection, selection,
                                             selectionArgs,
                                             sortOrder);

    return(new CrossProcessCursorWrapper(result));
}

@Override
public Uri insert(Uri uri, ContentValues values) {
    checkTainted();

    return(getContext().getContentResolver().insert(convertUri(uri),
                                                    values));
}

@Override
public int update(Uri uri, ContentValues values, String selection,
                  String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().update(convertUri(uri),
                                                    values, selection,
                                                    selectionArgs));
}

@Override
public int delete(Uri uri, String selection, String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().delete(convertUri(uri),
                                                    selection,
                                                    selectionArgs));
}

@Override
public String getType(Uri uri) {
    checkTainted();

    return(getContext().getContentResolver().getType(convertUri(uri)));
}

private void checkTainted() {
    if (tainted) {
        throw new RuntimeException(getContext().getString(R.string.tainted_abort));
    }
}

// following from
// http://stackoverflow.com/a/5243978/115145
```

PLUGIN PATTERNS

```
public class CrossProcessCursorWrapper extends CursorWrapper
    implements CrossProcessCursor {
    public CrossProcessCursorWrapper(Cursor cursor) {
```

Note that this implementation has been largely untested by this book's author, though it appears to work.

The manifest for this project has three items of note:

- It has the `<uses-permission>` element for `READ_CONTACTS`, while our consumer project will not
- It has a `<permission>` element, defining a custom `com.commonware.android.cproxy.PLUGIN` permission that has signature-level protection
- It has our `<provider>`, requiring that custom permission, and declaring its authority to be `com.commonware.android.cproxy.CALL_LOG`

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.cproxy.provider"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="9"
        android:targetSdkVersion="11"/>

    <uses-permission android:name="android.permission.READ_CONTACTS"/>

    <permission
        android:name="com.commonware.android.cproxy.PLUGIN"
        android:protectionLevel="signature">
    </permission>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".CallLogProxy"
            android:authorities="com.commonware.android.cproxy.CALL_LOG"
            android:permission="com.commonware.android.cproxy.PLUGIN">
        </provider>
    </application>
</manifest>
```

Note that a complete `AbstractCProxy` implementation should forward along all the other methods as well (e.g., `call()`).

Consumer

Our Consumer project is nearly identical to the CalendarContract sample [from elsewhere in this book](#).

However, instead of the READ_CONTACTS permission, we declare that we need the com.commonware.android.cproxy.PLUGIN permission instead:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.cproxy.consumer"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="11"
        android:targetSdkVersion="11"/>

    <uses-permission android:name="com.commonware.android.cproxy.PLUGIN"/>

    <permission
        android:name="com.commonware.android.cproxy.PLUGIN"
        android:protectionLevel="signature">
    </permission>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name=".CProxyConsumerActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Also, our CONTENT_URI is no longer the one found on CallLog, but rather one identifying our proxy:

```
private static final Uri CONTENT_URI=
    Uri.parse("content://com.commonware.android.cproxy.CALL_LOG");
```

And there are minor changes because we are querying CallLog (indirectly) rather than CalendarContract, such as a change in the columns for our projection:

```
private static final String[] PROJECTION=new String[] {  
    CallLog.Calls._ID, CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

Otherwise, the consumer projects are the same. The difference is that our consumer project does not need the READ_CONTACTS permission the same way that the original needed the READ_CALENDAR permission.

In this case, the consumer project depends entirely upon the existence of the plugin — otherwise, the consumer project has no value. Hence, in this case, going the plugin route is silly. But an application that could use the CallLog but does not depend upon it could use this approach to isolate the READ_CONTACTS requirement in a plugin, so users could elect to install the plugin or not, and the main app would not need to request READ_CONTACTS and add to the roster of permissions the user must agree to up front.

Note that, in principle, the consumer should contain some of the same defenses against custom permission changes that the proxy does (in the form of those checkTainted() calls). This is covered in greater detail in [the chapter on advanced permissions](#).

Limitations of the Approach

There will be additional overhead in using the proxy, which will hamper performance. Ideally, this plugin mechanism is only used for features that need light use of the protected ContentProvider, so the overhead will not be a burden to the user.

PackageManager Tricks

PackageManager is your primary means of introspection at the component level, to determine what else is installed on the device and what components they export (activities, etc.). As such, there are many ways you can use PackageManager to determine if something you want is possible or not, so you can modify your behavior accordingly (e.g., disable action bar items that are not possible).

This chapter will outline some ways you can use PackageManager to find out what components are available to you on a device.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Asking Around

The ways to find out whether there is an activity that will respond to a given Intent are by means of `queryIntentActivityOptions()` and the somewhat simpler `queryIntentActivities()`.

The `queryIntentActivityOptions()` method takes the caller `ComponentName`, the “specifics” array of Intent instances, the overall Intent representing the actions you are seeking, and the set of flags. It returns a List of Intent instances matching the stated criteria, with the “specifics” ones first.

If you would like to offer alternative actions to users, but by means other than `addIntentOptions()`, you could call `queryIntentActivityOptions()`, get the `Intent` instances, then use them to populate some other user interface (e.g., a toolbar).

A simpler version of this method, `queryIntentActivities()`, is used by the [Introspection/Launchalot](#) sample application. This presents a “launcher” — an activity that starts other activities — but uses a `ListView` rather than a grid like the Android default home screen uses.

Here is the Java code for Launchalot itself:

```
package com.commonware.android.launchalot;

import android.app.ListActivity;
import android.content.ComponentName;
import android.content.Intent;
import android.content.pm.ActivityInfo;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.ListView;
import android.widget.TextView;
import java.util.Collections;
import java.util.List;

public class Launchalot extends ListActivity {
    AppAdapter adapter=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        PackageManager pm=getPackageManager();
        Intent main=new Intent(Intent.ACTION_MAIN, null);

        main.addCategory(Intent.CATEGORY_LAUNCHER);

        List<ResolveInfo> launchables=pm.queryIntentActivities(main, 0);

        Collections.sort(launchables,
            new ResolveInfo.DisplayNameComparator(pm));

        adapter=new AppAdapter(pm, launchables);
        setListAdapter(adapter);
    }
}
```

PACKAGEMANAGER TRICKS

```
@Override
protected void onItemClick(ListView l, View v,
                           int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);
    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
               Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);

    startActivity(i);
}

class AppAdapter extends ArrayAdapter<ResolveInfo> {
    private PackageManager pm=null;

    AppAdapter(PackageManager pm, List<ResolveInfo> apps) {
        super(Launcher.this, R.layout.row, apps);
        this.pm=pm;
    }

    @Override
    public View getView(int position, View convertView,
                       ViewGroup parent) {
        if (convertView==null) {
            convertView=new View(parent);
        }

        bindView(position, convertView);

        return(convertView);
    }

    private View newView(ViewGroup parent) {
        return(getLayoutInflater().inflate(R.layout.row, parent, false));
    }

    private void bindView(int position, View row) {
        TextView label=(TextView)row.findViewById(R.id.label);

        label.setText(getItem(position).loadLabel(pm));

        ImageView icon=(ImageView)row.findViewById(R.id.icon);

        icon.setImageDrawable(getItem(position).loadIcon(pm));
    }
}
```

In onCreate(), we:

PACKAGEMANAGER TRICKS

1. Get a `PackageManager` object via `getPackageManager()`
2. Create an `Intent` for `ACTION_MAIN` in `CATEGORY_LAUNCHER`, which identifies activities that wish to be considered “launchable”
3. Call `queryIntentActivities()` to get a List of `ResolveInfo` objects, each one representing one launchable activity
4. Sort those `ResolveInfo` objects via a `ResolveInfo.DisplayNameComparator` instance
5. Pour them into a custom `AppAdapter` and set that to be the contents of our `ListView`

`AppAdapter` is an `ArrayAdapter` subclass that maps the icon and name of the launchable Activity to a row in the `ListView`, using a custom row layout.

Finally, in `onListItemClick()`, we construct an `Intent` that will launch the clicked-upon Activity, given the information from the corresponding `ResolveInfo` object. Not only do we need to populate the `Intent` with `ACTION_MAIN` and `CATEGORY_LAUNCHER`, but we also need to set the component to be the desired Activity. We also set `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` flags, following Android’s own launcher implementation from the Home sample project. Finally, we call `startActivity()` with that `Intent`, which opens up the activity selected by the user.

The result is a simple list of launchable activities:

Figure 689: The Launchalot sample application

There is also a `resolveActivity()` method that takes a template Intent, as do `queryIntentActivities()` and `queryIntentActivityOptions()`. However, `resolveActivity()` returns the single best match, rather than a list.

NOTE: On modern versions of Android, there is a `LauncherApps` class that simplifies a lot of this and takes things like Android Work profiles into account. For really implementing a home screen-style launcher, you will probably want to use `LauncherApps`. However, using `PackageManager` to find what can handle certain Intent structures is used for other purposes beyond home screen launchers.

Preferred Activities

Users, when presented with a default activity chooser, usually have the option to check a `CheckBox` indicating that they want to make their next choice be the default for this action for now on. The next time they do whatever they did to bring up the chooser, it should go straight to this default. This is known in the system as the “preferred activity” for an Intent structure, and is stored in the system as a set of `IntentFilter` objects and the corresponding `ComponentName` of the preferred activity.

PACKAGEMANAGER TRICKS

To find out what the preferred activities are on a given device, you can ask PackageManager to `getPreferredActivities()`. You pass in a `List<IntentFilter>` and a `List<ComponentName>`, and Android fills in those lists with the preferred activity information.

To see this in action, take a look at the [Introspection/PrefActivities](#) sample application. This simply loads all of the information into a `ListView`, using `android.R.layout.simple_list_item_2` as a row layout for a title-and-description pattern.

The PackageManager logic is confined to `onCreate()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    PackageManager mgr=getPackageManager();

    mgr.getPreferredActivities(filters, names, null);
    setListAdapter(new IntentFilterAdapter());
}
```

In this case, the two lists are data members of the activity:

```
ArrayList<IntentFilter> filters=new ArrayList<IntentFilter>();
ArrayList<ComponentName> names=new ArrayList<ComponentName>();
```

Most of the logic is in formatting the `ListView` contents. `IntentFilter`, unfortunately, does not come with a method that gives us a human-readable dump of its definition. As a result, we need to roll that ourselves. Compounding the problem is that `IntentFilter` tends to return `Iterator` objects for its collections (e.g., roster of actions), rather than something `Iterable`. The activity leverages an `Iterator`-to-`Iterable` wrapper culled from [a Stack Overflow answer](#) to help with this. The `IntentFilterAdapter` and helper code looks like this:

```
// from http://stackoverflow.com/a/8555153/115145

public static <T> Iterable<T> in(final Iterator<T> iterator) {
    class SingleUseIterable implements Iterable<T> {
        private boolean used=false;

        @Override
        public Iterator<T> iterator() {
            if (used) {
                throw new IllegalStateException("Already invoked");
            }
            used=true;
        }
    }
    return new SingleUseIterable();
}
```

```
        return iterator;
    }
}
return new SingleUseIterable();
}

class IntentFilterAdapter extends ArrayAdapter<IntentFilter> {
    IntentFilterAdapter() {
        super(PreferredActivitiesDemoActivity.this,
            android.R.layout.simple_list_item_2, android.R.id.text1,
            filters);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView filter=(TextView)row.findViewById(android.R.id.text1);
        TextView name=(TextView)row.findViewById(android.R.id.text2);

        filter.setText(buildTitle(getItem(position)));
        name.setText(names.get(position).getClassName());

        return(row);
    }

    String buildTitle(IntentFilter filter) {
        StringBuilder buf=new StringBuilder();
        boolean first=true;

        if (filter.countActions() > 0) {
            for (String action : in(filter.actionsIterator())) {
                if (first) {
                    first=false;
                }
                else {
                    buf.append('/');
                }

                buf.append(action.replaceAll("android.intent.action.", ""));
            }
        }

        if (filter.countDataTypes() > 0) {
            first=true;

            for (String type : in(filter.typesIterator())) {
                if (first) {
                    buf.append(" : ");
                    first=false;
                }
                else {
                    buf.append('|');
                }
            }
        }
    }
}
```

```
        buf.append(type);
    }
}

if (filter.countDataSchemes() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataScheme(0));

    if (filter.countDataSchemes() > 1) {
        buf.append(" (other schemes)");
    }
}

if (filter.countDataPaths() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataPath(0));

    if (filter.countDataPaths() > 1) {
        buf.append(" (other paths)");
    }
}

return(buf.toString());
}
```

The resulting activity shows a simple description of the IntentFilter along with the class name of the corresponding activity in each row:

Figure 690: Preferred Activities on a Stock HTC One S

Another way to think about preferred activities is to determine what specific activity will handle a `startActivity()` call on some `Intent`. If there is only one alternative, or the user chose a preferred activity, that activity should handle the `Intent`. Otherwise, the activity handling the `Intent` *should* be one implementing a chooser. The `resolveActivity()` method on `PackageManager` can let us know what will handle the `Intent`.

To examine what `resolveActivity()` returns, take a look at the [Introspection/Resolver](#) sample application.

The activity — which uses `Theme.NoDisplay` and so has no UI of its own — is fairly short:

```
package com.commonware.android.resolver;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Bundle;
import android.widget.Toast;
```

```
public class ResolveActivityDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PackageManager mgr=getPackageManager();
        Intent i=
            new Intent(Intent.ACTION_VIEW,
                Uri.parse("http://commonsware.com"));
        ResolveInfo ri=
            mgr.resolveActivity(i, PackageManager.MATCH_DEFAULT_ONLY);

        Toast.makeText(this, ri.loadLabel(mgr), Toast.LENGTH_LONG).show();

        startActivity(i);
        finish();
    }
}
```

We get a `PackageManager`, create an `Intent` to test, and pass the `Intent` to `resolveActivity()`. We include `MATCH_DEFAULT_ONLY` so we only get activities that have `CATEGORY_DEFAULT` in their `<intent-filter>` elements. We then use `loadLabel()` on the resulting `ResolveInfo` object to get the display name of the activity, toss that in a `Toast`, and invoke `startActivity()` on the `Intent` to confirm the results.

On a device with only one option, or with a default chosen, the `Toast` will show the name of the preferred activity (e.g., `Browser`). On most devices with more than one option, the `startActivity()` call will display a chooser, and the `Toast` will show the display name of the chooser (e.g., `“Android System”`).

However, on some devices — notably newer models from HTC distributed in the US — `resolveActivity()` indicates that `HTCLinkifyDispatcher` is the one that will handle `ACTION_VIEW` on a URL... even if there is more than one browser installed and no default has been specified. This is part of a workaround that HTC added in 2012 to help deal with a patent dispute with Apple.

Middle Management

The `PackageManager` class offers much more than merely `queryIntentActivities()` and `queryIntentActivityOptions()`. It is your gateway to all sorts of analysis of what is installed and available on the device where your application is installed and available. If you want to be able to intelligently connect to third-party applications based on whether or not they are around, `PackageManager` is what you will want.

Finding Applications and Packages

Packages are what get installed on the device — a package is the in-device representation of an APK. An application is defined within a package's manifest. Between the two, you can find out all sorts of things about existing software installed on the device.

Specifically, `getInstalledPackages()` returns a List of `PackageInfo` objects, each of which describes a single package. Here, you can find out:

1. The version of the package, in terms of a monotonically increasing number (`versionCode`) and the display name (`versionName`)
2. Details about all of the components — activities, services, etc. — offered by this package
3. Details about the permissions the package requires

Similarly, `getInstalledApplications()` returns a List of `ApplicationInfo` objects, each providing data like:

1. The user ID that the application will run as
2. The path to the application's private data directory
3. Whether or not the application is enabled

In addition to those methods, you can call:

1. `getApplicationIcon()` and `getApplicationLabel()` to get the icon and display name for an application
2. `getLaunchIntentForPackage()` to get an Intent for something launchable within a named package
3. `setApplicationEnabledSetting()` to enable or disable an application

Finding Resources

You can access resources from another application, apparently without any security restrictions. This may be useful if you have multiple applications and wish to share resources for one reason or another.

The `getResourcesForActivity()` and `getResourcesForApplication()` methods on `PackageManager` return a `Resources` object. This is just like the one you get for your own application via `getResources()` on any `Context` (e.g., `Activity`). However, in

this case, you identify what activity or application you wish to get the Resources from (e.g., supply the application's package name as a `String`).

There are also `getText()` and `getXml()` methods that dive into the Resources object for an application and pull out specific `String` or `XmlPullParser` objects. However, these require you to know the resource ID of the resource to be retrieved, and that may be difficult to manage between disparate applications.

Finding Components

Not only does Android offer “query” and “resolve” methods to find activities, but it offers similar methods to find other sorts of Android components:

1. `queryBroadcastReceivers()`
2. `queryContentProviders()`
3. `queryIntentServices()`
4. `resolveContentProvider()`
5. `resolveService()`

For example, you could use `resolveService()` to determine if a certain remote service is available, so you can disable certain UI elements if the service is not on the device. You could achieve the same end by calling `bindService()` and watching for a failure, but that may be later in the application flow than you would like.

There is also a `setComponentEnabledSetting()` to toggle a component (activity, service, etc.) on and off. While this may seem esoteric, there are a number of possible uses for this method, such as:

1. Flagging a launchable activity as disabled in your manifest, then enabling it programmatically after the user has entered a license key, achieved some level or standing in a game, or any other criteria
2. Controlling whether a `BroadcastReceiver` registered in the manifest is hooked into the system or not, replicating the level of control you have with `registerReceiver()` while still taking advantage of the fact that a manifest-registered `BroadcastReceiver` can be started even if no other component of your application is running

Searching with SearchManager

One of the firms behind the Open Handset Alliance — Google — has a teeny weeny Web search service, one you might have heard of in passing. Given that, it's not surprising that Android has some amount of built-in search capabilities.

Specifically, Android has “baked in” the notion of searching not only on the device for data, but over the air to Internet sources of data.

Your applications can participate in the search process, by triggering searches or perhaps by allowing your application's data to be searched.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

Hunting Season

There are two types of search in Android: local and global. Local search searches within the current application; global search searches the Web via Google's search engine. You can initiate either type of search in a variety of ways, including:

1. You can call `onSearchRequested()` from a button or menu choice, which will initiate a local search (unless you override this method in your activity)
2. You can directly call `startSearch()` to initiate a local or global search, including optionally supplying a search string to use as a starting point

SEARCHING WITH SEARCHMANAGER

3. You can elect to have keyboard entry kick off a search via `setDefaultKeyMode()`, for either local search (`setDefaultKeyMode(DEFAULT_KEYS_SEARCH_LOCAL)`) or global search (`setDefaultKeyMode(DEFAULT_KEYS_SEARCH_GLOBAL)`)

In either case, the search appears as a set of UI components across the top of the screen, with a suggestion list (where available) and IME (where needed).

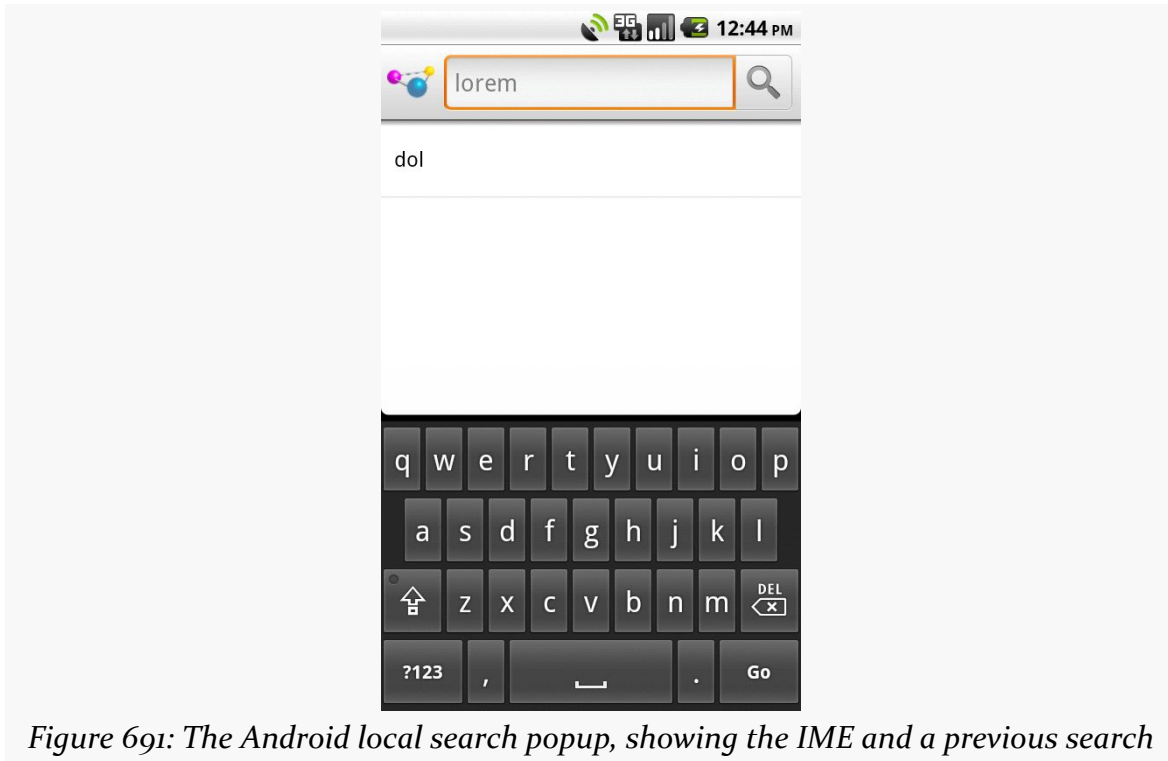

Figure 691: The Android local search popup, showing the IME and a previous search

Figure 692: The Android global search popup

Where that search suggestion comes from for your local searches will be covered later in this chapter.

Search Yourself

Over the long haul, there will be two flavors of search available via the Android search system:

- Query-style search, where the user's search string is passed to an activity which is responsible for conducting the search and displaying the results
- Filter-style search, where the user's search string is passed to an activity on every keypress, and the activity is responsible for updating a displayed list of matches

Since the latter approach is decidedly under-documented, let's focus on the first one.

Craft the Search Activity

The first thing you are going to want to do if you want to support query-style search in your application is to create a search activity. While it might be possible to have a single activity be both opened from the launcher and opened from a search, that might prove somewhat confusing to users. Certainly, for the purposes of learning the techniques, having a separate activity is cleaner.

The search activity can have any look you want. In fact, other than watching for queries, a search activity looks, walks, and talks like any other activity in your system.

All the search activity needs to do differently is check the intents supplied to `onCreate()` (via `getIntent()`) and `onNewIntent()` to see if one is a search, and, if so, to do the search and display the results.

For example, let's look at the [Search/Lorem](#) sample application. This starts off as a version of the list-of-lorem-ipsum-words application seen in various places in this book. Now, we update it to support searching the list of words for ones containing the search string.

The main activity and the search activity both share a common layout: a `ListView` plus a `TextView` showing the selected entry:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent" >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    />
    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
    />
</LinearLayout>
```

In terms of Java code, most of the guts of the activities are poured into an abstract `LoremBase` class:

SEARCHING WITH SEARCHMANAGER

```
package com.commonware.android.search;

import android.app.ListActivity;
import android.app.SearchManager;
import android.content.Intent;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.ListAdapter;
import android.widget.ListView;
import android.widget.TextView;
import android.widget.Toast;
import java.util.ArrayList;
import org.xmlpull.v1.XmlPullParser;

abstract public class LoremBase extends ListActivity {
    abstract ListAdapter makeMeAnAdapter(Intent intent);

    private static final int LOCAL_SEARCH_ID = Menu.FIRST+1;
    private static final int GLOBAL_SEARCH_ID = Menu.FIRST+2;
    TextView selection;
    ArrayList<String> items=new ArrayList<String>();

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        selection=(TextView)findViewById(R.id.selection);

        try {
            XmlPullParser xpp=getResources().getXml(R.xml.words);

            while (xpp.getEventType()!=XmlPullParser.END_DOCUMENT) {
                if (xpp.getEventType()==XmlPullParser.START_TAG) {
                    if (xpp.getName().equals("word")) {
                        items.add(xpp.getAttributeValue(0));
                    }
                }

                xpp.next();
            }
        } catch (Throwable t) {
            Toast
                .makeText(this, "Request failed: "+t.toString(), 4000)
                .show();
        }

        setDefaultKeyMode(DEFAULT_KEYS_SEARCH_LOCAL);

        onNewIntent(getIntent());
    }
}
```

```
@Override
public void onNewIntent(Intent intent) {
    ListAdapter adapter=makeMeAnAdapter(intent);

    if (adapter==null) {
        finish();
    }
    else {
        setListAdapter(adapter);
    }
}

public void onListItemClick(ListView parent, View v, int position,
    long id) {
    selection.setText(parent.getAdapter().getItem(position).toString());
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
    menu.add(Menu.NONE, LOCAL_SEARCH_ID, Menu.NONE, "Local Search")
        .setIcon(android.R.drawable.ic_search_category_default);
    menu.add(Menu.NONE, GLOBAL_SEARCH_ID, Menu.NONE, "Global Search")
        .setIcon(android.R.drawable.ic_menu_search)
        .setAlphabeticShortcut(SearchManager.MENU_KEY);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case LOCAL_SEARCH_ID:
            onSearchRequested();
            return(true);

        case GLOBAL_SEARCH_ID:
            startSearch(null, false, null, true);
            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

This activity takes care of everything related to showing a list of words, even loading the words out of an XML resource. What it does not do is come up with the ListAdapter to put into the ListView – that is delegated to the subclasses.

The main activity — LoremDemo — just uses a ListAdapter for the whole word list:

```
package com.commonware.android.search;
```

```
import android.content.Intent;
import android.widget.ArrayAdapter;
import android.widget.ListAdapter;

public class LoremDemo extends LoremBase {
    @Override
    ListAdapter makeMeAnAdapter(Intent intent) {
        return(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            items));
    }
}
```

The search activity, though, does things a bit differently.

First, it inspects the Intent supplied to the abstract `makeMeAnAdapter()` method. That Intent comes from either `onCreate()` or `onNewIntent()`. If the intent is an `ACTION_SEARCH`, then we know this is a search. We can get the search query and, in the case of this silly demo, spin through the loaded list of words and find only those containing the search string. That list then gets wrapped in a `ListAdapter` and returned for display:

```
@Override
ListAdapter makeMeAnAdapter(Intent intent) {
    ListAdapter adapter=null;

    if (intent.getAction().equals(Intent.ACTION_SEARCH)) {
        String query=intent.getStringExtra(SearchManager.QUERY);
        List<String> results=searchItems(query);

        adapter=new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            results);
        setTitle("LoremSearch for: "+query);
    }

    return(adapter);
}
```

The logic in the `searchItems()` method that actually finds the matches looks like:

```
List<String> results=new ArrayList<String>();

for (String item : items) {
    if (item.indexOf(query)>-1) {
        results.add(item);
    }
}

return(results);
```

We will see the rest of that method later in this chapter.

Update the Manifest

While this implements search, it doesn't tie it into the Android search system. That requires a few changes to the auto-generated `AndroidManifest.xml` file:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.search">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="false"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="Lorem Ipsum">
        <activity
            android:name=".LoremDemo"
            android:label="LoremDemo">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>

            <meta-data
                android:name="android.app.default_searchable"
                android:value=".LoremSearch"/>
        </activity>
        <activity
            android:name=".LoremSearch"
            android:label="LoremSearch"
            android:launchMode="singleTop">
            <intent-filter>
                <action android:name="android.intent.action.SEARCH"/>

                <category android:name="android.intent.category.DEFAULT"/>
            </intent-filter>

            <meta-data
                android:name="android.app.searchable"
                android:resource="@xml/searchable"/>
        </activity>
    </application>
</manifest>
```

The changes that are needed are:

- The LoremDemo main activity gets a meta-data element, with an android:name of android.app.default_searchable and a android:value of the search implementation class (.LoremSearch)
- The LoremSearch activity gets an intent filter for android.intent.action.SEARCH, so search intents will be picked up
- The LoremSearch activity is set to have android:launchMode = "singleTop", which means at most one instance of this activity will be open at any time, so we don't wind up with a whole bunch of little search activities cluttering up the activity stack
- Add android:label and android:icon attributes to the application element — these will influence how your application appears in the Quick Search Box among other places
- The LoremSearch activity gets a meta-data element, with an android:name of android.app.searchable and an android:value of an XML resource containing more information about the search facility offered by this activity (@xml/searchable)

```
<searchable xmlns:android="http://schemas.android.com/apk/res/android"
    android:label="@string/searchLabel"
    android:hint="@string/searchHint"

    android:searchSuggestAuthority="com.commonware.android.search.LoremSuggestionProvider"
    android:searchSuggestSelection=" ? "
    android:searchSettingsDescription="@string/global"
    android:includeInGlobalSearch="true"
/>
```

That XML resource provides many bits of information, of which only two are needed for simple search-enabled applications:

- What name should appear in the search domain button to the left of the search field, identifying to the user where she is searching (android:label)
- What hint text should appear in the search field, to give the user a clue as to what they should be typing in (android:hint)

The other attributes found in that file, and the other search-related bits found in the manifest, will be covered later in this chapter.

Searching for Meaning In Randomness

Given all that, search is now available — Android knows your application is searchable, what search domain to use when searching from the main activity, and the activity knows how to do the search.

The options menu for this application has both local and global search options. In the case of local search, we just call `onSearchRequested()`; in the case of global search, we call `startSearch()` with `true` in the last parameter, indicating the scope is global.

Figure 693: The Lorem sample application, showing the local search popup

Typing in a letter or two, then clicking Search, will bring up the search activity and the subset of words containing what you typed, with your search query in the activity title bar:

Figure 694: The results of searching for 'co' in the Lorem search sample

You can get the same effect if you just start typing in the main activity, since it is set up for triggering a local search.

May I Make a Suggestion?

When you do a global search, you are given “suggestions” of search words or phrases that may be what you are searching for, to save you some typing on a small keyboard:

Figure 695: Search suggestions after typing some letters in global search

Your application, if it chooses, can offer similar suggestions. Not only will this give you the same sort of drop-down effect as you see with the global search above, but it also ties neatly into the Quick Search Box, as we will see later in this chapter.

To provide suggestions, you need to implement a `ContentProvider` and tie that provider into the search framework. You have two major choices for implementing a suggestion provider: use the built-in “recent” suggestion provider, or create your own from scratch.

SearchRecentSuggestionsProvider

The “recent” suggestions provider gives you a quick and easy way to remember past searches and offer those as suggestions on future searches.

To use this facility, you must first create a custom subclass of `SearchRecentSuggestionsProvider`. Your subclass may be very simple, perhaps just a two-line constructor with no other methods. However, since Android does not automatically record recent queries for you, you will also need to give your search activity a way to record them such that the recent-suggestions provider can offer them as suggestions in the future.

SEARCHING WITH SEARCHMANAGER

Below, we have a `LoremSuggestionProvider`, extending `SearchRecentSuggestionsProvider`, that also supplies a “bridge” for the search activity to record searches:

```
package com.commonware.android.search;

import android.content.Context;
import android.content.SearchRecentSuggestionsProvider;
import android.provider.SearchRecentSuggestions;

public class LoremSuggestionProvider
    extends SearchRecentSuggestionsProvider {
    private static String
AUTH="com.commonware.android.search>LoremSuggestionProvider";

    static SearchRecentSuggestions getBridge(Context ctxt) {
        return(new SearchRecentSuggestions(ctxt, AUTH,
                                           DATABASE_MODE_QUERIES));
    }

    public LoremSuggestionProvider() {
        super();

        setupSuggestions(AUTH, DATABASE_MODE_QUERIES);
    }
}
```

The constructor, besides the obligatory chain to the superclass, simply calls `setupSuggestions()`. This takes two parameters:

1. The authority under which you will register this provider in the manifest (see below)
2. A flag indicating where the suggestions will come from — in this case, we supply the required `DATABASE_MODE_QUERIES` flag

Of course, since this is a `ContentProvider`, you will need to add it to your manifest:

```
<provider
    android:name=".LoremSuggestionProvider"
    android:authorities="com.commonware.android.search>LoremSuggestionProvider"/>
```

The other thing that `LoremSuggestionProvider` has is a static method that creates a properly-configured instance of a `SearchRecentSuggestions` object. This object knows how to save search queries to the database that the content provider uses, so they will be served up as future suggestions. It needs to know the same authority and flag that you provide to `setupSuggestions()`.

That `SearchRecentSuggestions` is then used by our `LoremSearch` class, inside its `searchItems()` method that actually examines the list of Latin words for matches:

```
private List<String> searchItems(String query) {
    LoremSuggestionProvider
        .getBridge(this)
        .saveRecentQuery(query, null);

    List<String> results=new ArrayList<String>();

    for (String item : items) {
        if (item.indexOf(query)>-1) {
            results.add(item);
        }
    }

    return(results);
}
```

In this case, we always record the search, though you can imagine that some applications might not save searches that are invalid for one reason or another.

Custom Suggestion Providers

If you want to provide search suggestions based on something else – actual data, searches conducted by others that you aggregate via a Web service, etc. — you will need to implement your own `ContentProvider` that supplies that information. As with `SearchRecentSuggestionsProvider`, you will need to add your `ContentProvider` to the manifest so that Android knows it exists.

The details for doing this will be covered in a future edition of this book. For now, you are best served with the Android SearchManager [documentation on the topic](#).

Integrating Suggestion Providers

Before your suggestions will appear, though, you need to tell Android to use your `ContentProvider` as the source of suggestions. There are two attributes on your searchable XML that make this connection:

1. `android:searchSuggestAuthority` indicates the content authority for your suggestions — this is the same authority you used for your `ContentProvider`
2. `android:searchSuggestSelection` is how the suggestion should be packaged as a query in the `ACTION_SEARCH` Intent — unless you have some reason to do otherwise, " ? " is probably a fine value to use

The result is that when we do our local search, we get the drop-down of past searches as suggestions:

Figure 696: The Android local search popup, showing the IME and a previous search

There is also a `clearHistory()` method on `SearchRecentSuggestions` that you can use, perhaps from a menu choice, to clear out the search history, in case it is cluttered beyond usefulness.

Putting Yourself (Almost) On Par with Google

The Quick Search Box is Android's new term for the search widget at the top of the home screen. This is the same UI that appears when your application starts a global search. When you start typing, it shows possible matches culled from both the device and the Internet. If you choose one of the suggestions, it takes you to that item – choose a contact, and you visit the contact in the Contacts application. If you choose a Web search term, or you just submit whatever you typed in, Android will fire up a Browser instance showing you search results from Google. The order of suggestions is adaptive, as Android will attempt to show the user the sorts of things the user typically searches for (e.g., if the user clicks on contacts a lot in prior searches, it may prioritize suggested contacts in the suggestion list).

Your application can be tied into the Quick Search Box. However, it is important to understand that being in the Quick Search Box does *not* mean that your content will be searched. Instead, your *suggestions provider* will be queried based on what the user has typed in, and those suggestions will be blended into the overall results.

And, your application will not show up in Quick Search Box suggestions automatically — the user has to “opt in” to have your results included.

And, until the user demonstrates an interest in your results, your application’s suggestions will be buried at the bottom of the list.

This means that integrating with the Quick Search Box, while still perhaps valuable, is not exactly what some developers will necessarily have in mind. That being said, here is how to achieve this integration.

NOTE: there is some flaw in the Android 2.2 emulator that prevents this from working, though it works fine on Android 2.2 hardware.

Implement a Suggestions Provider

Your first step is to implement a suggestions provider, as described in the [previous section](#). Again, Android does not search your application, but rather queries your suggestions provider. If you do not have a suggestions provider, you will not be part of the Quick Search Box. As we will see below, this approach means you will need to think about what sort of suggestion provider to create.

Augment the Metadata

Next, you need to tell Android to tie your application into the Quick Search Box suggestion list. To do that, you need to add the `android:includeInGlobalSearch` attribute to your searchable XML, setting it to `true`. You probably also should consider adding the `android:searchSettingsDescription`, as this will be shown in the UI for the user to configure what suggestions the Quick Search Box shows.

Convince the User

Next, the user needs to activate your application to be included in the Quick Search Box suggestion roster. To do that, the user needs to go into Settings, find where the “Searchable Items” screen is, and check the checkbox associated with your application:

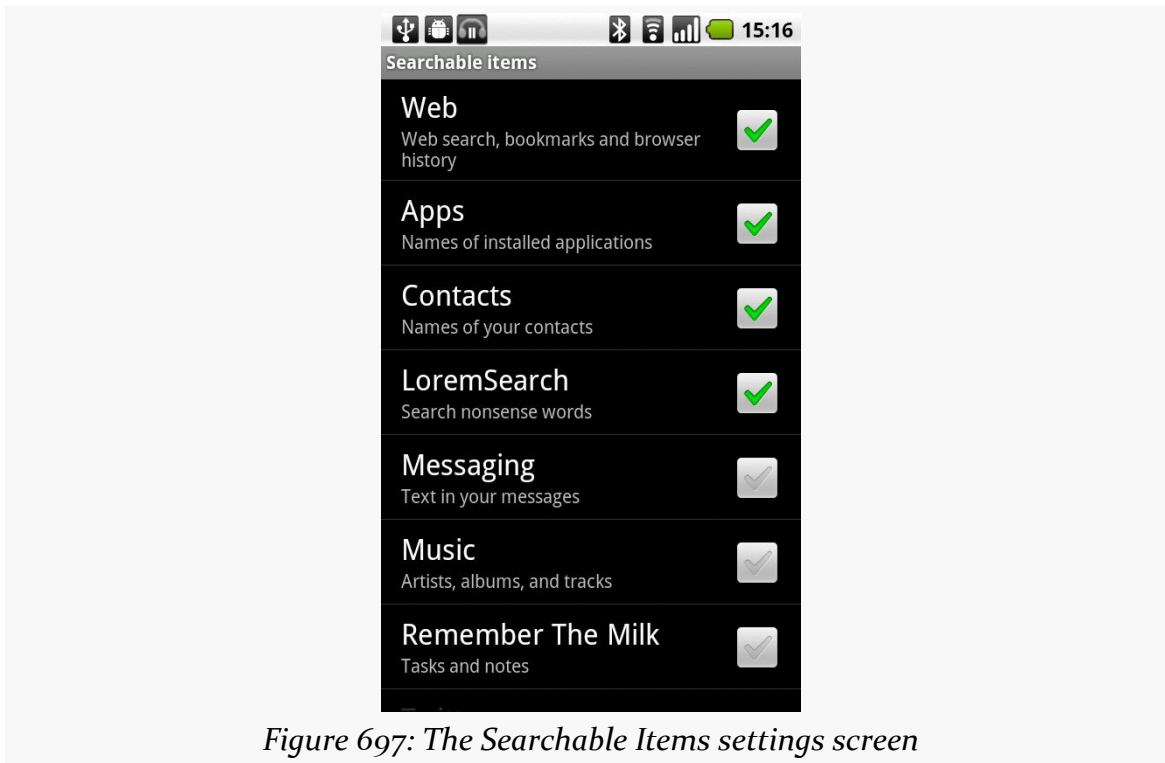

Figure 697: The Searchable Items settings screen

The precise location of the “Searchable Items” screen varies by OS version and possibly by device.

Your application’s label and the value of `android:searchSettingsDescription` are what appears to the left of the checkbox.

You have no way of toggling this on yourself — the user has to do it. You may wish to mention this in the documentation for your application.

The Results

If you and the user do all of the above, now when the user initiates a search, your suggestions will be poured into the suggestions list, at the bottom:

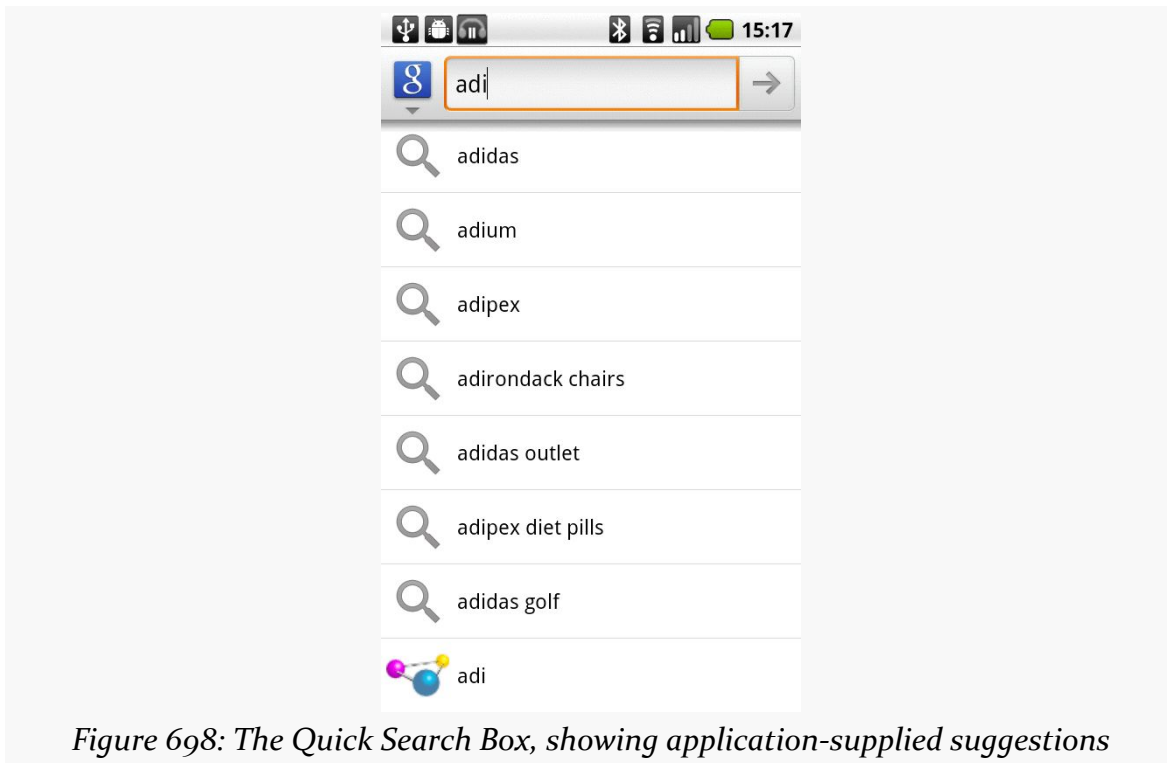

Figure 698: The Quick Search Box, showing application-supplied suggestions

On versions of Android prior to 2.2, to actually see your suggestions, the user also needs to click the arrow to “fold open” the actual suggestions:

Figure 699: The Quick Search Box, showing another placeholder for application-supplied suggestions

Even here, we do not see the actual suggestion. However, if the user clicks on that item, your suggestions then take over the list:

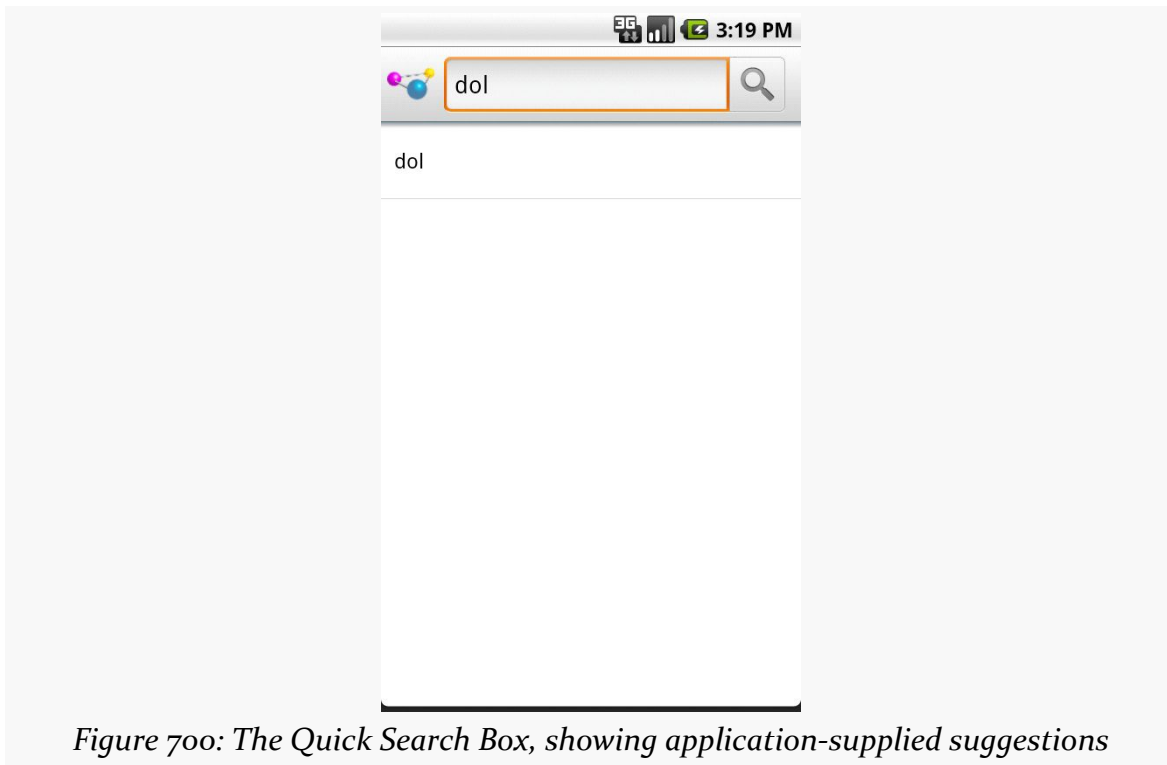

Figure 700: The Quick Search Box, showing application-supplied suggestions

Again, Android is not showing *actual data* from your application – our list of Latin words does not contain the value “dol”. Instead, Android is showing *suggestions* from your suggestion provider based on what the user typed in. In this case, our application’s suggestion provider is based on the built-in `SearchRecentSuggestionsProvider` class, meaning the suggestions are *past queries*, not actual results.

Hence, what you want to have appear in the Quick Search Box suggestion list will heavily influence what sort of suggestion provider you wish to create. While a `SearchRecentSuggestionsProvider` is simple, what you get in the Quick Search Box suggestions may not be that useful to users. Instead, you may wish to create your own custom suggestions provider, providing suggestions from actual data or other more useful sources, perhaps in addition to saved searches.

Remote Services and the Binding Pattern

Earlier in this book, we covered using services by sending commands to them to be processed. That “command pattern” is one of two primary means of interacting with a service — the binding pattern is the other. With the binding pattern, your service exposes a more traditional API, in the form of a “binder” object with methods of your choosing. On the plus side, you get a richer interface. However, it more tightly ties your activity to your service, which may cause you problems with configuration changes.

Either the command pattern or the binding pattern can be used, if desired, across process boundaries, with the client being some third-party application. In either case, you will need to export your service via an `<intent-filter>`. And, in the case of the binding pattern, your “binder” implementation will have some restrictions.

This chapter covers the binding pattern for local services, plus inter-process commands and binding (a.k.a., remote services).

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [broadcast Intents](#)
- [service theory](#)

The Binding Pattern

Implementing the binding pattern requires work on both the service side and the client side. The service will need to have a full implementation of the `onBind()` method, which typically just returns `null` or throws some sort of runtime exception for a service solely implementing the command pattern. And, the client (e.g., an activity) will need to ask to bind to the service, instead of (or perhaps in addition to) starting the service.

What the Service Does

The service implements a subclass of `Binder` that represents the service's exposed API. For a local service, your `Binder` can have pretty much whatever methods you want: method names, parameters, return types, and exceptions thrown are up to you. When you get into remote services, your `Binder` implementation will be substantially more constrained, to support inter-process communication.

Then, your `onBind()` method returns an instance of the `Binder`.

What the Client Does

Clients call `bindService()`, supplying the `Intent` that identifies the service, a `ServiceConnection` object representing the client side of the binding, and an optional `BIND_AUTO_CREATE` flag. As with `startService()`, `bindService()` is asynchronous. The client will not know anything about the status of the binding until the `ServiceConnection` object is called with `onServiceConnected()`. This not only indicates the binding has been established, but for local services it provides the `Binder` object that the service returned via `onBind()`. At this point, the client can use the `Binder` to ask the service to do work on its behalf.

Note that if the service is not already running, and if you provide `BIND_AUTO_CREATE`, then the service will be created first before being bound to the client. If you skip `BIND_AUTO_CREATE`, and the service is not already running, `bindService()` is supposed to return `false`, indicating there was no existing service to bind to. However, in actuality, Android returns `true`, due to [an apparent bug](#).

Eventually, the client will need to call `unbindService()`, to indicate it no longer needs to communicate with the service. For example, an activity might call `bindService()` in its `onCreate()` method, then call `unbindService()` in its `onDestroy()` method. Once you call `unbindService()`, your `Binder` object is no

longer safe to be used by the client. If there are no other bound clients to the service, Android will shut down the service as well, releasing its memory. Hence, we do not need to call `stopService()` ourselves – Android handles that, if needed, as a side effect of unbinding.

Your `ServiceConnection` object will also need an `onServiceDisconnected()` method. This will be called only if there is an unexpected disconnection, such as the service crashing with an unhandled exception.

A Binding Sample

In the chapter introducing services, we saw a sample app that would [download a file off of a Web server](#). That sample used the command pattern, telling the service what to download via an Intent extra. In this chapter, we will review a few variations of that sample, all of which use the binding pattern instead of the command pattern.

Right now, we are focused on local services, and so the [Binding/Local](#) sample project does the download via a local bound service.

We start by defining an interface that will serve as the “contract” between the client (fragment) and service. This interface, `IDownload`, contains a single `download()` method:

```
package com.commonware.android.advservice.binding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

Our service, `DownloadService`, implements just one method, `onBind()`, which returns an instance of a `DownloadBinder`:

```
package com.commonware.android.advservice.binding;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Binder;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
```

REMOTE SERVICES AND THE BINDING PATTERN

```
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends Binder implements IDownload {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }

        @Override
        public void run() {
            try {
                File root=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

                root.mkdirs();

                File output=new File(root, Uri.parse(url).getLastPathSegment());

                if (output.exists()) {
                    output.delete();
                }

                HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

                FileOutputStream fos=new FileOutputStream(output.getPath());
                BufferedOutputStream out=new BufferedOutputStream(fos);

                try {
                    InputStream in=c.getInputStream();
                    byte[] buffer=new byte[8192];
                    int len=0;

                    while ((len=in.read(buffer)) >= 0) {
                        out.write(buffer, 0, len);
                    }

                    out.flush();
                }
            }
        }
    }
}
```

```
    }  
    finally {  
        fos.getFD().sync();  
        out.close();  
        c.disconnect();  
    }  
}  
catch (IOException e2) {  
    Log.e("DownloadJob", "Exception in download", e2);  
}  
}  
}
```

DownloadBinder implements the IDownload interface. Its download() method, in turn, forks a DownloadThread to perform the download in the background — remember, for local services, the methods you invoke on the Binder are executed on whatever thread you call them on.

Our fragment, DownloadFragment, loads our layout, res/layout/main.xml, containing a Button to trigger the download:

```
<?xml version="1.0" encoding="utf-8"?>  
<Button xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/go"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:text="@string/go"/>
```

The implementation of onCreateView() simply loads that layout, gets the Button, sets up the fragment as being the click listener for the Button, and disables the Button:

```
@Override  
public View onCreateView(LayoutInflater inflater,  
                        ViewGroup container,  
                        Bundle savedInstanceState) {  
    View result=inflater.inflate(R.layout.main, container, false);  
  
    btn=(Button)result.findViewById(R.id.go);  
    btn.setOnClickListener(this);  
    btn.setEnabled(binding!=null);  
  
    return(result);  
}
```

The reason why we disable the Button is because we are not connected to our service at this point, and until we are, we cannot allow the user to try to download a file.

In `onAttach()` of our fragment, we bind to the service:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    appContext=(Application)host.getApplicationContext();
    appContext.bindService(new Intent(getActivity(),
                                   DownloadService.class), this,
                          Context.BIND_AUTO_CREATE);
}
```

You will notice something curious here: `getApplicationContext()`. Technically, we could bind to the service directly from the Activity, by calling `bindService()` on it, as `bindService()` is a method on Context. However, our service binding represents some state, and it is possible that this state will hold a reference to the Context that created the binding. In that case, we run the risk of leaking our original activity during a configuration change. The `getApplicationContext()` method returns the global Application singleton, which is a Context suitable for binding, but one that cannot be leaked, since it is already in a global scope. In effect, it is “pre-leaked”.

Some time after `onAttach()` is called and we call `bindService()`, our `onServiceConnected()` method will be called, as we designated our fragment to be the ServiceConnection. Here, we can cast the IBinder object we receive to be our IDownload interface to the service, and we can enable the Button:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=(IDownload)binder;
    btn.setEnabled(true);
}
```

Since we are implementing the ServiceConnection interface, our fragment also needs to implement the `onServiceDisconnected()` method, invoked if our service crashes. Here, we delegate responsibility to a `disconnect()` private method, which removes our link to the IDownload object and disables our Button:

```
@Override
public void onServiceDisconnected(ComponentName className) {
    disconnect();
}

private void disconnect() {
    binding=null;
    btn.setEnabled(false);
}
```

And, when our fragment is destroyed, we unbind from the service (using the same Context as before, from `getApplicationContext()`) and `disconnect()`:

```
@Override
public void onDestroy() {
    appContext.unbindService(this);
    disconnect();

    super.onDestroy();
}
```

However, in between `onServiceConnected()` and either `onServiceDisconnected()` or `onDestroy()`, the user can click the Button, which will trigger the download via a call to `download()` on our `IDownload` instance:

```
@Override
public void onClick(View view) {
    binding.download(TO_DOWNLOAD);
}
```

The `DownloadBindingDemo` activity adds our `DownloadFragment` via a `FragmentManager`:

```
package com.commonware.android.advservice.binding;

import android.app.Activity;
import android.os.Bundle;

public class DownloadBindingDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new DownloadFragment()).commit();
        }
    }
}
```

The fact that we are using a `FragmentManager` means that our `DownloadFragment` can be retained, which we set up in `onCreate()` of the fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
```

```
    setRetainInstance(true);  
}
```

This allows the fragment — serving as our `ServiceConnection` — to survive a configuration change, so we can cleanly unbind from the service when `onDestroy()` is called.

Starting and Binding

Some developers will use *both* `startService()` and `bindService()` at the same time. The typical argument is that they need frequent updates from the service (e.g., percentage of progress, for updating a `ProgressBar`) in the client and are concerned about the overhead of sending broadcasts.

With the advent of [LocalBroadcastManager and other event bus implementations](#), binding to a service you are using with `startService()` should no longer be necessary.

When IPC Attacks!

If you wish to extend the binding pattern to serve in the role of IPC, whereby other processes can get at your Binder and call its methods, you will need to use AIDL: the Android Interface Description Language. If you have used IPC mechanisms like SOAP, XML-RPC, DCOM, CORBA, or the like, you will recognize the notion of IDL. AIDL describes the public IPC interface, and Android supplies tools to build the client and server side of that interface.

With that in mind, let's take a look at AIDL and IPC.

Write the AIDL

IDLs are frequently written in a “language-neutral” syntax. AIDL, on the other hand, looks a lot like a Java interface file. For example, here is some AIDL:

```
package com.commonware.android.advservice.remotebinding;  
  
// Declare the interface.  
interface IDownload {  
    void download(String url);  
}
```

As you will notice, this looks suspiciously like the regular Java interface we used in the simple binding example earlier in this chapter.

As with a Java interface, you declare a package at the top. As with a Java interface, the methods are wrapped in an interface declaration (`interface IDownload { ... }`). And, as with a Java interface, you list the methods you are making available.

The differences, though, are critical.

First, not every Java type can be used as a parameter. Your choices are:

1. Primitive values (int, float, double, boolean, etc.)
2. String and CharSequence
3. List and Map (from `java.util`)
4. Any other AIDL-defined interfaces
5. Any Java classes that implement the `Parcelable` or `Serializable` interface

In the case of the latter two categories, you need to include `import` statements referencing the names of the classes or interfaces that you are using (e.g., `import com.commonware.android.ISomething`). This is true even if these classes are in your own package — you have to import them anyway.

Next, parameters can be classified as `in`, `out`, or `inout`. Values that are `out` or `inout` can be changed by the service and those changes will be propagated back to the client. Primitives (e.g., `int`) can only be `in`.

Also, you cannot throw any exceptions. You will need to catch all exceptions in your code, deal with them, and return failure indications some other way (e.g., error code return values).

Name your AIDL files with the `.aidl` extension and place them in the proper directory based on the package name:

- For native Android Studio projects, this will be an `aidl/` directory in your `src/` sourceset, as a peer of your `java/` directory, with the same sort of subdirectories-based-on-the-Java-package approach as you use for regular Java source code
- For Eclipse-compatible projects, the `.aidl` files will go alongside your `.java` files in the `src/` directory tree

When you build your project, either via an IDE or via Ant, the `aidl` utility from the Android SDK will translate your AIDL into a server stub and a client proxy.

Implement the Interface

Given the AIDL-created server stub, now you need to implement the service, either directly in the stub, or by routing the stub implementation to other methods you have already written.

The mechanics of this are fairly straightforward:

1. Create a private instance of the AIDL-generated `.Stub` class (e.g., `IDownload.Stub`)
2. Implement methods matching up with each of the methods you placed in the AIDL
3. Return this private instance from your `onBind()` method in the `Service` subclass

Note that AIDL IPC calls are synchronous, and so the caller is blocked until the IPC method returns. Hence, your services need to be quick about their work.

We will see examples of service stubs later in this chapter.

Service From Afar

So, given our AIDL description, let us examine a sample implementation, using AIDL for a remote service.

Our sample applications — shown in the [Binding/Remote/Service](#) and [Binding/Remote/Client](#) sample projects — simply move the service logic into a separate project from the client logic.

Service Names

To bind to a service's AIDL-defined API, you need to craft an `Intent` that can identify the service in question. In the case of a local service, that `Intent` can use the local approach of directly referencing the service class.

Obviously, that is not possible in a remote service case, where the service class is not in the same process, and may not even be known by name to the client.

When you define a service to be used by remote, you need to add an `<intent-filter>` element to your service declaration in the manifest, indicating how you want that service to be referred to by clients. The manifest for `RemoteService` is shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.advservice.remotebinding.svc"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET" />
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <service android:name=".DownloadService">
            <intent-filter>
                <action
                    android:name="com.commonware.android.advservice.remotebinding.IDownload" />
            </intent-filter>
        </service>
    </application>
</manifest>
```

Here, we say that the service can be identified by the name `com.commonware.android.advservice.IDownload`. So long as the client uses this name to identify the service, it can bind to that service's API.

In this case, the name is not an implementation, but the AIDL API, as you will see below. In effect, this means that so long as some service exists on the device that implements this API, the client will be able to bind to something.

Remote Services and Implicit Intents

We are used to a device having multiple activities that can respond to the same `<intent-filter>`. In that case, by default, the user will see a chooser if we try to start one of those activities.

We are used to a device having multiple `BroadcastReceiver` components that can respond to the same `<intent-filter>` (or `IntentFilter`). In that case, in a regular broadcast, all eligible receivers will receive it.

We are used to it being impossible to have multiple `ContentProvider` components with the same authority, as the second one fails on install with an `INSTALL_FAILED_CONFLICTING_PROVIDER` error.

What happens if there are *two* (or more) services installed on the device that claim to support the same `<intent-filter>`, but have different package names? You might think that this would fail on install, as happens with providers with duplicate authorities. Alas, it does not... prior to Android 5.0. Instead, the higher-priority `<intent-filter>` gets it (set via the `android:priority` attribute). If 2+ implementations have the same priority, the first one installed wins.

So, if we have `BadService` and `GoodService`, both responding to the same `<intent-filter>`, and a client app tries to communicate to `GoodService` via the implicit Intent matching that `<intent-filter>`, it might *actually* be communicating with `BadService`, simply because `BadService` was installed first. The user is oblivious to this.

Android 5.0 solves this by preventing binding using an implicit Intent. This, however, presents a conundrum:

- We cannot bind using an implicit Intent
- We do not know how to construct an explicit Intent identifying the desired service, as that might be from a third-party app

As you will see, when we examine the client side of this sample, we have to use `PackageManager` to convert an implicit Intent into a valid explicit Intent for our service. This not only allows us to comply with the Android 5.0 binding restriction, but it gives us an opportunity to detect and handle the cases where there is no matching service (e.g., the service app has not yet been installed) or when there is more than one matching service (e.g., `BadService` and `GoodService`). And the techniques that all of this uses works on pretty much any version of Android, so while we *need* them for Android 5.0 and higher, we can *use* them anywhere.

The Service

Beyond the manifest, the service implementation is not too unusual. There is the AIDL interface, `IDownload`:

REMOTE SERVICES AND THE BINDING PATTERN

```
package com.commonware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

And there is the actual service class itself, DownloadService:

```
package com.commonware.android.advservice.remotebinding.svc;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import com.commonware.android.advservice.remotebinding.IDownload;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends IDownload.Stub {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }

        @Override
        public void run() {
            try {
                File root=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);
```

```
root.mkdirs();

File output=new File(root, Uri.parse(url).getLastPathSegment());

if (output.exists()) {
    output.delete();
}

URLConnection c=(URLConnection)new URL(url).openConnection();

FileOutputStream fos=new FileOutputStream(output.getPath());
BufferedOutputStream out=new BufferedOutputStream(fos);

try {
    InputStream in=c.getInputStream();
    byte[] buffer=new byte[8192];
    int len=0;

    while ((len=in.read(buffer)) >= 0) {
        out.write(buffer, 0, len);
    }

    out.flush();
}
finally {
    fos.getFD().sync();
    out.close();
    c.disconnect();
}
}
catch (IOException e2) {
    Log.e("DownloadJob", "Exception in download", e2);
}
}
```

This is identical to the local binding example, with one key difference: DownloadService now extends IDownload.Stub rather than the generic Binder class.

The Client

The client — a revised version of DownloadFragment — connects to the remote service to ask it to download the file on the user's behalf. This has three changes of note over our original local implementation.

First, when we call download() on the IDownload object, we need to catch a RemoteException. This will be thrown if the service crashes during our request or otherwise is unable to return properly:

```
@Override
public void onClick(View view) {
    try {
        binding.download(TO_DOWNLOAD);
    }
    catch (RemoteException e) {
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
}
```

Second, our `onServiceConnected()` uses `IDownload.Stub.asInterface()` to convert the raw `IBinder` into an `IDownload` object for use:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding = IDownload.Stub.asInterface(binder);
    btn.setEnabled(true);
}
```

Third, our binding logic in `onAttach()` is significantly more complicated:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    appContext = (Application) host.getApplicationContext();

    Intent implicit = new Intent(IDownload.class.getName());
    List<ResolveInfo> matches = host.getPackageManager()
        .queryIntentServices(implicit, 0);

    if (matches.size() == 0) {
        Toast.makeText(host, "Cannot find a matching service!",
            Toast.LENGTH_LONG).show();
    }
    else if (matches.size() > 1) {
        Toast.makeText(host, "Found multiple matching services!",
            Toast.LENGTH_LONG).show();
    }
    else {
        Intent explicit = new Intent(implicit);
        ServiceInfo svcInfo = matches.get(0).serviceInfo;
        ComponentName cn = new ComponentName(svcInfo.applicationInfo.packageName,
            svcInfo.name);

        explicit.setComponent(cn);
        appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
    }
}
```

Here, we:

- Get the Application singleton Context as before
- Craft an implicit Intent for the service, using the appropriate action string (which, in this case, happens to be the fully-qualified name of the IDownload interface)
- Use PackageManager and queryIntentServices() to find out all services that implement a matching <intent-filter> for that implicit Intent
- Fail with a Toast if there is not exactly one such service
- Use the ServiceInfo object from our queryIntentServices() call to craft an explicit Intent, with the same structure as the implicit Intent had, but also with the actual matched component (via setComponent())
- Use the explicit Intent to bind to the service

Note that the client needs its own copy of IDownload.aidl. After all, it is a totally separate application, and therefore does not share source code with the service. In a production environment, we might craft and distribute a JAR file that contains the IDownload classes, so both client and service can work off the same definition (see [the upcoming chapter on reusable components](#)). For now, we will just have a copy of the AIDL.

If you compile both applications and upload them to the device, then start up the client, you can have the service download the file.

Servicing the Service

However, we do not get any result back from the service to know if the download succeeded or failed. That is likely to be rather important information for the user.

In principle, download() could return some success-or-failure indication... but then we would have a blocking call. Neither the client nor the service could proceed until the download is completed. That would require the client to manage its own background thread, which is a minor hassle. It also means that the service ties up one of a limited number of “Binder threads”, which is not a good idea.

Another approach would be to pass some sort of callback object with download(), such that the server could run the script asynchronously and invoke the callback on success or failure. This, though, implies that there is some way to have the client export an API to the service.

Fortunately, this is eminently doable, as you will see in this section, and the accompanying samples ([Binding/Callback/Service](#) and [Binding/Callback/Client](#)).

Callbacks via AIDL

AIDL does not have any concept of direction. It just knows interfaces, proxies, and stub implementations. In the preceding example, we used AIDL to have the service flesh out the stub implementation and have the client access the service via the AIDL-defined interface. However, there is nothing magic about services implementing interfaces and clients accessing them — it is equally possible to reverse matters and have the client implement something the service uses via an interface.

So, for example, we could create an `IDownloadCallback.aidl` file:

```
package com.commonware.android.advservice.callbackbinding;

// Declare the interface.
interface IDownloadCallback {
    void onSuccess();
    void onFailure(String msg);
}
```

Then, we can augment `IDownload` itself, to pass an `IDownloadCallback` with `download()`:

```
package com.commonware.android.advservice.callbackbinding;

import com.commonware.android.advservice.callbackbinding.IDownloadCallback;

// Declare the interface.
interface IDownload {
    void download(String url, IDownloadCallback cb);
}
```

Notice that we need to specifically import `IDownloadCallback`, just like we might import some “regular” Java interface. And, as before, we need to make sure the client and the server are working off of the same AIDL definitions, so these two AIDL files need to be replicated across each project.

But other than that one little twist, this is all that is required, at the AIDL level, to have the client pass a callback object to the service: define the AIDL for the callback and add it as a parameter to some service API call.

Of course, there is a little more work to do on the client and server side to make use of this callback object.

Revising the Client

On the client, we need to implement an `IDownloadCallback`. In `onSuccess()` and `onFailure()` we can do something like raise a Toast.

The catch is that we cannot be certain we are being called on the UI thread in our callback object. In fact, it is almost assured that we are not. So, we need to get our work moved over to the main application thread. To do that, this sample uses greenrobot's `EventBus`, having the `IDownloadCallback.Stub` post a `CallbackEvent` indicating success or failure:

```
IDownloadCallback.Stub cb=new IDownloadCallback.Stub() {
    @Override
    public void onSuccess() throws RemoteException {
        EventBus.getDefault().post(new CallbackEvent(true, null));
    }

    @Override
    public void onFailure(String msg) throws RemoteException {
        EventBus.getDefault().post(new CallbackEvent(false, msg));
    }
};

static class CallbackEvent {
    boolean succeeded=false;
    String msg=null;

    CallbackEvent(boolean succeeded, String msg) {
        this.succeeded=succeeded;
        this.msg=msg;
    }
}
```

The fragment itself registers for the event bus, and in `onEventMainThread()`, it raises the Toast:

```
public void onEventMainThread(CallbackEvent event) {
    if (getActivity()!=null) {
        if (event.succeeded) {
            Toast.makeText(getActivity(), "Download successful!",
                Toast.LENGTH_LONG).show();
        }
        else {
            Toast.makeText(getActivity(), event.msg, Toast.LENGTH_LONG).show();
        }
    }
}
```

```
}  
}
```

And, of course, we need to pass the `IDownloadCallback` object in our `download()` call:

```
@Override  
public void onClick(View view) {  
    try {  
        binding.download(TO_DOWNLOAD, cb);  
    }  
    catch (RemoteException e) {  
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);  
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();  
    }  
}
```

Revising the Service

The service also needs changing, to use the supplied callback object for the end results of the download.

`DownloadBinder` now receives an `IDownloadCallback` proxy in its `download()` method, which it passes along to the `DownloadThread`:

```
private static class DownloadBinder extends IDownload.Stub {  
    @Override  
    public void download(String url, IDownloadCallback cb) {  
        new DownloadThread(url, cb).start();  
    }  
}
```

Notice that the service's own API just needs the `IDownloadCallback` parameter, which can be passed around and used like any other Java object. The fact that it happens to cause calls to be made synchronously back to the remote client is invisible to the service.

`DownloadThread`, in turn, invokes `onSuccess()` or `onFailure()` as appropriate:

```
private static class DownloadThread extends Thread {  
    String url=null;  
    IDownloadCallback cb=null;  
  
    DownloadThread(String url, IDownloadCallback cb) {  
        this.url=url;  
        this.cb=cb;  
    }  
}
```

```
@Override
public void run() {
    try {
        File root=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

        root.mkdirs();

        File output=new File(root, Uri.parse(url).getLastPathSegment());

        if (output.exists()) {
            output.delete();
        }

        HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

        FileOutputStream fos=new FileOutputStream(output.getPath());
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
            InputStream in=c.getInputStream();
            byte[] buffer=new byte[8192];
            int len=0;

            while ((len=in.read(buffer)) >= 0) {
                out.write(buffer, 0, len);
            }

            out.flush();

            try {
                cb.onSuccess();
            }
            catch (RemoteException e) {
                Log.e("DownloadJob", "Exception when calling onSuccess()", e);
            }
        }
        finally {
            fos.getFD().sync();
            out.close();
            c.disconnect();
        }
    }
    catch (IOException e2) {
        Log.e("DownloadJob", "Exception in download", e2);

        try {
            cb.onFailure(e2.getMessage());
        }
        catch (RemoteException e) {
            Log.e("DownloadJob", "Exception when calling onFailure()", e2);
        }
    }
}
```

```
}  
}
```

Thinking About Security

Remote services, by definition, are available for anyone to connect to. This may or may not be a good idea.

If the only client of your remote service is some other app of yours, you could protect the service using [a custom signature-level permission](#).

If you anticipate third-party apps communicating with your service, you should strongly consider protecting the service with [an ordinary custom permission](#), so the *user* can vote on whether the communication is allowed.

For local services, the simplest way to secure the service is to not export it, typically by not having an `<intent-filter>` element for the `<service>` in the manifest. Then, your app is the only app that can work with the service.

The “Everlasting Service” Anti-Pattern

One anti-pattern that is all too prevalent in Android is the “everlasting service”. Such a service is started via `startService()` and never stops — the component starting it does not stop it and it does not stop itself via `stopSelf()`.

Why is this an anti-pattern?

1. The service takes up memory all of the time. This is bad in its own right if the service is not continuously delivering sufficient value to be worth the memory.
2. Users, fearing services that sap their device’s CPU or RAM, may attack the service with so-called “task killer” applications or may terminate the service via the Settings app, thereby defeating your original goal.
3. Android itself, due to user frustration with sloppy developers, will terminate services it deems ill-used, particularly ones that have run for quite some time.

Occasionally, an everlasting service is the right solution. Take a VOIP client, for example. A VOIP client usually needs to hold an open socket with the VOIP server to know about incoming calls. The only way to continuously watch for incoming

calls is to continuously hold open the socket. The only component capable of doing that would be a service, so the service would have to continuously run.

However, in the case of a VOIP client, or a music player, the user is the one specifically requesting the service to run forever. By using `startForeground()`, a service can ensure it will not be stopped due to old age for cases like this.

As a counter-example, imagine an email client. The client wishes to check for new email messages periodically. The right solution for this is the `AlarmManager` pattern described [elsewhere in this book](#). The anti-pattern would have a service running constantly, spending most of its time waiting for the polling period to elapse (e.g., via `Thread.sleep()`). There is no value to the user in taking up RAM to watch the clock tick. Such services should be rewritten to use `AlarmManager`.

Most of the time, though, it appears that services are simply leaked. That is one advantage of using `AlarmManager` and an `IntentService` – it is difficult to leak the service, causing it to run indefinitely. In fact, `IntentService` in general is a great implementation to use whenever you use the command pattern, as it ensures that the service will shut down eventually. If you use a regular service, be sure to shut it down when it is no longer actively delivering value to the user.

Advanced Manifest Tips

If you have been diligent about reading this book (versus having randomly jumped to this chapter), you will already have done a fair number of things with your project's `AndroidManifest.xml` file:

1. Used it to define components, like activities, services, content providers, and manifest-registered broadcast receivers
2. Used it to declare permissions your application requires, or possibly to define permissions that other applications need in order to integrate with your application
3. Used it to define what SDK level, screen sizes, and other device capabilities your application requires

In this chapter, we continue looking at things the manifest offers you, starting with a discussion of controlling where your [application gets installed](#) on a device, and wrapping up with a bit of information about [activity aliases](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Just Looking For Some Elbow Room

On October 22, 2008, the [HTC Dream](#) was released, under the moniker of “T-Mobile G1”, as the first production Android device.

Complaints about the lack of available storage space for applications probably started on October 23rd.

The Dream, while a solid first Android device, offered only 70MB of on-board flash for application storage. This storage had to include:

1. The Android application (APK) file
2. Any local files or databases the application created, particularly those deemed unsafe to put on the SD card (e.g., privacy)
3. Extra copies of some portions of the APK file, such as the compiled Dalvik bytecode, which get unpacked on installation for speed of access

It would not take long for a user to fill up 70MB of space, then have to start removing some applications to be able to try others.

Users and developers alike could not quite understand why the Dream had so little space compared to the available iPhone models, and they begged to at least allow applications to install to the SD card, where there would be more room. This, however, was not easy to implement in a secure fashion, and it took until Android 2.2 for the feature to become officially available.

If your app's `android:minSdkVersion` is 11 or higher, you can probably ignore all of this. At that time, what the Android SDK refers to as “internal storage” and “external storage” were moved to be part of one filesystem partition, and so there is no artificial division of space between the two.

But, if you are still supporting Android 2.2 and 2.3, you may wish to consider supporting having your app be installed to, or moved to, external storage.

Configuring Your App to Reside on External Storage

Indicating to Android that your application can reside on the SD card is easy... and necessary, if you want the feature. If you do not tell Android this is allowed, Android will *not* install your application to the SD card, nor allow the user to move the application to the SD card.

All you need to do is add an `android:installLocation` attribute to the root `<manifest>` element of your `AndroidManifest.xml` file. There are three possible values for this attribute:

ADVANCED MANIFEST TIPS

- `internalOnly`, the default, meaning that the application cannot be installed to the SD card
- `preferExternal`, meaning the application would like to be installed on the SD card
- `auto`, meaning the application can be installed in either location

If you use `preferExternal`, then your application will be initially installed on the SD card in most cases. Android reserves the right to still install your application on internal storage in cases where that makes too much sense, such as there not being an SD card installed at the time.

If you use `auto`, then Android will make the decision as to the installation location, based on a variety of factors. In effect, this means that `auto` and `preferExternal` are functionally very similar – all you are doing with `preferExternal` is giving Android a hint as to your desired installation destination.

Because Android decides where your application is initially installed, and because the user has the option to move your application between the SD card and on-board flash, you cannot assume any given installation spot. The exception is if you choose `internalOnly`, in which case Android will honor your request, at the potential cost of not allowing the installation at all if there is no more room in on-board flash.

For example, here is the manifest from the [SMS/Sender](#) sample project, profiled in [another chapter](#), showing the use of `preferExternal`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.READ_CONTACTS"/>
    <uses-permission android:name="android.permission.SEND_SMS"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/ic_launcher"
```

```
    android:label="@string/app_name">
    <activity
        android:name="Sender"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

Since this feature only became available in Android 2.2, to support older versions of Android, just have your build tools target API level 8 (e.g., `compileSdkVersion` of 8 or higher in `build.gradle` for Android Studio users, or `Project > Properties > Android` for those of you building with Eclipse) while having your `minSdkVersion` attribute in the manifest state the lowest Android version your application supports overall. Older versions of Android will ignore the `android:installLocation` attribute. So, for example, in the above manifest, the Sender application supports API level 4 and above (Android 1.6 and newer), but still can use `android:installLocation="preferExternal"`, because the build tools are targeting API level 8.

What the User Sees

On newer devices, such as those running Android 4.2, the user will see nothing different. That is because internal and external storage share a common pool of space, and therefore there is no advantage in having your application installed to external storage.

However, on, say, Android 2.3, you will see a difference in behavior.

For an application that wound up on external storage, courtesy of your choice of `preferExternal` or `auto`, the user will have an option to move it to the phone's internal storage. This can be done by choosing the application in the Manage Applications list in the Settings application, then clicking the "Move to phone" button.

Conversely, if your application is installed in on-board flash, and it is movable to external storage, they will be given that option with a "Move to SD card" button.

What the Pirate Sees

Ideally, the pirate sees nothing at all.

One of the major concerns with installing applications to the SD card is that the SD card is usually formatted FAT32 (vfat), offering no protection from prying eyes. The concern was that pirates could then just pluck the APK file off external storage and distribute it, even for paid apps from the Play Store.

Apparently, they solved this problem.

To quote the [Android developer documentation](#):

The unique container in which your application is stored is encrypted with a randomly generated key that can be decrypted only by the device that originally installed it. Thus, an application installed on an SD card works for only one device.

Moreover, this “unique container” is not normally mounted when the user mounts external storage on their host machine. The user mounts /mnt/sdcard; the “unique container” is /mnt/asec.

What Your App Sees... When External Storage is Inaccessible

So far, this has all seemed great for users and developers. Developers need to add a single attribute to the manifest, and Android 2.2+ users gain the flexibility of where the app gets stored.

Alas, there is a problem, and it is a big one: on Android 1.x and 2.x, either the host PC or the device can have access to the SD card, but not both. As a result, if the user makes the SD card available to the host PC, by plugging in the USB cable and mounting the SD card as a drive via a Notification or other means, that SD card becomes unavailable for running applications.

So, what happens?

1. First, your application is terminated forcibly, as if your process was being closed due to low memory. Notably, your activities and services will not be called with `onDestroy()`, and instance state saved via `onSaveInstanceState()` is lost.

ADVANCED MANIFEST TIPS

2. Second, your application is unhooked from the system. Users will not see your application in the launcher, your `AlarmManager` alarms will be canceled, and so on.
3. When the user makes external storage available to the phone again, your application will be hooked back into the system and will be once again available to the user (for example, your icon will reappear in the launcher)

The upshot: if your application is simply a collection of activities, otherwise not terribly connected to Android, the impact on your application is no different than if the user reboots the phone, kills your process via a so-called “task killer” application, etc. If, however, you are doing more than that, the impacts may be more dramatic.

Perhaps the most dramatic impact, from a user’s standpoint, will be if your application implements app widgets. If the user has your app widget on her home screen, that app widget will be removed when the SD card becomes unavailable to the phone. Worse, your app widget cannot be re-added to the home screen until the phone is rebooted (a limitation that hopefully will be lifted sometime after Android 2.2).

The user is warned about this happening, at least in general:

Figure 701: Warning when unmounting the SD card

ADVANCED MANIFEST TIPS

Two broadcast Intents are sent out related to this:

- ACTION_EXTERNAL_APPLICATIONS_UNAVAILABLE, when the SD card (and applications installed upon it) become unavailable
- ACTION_EXTERNAL_APPLICATIONS_AVAILABLE, when the SD card and its applications return to normal

Note that the documentation is unclear as to whether your own application, that had been on the SD card, can receive ACTION_EXTERNAL_APPLICATIONS_AVAILABLE once the SD card is back in action. There is an [outstanding issue on this topic](#) in the Android issue tracker.

Also note that all of these problems hold true for longer if the user physically removes the SD card from the device. If, for example, they replace the card with a different one — such as one with more space — your application will be largely lost. They will see a note in their applications list for your application, but the icon will indicate it is on external storage, and the only thing they can do is uninstall it:

Figure 702: The Manage Applications list, with an application shown from a removed SD card

Choosing Whether to Support External Storage

Given the huge problem from the previous section, the question of whether or not your application should support external storage is far from clear.

As the [Android developer documentation](#) states:

Large games are more commonly the types of applications that should allow installation on external storage, because games don't typically provide additional services when inactive. When external storage becomes unavailable and a game process is killed, there should be no visible effect when the storage becomes available again and the user restarts the game (assuming that the game properly saved its state during the normal Activity lifecycle).

Conversely, if your application implements any of the following features, it may be best to not support external storage:

1. Polling of Web services or other Internet resources via a scheduled alarm
2. Account managers and their corresponding sync adapters, for custom sources of contact data
3. App widgets, as noted in the previous section
4. Device administration extensions
5. Live folders
6. Custom soft keyboards ("input method engines")
7. Live wallpapers
8. Custom search providers

But, as noted earlier, this is not even usually necessary on API Level 11+ devices. Hence, even if your app would otherwise qualify for being installed to external storage, you may not wish to bother. If few devices (Android 2.2 and Android 2.3) might need the capability, it may not be worth the extra testing burden.

Using an Alias

As was mentioned in the [chapter on integration](#), you can use the PackageManager class to enable and disable components in your application. This works at the component level, meaning you can enable and disable activities, services, content providers, and broadcast receivers. It does not support enabling or disabling individual <intent-filter> stanzas from a given component, though.

Why might you want to do this?

1. Perhaps you have an activity you want to be available for use, but not necessarily available in the launcher, depending on user configuration or unlocking “pro” features or something
2. Perhaps you want to add browser support for certain MIME types, but only if other third-party applications are not already installed on the device

While you cannot control individual `<intent-filter>` stanzas directly, you can have a similar effect via an activity alias.

An activity alias is another manifest element — `<activity-alias>` – that provides an alternative set of filters or other component settings for an already-defined activity. For example, here is the `AndroidManifest.xml` file from the [Manifest/Alias](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
    android:versionName="1.0"
    package="com.commonware.android.alias"
    xmlns:android="http://schemas.android.com/apk/res/android">

    <supports-screens android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false" />
    <application android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity android:label="@string/app_name"
            android:name="AliasActivity">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
        <activity-alias android:label="@string/app_name2"
            android:name="ThisIsTheAlias"
            android:targetActivity="AliasActivity">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity-alias>
    </application>
</manifest>
```

Here, we have one `<activity>` element, with an `<intent-filter>` to put the activity in the launcher. We also have an `<activity-alias>` element... which puts a second icon in the launcher for the same activity implementation.

An activity alias can be enabled and disabled independently of its underlying activity. Hence, you can have one activity class have several independent sets of intent filters and can choose which of those sets are enabled at any point in time.

For testing purposes, you can also enable and disable these from the command line. Use the `adb shell pm disable` command to disable a component:

```
adb shell pm disable  
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

... and the corresponding `adb shell pm enable` command to enable a component:

```
adb shell pm enable  
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

In each case, you supply the package of the application (`com.commonware.android.alias`) and the class of the component to enable or disable (`com.commonware.android.alias.ThisIsTheAlias`), separated by a slash.

Getting Meta (Data)

Sometimes, you may want to put more data in the manifest, associated with your components. You will frequently see this for use with libraries or plugin distribution models, where sharing some configuration data between parties could eliminate a bunch of API code that a reuser might need to implement.

To support this, Android offers a `<meta-data>` element as a child of `<activity>`, `<activity-alias>`, `<receiver>`, or `<service>`. Each `<meta-data>` element has an `android:name` attribute plus an associated value, supplied by either an `android:value` attribute (typically for literals) or an `android:resource` attribute (for references to resources).

Other parties can then get at this information via `PackageManager`. So, for example, the implementer of a plugin could have `<meta-data>` elements indicating details of how the plugin should be used (e.g., desired polling frequency), and the host of the plugin could then get that configuration data without the plugin author having to mess around with implementing some Java API for it.

For example, Roman Nurik's [DashClock](#) is a [lockscreen app widget](#) designed to serve as a replacement for the clock app widget that ships with many Android 4.2+ devices. Not only does it display the time, but it is a plugin host, allowing third party

developers to supply “extensions” that can also display data in the app widget. This way, users can set up a single lockscreen app widget and get at a bunch of useful information.

DashClock’s extension API makes use of `<meta-data>` to pass configuration data from the extension to DashClock itself. The implementation of a DashClock extension is a service, and so the extension’s `<service>` element will have a batch of `<meta-data>` elements with this configuration data:

```
<service android:name=".ExampleExtension"
    android:icon="@drawable/ic_extension_example"
    android:label="@string/extension_title"
    android:permission="com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA">
    <intent-filter>
        <action android:name="com.google.android.apps.dashclock.Extension" />
    </intent-filter>
    <meta-data android:name="protocolVersion" android:value="1" />
    <meta-data android:name="description"
        android:value="@string/extension_description" />
    <!-- A settings activity is optional -->
    <meta-data android:name="settingsActivity"
        android:value=".ExampleSettingsActivity" />
</service>
```

(sample from [the DashClock documentation](#))

Here, the developer can specify:

- What version of the communications protocol is supported, so DashClock can update its protocol over time yet remain backwards-compatible with older extensions, via the `protocolVersion` entry
- What the description is for the extension, used in DashClock’s configuration screens to let the user know what available extensions there are, via the `description` entry
- What activity, if any, does the extension supply that allows the user to configure that extension, that DashClock should provide access to from its own settings activity, via the `settingsActivity` entry

In all three cases, DashClock uses `android:value`. Note that `android:value` *does* support the use of resources — the value of `description` is a reference to the `extension_description` string resource, for example.

To retrieve that metadata, an app can ask for `PackageManager.GET_META_DATA` as a flag on `PackageManager` [methods for introspection](#), like `queryIntentActivities()`.

ADVANCED MANIFEST TIPS

In the case of DashClock, it retrieves all implementations of its plugin by asking Android what *services* have an `<intent-filter>` with an `<action>` of `com.google.android.apps.dashclock.Extension`, via `queryIntentServices()`, asking for `PackageManager` to also supply each service's metadata:

```
List<ResolveInfo> resolveInfos = pm.queryIntentServices(  
    new Intent(DashClockExtension.ACTION_EXTENSION),  
    PackageManager.GET_META_DATA);
```

(from [the ExtensionManager.java file](#) in the DashClock source code)

Each `ResolveInfo` object that comes back in the list will have a `serviceInfo` field containing details of the service. Because `GET_META_DATA` was passed in as a flag, the `serviceInfo` will have a `Bundle` named `metaData` which will contain the key/value pairs specified by the `<meta-data>` elements. DashClock can then grab that data and use it to populate its own object model:

```
for (ResolveInfo resolveInfo : resolveInfos) {  
    ExtensionListing listing = new ExtensionListing();  
    listing.componentName = new  
ComponentName(resolveInfo.serviceInfo.packageName,  
        resolveInfo.serviceInfo.name);  
    listing.title = resolveInfo.loadLabel(pm).toString();  
    Bundle metaData = resolveInfo.serviceInfo.metaData;  
    if (metaData != null) {  
        listing.protocolVersion = metaData.getInt("protocolVersion");  
        listing.description = metaData.getString("description");  
        String settingsActivity = metaData.getString("settingsActivity");  
        if (!TextUtils.isEmpty(settingsActivity)) {  
            listing.settingsActivity = ComponentName.unflattenFromString(  
                resolveInfo.serviceInfo.packageName + "/" +  
settingsActivity);  
        }  
    }  
}
```

(from [the ExtensionManager.java file](#) in the DashClock source code)

The `<meta-data>` element supports five data types for `android:value`:

- String
- Integer
- Boolean (specified as `true` or `false` in the `android:value` attribute)
- Float

It also supports colors, specified in `#AARRGGBB` and similar formats, which, according to [the documentation](#), is returned as a string.

ADVANCED MANIFEST TIPS

In this fashion, extension developers can supply enough information for DashClock to allow the user to see the list of installed extensions, choose which one(s) they want, and configure those (where applicable). Actually getting the *content* to display will need to be done at runtime, in this case via making requests of the service to supply a `ExtensionData` structure with the messages, icon, and so forth to be displayed.

Miscellaneous Integration Tips

This chapter is a collection of other miscellaneous integration and introspection tips and techniques that you might find useful in your Android apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Take the Shortcut

Another way to integrate with Android is to offer custom shortcuts. Shortcuts are available from the home screen. Whereas app widgets allow you to draw on the home screen, shortcuts allow you to wrap a custom Intent with an icon and caption and put that on the home screen. You can use this to drive users not just to your application's "front door", like the launcher icon, but to some specific capability within your application, like a bookmark.

In our case, in the [Introspection/QuickSender](#) sample project, we will allow users to create shortcuts that use ACTION_SEND to send a pre-defined message, either to a specific address or anywhere, as we have seen [before in this chapter](#).

Once again, the key is in the intent filter.

Registering a Shortcut Provider

Here is the manifest for QuickSender:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
    android:versionName="1.0"
    package="com.commonware.android.qsender"
    xmlns:android="http://schemas.android.com/apk/res/android">

    <supports-screens android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false" />
    <application android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity android:label="@string/app_name"
            android:name="QuickSender">
            <intent-filter>
                <action android:name="android.intent.action.CREATE_SHORTCUT" />
                <category android:name="android.intent.category.DEFAULT" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Our single activity does not implement a traditional launcher `<intent-filter>`. Rather, it has one that watches for a `CREATE_SHORTCUT` action. This does two things:

- It means that our activity will show up in the list of possible shortcuts a user can configure
- It means this activity will be the recipient of a `CREATE_SHORTCUT` Intent if the user chooses this application from the shortcuts list

Implementing a Shortcut Provider

The job of a shortcut-providing activity is to:

1. Create an Intent that will be what the shortcut launches
2. Return that Intent and other data to the activity that started the shortcut provider
3. Finally, `finish()`, so the caller gets control

You can see all of that in the `QuickSender` implementation:

```
package com.commonware.android.qsender;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.widget.TextView;
```

```
public class QuickSender extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void save(View v) {
        Intent shortcut=new Intent(Intent.ACTION_SEND);
        TextView addr=(TextView)findViewById(R.id.addr);
        TextView subject=(TextView)findViewById(R.id.subject);
        TextView body=(TextView)findViewById(R.id.body);
        TextView name=(TextView)findViewById(R.id.name);

        if (!TextUtils.isEmpty(addr.getText())) {
            shortcut.putExtra(Intent.EXTRA_EMAIL,
                             new String[] { addr.getText().toString() });
        }

        if (!TextUtils.isEmpty(subject.getText())) {
            shortcut.putExtra(Intent.EXTRA_SUBJECT, subject.getText().toString());
        }

        if (!TextUtils.isEmpty(body.getText())) {
            shortcut.putExtra(Intent.EXTRA_TEXT, body.getText().toString());
        }

        shortcut.setType("text/plain");

        Intent result=new Intent();

        result.putExtra(Intent.EXTRA_SHORTCUT_INTENT, shortcut);
        result.putExtra(Intent.EXTRA_SHORTCUT_NAME, name.getText().toString());
        result.putExtra(Intent.EXTRA_SHORTCUT_ICON_RESOURCE,
                        Intent.ShortcutIconResource.fromContext(this,
                                                                R.drawable.icon));

        setResult(RESULT_OK, result);
        finish();
    }
}
```

The shortcut Intent is the one that will be launched when the user taps the shortcut icon on the home screen. The result Intent packages up shortcut plus the icon and caption, where the icon is converted into an Intent.ShortcutIconResource object. That result Intent is then used with the setResult() call, to pass that back to whatever called startActivityForResult() to open up QuickSender. Then, we finish().

At this point, all the information about the shortcut is in the hands of Android (or, more accurately, the home screen application), which can add the icon to the home screen.

Using the Shortcuts

To create a custom shortcut using QuickSender, long-tap on the background of the home screen to bring up the customization options:

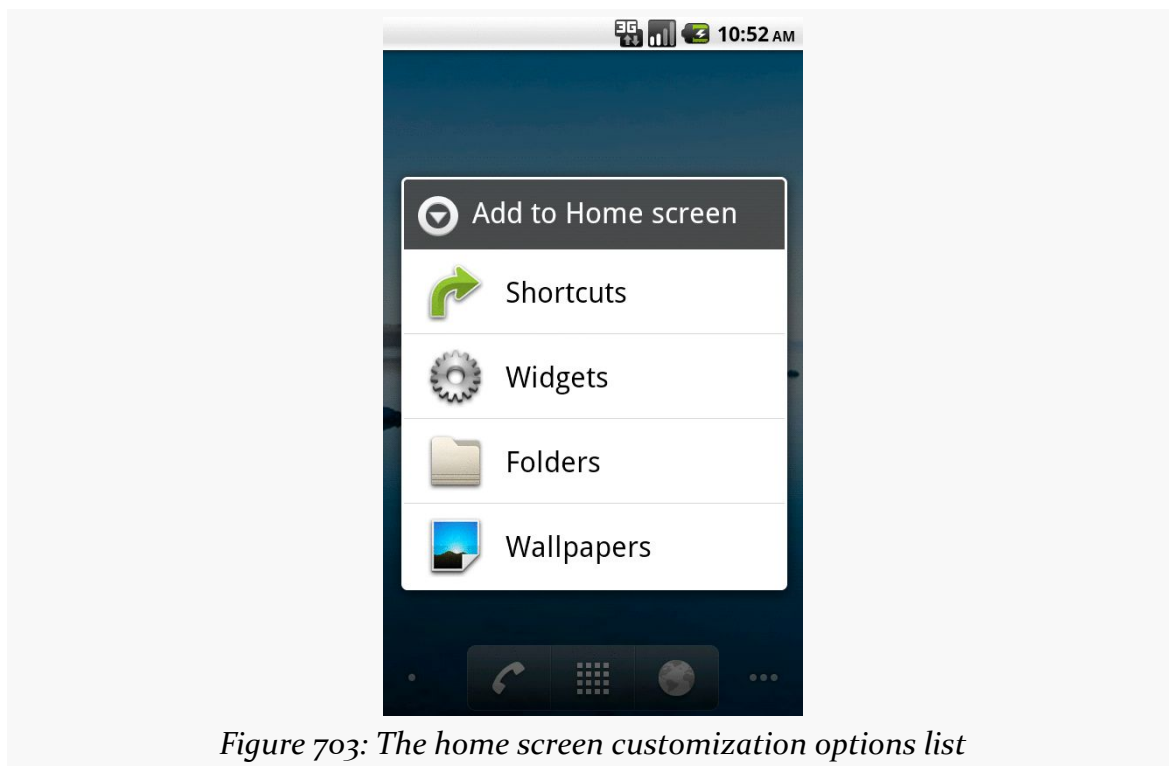

Figure 703: The home screen customization options list

Choose Shortcuts, and scroll down to find QuickSender in the list:

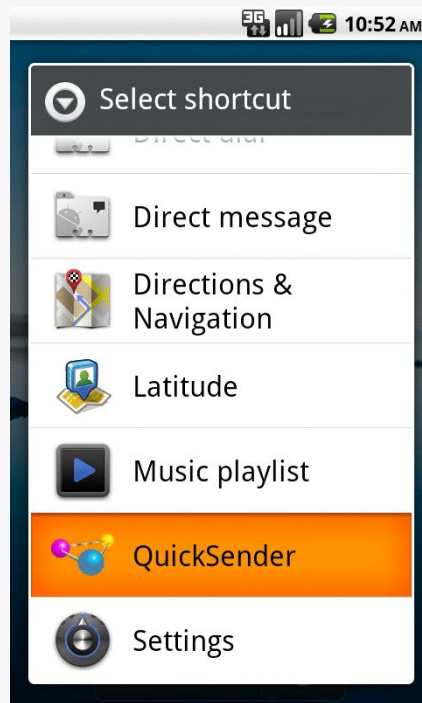

Figure 704: The available types of shortcuts

Click the QuickSender entry, which will bring up our activity with the form to define what to send:

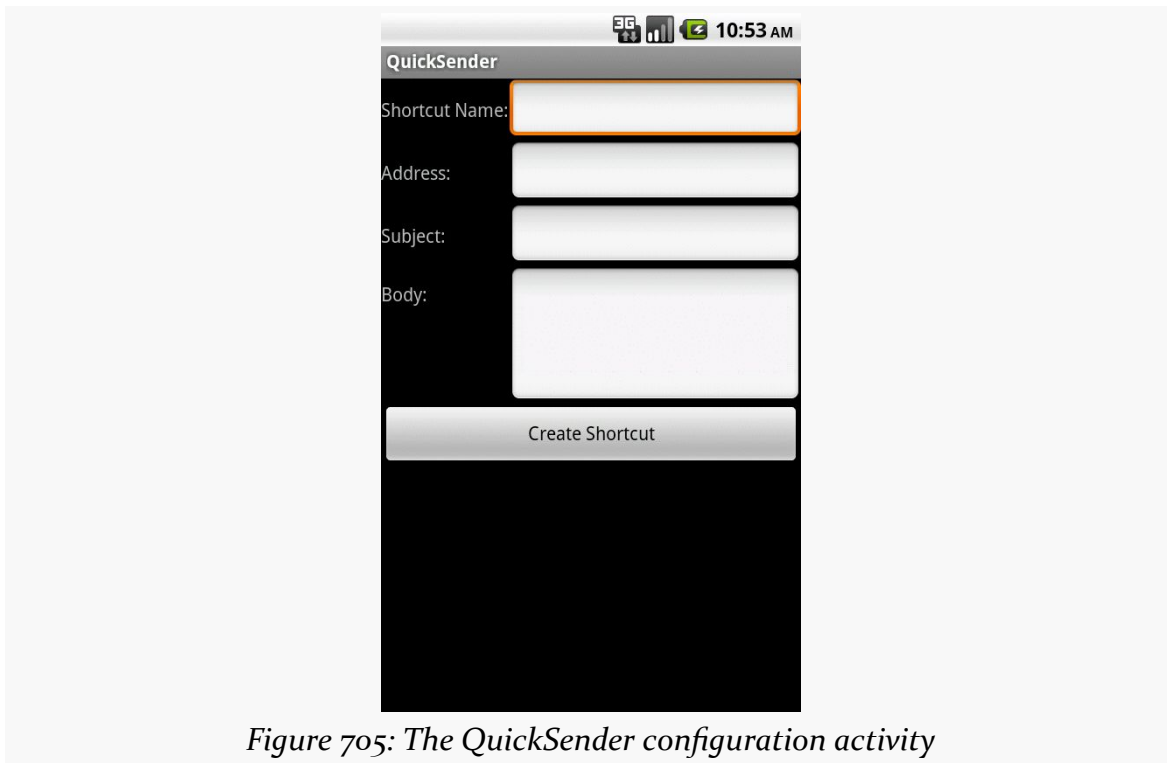

Figure 705: The QuickSender configuration activity

Fill in the name, either the subject or body, and optionally the address. Then, click the Create Shortcut button, and you will find your shortcut sitting on your home screen:

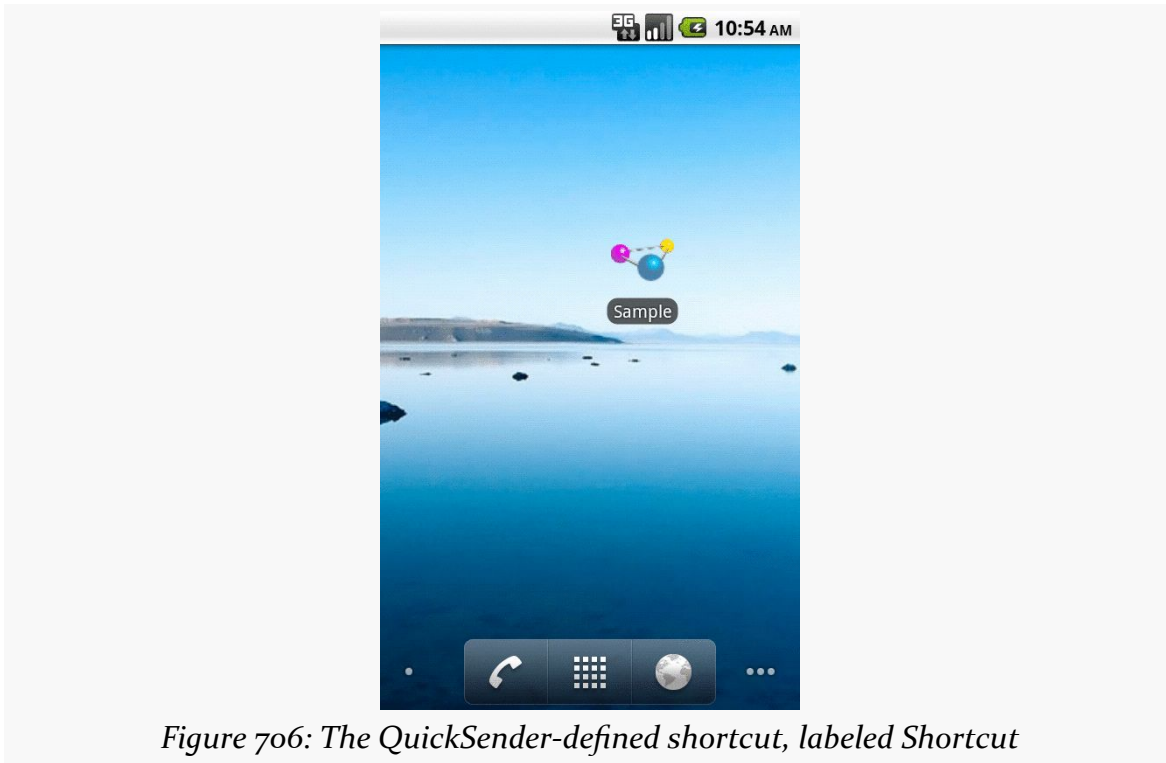

Figure 706: The QuickSender-defined shortcut, labeled Shortcut

If you launch that shortcut, and if there is more than one application on the device set up to handle `ACTION_SEND`, Android will bring up a special chooser, to allow you to not only pick how to send the message, but optionally make that method the default for all future requests:

Figure 707: The ACTION_SEND request, as triggered by the shortcut

Depending on what you choose, of course, will dictate how the message actually gets sent.

Homing Beacons for Intents

If you are encountering problems with Intent resolution — you create an Intent for something and try starting an Activity or Service with it, and it does not work — you can add the `FLAG_DEBUG_LOG_RESOLUTION` flag to the Intent. This will dump information to LogCat about how the Intent resolution occurred, so you can better diagnose what might be going wrong.

Reusable Components

In the world of Java outside of Android, reusable components rule the roost. Whether they are simple JARs, are tied in via inversion-of-control (IoC) containers like [Spring](#), or rely on enterprise service buses like [Mule](#), reusable Java components are a huge portion of the overall Java ecosystem. Even full-fledged applications, like [Eclipse](#) or [NetBeans](#), are frequently made up of a number of inter-locking components, many of which are available for others to use in their own applications.

Android, too, supports this sort of reuse. In some cases, it follows standard Java approaches. However, in other cases, unique Android aspects, such as resources, steer developers in different directions for reuse.

This chapter will outline what reuse models are in use today and how you can package your own components for reuse.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Where Do I Find Them?

Android historically has not had a “go-to” place to find reusable components. [The Android Arsenal](#) is probably the largest collection at present. Beyond that, look for recommendations in Stack Overflow answers, blog posts, and the like.

How Are They Packaged?

There are three main ways that reusable code gets packaged on Android: as a traditional Java JAR, as an Android library project, or (technically) as an APK. The last approach is usually used by apps that have user value in their own right, but also expose some sort of integration API for use by other apps, that you can take advantage of.

JARs

Android code that is pure *code*, without requiring its own resources, can be packaged into a JAR, no differently than can regular Java code outside of Android.

As was covered [earlier in the book](#), to use such a JAR, just drop it into `libs/`. Its contents will be added to your compile path (so you can reference classes from the library) and its contents will be packaged in your APK (so those references will work at runtime).

Library Projects

Android code that relies upon resources — such as many reusable UI components, such as custom widgets — cannot be packaged as a simple JAR, as there is no way of packaging the Android resources in that JAR. Instead, Google created [the Android library project](#) as the “unit of reuse” for such cases.

Android library projects are sometimes published in full source form (usually open source projects), and sometimes are published as AARs in an artifact repository. Eclipse users can readily use the full-source library projects, but have [limited ability](#) to use AARs. Android Studio users can use either, and AARs may be as simple as adding a single line to `build.gradle`.

APKs

Using JARs or library projects fits in the “traditional” model of compile-time reuse. Android’s many IPC mechanisms offer plenty of options for run-time reuse, where your app communicates with another app, having that app do things on your behalf. In this case, the primary unit of reuse is not the JAR, or the library project, but the APK.

For example, [the ZXing project](#) publishes [the Barcode Scanner app](#). This app not only allows *users* to scan barcodes, but allows *other apps* to scan barcodes, by asking Barcode Scanner to scan the barcodes and return results.

To integrate with such an app, you will need to find the instructions from the app's developers on how to do that. Sometimes, they will tell you things that you would use directly (e.g., “call `startActivityForResult()` with an Intent that contains...”). Sometimes, they will distribute a client-side JAR that you can use that wraps up the low-level IPC details into something a bit easier to consume. For example, ZXing distributes an [IntentIntegrator.java class file](#) that you can use that not only handles requesting the scans, but also helping the user install Barcode Scanner if it is not already installed.

How Do I Create Them?

To create a reusable component, you start by getting a working code base, one that implements whatever it is that you desire. From there, you need to choose which of those aforementioned distribution patterns you believe is appropriate:

- JAR
- Standard library project
- Eclipse-compatible binary-only library project
- APK (with optional client-side JAR)

That, in turn, will drive how you take your code and create such a package. The basics of how to do that for the different alternatives is described in the following sections.

JARs

Creating a JAR for a reusable chunk of Android-related code is not significantly different than is creating a JAR for a reusable chunk of “ordinary” Java code.

First, you need a project that represents the “resuable chunk of Android-related code”. An easy way to do this is to just create a standard Android library project, but one where you do not bother creating any resources.

Once the code is ready for distribution, you can create a JAR from the compiled Java classes by your favorite traditional means. The author of this book, for example, adds custom Gradle tasks for this:

// from <http://stackoverflow.com/a/19484146/115145>

```
android.libraryVariants.all { variant -> def name = variant.buildType.name if
(name.equals(com.android.builder.core.BuilderConstants.DEBUG)) { return; // Skip
debug builds. } def task = project.tasks.create "jar${name.capitalize()}", Jar
task.dependsOn variant.javaCompile task.from variant.javaCompile.destinationDir
task.archiveName = "cwac-${task.archiveName}" task.exclude('com/commonsware/
cwac//BuildConfig.')
```

This will create JAR-building Gradle tasks for all non-debug build types, so you get Gradle tasks like `jarRelease`. It specifically excludes `BuildConfig`, which the CWAC libraries never use, but otherwise takes all of the library classes and packages them in a JAR, named after the library and version, with a `cwac-` prefix.

If your reusable code is pure Java, not involving Android at all, you are welcome to create a plain Java project and create your JAR from that. The only major recommendation would be to ensure that you are using some `android.jar` from the SDK, rather than a `JDK rt.jar`, to ensure that you are sticking with classes and methods that are in Android's subset of the Java SE class library.

Standard Library Projects

In many respects, distributing a standard Android library project is even easier: just ZIP it up. Or, if it is in a public source control repository (e.g., GitHub), reusers can obtain it from that repository.

Of course, this will distribute the source code along with the resources and everything else. This is typical for an open source library project.

Android Studio and Gradle users can create AARs from their library projects. The `assembleRelease` task will create an AAR for the library in `build/outputs/aar`, named after the library and version (e.g., `pager-0.2.3.jar`).

Eclipse-Compatible Binary-Only Library Projects

AARs do not ship Java source code, but rather only binaries. However, AARs are not readily consumable from Eclipse.

It is possible to create an Eclipse-Compatible binary-only library project, one where your source code is replaced by a JAR. This can be useful for proprietary library

projects, for example. However, there is one noteworthy limitation with today's tools: the library project cannot itself depend upon a JAR or another library project.

For simpler library projects, the recipe is straightforward, given an already-existing Android library project:

1. Compile the Java source (e.g., via Ant) and turn it into a JAR file.
2. Create a copy of your original Android library project to serve as a distribution Android library project.
3. Place the compiled JAR from step #1 and put it in `libs/` of the distribution library project from step #2.
4. Delete everything in `src/` of the distribution library project (but leave the now-empty `src/` directory there).
5. Distribute the distribution library project (e.g., ZIP it up)

For example, an Ant target to create a distribution ZIP might be:

```
<target name="jar" depends="release">
  <delete file="bin/WhateverYouWantToCallYourLibrary.jar" />
  <jar destfile="bin/WhateverYouWantToCallYourLibrary.jar">
    <fileset dir="bin/classes">
      <exclude name="**/BuildConfig.class" />
      <exclude name="**/R.class" />
      <exclude name="**/R$.class" />
    </fileset>
  </jar>
</target>
<target name="dist" depends="jar">
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/libs">
    <fileset dir="libs/" />
  </copy>
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/res">
    <fileset dir="res/" />
  </copy>
  <copy
    file="bin/WhateverYouWantToCallYourLibrary.jar"
    todir="/tmp/WhateverYouWantToCallYourLibrary/libs" />
  <copy
    file="AndroidManifest.xml"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="build.xml" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy
    file="project.properties"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="LICENSE" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <mkdir dir="/tmp/WhateverYouWantToCallYourLibrary/src" />
  <zip
    destfile="/tmp/WhateverYouWantToCallYourLibrary.zip"
    basedir="/tmp/"
```

```
includes="WhateverYouWantToCallYourLibrary/**"  
whenempty="create" />  
<delete dir="/tmp/WhateverYouWantToCallYourLibrary" />  
</target>
```

Assuming the existence of a `/tmp/` directory (e.g., OS X or Linux), this will result in a `WhateverYouWantToCallYourLibrary.zip` file in `/tmp/`. Along the way, we:

- Copy the `libs/` and `res/` trees from your source library project to a temporary distribution directory
- Copy your compiled JAR into the `libs/` subdirectory of the temporary distribution directory
- Copy other miscellaneous files, like your `LICENSE` file for your software license terms, into the root of the temporary distribution directory
- Create an empty `src/` subdirectory in the temporary distribution directory
- ZIP up the temporary distribution directory to a ZIP file
- Delete the temporary distribution directory

APK

Most of your work for this distribution model is in writing and distributing the app to your end users, through the Play Store or your other chosen distribution channels.

In addition to that, you need to either document to reusers what sorts of IPC your app supports, or create a JAR or library project that reusers can use to perform that sort of integration. In the latter case, you would have a separate project representing that JAR or library project that you would distribute using any of the aforementioned approaches.

Other Considerations for Publishing Reusable Code

Of course, there is more to publishing a reusable component than code and perhaps Android resources. The following sections outline some other things to consider as you contemplate offering some code base up for reuse by third parties.

Licensing

Your reusable code should be accompanied by adequate licensing information.

Your License

The first license you should worry about is your own. Is your component open source? If so, you will want to ship a license file containing those terms. If your component is not open source, make sure there is a license agreement shipped with the component that lets the reuser know the terms of use.

Bear in mind that not all of your code necessarily has to have the same license. For example, you might have a proprietary license for the component itself, but have sample code be licensed under Apache License 2.0 for easy copy-and-paste.

Third-Party License Impacts

You may need to include licenses for third party libraries that you have to ship along with your own JAR. Obviously, those licenses would need to give you redistribution rights — otherwise, you cannot ship those libraries in the first place.

Sometimes, the third party licenses will impact your project more directly, such as:

1. Incorporating a GPL library may require your project to be licensed under the same license
2. Adding support for Facebook data may require you to limit your API or require reusers to supply API access keys, since you probably do not have rights to redistribute Facebook data

Documenting the Usage

If you are expecting people to reuse your code, you are going to have to tell them how to do that. Usually, these sorts of packages ship documentation with them, sometimes a clone of what is available online. That way, developers can choose the local or hosted edition of the documentation as they wish.

Note that generated documentation (e.g., Javadocs) may still need to be shipped or otherwise supplied to reusers, if you are not providing the source code in the package. Without the source code, reusers cannot regenerate the Javadocs.

Many open source projects eschew formal documentation in favor of simple JavaDocs, plus “documentation in the form of a test suite” or “documentation in the form of sample apps”. While test suites and sample apps are useful supplements, they are not always an effective replacement for written documentation. And, while

JavaDocs are useful for reference material, they are often difficult to comprehend for those trying to get started with the code and not knowing where to begin.

Naming Conventions

Make sure that your Java code is in a package that is likely to be distinct from any others that reusers might already have. Typically, this means that the package name is based on a domain name that you control, much like the package name for Android apps themselves. Whatever you do, please do not publish your own code as `android.*`, unless you are contributing this code to the Android open source project, as `android.*` is reserved for use by Android itself.

(The author of this book would also appreciate it if you would not use `com.commonsware.*`)

Also, be careful about the names of your resources. While your Java code resides in its own namespace, your resources are pooled with all other resources in use by the app. As a result, if you decide to reference `R.layout.main` thinking that it will be *your* `main.xml` layout resource, it might actually be replaced by a `main.xml` resource written by the app developer. You may wish to use some sort of a prefix convention on your resource names to reduce the odds of accidental collision:

- [ActionBarSherlock](#) uses `abs__`
- [ViewPagerIndicator](#) uses `vpi__`
- And so on

Trail: Scripting Languages

The Role of Scripting Languages

A scripting language, for the purpose of this book, has two characteristics:

1. It is interpreted from source and so does not require any sort of compilation step
2. It cannot (presently) be used to create a full-fledged Android application without at least some form of custom Java-based stub, and probably much more than that

In this part of the book, we will look at scripting languages on Android and what you can accomplish with them, despite any limitations inherent in their collective definition.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

All Grown Up

Interpreted languages have been a part of the programming landscape for decades. The language most associated with the desktop computer revolution — BASIC — was originally an interpreted language. However, the advent of MS-DOS and the IBM PC (and clones) led developers in the direction of C for “serious programming”, for reasons of speed. While interpreted languages continued to evolve, they tended to be described as “scripting” languages, used to glue other applications together. Perl, Python, and the like were not considered “serious” contenders for application development.

The follow-on revolution, for the Internet, changed all of that. Most interactive Web sites were written as CGI scripts using these “toy” languages, Perl first and foremost. Even in environments where Perl was unpopular, such as Windows, Web applications were still written using scripting languages, such as VBScript in Active Server Pages (ASP). While some firms developed Web applications using C/C++, scripting languages ruled the roost. That remains to this day, where you are far more likely to find people writing Web applications in PHP or Ruby than you will find them writing in C or C++. The most likely compiled language for Web development — Java — is still technically an interpreted language, albeit not usually considered a scripting language.

Nowadays, writing major components of an application using a scripting language is not terribly surprising. While this is still most common with Web applications, you can find scripting languages used in the browser (JavaScript), games (Lua), virtual worlds (LSL), and so on. Even though these languages execute more slowly than their C/C++ counterparts, they offer much greater flexibility, and faster CPUs make the performance of scripts less critical.

Following the Script

Scripting languages are not built into Android, beyond the JavaScript interpreter in the WebKit Web browser. Despite this, there is quite a bit of interest in scripting on Android, and the biggest reasons for this come down to experience and comfort level.

Your Expertise

Perhaps you have spent your entire career writing Python scripts, or you cut your teeth on Perl CGI programs, or you have gotten seriously into Ruby development.

Maybe you used Java in previous jobs and hate it with the fiery passion of a thousand suns.

Regardless of the cause, your expertise may lie outside the traditional Android realm of Java-based development. Perhaps you would never touch Android if you had to write in Java, or maybe you feel you would just be significantly more productive in some other language. How much that productivity gain is real versus “in your head” is immaterial — if you want to develop in some other language, you owe it to yourself to try.

Your Users' Expertise

Maybe you are looking to create a program where not only you can write scripts, but so can your users. This might be a utility, or a game, or rulesets for email management, or whatever.

In that case, you need:

1. Something interpreted, so you can execute what the user types in
2. Something embeddable, so your larger application (typically written in Java, of course) is capable of executing those scripts
3. Something your users will be comfortable using for scripting

The last criterion is perhaps the toughest, as non-developers typically have limited experience in writing scripts in any language, let alone one that runs on Android. Perhaps the most popular such language is Basic, in the form of VBA and VBScript on Windows... but there are no interpreters for those languages for Android at this time.

Crowd-Developing

Perhaps your users will not only be entering scripts for their own benefit, but for others' benefit as well.

Many platforms have been improved by power users and amateur developers alike. Browser users gain from those writing GreaseMonkey scripts. Bloggers benefit from those writing WordPress themes. And so on.

To facilitate this sort of work, not only do you need an interpreted, embeddable, user-familiar scripting environment, but you need some means for users to publish their scripts and download the scripts of others. Fortunately, with Android having near-continuous connectivity, your challenge will lie more on organizing and hosting the scripts, more so than getting them on and off of devices.

Going Off-Script

Scripting languages on Android have their fair share of issues. It is safe to say that while Android does not prohibit the use of scripting languages, its architecture does not exactly go out of its way to make them easy to use, either.

Security

For a scripting language to do much that is interesting, it is going to need some amount of privileges. A script cannot access the Internet unless its process has that right. A script cannot modify the user's contacts unless its process has that right. And so on.

For scripts you write, so long as those scripts cannot be modified readily by malware authors, security is whatever you define it to be. If your script-based application needs Internet access, so be it.

For scripts your users write, things get a bit more challenging, since permissions cannot be modified on the fly by applications. Many interpreters will tend to request (or otherwise have access to) permissions that are broader than any individual user might need, because those permissions are needed by somebody. However, the risk is still minimal to the user, so long as they are careful with the scripts they write.

For scripts your users might download, written by others, security becomes a big problem. If the interpreter has a wide range of permissions, downloaded scripts can easily host malware that exploits those permissions for nefarious ends. An interpreter with both Internet access and the right to read the user's contacts means that any script the user might download and run could copy the user's contact data and send it to spammers or identity thieves.

Performance

Java, as interpreted by the Dalvik virtual machine, is reasonably fast, particularly on Android 2.2 and newer versions. C/C++, through the NDK, is far faster.

Scripting languages are a mixed bag.

Some scripting languages for Android have interpreters that are implemented in C code. Those interpreters' performance is partly a function of how well they were written and ported over to the chipsets Android runs on. However, if those interpreters expose Android APIs to the language, that can add considerable overhead. For example, the Scripting Layer for Android (SL4A) makes Android APIs available to scripting languages via a tiny built-in Java Web server and a Web service API. While convenient for language integration, converting simple Java calls into Web service calls slows things down quite a bit.

Some scripting languages have interpreters that themselves are written in Java and run on the virtual machine. Those are likely to perform worse on an Android device than when they are run on a desktop or server, simply because of the performance differences between the standard Java VMs and the Dalvik VM. However, they will have quicker access to the Java class libraries that make up much of Android than will C-based interpreters.

Cross-Platform Compatibility

Most of the scripting languages for Android are ports from versions that run across multiple platforms. This is one of their big benefits – that is where you and your users may have gained experience with those languages. However, just as, say, Perl and Python run a bit differently on Windows than on Linux or OS X, there will be some differences in how those languages run on Android. The Android operating system is not a traditional Linux environment, and so file paths, environment variables, available pre-installed programs, and the like will not be the same. Some of those may, in turn, impact how the scripting languages operate. You may need to make some modification to any existing scripts for those languages that you attempt to run on Android.

Maturity... On Android

Some scripting languages that have been ported to Android are rather old, like Perl and Python. Others are old and somewhat abandoned for traditional development, like BeanShell. Yet others are fairly new to the programming scene altogether, like JRuby.

However, none of them have a long track record on Android, simply because Android itself has not been around very long. This has several implications:

1. There is more likely to be bugs in newer ports of a language than older ports
2. Fewer people will have experience in supporting these languages on Android (compared to supporting them on Linux, for example)
3. The number of production applications built using these languages on Android is minuscule compared to their use on more traditional environments

The Scripting Layer for Android

When it comes to scripting languages on Android, the first stop should always be the [Scripting Layer for Android](#) (SL4A). Led by Damon Kohler, this project is rather popular, both among hardcore Android developers and those people looking to automate a bit more of their Android experience.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

The Role of SL4A

What started as an experiment to get Python and Lua going on Android, back in late 2008, turned into a more serious endeavor in June 2009, when the Android Scripting Environment (now called the Scripting Layer for Android, or SL4A) was announced on the [Google Open Source blog](#) and the Google Code site for it was established. Since then, SL4A has been a magnet for people interested in getting their favorite language working on Android or advancing its support.

On-Device Development

Historically, the primary role of SL4A was as a tool to allow people to put together scripts, often written on the device itself, to take care of various chores. This appealed to developers who were looking for something lightweight compared to the Android SDK and Java. For those used to tinkering with scripts on other mobile Linux platforms (e.g., the Nokia N800 running Maemo), SL4A promised a similar sort of capability.

Over time, SL4A's scope in this area has grown, including preliminary support for SL4A scripts packaged as APK files, much like an Android application written in Java or any of the alternative frameworks described in this book.

Getting Started with SL4A

SL4A is a bit more difficult to install than is the average Android application, due to the various interpreters it uses and their respective sizes. That being said, none of the steps involved with getting SL4A set up are terribly difficult, and most are just part of the application itself.

Installing SL4A

At the time of this writing, SL4A is not distributed via the Android Market. Instead, you can download it to your device off of the [SL4A Web site](#). Perhaps the easiest way to do that is to scan the QR code on the SL4A home page using [Barcode Scanner](#) or a similar utility.

Installing Interpreters

When you first install SL4A, the only available scripting language is for shell scripts, as that is built into Android itself. If you want to work with other interpreters, you will need to download those. That is why the base SL4A download is so small (~200KB) — most of the smarts are separate downloads, largely due to size.

To add interpreters, launch SL4A from the launcher, then choose View > Interpreters from the option menu. You will be presented with the (presently short) list of installed interpreters:

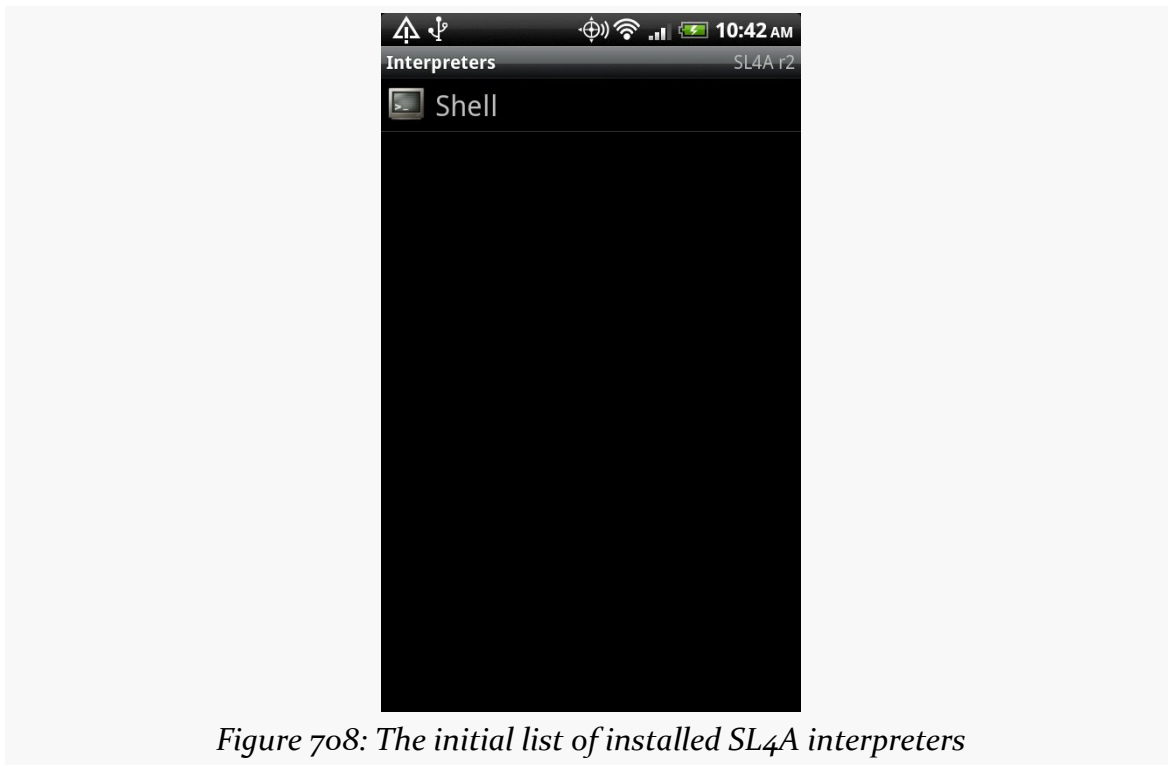

Figure 708: The initial list of installed SL4A interpreters

Then, to install additional interpreters, choose Add from the option menu. You will be given a roster of SL4A-compatible interpreters to choose from:

Figure 709: The list of available SL4A interpreters

Click on one of the interpreters, and this will trigger the download of an APK file for that specific interpreter. Slide down the notification drawer and click on that APK file to continue the installation process. When the APK itself is installed, open up that interpreter (e.g., click the “Open” button when the install is done). That will bring up an activity to let you download the rest of the interpreter binaries:

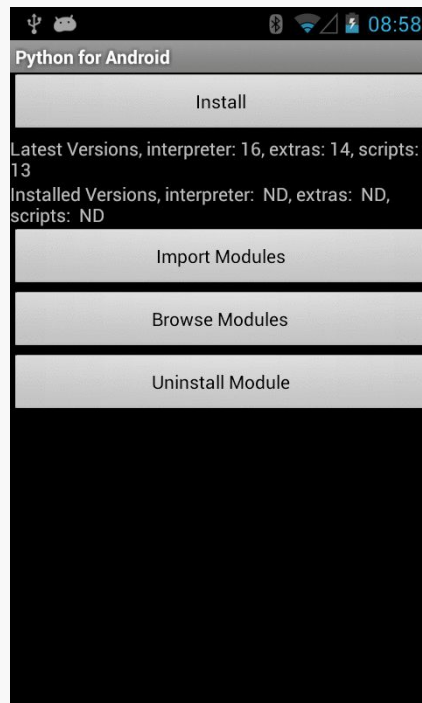

Figure 710: Downloading the Python SL4A interpreter, continued

Click the Install button, and SL4A will download and install the interpreter's component parts:

Figure 711: Downloading the Python SL4A interpreter

This may take one or several downloads, depending on the interpreter. When done, and after a few progress dialogs' worth of unpacking, the interpreter will appear in the list of interpreters:

Figure 712: The updated list of installed SL4A interpreters

Note that the interpreters will be installed on your device’s “external storage” (typically some flavor of SD card), due to their size. You will find an SL4A/ directory on that card with the interpreters and scripts.

Running Supplied Scripts

Back on the Scripts activity (e.g., what you see when you launch SL4A from the launcher), you will be presented with a list of the available scripts. Initially, these will be ones that shipped with the interpreters, as examples for how to write SL4A scripts in that language:

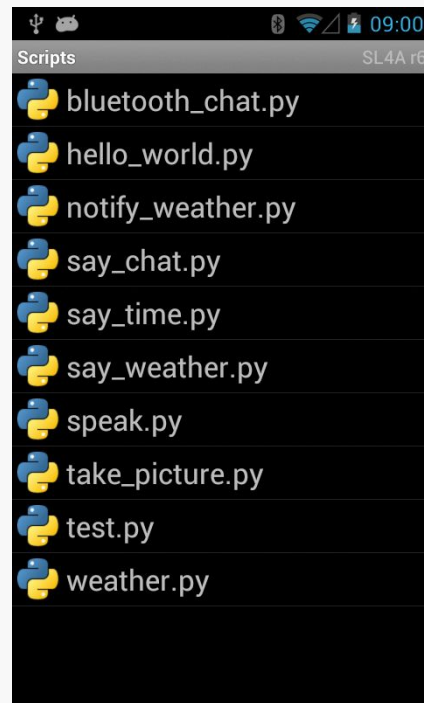

Figure 713: The list of SL4A scripts

Tapping on any of these scripts will bring up a “quick actions” balloon:

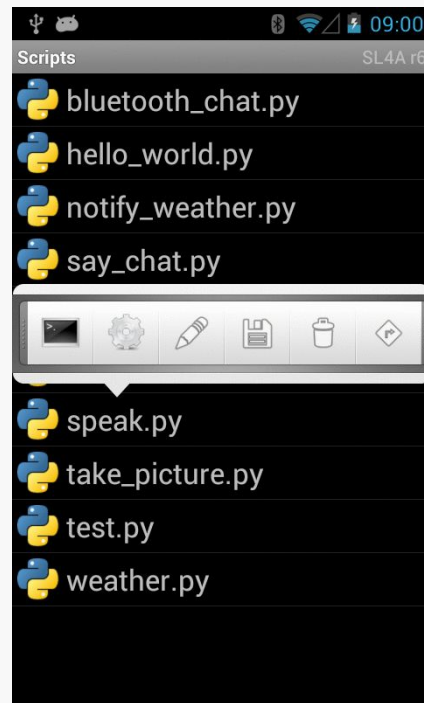

Figure 714: Quick actions for the speak.py script

Click the little shell icon to run it, showing its terminal output along the way:

Figure 715: The visual results of running the speak.py SL4A script

Writing SL4A Scripts

While the scripts supplied with the interpreters are... entertaining, they only scratch the surface of what an SL4A script can accomplish. Of course, to go beyond what is there, you will need to start writing some scripts.

Editing Options

Since scripts are stored on your SD card (or whatever the “external storage” is for your device), you can create scripts using some other computer — one with fancy things like “mice” and “ergonomic keyboards” — and transfer it over via USB, like you would transfer over an MP3 file. This eases typing, but it will make for an awkward development cycle, since your computer and the Android device cannot both have access to the SD card simultaneously. The mount/unmount process may get a bit annoying. On the other hand, this is a great way to transfer over a script you obtained from somebody else.

Another option is to edit your scripts on the device. SL4A has a built in script editor designed for this purpose. Of course, the screen may be a bit small and the keyboard may be a bit... soft, but this is a great answer for small scripts.

To add a new script, from the Scripts activity, choose Add from the option menu. This will bring up a roster of available scripting languages and other items (e.g., add a folder):

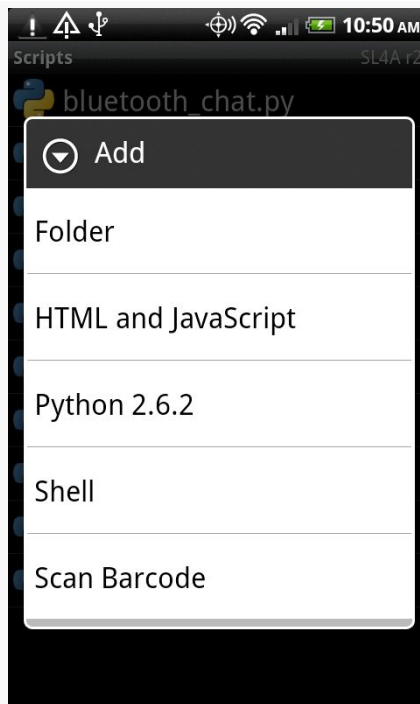

Figure 716: The add-script language selection dialog

(the “Scan Barcode” option gives you an easy route to install a third-party script, one encoded in a QR code)

Tap the language you want, and you will be taken into the script editor:

The field at the top is for the script name, and the large text area at the bottom is for the script itself. A file extension and boilerplate code will be supplied for you automatically.

In fact, that boilerplate code is rather important, as you will see momentarily.

To edit an existing script, long-tap on the script in the list and choose Edit from the context menu.

To save your changes to a new or existing script, choose the Save option from the script editor option menu. You can also “Save and Run” to test the script immediately.

Calling Into Android

In the real world, Perl knows nothing about Android. Neither does Python, BeanShell, or most of the other scripting languages available for SL4A. This would be rather limiting, as most of what you would want a script to do will have to deal with the device to some level: collect input, get a location, say some text using speech synthesis, dial the phone, etc.

Fortunately, SL4A has a solution, one of those “so crazy, it just might work” sorts of solutions: SL4A has a built-in RPC server. While implementing a server on a smartphone is not something one ordinarily does, it provides an ingenious bridge from the scripting language to the device itself.

Each scripting language is given a local object proxy that works with the RPC server. For example, here is a Python script that speaks the current time:

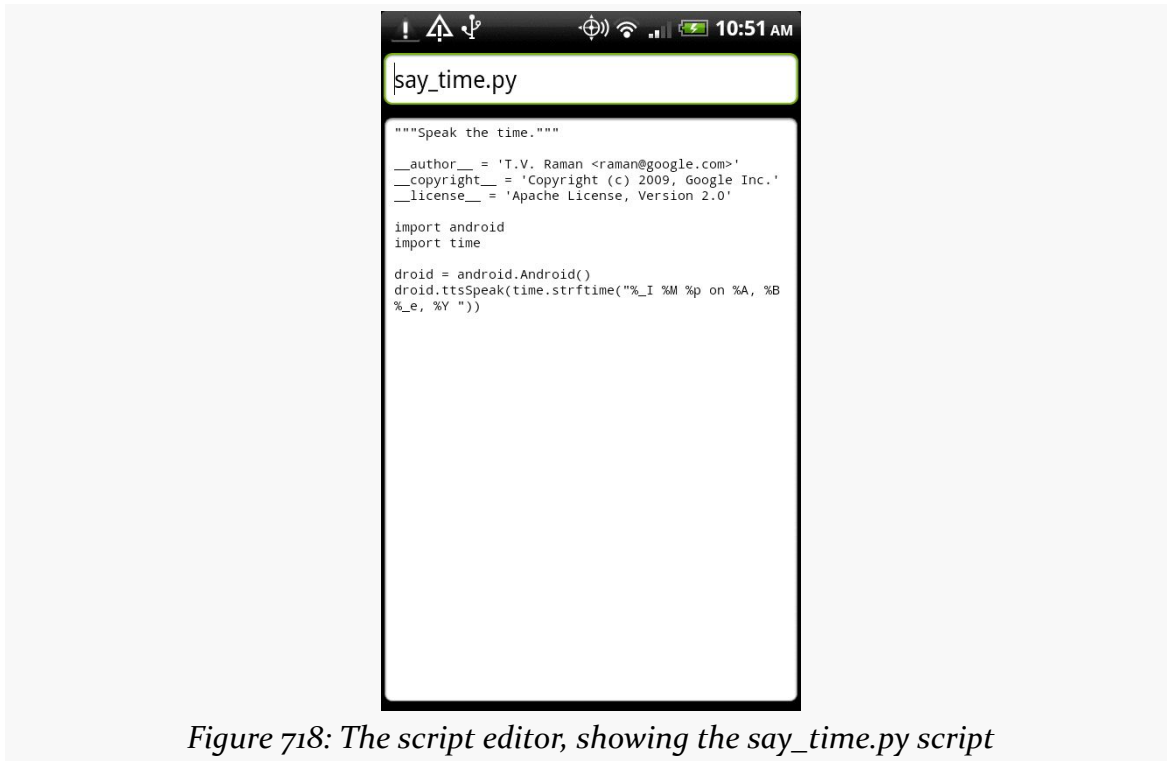

Figure 718: The script editor, showing the say_time.py script

The `import android` and `droid=android.Android()` statements establish a connection between the Python interpreter and the SL4A RPC server. From that point, the `droid` object is available for use to access Android capabilities — in this case, speaking a message.

Python does not strictly realize that it is accessing local functionality. It simply makes RPC calls, ones that just so happen to be fulfilled on the device rather than via some remote RPC server accessed over the Internet.

Browsing the API

Therefore, SL4A effectively exposes an API to each of its scripting languages, via this RPC bridge. While the API is not huge, it accomplishes a lot and is ever-growing.

If you are editing scripts on the device, you can browse the API by choosing the API Browser option menu from the script editor. This brings up a list of available methods on your RPC proxy (e.g., droid) that you can call:

Figure 719: The script editor's API browser

Tapping on any item in the list will “unfold” it to provide more details, such as the parameter list. Long-tapping on an item brings up a context menu where you can:

1. insert a template call to the method into your script at the cursor position
2. “prompt” you for the parameter values for the method, then insert the completed method call into your script

It is also possible to [browse the API](#) in a regular Web browser, if you are developing scripts off-device.

Running SL4A Scripts

Scripts are only useful if you run them, of course. We have seen two options for running scripts: tapping on them in the scripts list, or choosing “Save & Run” from the script editor. Those are not your only options, however.

Background

If you long-tap on a script in the script list, you will see a context menu option to “Start in Background”. As the name suggests, this kicks off the script in the background. Rather than seeing the terminal window for the script, the script just runs. A notification will appear in the status bar, with the SL4A icon, indicating that the RPC server is in operation and that script(s) may be running.

Shortcuts

Rather than have to open up SL4A every time, you can set up shortcuts on your home screen to run individual scripts.

Android 1.x/2.x

Just long-tap on the home screen background and choose Shortcuts from the context menu, then Scripts from the available shortcuts. This brings up the scripts list, but this time, when you choose a script, you are presented with a quick actions balloon for how to start it: in a terminal or in the background:

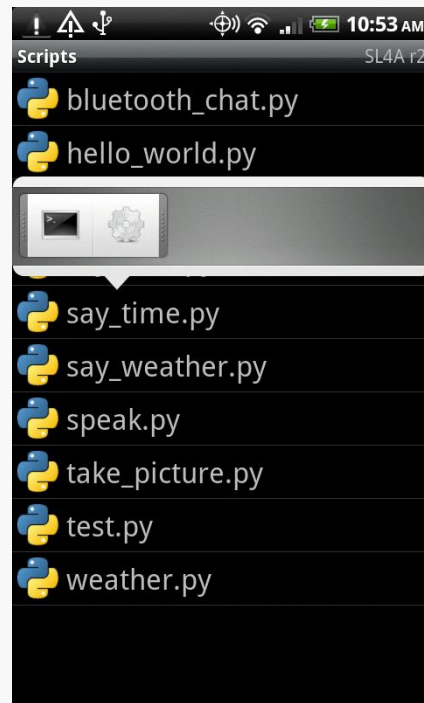

Figure 720: Configuring an SL4A shortcut

Choose one, and at this point, a shortcut, with the interpreter's icon and the name of the script, will appear on your home screen. Tapping it runs the script.

Android 3.0+

Go to where you install home screen widgets (e.g., “Widgets” tab in launcher), and you should see a “Scripts” entry:

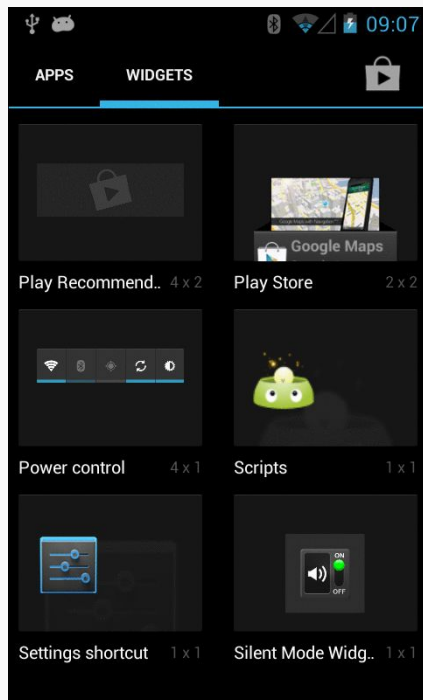

Figure 721: SL4A Shortcuts Option on Nexus S, Android 4.1

Add that to your home screen, the same as you would any other app widget (e.g., long press, then drag to the desired spot). That, in turn, will bring up the list of available scripts. Tapping on a script, as with Android 1.x/2.x, brings up a quick actions balloon for how to start it: in a terminal or in the background (see screenshot in previous section). This will then set up your shortcut on your home screen, so tapping it will launch your chosen script.

Other Alternatives

Users of Locale — an application designed to trigger events at certain times or when you get to certain locations — can trigger SL4A scripts in addition to invoking standard built-in tools.

In addition, there is [preliminary support](#) in SL4A for packaging scripts as APK files for wider distribution.

Potential Issues

As the SL4A Web site indicates, SL4A is “alpha-quality”. It is not without warts. How much those warts are an issue for you, in terms of crafting and running utility scripts, is up to you.

Security... From Scripts

SL4A itself holds a long list of Android permissions, including:

1. The ability to read your contact data
2. The ability to call phone numbers and place SMS messages
3. Access to your location
4. Access to your received SMS/MMS messages
5. Bluetooth access
6. Internet access
7. The ability to write to the SD card
8. The ability to record audio and take pictures
9. The ability to keep your device awake
10. The ability to retrieve the list of running applications and restart other applications
11. And so on

Hence, its scripts — via the RPC-based API — can perform all of those actions. For example, a script you download from a third party could read all your contacts and send that information to a spammer. Hence, you should only run scripts that you trust, since SL4A effectively “wires open” many aspects of Android’s standard security protections.

Security... From Other Apps

Originally, the on-device Web service supplying the RPC-based API was wide open. Any program that could find the port could connect to that Web service and invoke operations. That would not necessarily be all that bad... except that the Web service runs in its own process with its own permissions, and it may have permissions that other applications lack (e.g., right to access the Internet or to read contacts). Given that, malware could use SL4A to do things that it, by itself, could not do, allowing it to sneak onto more devices.

SL4A now uses a token-based authentication mechanism for using the Web service, to help close this loophole. In principle, only SL4A scripts should be able to use the RPC server.

JVM Scripting Languages

The Java virtual machine (JVM) is a remarkably flexible engine. While it was originally developed purely for Java, it has spawned its own family of languages, just as Microsoft's CIL supports multiple languages for the Windows platform. Some languages targeting the JVM as a runtime will work on Android, since the regular Java VM and Android's Dalvik VM are so similar.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Some of the sample code demonstrates JUnit test cases, so reading [the chapter on unit testing](#) may be useful.

Languages on Languages

Except for the handful of early language interpreters and compilers hand-constructed in machine code, every programming language is built atop earlier ones. C and C++ are built atop assembly language. Many other languages, such as Java itself, are built atop C/C++.

Hence, it should not come as much of a surprise that an environment as popular as Java has spawned another generation of languages whose implementations are in Java.

There are a few flavors of these languages. Some, like Scala and Clojure, are compiled languages whose compilers created JVM bytecodes, no different than would a Java compiler. These do not strictly qualify as a “scripting language”, however, since they typically compile their source code to bytecode ahead of time.

Some Java-based scripting languages use fairly simple interpreters. These interpreters convert scripting code into parsed representations (frequently so-called “abstract syntax trees”, or ASTs), then execute the scripts from their parsed forms. Most scripting languages at least start here, and some, like BeanShell, stick with this implementation.

Other scripting languages try to bridge the gap between a purely interpreted language and a compiled one like Scala or Clojure. These languages turn the parsed scripting code into JVM bytecode, effectively implementing their own just-in-time compiler (JIT). Since many Java runtimes themselves have a JIT to turn bytecode into machine code (“opcode”), languages with their own JIT can significantly outperform their purely-interpreted counterparts. JRuby and Rhino are two languages that have taken this approach.

A Brief History of JVM Scripting

Back in the beginning, the only way to write for the JVM was in Java itself. However, since writing language interpreters is a common pastime, it did not take long for people to start implementing interpreters in Java. These had their niche audiences, but there was only modest interest in the early days — interpreters made Java applets too large to download, for example.

Things got a bit more interesting in 1999, when IBM [released](#) the Bean Scripting Framework (BSF). This offered a uniform API for scripting engines, meaning that a hosting Java application could write to the BSF API, then plug in arbitrary interpreters at runtime. It was even possible, with a bit of extra work, to allow new interpreters to be downloaded and used on demand, rather than having to be pre-installed with the application. BSF also standardized how to inject Java objects into the scripting engines themselves, for access by the scripts. This allowed scripts to work with the host application’s objects, such as allowing scripts to manipulate the contents of the [jEdit](#) text editor.

This spurred interest in scripting. In addition to some IBM languages (e.g., [NetREXX](#)) supporting BSF natively, other languages, like [BeanShell](#), created BSF adapters to allow their languages to participate in the BSF space. On the consumer side, various Web frameworks started supporting BSF scripting for dynamic Web content generation, and so forth.

Interest was high enough that Apache took over stewardship of [BSF](#) in 2003. Shortly thereafter, Sun and others started work on [JSR-223](#), which added the `javax.script`

framework to Java 6. The `javax.script` framework advanced the BSF concept and standardized it as part of Java itself.

At this point, most JVM scripting languages that are currently maintained support `javax.script` integration, and may also support integration with the older BSF API as well.

Android does not include `javax.script` as part of its subset of the Java SE class library from the Apache Harmony project. This certainly does not preclude integrating scripting languages into Android applications, but it does raise the degree of difficulty a bit.

Limitations

Of course, JVM scripting languages do not necessarily work on Android without issue. There may be some work to get a JVM language going on Android, above and beyond the [challenges for scripting languages](#) in general on Android.

Android SDK Limits

Android is not Java SE, or Java ME, or even Java EE. While Android has many standard Java classes, it does not have a class library that matches any traditional pattern. As such, languages built assuming Java SE, for example, may have some dependency issues.

For languages where you have access to the source code, removing these dependencies may be relatively straightforward, particularly if they are ancillary to the operation of the language itself. For example, the language may come with miniature Swing IDEs, support for scripted servlets, or other capabilities that are not particularly relevant on Android and can be excised from the source code.

Wrong Bytecode

Android runs Dalvik bytecode, not Java bytecode. The conversion from Java bytecode to Dalvik bytecode happens at compile time. However, the conversion tool is rather finicky — it wants bytecode from Sun/Oracle's Java 1.5 or 1.6, nothing else. This can cause some problems:

1. You may encounter a JAR that is old enough to have been compiled with Java 1.4.2

2. You may encounter JARs compiled using other compilers, such as the GNU Compiler for Java (GCJ), common on Linux distributions
3. Java 7 has bytecode differences from Java 6; users of Java 7 need to compile their Java classes to Java 6 bytecode
4. Languages that have their own JIT compilers will have problems, because their JIT compilers will be generating Java bytecodes, not Dalvik bytecodes, meaning that the JIT facility needs to be rewritten or disabled

Again, if you have the source code, recompiling on an Android-friendly Java compiler should be a simple process.

Age

The heyday of some JVM languages is in the past. As such, you may find that support for some languages will be limited, simply because few people are still interested in them. Finding people interested in those languages on Android — the cross-section of two niches — may be even more of a problem.

SL4A and JVM Languages

SL4A supports three JVM languages today:

1. BeanShell
2. JRuby
3. Rhino (JavaScript)

You can use those within your SL4A environment no different than you can any other scripting language (e.g., Perl, Python, PHP). Hence, if what you are looking for is to create your own personal scripts, or writing small applications, SL4A saves you a lot of hassle. If there is a JVM scripting language you like but is not supported by SL4A, adding support for new interpreters within SL4A is fairly straightforward, though the APIs may change as SL4A is undergoing a fairly frequent set of revisions.

Embedding JVM Languages

While SL4A will drive end users towards writing their own scripts or miniature applications using JVM languages, another use of these languages is for embedding in a full Android application. Scripting may accelerate development, if the developers are more comfortable with the scripted language than with Java. Also, if

the scripts are able to be modified or expanded by users, an ecosystem may emerge for user-contributed scripts.

Architecture for Embedding

Embedding a scripting language is not something to be undertaken lightly, even on a desktop or server application. Mobile devices running Android will have similar issues.

Asynchronous

One potential problem is that a script may take too long to execute. Android's architecture assume that work triggered by buttons, menus, and the like will either happen very quickly or will be done on background threads. Particularly for user-generated scripts, the script execution time is unknowable in advance — it might be a few milliseconds, or it might be several seconds. Hence, any implementation of a scripting extension for an Android application needs to consider executing all scripts in a background thread. This, of course, raises its own challenges for reflecting those scripts' results on-screen, since GUI updates cannot be done on a background thread.

Security

Scripts in Android inherit the security restrictions of the process that runs the script. If an application has the right to access the Internet, so will any scripts run in that application's process. If an application has the right to read the user's contacts, so will any scripts run in that application's process. And so on. If the scripts in question are created by the application's authors, this is not a big deal — the rest of the application has those same permissions, after all. But, if the application supports user-authored scripts, it raises the potential of malware hijacking the application to do things that the malware itself would otherwise lack the rights to do.

Inside the InterpreterService

One way to solve both of those problems is to isolate the scripting language in a self-contained low-permission APK — “sandboxing” the interpreter so the scripts it executes are less able to cause harm. This APK could also arrange to have the interpreter execute its scripts on a background thread. An even better implementation would allow the embedding application to decide whether or not

the “sandbox” is important — applications with a controlled source of scripts may not need the extra security or the implementation headaches it causes.

With that in mind, let us take a look at the [JVM/InterpreterService](#) sample project, one possible implementation of the strategy described above.

The Interpreter Interface

The InterpreterService can support an arbitrary number of interpreters, via a common interface. This interface provides a simplified API for having an interpreter execute a script and return a result:

```
package com.commonware.abj.interp;

import android.os.Bundle;

public interface I_Interpreter {
    Bundle executeScript(Bundle input);
}
```

As you can see, it is very simplified, offering just a single executeScript() method. That method accepts a Bundle (a key-value store akin to a Java HashMap) as a parameter — that Bundle will need to contain the script and any other objects needed to execute the script.

The interpreter will return another Bundle from executeScript(), containing whatever data it wants the script’s requester to have access to.

For example, here is the implementation of EchoInterpreter, which just returns the same Bundle that was passed in:

```
package com.commonware.abj.interp;

import android.os.Bundle;

public class EchoInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        return(input);
    }
}
```

A somewhat more elaborate sample is the SQLiteInterpreter:

```
package com.commonware.abj.interp;

import android.database.Cursor;
```

```
import android.database.sqlite.SQLiteDatabase;
import android.os.Bundle;

public class SQLiteInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        Bundle result=new Bundle(input);
        String script=input.getString(InterpreterService.SCRIPT);

        if (script!=null) {
            SQLiteDatabase db=SQLiteDatabase.create(null);
            Cursor c=db.rawQuery(script, null);

            c.moveToFirst();

            for (int i=0;i<c.getColumnCount();i++) {
                result.putString(c.getColumnName(i), c.getString(i));
            }

            c.close();
            db.close();
        }

        return(result);
    }
}
```

This class accepts a script, in the form of a SQLite database query. It extracts the script from the Bundle, using a pre-defined key (InterpreterService.SCRIPT). Assuming there is such a script, it creates an empty in-memory database and executes the SQLite query against that database.

The results come back in the form of a Cursor — itself a key-value store. SQLiteInterpreter takes those results and pours them into a Bundle to be returned.

The Bundle being returned starts from a copy of the input Bundle, so the script requester can embed in the input Bundle any identifiers it needs to determine how to handle the results from executing this script.

SQLiteInterpreter is not terribly flexible, but you can use it for simple numeric and string calculations, such as the following script:

```
SELECT 1+2 AS result, 'foo' AS other_result, 3*8 AS third_result;
```

This would return a Bundle containing a key of result with a value of 3, a key of other_result with a value of foo, and a key of third_result with a value of 24.

Of course, it would be nice to support more compelling interpreters, and we will examine a pair of those later in this chapter.

Loading Interpreters and Executing Scripts

Of course, having a nice clean interface to the interpreters does nothing in terms of actually executing them on a background thread, let alone sandboxing them. The `InterpreterService` class itself handles that.

`InterpreterService` is an `IntentService`, which automatically routes incoming `Intent` objects (from calls to `startService()`) to a background thread via a call to `onHandleIntent()`. `IntentService` will queue up `Intent` objects if needed, and `IntentService` even automatically shuts down if there is no more work to be done.

Here is the implementation of `onHandleIntent()` from `InterpreterService`:

```
@Override
protected void onHandleIntent(Intent intent) {
    String action=intent.getAction();
    I_Interpreter interpreter=interpreters.get(action);

    if (interpreter==null) {
        try {
            interpreter=(I_Interpreter)Class.forName(action).newInstance();
            interpreters.put(action, interpreter);
        }
        catch (Throwable t) {
            Log.e("InterpreterService", "Error creating interpreter", t);
        }
    }

    if (interpreter==null) {
        failure(intent, "Could not create interpreter: "+intent.getAction());
    }
    else {
        try {
            success(intent,
interpreter.executeScript(intent.getBundleExtra(BUNDLE)));
        }
        catch (Throwable t) {
            Log.e("InterpreterService", "Error executing script", t);

            try {
                failure(intent, t);
            }
            catch (Throwable t2) {
                Log.e("InterpreterService",
                    "Error returning exception to client",
                    t2);
            }
        }
    }
}
```

```
}  
}  
}  
}
```

We keep a cache of interpreters, since initializing their engines may take some time. That cache is keyed by the interpreter's class name, and that key comes in to the service by way of the action on the Intent that was used to start the service. In other words, the script requester tells us, by way of the Intent used in `startService()`, which interpreter to use.

Those interpreters are created using reflection. This way, `InterpreterService` has no compile-time knowledge of any given interpreter class. Interpreters can come and go, but `InterpreterService` remains the same.

Assuming an interpreter was found (either cached or newly created), we have it execute the script, with the input `Bundle` coming from an “extra” on the Intent. Methods named `success()` and `failure()` are then responsible for getting the results to the script requester... as will be seen in the next section.

Delivering Results

Script requesters can get the results of the script back — in the form of the interpreter's output `Bundle` — in one of two ways.

One option is a private broadcast Intent. This is a broadcast Intent where the broadcast is limited to be delivered only to a specific package, not to any potential broadcast receiver on the device.

The other option is to supply a `PendingIntent` that will be sent with the results. This could be used by an Activity and `createPendingIntent()` to have control routed to its `onActivityResult()` method. Or, an arbitrary `PendingIntent` could be created, to start another activity, for example.

The implementations of `success()` and `failure()` in `InterpreterService` simply build up an Intent containing the results to be delivered:

```
private void success(Intent intent, Bundle result) {  
    Intent data=new Intent();  
  
    data.putExtras(result);  
    data.putExtra(RESULT_CODE, SUCCESS);  
}
```

```
    send(intent, data);
}

private void failure(Intent intent, String message) {
    Intent data=new Intent();

    data.putExtra(ERROR, message);
    data.putExtra(RESULT_CODE, FAILURE);

    send(intent, data);
}

private void failure(Intent intent, Throwable t) {
    Intent data=new Intent();

    data.putExtra(ERROR, t.getMessage());
    data.putExtra	TRACE, getStackTrace(t));
    data.putExtra(RESULT_CODE, FAILURE);

    send(intent, data);
}
```

These, in turn, delegate the actual sending logic to a `send()` method that delivers the result Intent via a private broadcast or a `PendingIntent`, as indicated by the script requester:

```
private void send(Intent intent, Intent data) {
    String broadcast=intent.getStringExtra(BROADCAST_ACTION);

    if (broadcast==null) {
        PendingIntent pi=(PendingIntent)intent.getParcelableExtra(PENDING_RESULT);

        if (pi!=null) {
            try {
                pi.send(this, Activity.RESULT_OK, data);
            }
            catch (PendingIntent.CanceledException e) {
                // no-op -- client must be gone
            }
        }
    }
    else {
        data.setPackage(intent.getStringExtra(BROADCAST_PACKAGE));
        data.setAction(broadcast);

        sendBroadcast(data);
    }
}
```

Packaging the InterpreterService

There are three steps for integrating InterpreterService into an application.

First, you need to decide what APK the InterpreterService goes in – the main one for the application (no sandbox) or a separate low-permission one (sandbox).

Second, you need to decide what interpreters you wish to support, writing I_Interpreter implementations and getting the interpreters' JARs into the project's libs/ directory.

Third, you need to add the source code for InterpreterService along with a suitable <service> entry in AndroidManifest.xml. This entry will need to support <intent-filter> elements for each scripting language you are supporting, such as:

```
<service
  android:name=".InterpreterService"
  android:exported="false">
  <intent-filter>
    <action android:name="com.commonware.abj.interp.EchoInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.SQLiteInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.BshInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.RhinoInterpreter"/>
  </intent-filter>
</service>
```

From there, it is a matter of adding in appropriate startService() calls to your application wherever you want to execute a script, and processing the results you get back.

Using the InterpreterService

To use the InterpreterService, you need to first determine which I_Interpreter engine you are using, as that forms the action for the Intent to be used with the InterpreterService. Create an Intent with that action, then add in an InterpreterService.BUNDLE extra for the script and other data to be supplied to the interpreter. Also, you can add an InterpreterService.BROADCAST_ACTION, to be used by InterpreterService to send results back to you via a broadcast Intent.

Finally, call `startService()` on the `Intent`, and the results will be delivered to you asynchronously.

For example, here is a test method from the `EchoInterpreterTests` test case:

```
package com.commonware.abj.interp;

import android.os.Bundle;

public class EchoInterpreterTests extends InterpreterTestCase {
    protected String getInterpreterName() {
        return("com.commonware.abj.interp.EchoInterpreter");
    }

    public void testNoInput() {
        Bundle results=execServiceTest(new Bundle());

        assertNotNull(results);
        assert (results.size() == 0);
    }

    public void testWithSomeInputJustForGrins() {
        Bundle input=new Bundle();

        input.putString("this", "is a value");

        Bundle results=execServiceTest(input);

        assertNotNull(results);
        assertEquals(results.getString("this"), "is a value");
    }
}
```

The echo “interpreter” simply echoes the input `Bundle` into the output. The `execServiceTest()` method is inherited from the `InterpreterTestCase` base class:

```
protected Bundle execServiceTest(Bundle input) {
    Intent i=new Intent(getInterpreterName());

    i.putExtra(InterpreterService.BUNDLE, input);
    i.putExtra(InterpreterService.BROADCAST_ACTION, ACTION);

    getContext().startService(i);

    try {
        latch.await(5000, TimeUnit.MILLISECONDS);
    }
    catch (InterruptedException e) {
        // just keep rollin'
    }
}
```

```
return(results);  
}
```

The `execServiceTest()` method uses a `CountDownLatch` to wait on the interpreter to do its work before proceeding (or 5000 milliseconds, whichever comes first). The broadcast Intent containing the results, registered to watch for `com.commonware.abj.interp.InterpreterTestCase` broadcasts, stuffs the output Bundle in a results data member and drops the latch, allowing the main test thread to continue.

BeanShell on Android

What if Java itself were a scripting language? What if you could just execute a snippet of Java code, outside of any class or method? What if you could still import classes, call static methods on classes, create new objects, as well?

That was what BeanShell offered, back in its heyday. And, since BeanShell does not use sophisticated tricks with its interpreter – like JIT compilation of scripting code — BeanShell is fairly easy to integrate into Android.

What is BeanShell?

[BeanShell](#) is Java on Java.

With BeanShell, you can write scripts in loose Java syntax. Here, “loose” means:

1. In addition to writing classes, you can execute Java statements outside of classes, in a classic imperative or scripting style
2. Data types are optional for variables
3. Not every language feature is supported, particularly things like annotations that did not arrive until Java 1.5
4. Etc.

BeanShell was originally developed in the late 1990’s by Pat Niemeyer. It enjoyed a fair amount of success, even being considered as a standard interpreter to ship with Java ([JSR-274](#)). However, shortly thereafter, BeanShell lost momentum, and it is no longer being actively maintained. That being said, it works quite nicely on Android... once a few minor packaging issues are taken care of.

Getting BeanShell Working on Android

BeanShell has two main problems when it comes to Android:

- The publicly-downloadable JAR was compiled for Java 1.4.2, and Android requires Java 5 or newer
- The source code includes various things, like a Swing-based GUI and a servlet, that have no real place in an Android app and require classes that Android lacks

Fortunately, with BeanShell being open source, it is easy enough to overcome these challenges. You could download the source into an Android library project, then remove the classes that are not necessary (e.g., the servlet), and use that library project in your main application. Or, you could use an Android project for creating a JAR file that was compiled against the Android class library, so you are certain everything is supported.

However, the easiest answer is to use SL4A's BeanShell JAR, since they have solved those problems already. The JAR can be found in the [SL4A source code repository](#), though you will probably need to check out the project using Mercurial, since JARs cannot readily be downloaded from the Google Code Web site.

Integrating BeanShell

The BeanShell engine is found in the `bsh.Interpreter` class. Wrapping one of these in an `I_Interpreter` interface, for use with `InterpreterService`, is fairly simple:

```
package com.commonware.abj.interp;

import android.os.Bundle;
import bsh.Interpreter;

public class BshInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        Interpreter i=new Interpreter();
        Bundle output=new Bundle(input);
        String script=input.getString(InterpreterService.SCRIPT);

        if (script != null) {
            try {
                i.set(InterpreterService.BUNDLE, input);
                i.set(InterpreterService.RESULT, output);

                Object eval_result=i.eval(script);
```

```
        output.putString("result", eval_result.toString());
    }
    catch (Throwable t) {
        output.putString("error", t.getMessage());
    }
}

return(output);
}
```

BeanShell interpreters are fairly inexpensive objects, so we create a fresh Interpreter for each script, so one script cannot somehow access results from prior scripts. After setting up the output Bundle and extracting the script from the input Bundle, we inject both Bundle objects into BeanShell itself, where they can be accessed like global variables, named `_bundle` and `_result`.

At this point, we evaluate the script, using the `eval()` method on the Interpreter object. If all goes well, we convert the object returned by the script into a String and tuck it into the output Bundle, alongside anything else the script may have put into the Bundle. If there is a problem, such as a syntax error in the script, we put the error message into the output Bundle.

So long as the InterpreterService has an `<intent-filter>` for the `com.commonware.abj.interp.BshInterpreter` action, and so long as we have a BeanShell JAR in the project's `libs/` directory, InterpreterService is now capable of executing BeanShell scripts as needed.

With our inherited `execServiceTest()` method handling invoking the InterpreterService and waiting for responses, we can “simply” put our script as the InterpreterService.SCRIPT value in the input Bundle, and see what we get out. The first test script returns a simple value; the second test script directly calls methods on the output Bundle to return its results.

Rhino on Android

JavaScript arrived on the language scene hot on the heels of Java itself. The name was chosen for marketing purposes more so than for any technical reason. Java and JavaScript had little to do with one another, other than both adding interactivity to Web browsers. And while Java has largely faded from mainstream browser usage, JavaScript has become more and more of a force on the browser, and even now on Web servers.

And, along the way, the Mozilla project put JavaScript on Java and gave us Rhino.

What is Rhino?

If BeanShell is Java in Java, [Rhino](#) is JavaScript in Java.

As part of Netscape's failed "Javagator" attempt to create a Web browser in Java, they created a JavaScript interpreter for Java, code-named Rhino after the cover of O'Reilly Media's [JavaScript: The Definitive Guide](#). Eventually, Rhino was made available to the Mozilla Foundation, which has continued maintaining it. At the present time, Rhino implements JavaScript 1.7, so it does not support the latest and greatest JavaScript capabilities, but it is still fairly full-featured.

Interest in Rhino has ticked upwards, courtesy of interest in using JavaScript in places other than Web browsers, such as server-side frameworks. And, of course, it works nicely with Android.

Getting Rhino Working on Android

Similar to BeanShell, Rhino has a few minor source-level incompatibilities with Android. However, these can be readily pruned out, leaving you with a still-functional JavaScript interpreter. However, once again, it is easiest to use [SL4A's Rhino JAR](#), since all that work is done for you.

Integrating Rhino

Putting an I_Interpreter facade on Rhino is incrementally more difficult than it is for BeanShell, but not by that much:

```
package com.commonware.abj.interp;

import android.os.Bundle;
import org.mozilla.javascript.*;

public class RhinoInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        String script=input.getString(InterpreterService.SCRIPT);
        Bundle output=new Bundle(input);

        if (script != null) {
            Context ctxt=Context.enter();

            try {
                ctxt.setOptimizationLevel(-1);
```

```
Scriptable scope=ctxt.initStandardObjects();
Object jsBundle=Context.javaToJS(input, scope);
ScriptableObject.putProperty(scope, InterpreterService.BUNDLE,
                             jsBundle);

jsBundle=Context.javaToJS(output, scope);
ScriptableObject.putProperty(scope, InterpreterService.RESULT,
                             jsBundle);

String result=
    Context.toString(ctxt.evaluateString(scope, script,
                                         "<script>", 1, null));

    output.putString("result", result);
}
finally {
    Context.exit();
}
}

return(output);
}
```

As with BshInterpreter, RhinoInterpreter sets up the output Bundle and extracts the script from the input Bundle. Assuming there is a script, RhinoInterpreter then sets up a Rhino Context object, which is roughly analogous to the BeanShell Interpreter object. One key difference is that you need to clean up the Context, by calling a static `exit()` method on the Context class, whereas with a BeanShell Interpreter, you just let garbage collection deal with it.

Rhino has a JIT compiler, one that unfortunately will not work with Android, since it generates Java bytecode, not Dalvik bytecode. However, Rhino lets you turn that off, by calling `setOptimizationLevel()` on the Context object with a value of `-1` (meaning, in effect, disable all optimizations).

After that, we:

1. Create a language scope for our script and inject standard JavaScript global objects into that scope
2. Wrap our two Bundle objects with JavaScript proxies via calls to `javaToJS()`, then injecting those objects into the scope as

`_bundle` and `_result` via `putProperty()` calls

1. Execute the script via a call to `evaluateString()` on the Context object, converting the resulting object into a String and pouring it into the output Bundle

If our `InterpreterService` has an `<intent-filter>` for the `com.commonware.abj.interp.RhinoInterpreter` action, and so long as we have a Rhino JAR in the project's `libs/` directory, `InterpreterService` can now invoke JavaScript.

Other JVM Scripting Languages

As mentioned previously, there are many languages that, themselves, are implemented in Java and can be ported to Android, with varying degrees of difficulty. Many of these languages are fairly esoteric. Some, like JRuby, have evolved to the point where they transcend a simple “scripting language” on Android.

However, there are two other languages worth mentioning, as they are fairly well-known in Java circles: Groovy and Jython.

Groovy

[Groovy](#) is perhaps the most popular Java-based language that does not have its roots in some other previous language (Java, JavaScript, Python, etc.). Designed in some respects to be a “better Java than Java”, Groovy gives you access to Java classes while allowing you to write scripts with dynamic typing, closures, and so forth. Groovy has an extensive community, complete with a fair number of Groovy-specific libraries and frameworks, plus some books on the market.

At the time of this writing, it does not appear that Groovy has been successfully ported to work on Android, though.

Jython

[Jython](#) is an implementation of a Python language interpreter in Java. It has been around for quite some time, and gives you Python syntax with access to standard Java classes where needed. While the Jython community is not as well-organized as that of Groovy, there are plenty of books covering the use of Jython.

Jython's momentum has flagged a bit in recent months, in part due to Sun's waning interest in the technology and the departure of Sun employees from the project.

One [attempt](#) to get Jython working with Android has been shut down, with people steered towards SL4A. It is unclear if others will make subsequent attempts.

Trail: Other Tools

Advanced Emulator Capabilities

The Android emulator, at its core, is not that complex. Once you have one or more Android virtual devices (AVDs) defined, using them is a matter of launching the emulator and installing your app upon it. With Android Studio and Eclipse, those two steps can even be combined — the IDE will automatically start an emulator instance if one is needed.

However, there is much more to the Android emulator. This chapter will explore various advanced features of the emulator and how you can use them.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

x86 Images

Normally, the Android emulator emulates a device with an ARM-based CPU. That matches with most Android devices available to users today. However, most developers are developing on an x86-based development machine, not one powered by ARM. As a result, the normal Android emulator has to convert ARM instructions to x86 instructions before executing them, slowing down performance.

Some versions of the Android emulator, though, have an x86 version as well. Where available, these *can* run much more quickly than will their ARM counterparts on an x86 development machine.

ADVANCED EMULATOR CAPABILITIES

The emphasis on *can* is that your development machine must have things set up properly first. Linux users need KVM, while Mac and Windows users need the “Intel Hardware Accelerated Execution Manager” (available from the SDK Manager). The latter must be manually installed once downloaded — please consult [the Android tools documentation](#) for details.

Also, this only works for certain CPU architectures, ones that support virtualization in hardware:

- Intel Virtualization Technology (VT, VT-x, vmx) extensions
- AMD Virtualization (AMD-V, SVM) extensions (Linux only)

Those virtualization extensions must also be enabled in your device’s BIOS, and other OS-specific modifications may be required.

Android 4.0.3

An x86 image for Android 4.0.3 is available from your SDK Manager:

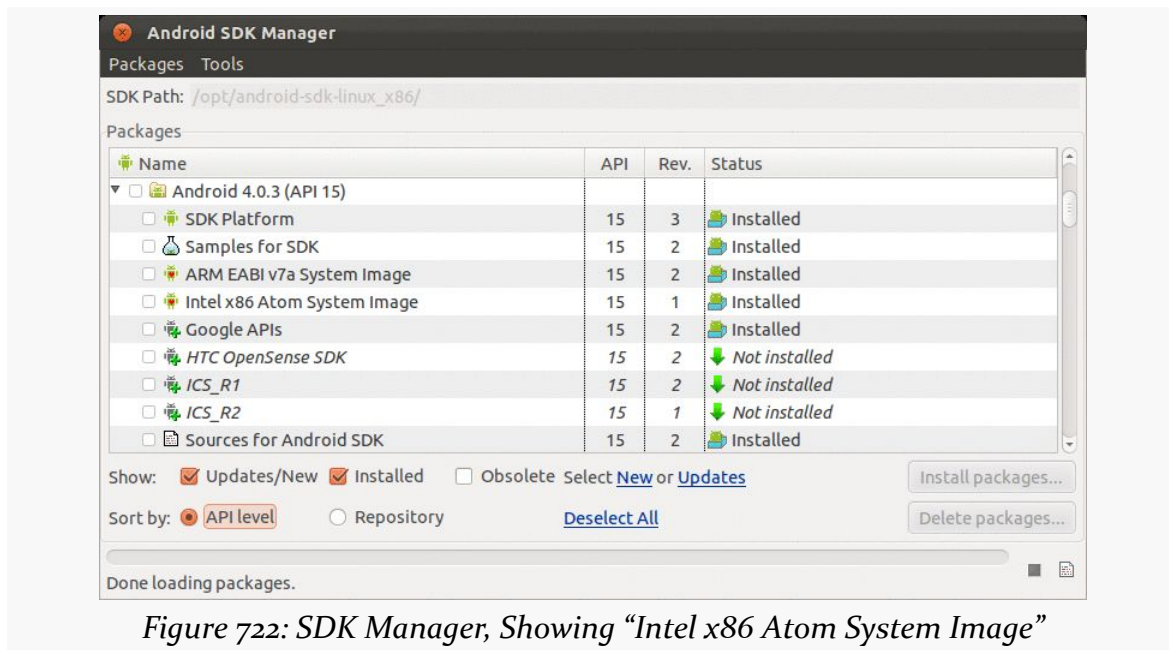

Figure 722: SDK Manager, Showing “Intel x86 Atom System Image”

When you download that, the next time you choose API Level 15 for an AVD, you will have an option of CPU architecture:

ADVANCED EMULATOR CAPABILITIES

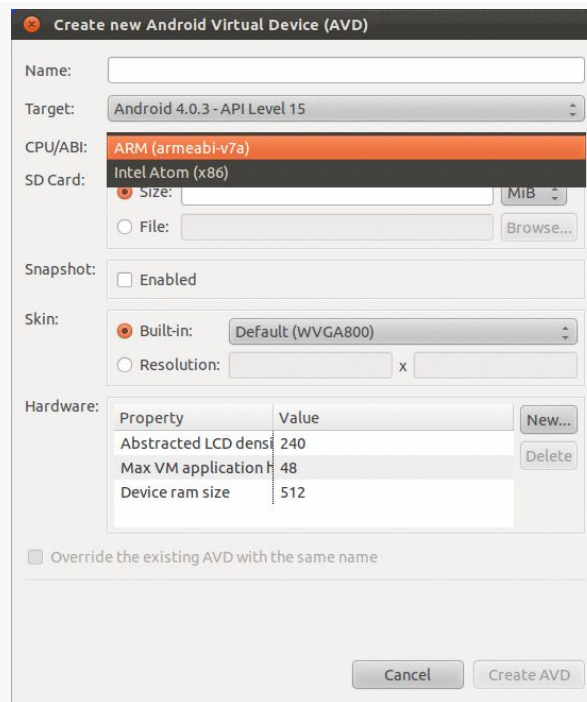

Figure 723: AVD Manager, Showing CPU/ABI Options

Note that this only works for the plain Android API Level 15 AVD, not the one containing Google Maps, which is only available for ARM at this time.

There are similar x86 images available for other newer Android versions, such as 4.1 and 4.2.

Android 2.3.3

An x86 image for Android 2.3.3 is also available from your SDK Manager, though with a slightly different entry:

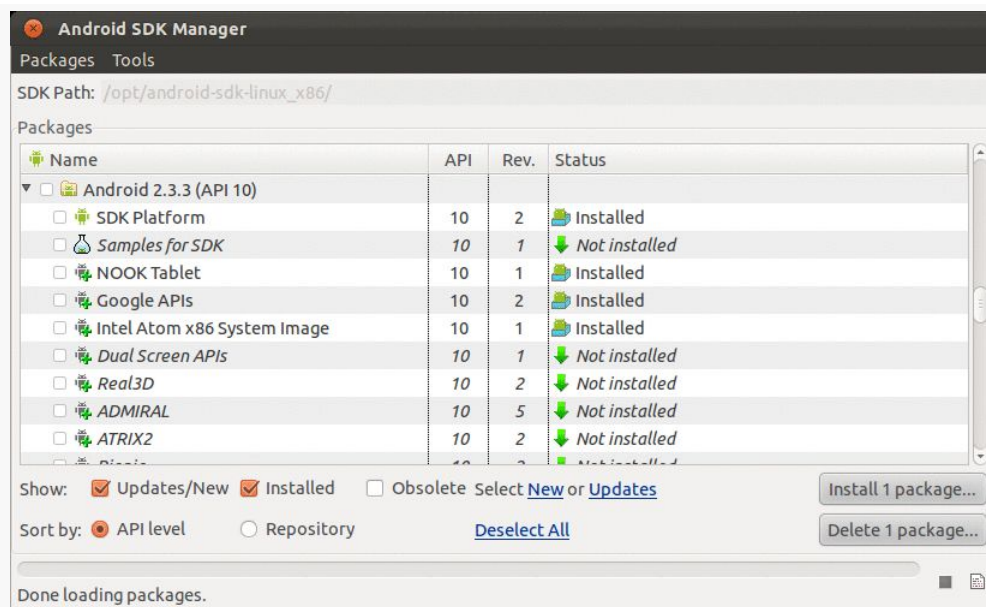

Figure 724: SDK Manager, Showing “Intel Atom x86 System Image”

This shows up as a separate target in your AVD Manager (“Intel Atom x86 System Image”), rather than a CPU/ABI value that you toggle.

Hardware Graphics Acceleration

The other way to speed up the emulator is to have it use the graphic card or GPU of your development machine to accelerate the graphics rendering of the emulator window. By default, the emulator will use software-based rendering, without the GPU, which is slow in general and worse when running an ARM-based image.

Whether this will work or not for you will depend in part upon your graphics drivers of your development machine.

There are two ways to configure GPU emulation, depending upon when you created your AVD.

Old AVDs

To try using GPU emulation, for an AVD (new or existing), click the “New...” button to the right of the list of hardware options in the AVD configuration editor:

ADVANCED EMULATOR CAPABILITIES

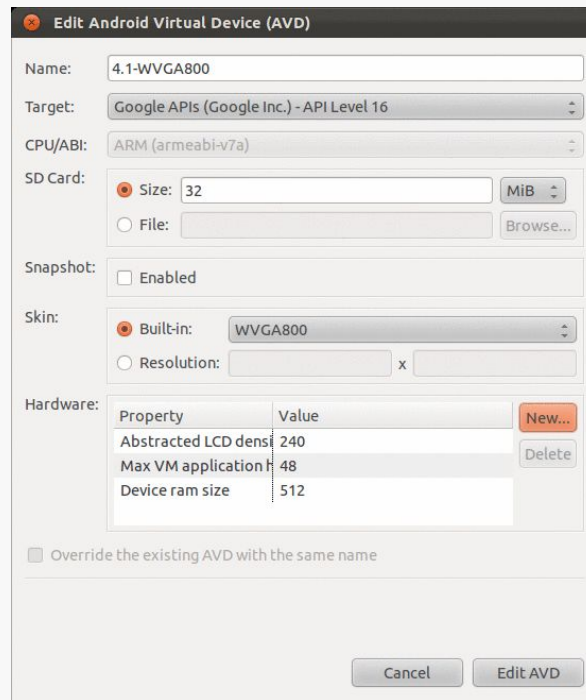

Figure 725: AVD Configuration Editor, With “New...” Button Focused

In the dialog that appears, choose “GPU Emulation” in the drop-down:

Figure 726: AVD Hardware Options Dialog

Then click OK, which will add “GPU Emulation” to the table:

ADVANCED EMULATOR CAPABILITIES

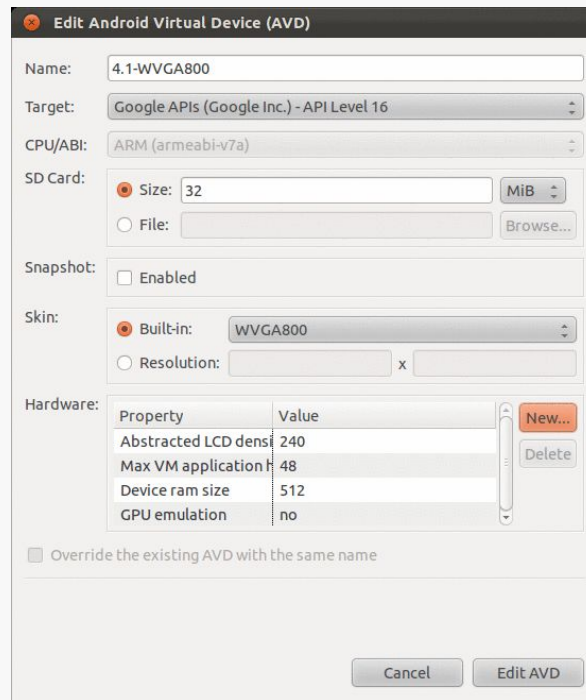

Figure 727: AVD Configuration Editor, Showing “GPU Emulation” Option

If it has “no” as the corresponding value — and it should by default — click on the “no” to display a drop-down where you can toggle it to “yes”.

Also, you need to make sure that the “Enabled” checkbox in the Snapshot group box is unchecked.

New AVDs

On a newer AVD configuration editor, there is a “Use Host GPU” checkbox that you can check to try using GPU emulation:

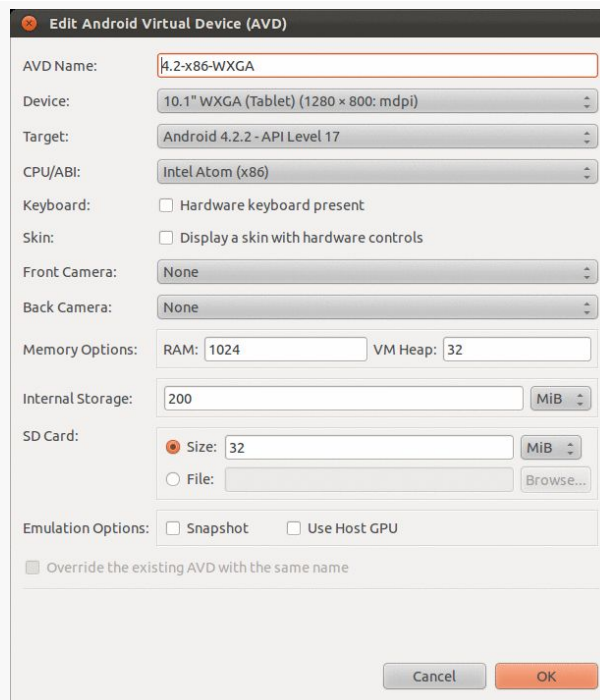

Figure 728: New AVD Configuration Editor, Showing “Use Host GPU” Option

Defining New Devices

Your Android development environment will have several device definitions ready for you to use. Some will come from Google. Others may come from device vendors, such as Amazon shipping device definitions for the Kindle Fire series. And you can define your own, to attempt to (roughly) model other devices beyond those already in your roster.

In the AVD Manager, on the Device Definitions tab, you can click the “New Device...” button on the right:

ADVANCED EMULATOR CAPABILITIES

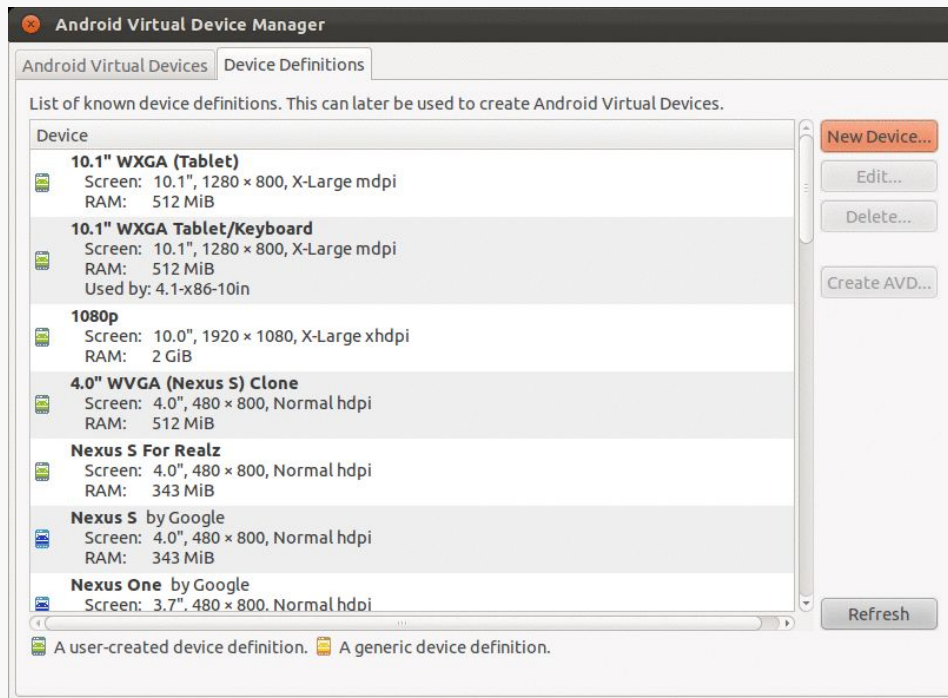

Figure 729: AVD Manager, Device Definitions Tab

That will bring up an empty device definition dialog:

ADVANCED EMULATOR CAPABILITIES

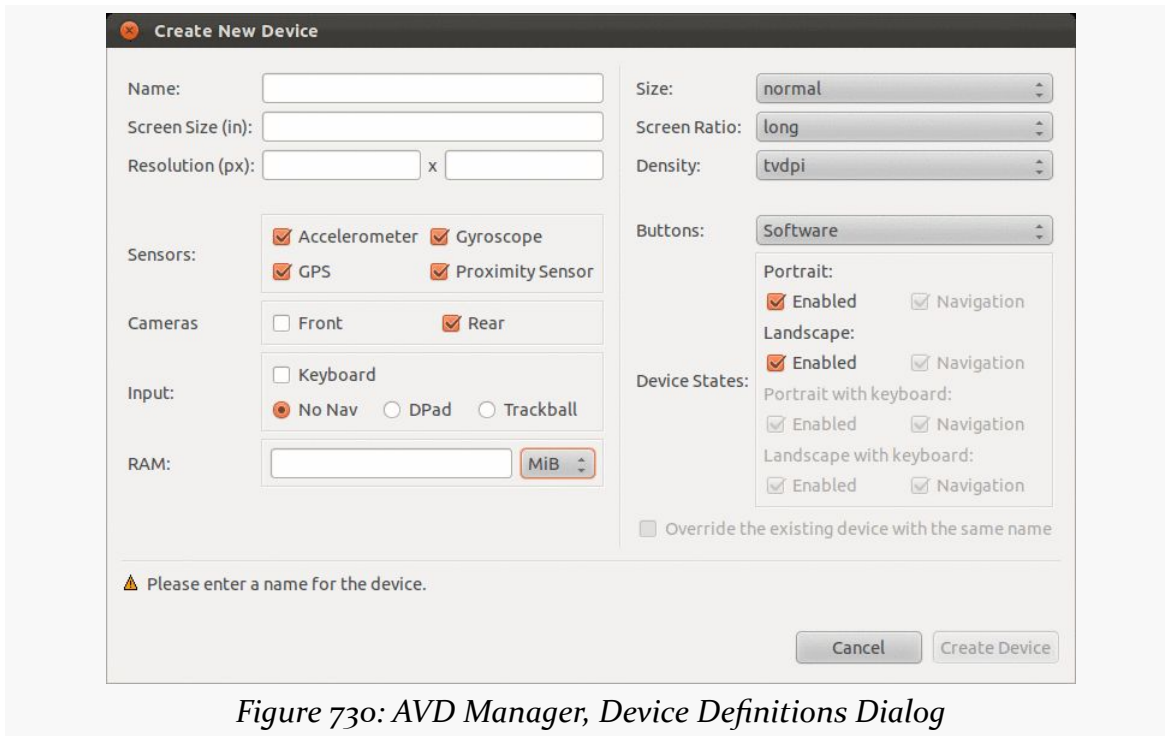

Figure 730: AVD Manager, Device Definitions Dialog

Alternatively, you can highlight an existing definition. If it is one you defined yourself, you will have an “Edit...” button to modify the definition. If it is a definition that came from Google or another vendor, that button will be labeled “Clone...” and will allow you to create a new definition cloned from the existing one. You can clone one of your own as well, by editing it and giving it a new name.

There are lots of things that you can configure for a device definition. The major ones are:

- The name of the definition, to control what it is called in the drop-down of available devices when you go to create an AVD
- The diagonal screen size of the device in inches, plus its resolution in pixels
- The screen size, ratio (long or not-long), and density buckets the emulator should use — note that these will be pre-populated based on your size and resolution values, but you can override them if needed
- What sensors the device should claim to have (e.g., accelerometer)
- What cameras the device should claim to have
- Whether the device has a keyboard for input and/or some sort of navigation pointer (e.g., a trackball)
- How much system RAM should be on the device

- Whether or not the HOME, BACK, etc. buttons are implemented in hardware or in software
- What orientations are supported (and if you specified a keyboard, whether the keyboard is available in those orientations)

Keyboard Behavior

The Android emulator can emulate devices that have, or do not have, a physical keyboard. Most Android devices do not have a physical keyboard, and so the emulator is set up to behave the same. However, this means that typing on your development machine's keyboard will not work in `EditText` widgets and the like — you have to tap out what you want to type on the on-screen keyboard.

If you wish to switch your emulator to emulate a device with a physical keyboard — either “for realz” or just to simplify working with the emulator on your development machine — you can do so.

For older AVDs, click that “New...” button next to the list of hardware options, as described in the preceding section. Choose “Keyboard support” from the drop-down, click OK, and toggle the value for that hardware option to “yes”.

For newer AVDs, check the “Hardware keyboard present” checkbox.

Headless Operation

Sometimes, you want an emulator without a GUI. Typically, this is used for continuous integration or some other server-based testing solution — you use the “headless” emulator to run tests, even on a machine that lacks any GUI capability.

To do this, you will need to run the emulator from the command-line. Run `emulator -no-window -avd ...`, where ... is the name of your AVD (e.g., the value in the left column of the list of AVDs in the AVD Manager). To test this first in normal mode, run the command without the `-no-window` switch.

The simplest solution to get rid of the emulator instance is to kill its process.

There are many other [command-line switches for the emulator](#) that you may wish to investigate. While most of these have UI analogues in the AVD Manager, the switches would be necessary to replicate some of those for headless operation.

Using Lint

As C/C++ developers are well aware, `lint` is not merely something that collects in pockets and belly buttons.

`lint` is a long-standing C/C++ utility that points out issues in a code base that are not errors or warnings, but are still indicative of a likely flaw in the code. After all, what might be legal from a syntax standpoint may still be a bug when used.

The Android tools now have their own equivalent tool, Lint, integrated into Android Studio and Eclipse, for reporting similar sorts of issues with an Android project's Java code, resources, and manifest. You can also get Lint reports from the command line, such as via Gradle for Android, perhaps as part of integrating your builds into a continuous integration server.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What It Is

Lint can be best described as “a pest, but a good pest”.

Normally, what stops you from building your app are compiler errors: bad Java syntax, malformed XML resource files, and the like. At the command line, these stop an in-progress build and dump error messages to the console. In Android Studio, these are noted in a log and also by notations in the source code. In Eclipse, these result in red “X” notations on the files in the Package Explorer, and frequently result

in red squiggle lines underneath the offending Java or XML when viewed in an editor. You also may get yellow squiggle lines for warnings — things the compiler will allow but the compiler thinks may be a problem.

However, there are many things that might be syntactically valid but are not a good idea from an Android standpoint. For example, if you specify a minimum SDK version of API Level 8, and you try using a class that only exists on API Level 11, that's a problem if you are not handling it correctly and avoiding this class on the older-yet-supported devices. Yet, if your build target is API Level 11 or higher, it is perfectly valid syntax and would compile just fine.

Lint is designed to encapsulate rules that transcend syntax, to add more errors and warnings that reflect good Android practices beyond simple validity.

When It Runs

Running Lint sometimes happens automatically (e.g., from your IDE) or sometimes happens manually. The following sections outline the various possibilities.

Android Studio

By default, in Android Studio, Lint will run when you save a file, giving you error (red) or warning (yellow) squiggles for things that run afoul of Lint rules:

Figure 731: Android Studio Lint Error

You can manually invoke it via Analyze > Inspect Code... from the main menu, though this also seems to perform a bunch of other analysis that is not necessarily relevant for you as an Android developer, such as “J2ME issues”.

Figure 732: Android Studio Inspection Results

Eclipse

By default, in Eclipse, Lint will run when you save a file and when you export an APK (e.g., to distribute in production). You can also force a full Lint run in Eclipse at any point by clicking its toolbar button (looks like a green checkmark in a box), or by right-clicking over a project and choosing Android Tools > Run Lint from the context menu. In addition to giving you classic Eclipse error and warning markers in the files, there is also a “Lint Warnings” view showing a table of all the errors and warnings in one place:

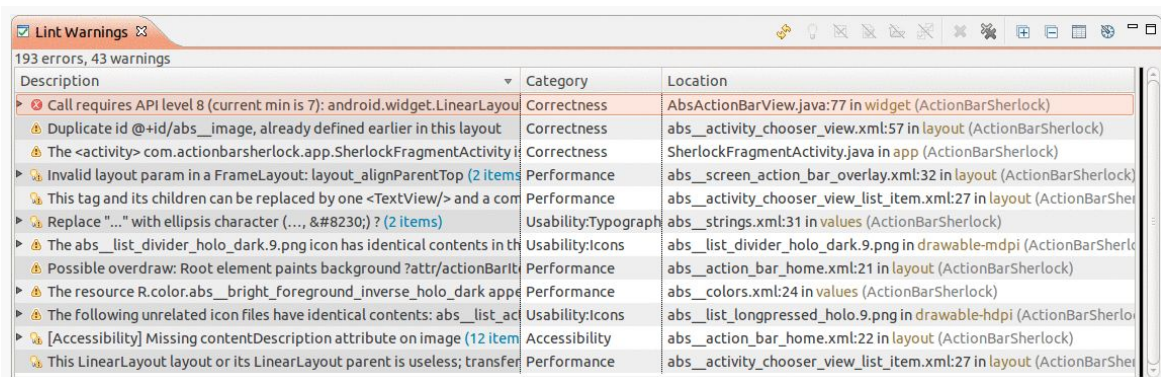

Figure 733: Eclipse Lint Warnings View

Command Line

To run Lint from the command line, just run `lint`, passing it the path to some directory. If the directory is an Android project directory, `lint` will dump the errors and warnings to the console. If the directory is not an Android project directory, `lint` will sweep all subdirectories to find any Android projects, then report those projects' errors and warnings.

```
$ lint .

Scanning .:
.....
Scanning . (Phase 2): ..
res/drawable/eject.png: Warning: The resource R.drawable.eject appears to be
unused [UnusedResources]

@string resource [HardcodedText]
    android:text="Stop"
    ^
0 errors, 10 warnings
```

However, frequently it is more convenient as a developer to have the command-line lint generate an HTML report, instead of dumping everything just to the console. To do that, use the `--html` switch, passing a path to the report file to be generated. For local use, that is all you need. If you wish to host the report somewhere, also add the `--url` switch, indicating where the report will live on a Web server (e.g., your continuous integration server). For example, this command runs lint in the current working directory, generating a `/tmp/lint.html` file (plus a `/tmp/lint_files/` directory of images and CSS files), mapping the URLs to work on a specific base URL:

```
lint --html /tmp/lint.html --url .=http://misc.commonsware.com/lint
```

This report [can be viewed in your Web browser](#) to see what the output looks like.

You can also invoke Lint via `gradle lint` or a per-variant edition (e.g., `gradle lintRelease`). This will write results to an XML file in `build/outputs/` based upon product variant (e.g., `build/outputs/lint-results-release.xml` for a `gradle lintRelease` run). It will also emit an HTML file with the same base name in the same directory. These contain the same basic information as you get from the

command-line output, with the XML in particular designed to be consumed by other tools, such as a continuous integration server.

What to Fix

In Android Studio, clicking on a red or yellow squiggle will pop up an adjacent “lightbulb” drop-down offering ways to fix the problem:

Inside of Eclipse, some of the Lint warnings and errors come with “quick fixes”, which you can bring up via `<Ctrl>-<1>`. For example:

- Errors related to accessing classes or methods higher than your `minSdkVersion` have “quick fixes” to add the `@TargetApi` annotation to the class or method containing your code
- Warnings related to hard-coded strings in layouts or the manifest have “quick fixes” to convert those strings into string resources

All warnings and errors will have “quick fixes” to suppress that warning or error in the future, by adding notations to the file to that effect.

What to Configure

You have some measure of control over Lint’s behavior. The exact means of doing so varies significantly depending upon whether you are using Eclipse or running Lint from the command line.

Android Studio

In Android Studio, you can configure Lint’s behavior via the Project Settings dialog, accessible via `File > Settings`:

USING LINT

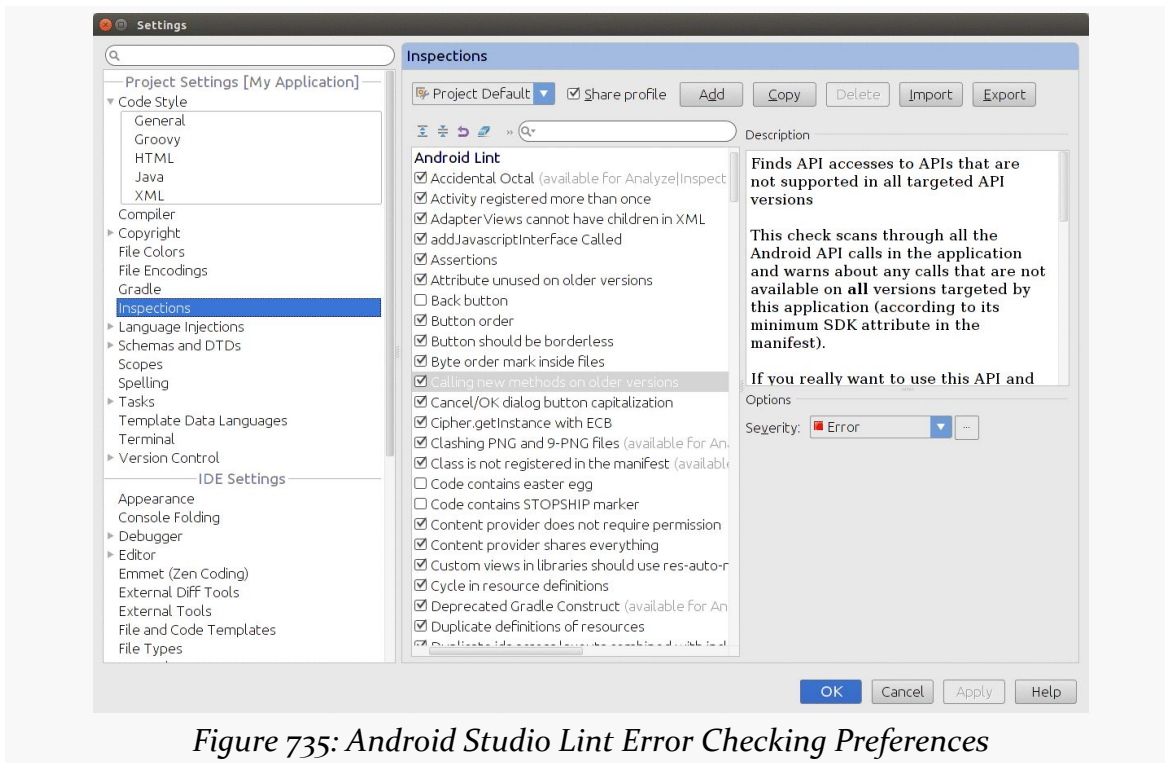

Figure 735: Android Studio Lint Error Checking Preferences

You can change some details about the specific checks that Lint makes:

- the severity of the issue, usually set to Warning or Error
- whether the specific issue should be ignored rather than executed

To do this, you may wish to create your own inspection profile, rather than modifying the stock “Project Default” profile. To do this, just click the “Copy” button in the Inspections page of the Settings dialog and supply a name for the new profile.

The above recipe changes the inspections for the individual project. To change them for new projects, go into File > Other Settings > Default Settings, and make your changes there.

Eclipse

In Eclipse, you can configure Lint’s behavior via Eclipse’s Preferences dialog. Go into Android > Lint Error Checking to see your available options:

USING LINT

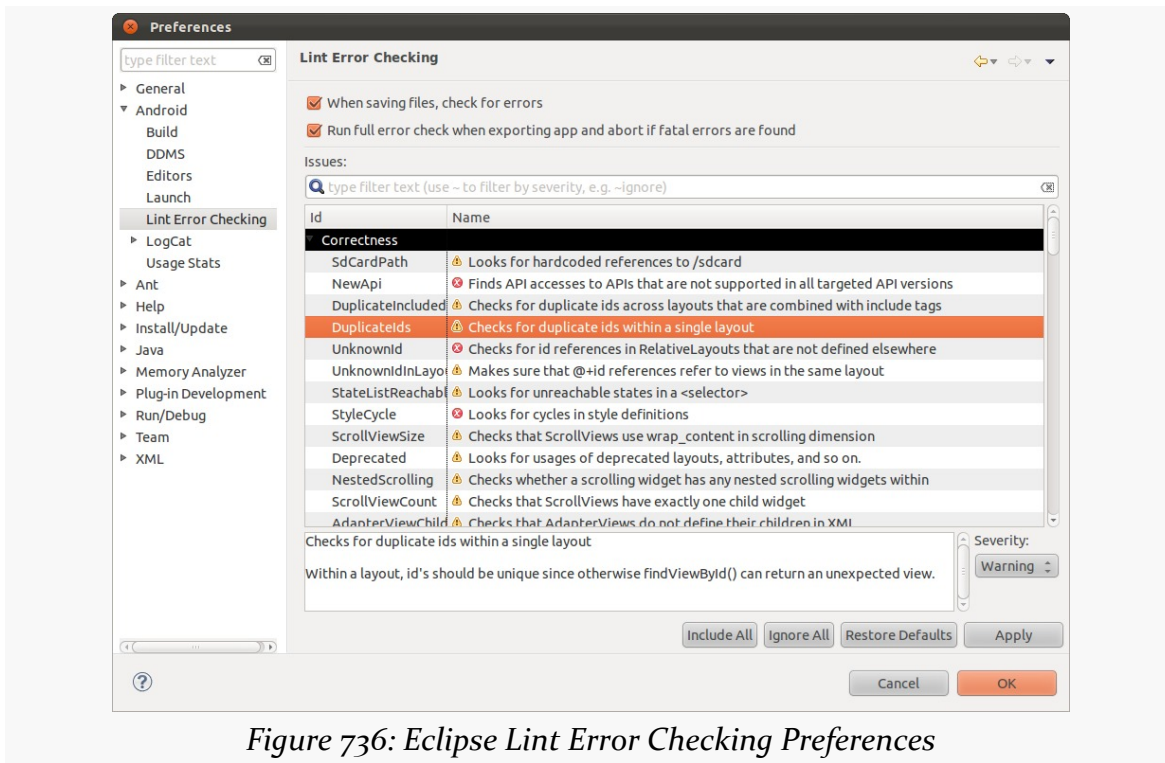

Figure 736: Eclipse Lint Error Checking Preferences

In addition to configuring the automatic Lint checks (e.g., on each file save), you can change some details about the specific checks that Lint makes:

- the severity of the issue, usually set to Warning or Error
- whether the specific issue should be ignored rather than executed

To change Lint behavior on a per-project basis, go into the project properties, click on the “Android Lint Preferences” category, and you will see a similar table of issues, which you can configure for this specific project.

Also, from the “Lint Warnings” view, you can elect to suppress certain warnings, either for the entire workspace, the entire project, or for the specific file in which the warning is being presented.

Command Line

One way to suppress issues from the command line is to add the `--disable` switch, listing the issues (or categories of issues) to skip. You can use the `--list` switch to see what checks are available:

USING LINT

```
$ lint --list
Valid issue categories:
  Correctness
  Correctness:Messages
  Security
  Performance
  Usability:Typography
  Usability:Icons
  Usability
  Accessibility
  Internationalization

Valid issue id's:
"ContentDescription": Ensures that image widgets provide a contentDescription
"FloatMath": Suggests replacing java.lang.Math calls with
               android.util.FloatMath to avoid conversions
"FieldGetter": Suggests replacing uses of getters with direct field access
               within a class
"SdCardPath": Looks for hardcoded references to /sdcard
"NewApi": Finds API accesses to APIs that are not supported in all targeted
          API versions
"DuplicateIncludedIds": Checks for duplicate ids across layouts that are
                       combined with include tags
"DuplicateIds": Checks for duplicate ids within a single layout
"UnknownId": Checks for id references in RelativeLayouts that are not defined
             elsewhere
...
```

(where the ... is simply a truncation of the list shown here, which is very long)

If, for example, you wanted to run lint and skip all performance issues, you could use `lint --disable Performance`. If you are uncertain what a particular issue means, the `--show` switch can dump details about the issue:

```
$ lint --show FieldGetter
FieldGetter
-----
Summary: Suggests replacing uses of getters with direct field access within a
class

Priority: 4 / 10
Severity: Warning
Category: Performance
NOTE: This issue is disabled by default!
You can enable it by adding --enable FieldGetter

Accessing a field within the class that defines a getter for that field is at
least 3 times faster than calling the getter. For simple getters that do
nothing other than return the field, you might want to just reference the
local field directly instead.
```

USING LINT

More information: http://developer.android.com/guide/practices/design/performance.html#internal_get_set

Another option is to create a `lint.xml` file, in the root directory of your project, containing information about which particular issues should be suppressed for that project. The benefit here is that you can configure suppression at a finer granularity, blocking issues for certain files or directories and allowing them for others. The sample `lint.xml` from [the Lint documentation](#) looks like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<lint>
  <!-- Disable the given check in this project -->
  <issue id="IconMissingDensityFolder" severity="ignore" />

  <!-- Ignore the ObsoleteLayoutParam issue in the given files -->
  <issue id="ObsoleteLayoutParam">
    <ignore path="res/layout/activation.xml" />
    <ignore path="res/layout-xlarge/activation.xml" />
  </issue>

  <!-- Ignore the UselessLeaf issue in the given file -->
  <issue id="UselessLeaf">
    <ignore path="res/layout/main.xml" />
  </issue>

  <!-- Change the severity of hardcoded strings to "error" -->
  <issue id="HardcodedText" severity="error" />
</lint>
```

You can also have a similar `lint.xml` file that you use outside of any project, by passing in the `--config` switch pointing to it.

Note that it is unclear how these switches would be provided to the stock Gradle for Android lint tasks.

Using Hierarchy View

Android comes with a Hierarchy View tool, designed to help you visualize your layouts as they are seen in a running activity in a running emulator. So, for example, you can determine how much space a certain widget is taking up, or try to find where a widget is hiding that does not appear on the screen.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Launching Hierarchy View

To use the Hierarchy View, you first need to fire up your emulator, install your application, launch your activity, and navigate to the spot you wish to examine. Note that you cannot use Hierarchy View with a production Android device [without some help](#).

To launch Hierarchy View, you have two options:

1. From Eclipse, open the Hierarchy View perspective
2. Use the Android Device Monitor. In Android Studio, this is available from the Tools > Android menu. From the command line, run the `monitor` program to bring up the Android Device Monitor. In the Android Device Monitor, choose Window > Open Perspective from the main menu, and open Hierarchy View:

USING HIERARCHY VIEW

Figure 737: Hierarchy View, in Eclipse, As Originally Opened

The roots of the tree-table on the left show the emulator instances presently running on your development machine. The leaves represent applications running on that particular emulator. Your activity will be identified by application package and class (e.g., `com.commonware.android.files/...`).

Viewing the View Hierarchy

Where things get interesting, though, is when you double-click on your activity in the tree-table. After a few seconds, the details spring into, er, view:

USING HIERARCHY VIEW

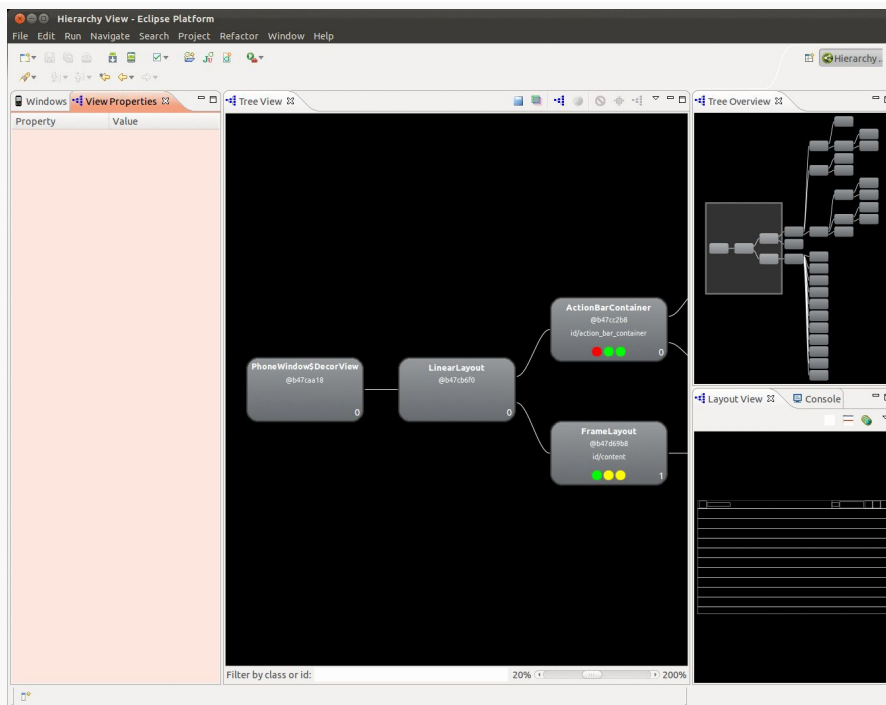

Figure 738: Hierarchy View, in Eclipse, Showing an Activity

The main area of the Layout View shows a tree of the various widgets and stuff that make up your activity, starting from the overall system window and driving down into the individual UI widgets that users are supposed to interact with. This includes both widgets and containers defined by your application and others that are supplied by the system, including the title bar.

Clicking on one of the views adds more information to this perspective:

USING HIERARCHY VIEW

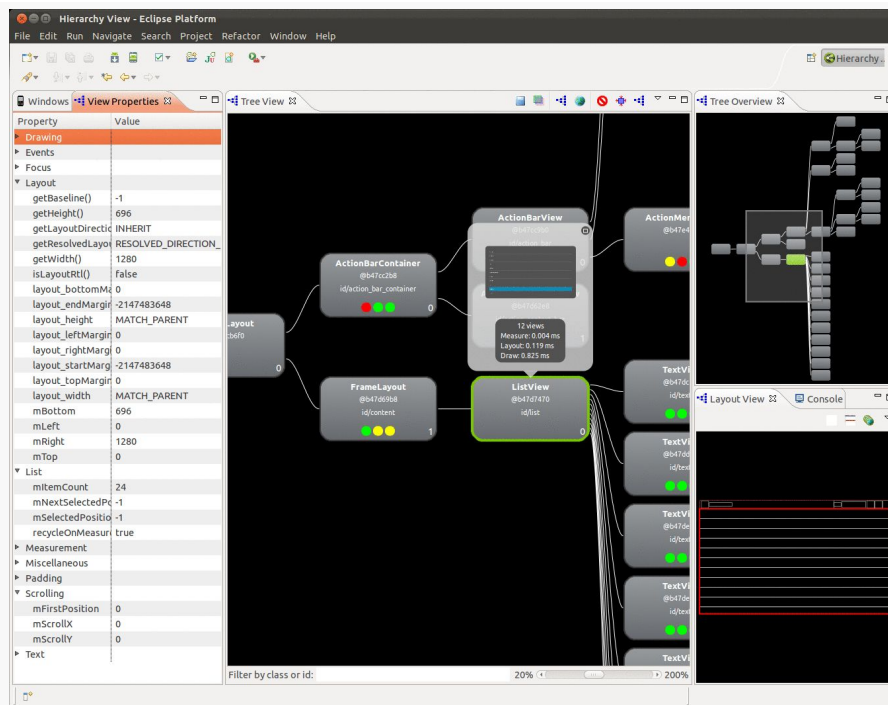

Figure 739: Hierarchy View, in Eclipse, Showing a View's Details

Now, we get:

- In the left region of the Viewer, we see the properties of the selected widget or container, in its own tree-table.
- In the Tree View in the middle, the selected widget or container has a pop-up bubble with what that particular View looks like on the screen, along with some performance timing data.
- In the Tree Overview in the upper-right portion of the tool, our selected View is highlighted in green.
- In the Layout View in the lower-right portion of the tool, our selected View is highlighted in red in the wireframe.

From the toolbar above the Tree View, you can:

- Save the tree diagram as a PNG file
- Save the UI as a Photoshop PSD file, with different layers for the different widgets and containers
- Force the UI to repaint in the emulator or re-load the hierarchy, in case you have made changes to a database or to the app's contents and need a fresh diagram

ViewServer

One major limitation of Hierarchy View is that it only works with the emulator by default. There is no means for it to pull information from random activities running on production hardware.

However, Romain Guy, one of the core Android engineers, has published [a ViewServer open-source component](#) that gets around this limitation.

If you add the ViewServer source code to your project, and register your activities as they are created (and remove them when they are destroyed), you will be able to use Hierarchy View with them. However, this is a bit dangerous on a production app, so you should strongly consider using `BuildConfig.DEBUG` to only enable this logic in debug builds.

Blending in the `BuildConfig.DEBUG` concept with Mr. Guy's supplied sample usage, we get something like this:

```
public class MyActivity extends Activity {
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        // Set content view, etc.

        if (BuildConfig.DEBUG) ViewServer.get(this).addWindow(this);
    }

    public void onDestroy() {
        if (BuildConfig.DEBUG) ViewServer.get(this).removeWindow(this);

        super.onDestroy();
    }

    public void onResume() {
        super.onResume();

        if (BuildConfig.DEBUG) ViewServer.get(this).setFocusedWindow(this);
    }
}
```

Also note that ViewServer requires that your application hold the `INTERNET` permission, which you may already have requested for other reasons.

Using DDMS

Another tool in the Android developer’s arsenal is the Dalvik Debug Monitor Service (DDMS). This is a “Swiss army knife”, allowing you to do everything from browse log files, update the GPS location provided by emulator, simulate incoming calls and messages, and browse the on-emulator storage to push and pull files.

We have already seen the use of DDMS [for viewing your logs via the LogCat view](#). This chapter will explore a few other uses of DDMS beyond LogCat.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on using LogCat](#).

While not strictly a prerequisite, you will find detailed coverage of other features of DDMS in [the chapter on memory leak analysis using MAT](#) and [the chapter on measuring bandwidth consumption](#).

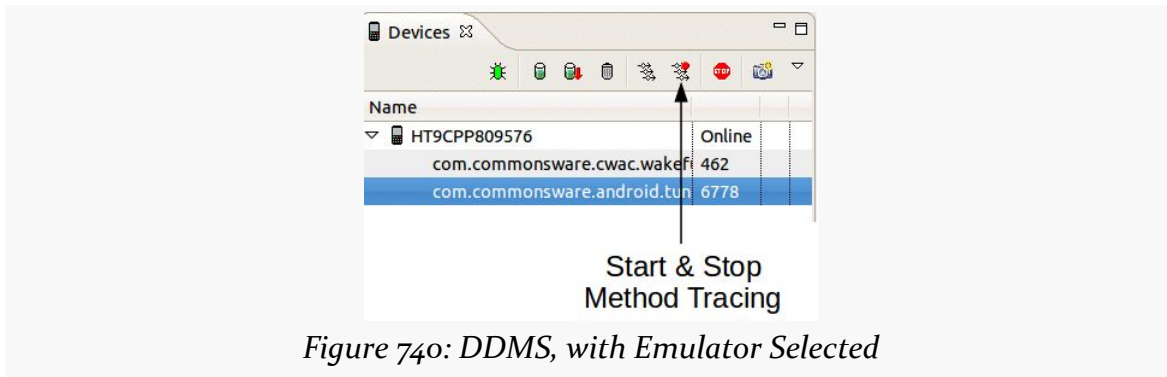

Starting DDMS

As a reminder, to launch DDMS, you have two options:

1. From Eclipse, choose the DDMS perspective
2. From the command line, run the `monitor` program to bring up the Android Device Monitor — the DDMS perspective should appear by default

USING DDMS

DDMS will initially display a tree of emulators and devices and the running programs on each. Clicking on an emulator or device allows you to use the rest of the tools to work with that specific Android environment.

File Push and Pull

The File Explorer view in DDMS allows you to upload and download files from your selected device or emulator. The view shows a typical file explorer-type tree of available folders and files on your selected device or emulator, which you can navigate as you would similar sorts of explorers you have no doubt seen elsewhere.

The toolbar above the view gives you three choices, once you have a folder or file selected:

- Push a file to the device, either into a selected folder or to replace a selected file
- Pull a file from the device to your development machine
- Delete a selected file

There are a few caveats to this:

1. You cannot pull or delete a folder.
2. You cannot create directories through this tool. You will either need to use `adb shell` or create them from within your application.
3. While you can putter through most of the files on an emulator, you can access very little outside of `/mnt/sdcard` on an actual device, due to Android security restrictions.

Screenshots

To take a screenshot of the Android emulator or device, click on the camera icon in the toolbar in the Devices view. This will bring up a dialog box containing an image of the current screen:

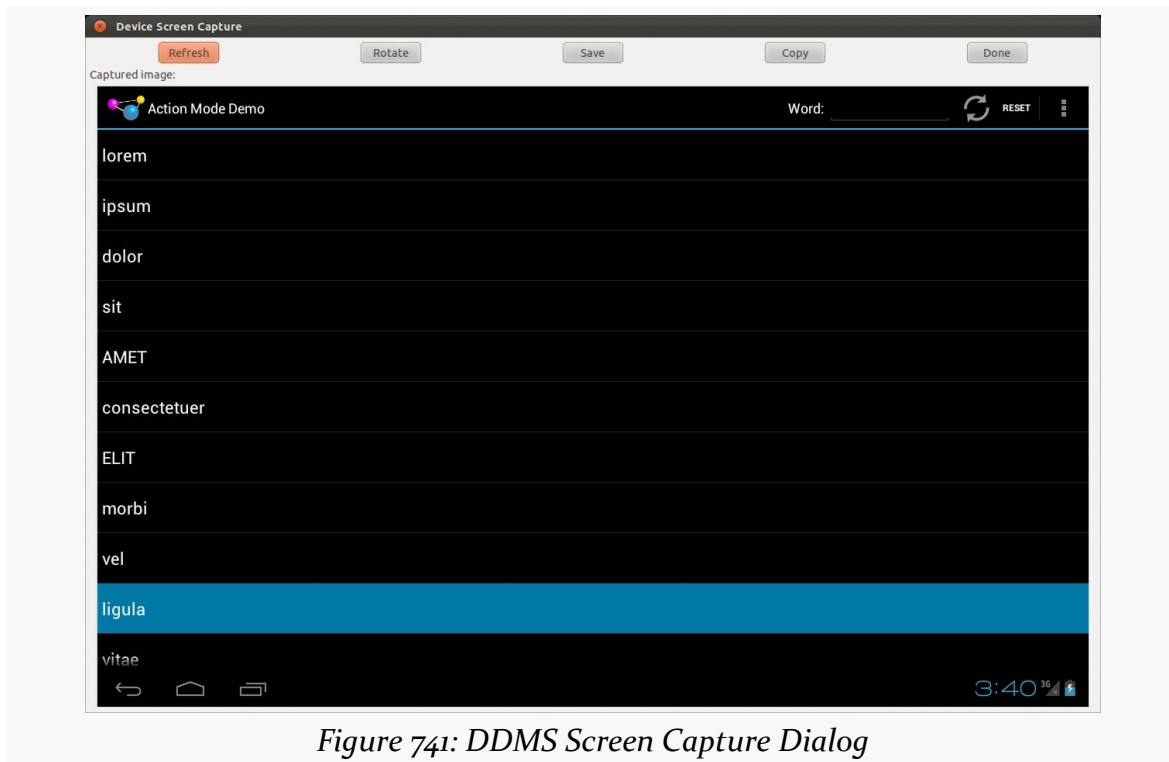

Figure 741: DDMS Screen Capture Dialog

From here, you can click “Save” to save the image as a PNG file somewhere on your development machine, “Refresh” to update the image based on the current state of the emulator or device, “Rotate” to change the orientation of the screenshot, or “Done” to close the dialog.

Location Updates

To use DDMS to supply location updates to your application, the first thing you must do is have your application use the GPS LocationProvider, as that is the one that DDMS is set to update.

USING DDMS

Then, in the Emulator Control view, you will see a Location Controls section. Here, you will find a smaller tabbed pane with three options for specifying locations: Manual, GPX, and KML:

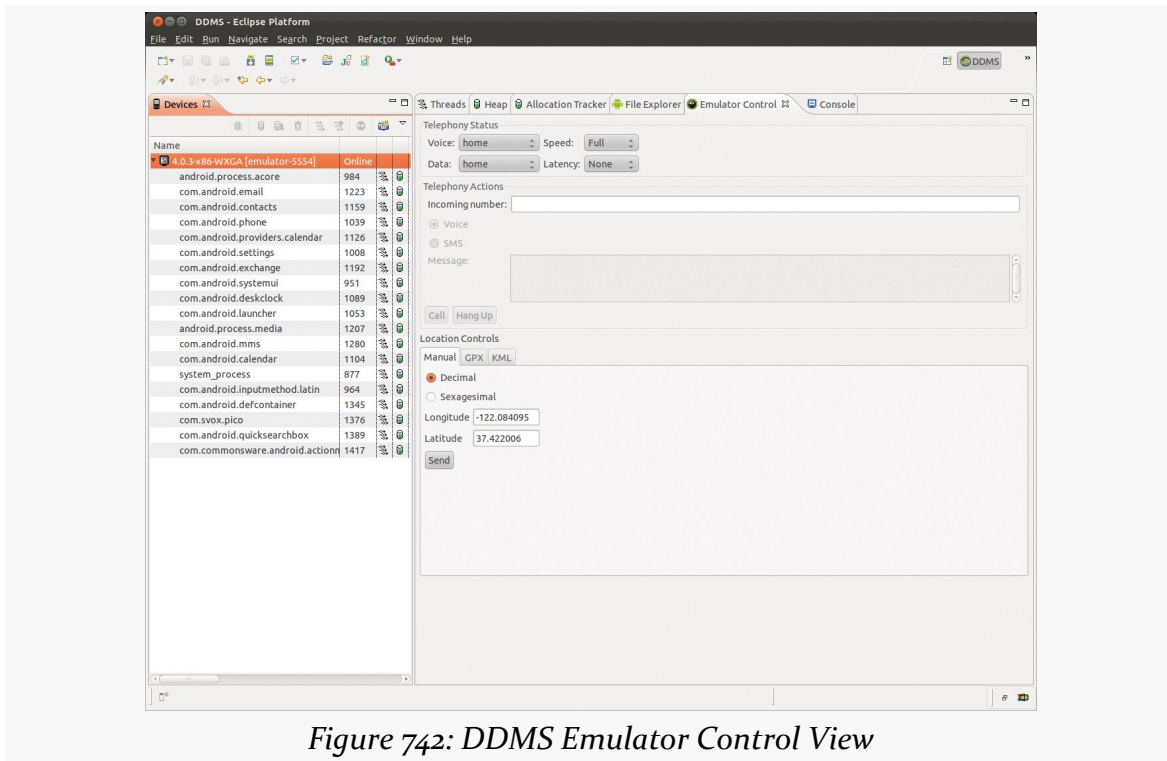

Figure 742: DDMS Emulator Control View

The Manual tab is fairly self-explanatory: provide a longitude and latitude, in decimal degrees, and click the Send button to submit that location to the emulator. The emulator, in turn will notify any location listeners of the new position. The fields are pre-populated with the longitude and latitude of a building on Ampitheater Parkway, in Mountain View, CA, USA.

Note that you cannot simulate GPS on a device this way, only on an emulator.

Placing Calls and Messages

If you want to simulate incoming calls or SMS messages to the Android emulator, DDMS can handle that as well.

On the Emulator Control view, above the Location Controls group, is the Telephony Actions group.

USING DDMS

To simulate an incoming call, fill in a phone number, choose the Voice radio button, and click Call. At that point, the emulator will show the incoming call, allowing you to accept it (via the green phone button) or reject it (via the red phone button):

To simulate in an incoming text message, fill in a phone number, choose the SMS radio button, enter a message in the provided text area, and click Send. The text message will then be delivered to the emulator as if it came in over the air.

Note that you cannot simulate SMSes on a device this way, only on an emulator.

Trail: Tuning Android Applications

Issues with Speed

Mobile devices are never fast enough. Either they are slow in general (e.g., slow CPU) or they are slow for particular operations (e.g., advanced game graphics).

What you do not want is for your application to be unnecessarily slow, where the user determines what is and is not “necessary”. Your opinion of what is “necessary”, alas, is of secondary importance.

This part of the book will focus on speed, including how you can measure and reduce lag in your applications. First, though, let’s take a look at some of the specific issues surrounding speed.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Getting Things Done

In some cases, you simply cannot seem to get the work done that you want to accomplish. Your database query seems slow. Your encryption algorithm seems slow. Your image processing logic seems slow. And so on.

The limits of the device will certainly make this more of a problem than it might otherwise be. Even a current-era dual-core device will be slow compared to your average notebook or desktop. Also, this sort of speed issue is pervasive throughout computing, with decades of experience to help developers learn how to write leaner code.

This part of the book will aim to help you identify where the problem spots are, so you know what needs optimization, and then some Android-specific techniques for trying to improve matters.

Your UI Seems... Janky

Sometimes, the speed would be less of an issue for the user, if it was not freezing the UI or otherwise making it appear sluggish and “[janky](#)”.

The Android widget framework operates in a single-threaded mode. All UI changes — from setting the text of a `TextView` to handling scrolling of a `GridView` — are processed as events on an event queue by the main application thread. That same thread is used for most UI callbacks, including activity lifecycle methods (e.g., `onCreate()`) and UI event methods (e.g., `onClick()` of a `Button`, `getView()` of an `Adapter`). Any time you take in those methods on the main application thread tie up that thread, preventing it from processing other GUI events or dispatching user input. For example, if your `getView()` processing in an `Adapter` takes too long, scrolling a `ListView` may appear slow compared to other `ListView` widgets in other applications.

Your objective is to identify where things are slow and move them into background operations. Some of this has been advised since the early days of Android, such as moving all network I/O to background threads. Some of this has arisen more recently, such as the move to use the “loader” framework to help you get data from data stores in the background for populating your UI.

This part of the book will point out ways for you to find out where you may be doing unfortunate things on the main application thread and techniques for getting that work handled by a background thread, or possibly eliminated outright.

Not Far Enough in the Background

Sometimes, even work you are trying to do in the background will seem to impact the foreground.

For example, you might think that your `Service` is automatically in the background. An `IntentService` does indeed use a background thread for processing commands via `onHandleIntent()`. However, all lifecycle methods of any `Service`, including `onStartCommand()`, are called on the main application thread. Hence, any time you take in those lifecycle methods will steal time away from GUI processing for the

main application thread. The same holds true for `onReceive()` of a `BroadcastReceiver` and all the main methods of a `ContentProvider` (e.g., `query()`).

Even your background threads may not be sufficiently in the background. A process runs with a certain priority, using Linux process management APIs, based upon its state (e.g., if there is an activity in the foreground, it runs at a higher priority than if the process solely hosts some service). This will help to cap the CPU utilization of the background work, but only to a point. Similarly, threads that you fork — directly or via something like `IntentService` — may run at default priority rather than a lower priority. Even with lower priorities for the thread or process, every CPU instruction executed in the background is one clock tick that cannot be utilized by the foreground.

This part of the book will help you identify where you are taking lots of time on various threads and will help you manually manage priorities to help minimize the foreground impact of those threads, in addition to helping you reduce the amount of work those threads have to do.

Playing with Speed

Games, more so than most other applications, are highly speed-dependent. Everyone is seeking the “holy grail” of 60 frames per second (FPS) necessary for smooth animated effects. Not achieving that frame rate overall may mean the application will not appear quite as smooth; sporadically falling below that frame rate will result in jerky animation effects, much like the “janky” UIs in a non-game Android application.

For example, a classic problem with Android game development is garbage collection (GC). Only since the Gingerbread release of Android is the garbage collector concurrent, meaning that it runs in tandem with application code on a parallel thread. Historically, the Android garbage collector was a “stop the world” implementation, that would freeze the game long enough for a bit of GC work to be done before the game could continue. This behavior pretty much guaranteed sporadic failures to maintain a consistent frame rate. This caused game developers to have to take particular steps to avoid generating any garbage, such as maintaining its own object pools, to minimize or eliminate garbage collection pauses.

This book does not focus much on specific issues related to game development, though many of the techniques outlined here will be relevant for game developers.

Finding CPU Bottlenecks

CPU issues tend to manifest themselves in three ways:

- The user has a bad experience when using your app directly — scrolling is sluggish, activities take too long to display, etc.
- The user has a bad experience when your app is running in the background, such as having slower frame rates on their favorite game because you are doing something complex in a service
- The user has poor battery performance, driven by your excessive CPU utilization

Regardless of how the issue appears to the user, in the end, it is a matter of you using too much CPU time. That could be simply because your application is written to be constantly active (e.g., you have an everlasting service that uses `TimerTask` to wake up every second and do something). There is little anyone can do to help that short of totally rethinking the app's architecture (e.g., switch to `AlarmManager` and allow the user to configure the polling period).

However, in many cases, the problem is that you are using algorithms – yours or ones built into Android — that simply take too long when used improperly. This chapter will help you identify these bottlenecks, so you know what portions of your code need to be optimized in general or apply the techniques described in later chapters of this part of the book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

Traceview

The #1 tool in your toolbox for finding out where bottlenecks are occurring in your application is Traceview. This is available both within the Eclipse environment — though not as a separate perspective — and as a standalone tool.

What Is Traceview?

Traceview is Android's take on a method profiler. Profilers have existed for most other platforms, in one form or fashion, dating back to the mainframe days.

Technically, the profiling in Android is performed by the Dalvik virtual machine, under the direction of either DDMS or requests from your application code. Dalvik will write the “trace data” (call graphs showing methods, what they call, and the amount of time in each) to a file on external storage of the device or emulator. Traceview then views these trace files in a GUI, allowing you to visualize “hot spots”, drill down to find where the time is being taken, and so forth.

At the time of this writing, Traceview is designed for use on single-core devices. Results on multi-core devices may be difficult to interpret.

Collecting Trace Data

Hence, the first step for finding where your CPU bottlenecks lie comes in the form of collecting trace data, to analyze with Traceview. As mentioned, there are two approaches for requesting trace data be logged: using the Debug class, and using DDMS.

Debug Class

If you know what chunk of code you want to profile, one way to arrange for the profile is to call `startMethodTracing()` on the Debug class. This takes the name of a trace file as a parameter and will begin recording all activity to that file, stored in the root of your external storage. You need to call `stopMethodTracing()` at some point to stop the trace — failing to do so will leave you with a corrupt trace file in the end.

Note that your application will need the `WRITE_EXTERNAL_STORAGE` permission for this to work. If your application does not normally need this permission, make yourself a note to remove it before you ship the production edition of your product, as there is no sense asking for any more permissions than you absolutely need. Also,

your device or emulator will need enough external storage to hold the file, which can get very large for long traces — 100MB a minute is well within reason.

DDMS

Alternatively, you can initiate tracing via a toolbar button in DDMS. In both the DDMS perspective in Eclipse and the standalone DDMS, there is a button in the toolbar above the tree-table of devices and processes that toggles tracing on and off:

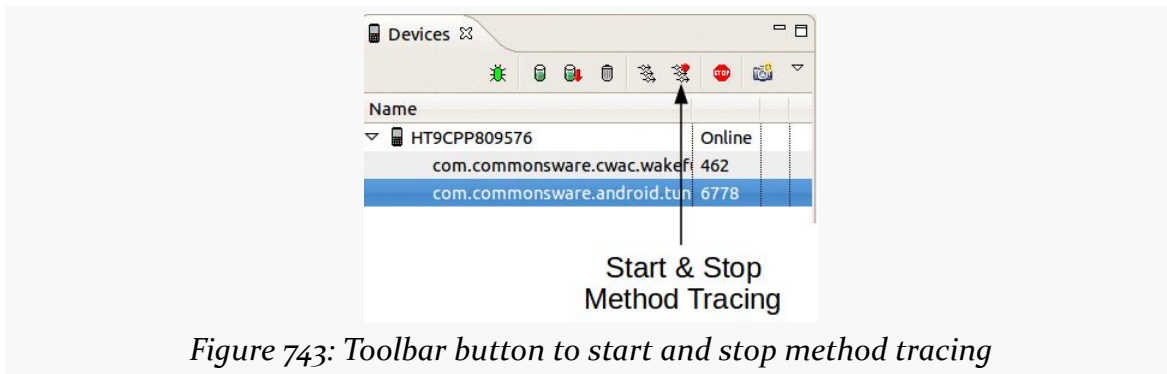

Figure 743: Toolbar button to start and stop method tracing

On Android 2.1 and earlier, this will write the trace out to a file on external storage, much as `startMethodTracing()` does. Hence, your application will need `WRITE_EXTERNAL_STORAGE` in this case, plus have enough external storage space to hold the file.

On Android 2.2 and newer, though, this data is written straight to the development machine, bypassing external storage. This means you do not need to worry about permissions or free space on your external storage. Hence, unless your problem only exists on Android 2.1 and earlier, you may find it easier to do your Traceview work on a newer Android device or emulator image. The file will wind up in your development machine's temporary directory (e.g., `/tmp` on Linux).

Performance While Tracing

Writing out each method invocation to a trace file adds significant overhead to your application. Run times can easily double or more. Hence, absolute times while tracing is enabled are largely meaningless — instead, as you analyze the data in Traceview, the goal is to examine relative times (i.e., such-and-so method takes up X% of the CPU time shown in the trace).

FINDING CPU BOTTLENECKS

Also, running Traceview disables the JIT engine in Dalvik, further harming performance. Notably, this will not affect any native code you have added via the NDK, so an application run in Traceview will give you unusual results (much worse Java performance, more normal native performance).

Displaying Trace Data

Given that we have collected a trace file with data, the next step is to open up Traceview on that file. Depending on how you collected the file, Traceview may appear “automagically”, or it may require you to manually start it up and point it to the trace file.

Eclipse/DDMS

If you used the DDMS perspective in Eclipse to record the trace data, the Debug perspective in Eclipse will automatically open up when you stop the tracing, showing you a Traceview tool:

Figure 744: Debug perspective in Eclipse showing Traceview (middle left)

Standalone Traceview

If you used standalone DDMS and run a trace on Android 2.2 and up, it will automatically launch in the standalone Traceview utility.

If your trace file wound up on external storage on your device or emulator, you will need to download it to your development machine, whether using the File Manager within DDMS, or via the `adb pull` command. Once on your development machine, you can view it in the standalone Traceview tool using the `traceview` command:

```
traceview <path-to-trace-file>
```

Or, you can import the file into your Eclipse project, then double-click on it in the Project Explorer to view it in the Traceview tool.

Interpreting Trace Data

Of course, the challenge is in making sense of what Traceview is trying to present.

For example, a classic performance bug in Java development is using string concatenation:

```
package com.commonware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringConcatActivity extends BaseActivity {
    StringConcatTask createTask(TextView msg, View v) {
        return(new StringConcatTask(msg, v));
    }

    class StringConcatTask extends BaseTask {
        StringConcatTask(TextView msg, View v) {
            super(msg, v);
        }

        protected String doTest() {
            String result="This is a string";

            result+=" -- that varies --";
            result+=" and also has ";
            result+=String.valueOf(4);
            result+=" hyphens in it";

            return(result);
        }
    }
}
```

FINDING CPU BOTTLENECKS

```
}  
}  
}
```

Here is a Traceview screen showing that code executed 100,000 times, as packaged in a StringPerfConcat activity in the [Tuning/Traceview](#) sample project:

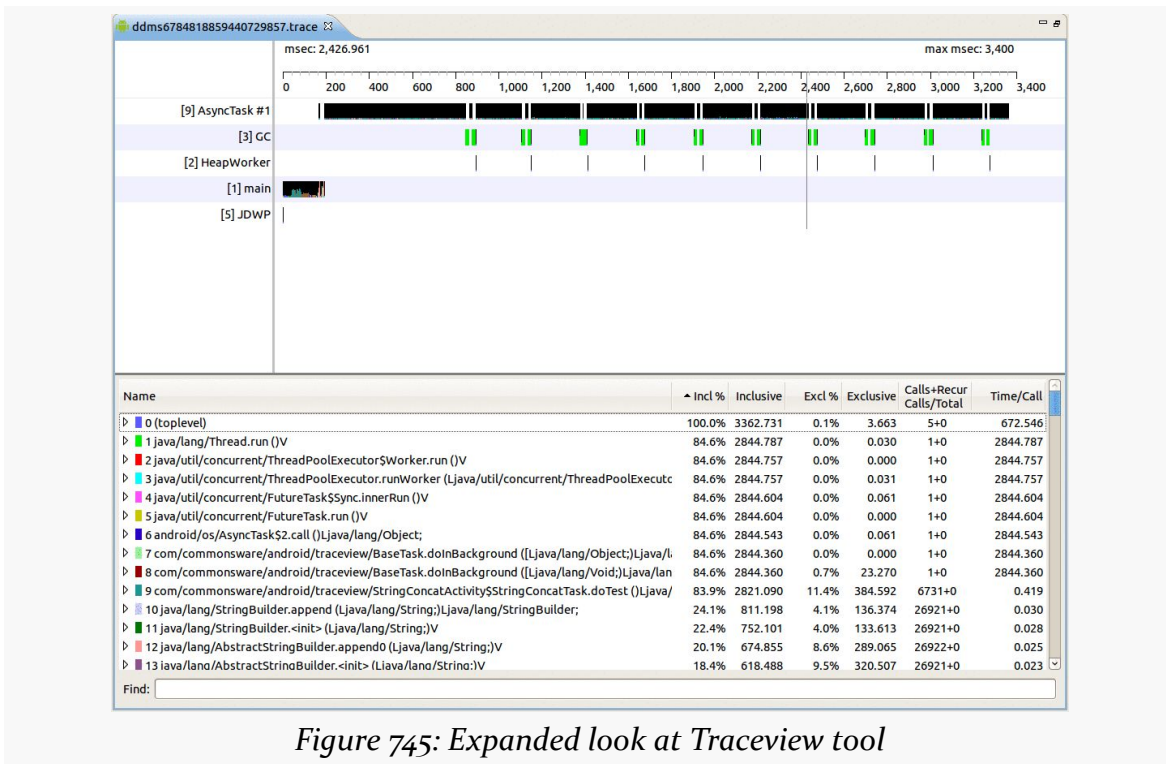

Figure 745: Expanded look at Traceview tool

The bars in the top portion of the display show different threads in the running application, in a timeline fashion, with time running from left to right. The “main” bar shows the main application thread, spending most of its time initializing the activity. The GC and HeapWorker threads are involved in garbage collection, popping in from time to time to collect garbage during 100,000 iterations of the above algorithm. Those 100,000 iterations are run in an AsyncTask, so we do not encounter an application-not-responding (ANR) dialog, and that is the “AsyncTask #1” thread at the top of the diagram.

FINDING CPU BOTTLENECKS

Figure 746: Zoomed in look at the TraceView thread timelines

You will notice that the horizontal timeline bars are not contiguous – there are gaps. In fact, if you were to combine all of the timelines into one, the “holes” in most of the rows would be filled by time in another row. This is illustrating that there is only one core on most Android device CPUs (these images were taken from a test run on a single-core Nexus One). We think of AsyncTask as moving work to the background, but it is important to remember that it still is consuming CPU time, even if the background thread means that we are not tying up the main application thread.

The bottom half of the display shows what methods are taking up all of the time, inclusively, in descending order. By “inclusively”, Traceview means “code executed in this method and any methods it invokes”. Hence, the top “100.0%” line shows the entry point to the whole application, and the next line shows where the AsyncTask’s background thread is being forked, and so on.

Typically, you want to find lines that reference your code. In this case, lines 7–9 are from the `com.commonware` package. Let’s focus on those:

▷	7	com/commonware/android/traceview/BaseTask.doInBackground ([Ljava/lang/Object;)Ljava/l	84.6%	2844.360	0.0%	0.000	1+0	2844.360
▷	8	com/commonware/android/traceview/BaseTask.doInBackground ([Ljava/lang/Void;)Ljava/lan	84.6%	2844.360	0.7%	23.270	1+0	2844.360
▷	9	com/commonware/android/traceview/StringConcatActivity\$stringConcatTask.doTest ()Ljava/	83.9%	2821.090	11.4%	384.592	6731+0	0.419

Figure 747: Sample application method calls in Traceview

On their own, these lines are not especially informative. However, if we fold open the bottom row, using the arrow indicator on the left, we can drill down into what is going on inside that particular method, which happens to be the algorithm shown earlier in this section:

FINDING CPU BOTTLENECKS

Name	▲ Incl %	Inclusive	Excl %	Exclusive	Calls+Recur Calls/Total	Time/Call
8 com/commonsware/android/traceview/BaseTask.doinBackground ([Ljava/lang/Void;)Ljava/lang/	84.6%	2844.360	0.7%	23.270	1+0	2844.360
9 com/commonsware/android/traceview/StringConcatActivity\$stringConcatTask.doTest ()Ljava/	83.9%	2821.090	11.4%	384.592	6731+0	0.419
Parents						
Children						
self	13.6%	384.592				
10 java/lang/StringBuilder.append (Ljava/lang/String;)Ljava/lang/StringBuilder;	28.8%	811.167			26920/26921	
11 java/lang/StringBuilder.<init> (Ljava/lang/String;)V	26.7%	752.101			26921/26921

18 java/lang/String.valueOf (Ljava/lang/Object;)Ljava/lang/String;	7.5%	210.788			26921/26921	
22 java/lang/String.valueOf (I)Ljava/lang/String;	5.0%	142.051			6730/6730	
113 dalvik/system/VMDebug.startClassPrep (I)V	0.0%	0.214			2/25	

Figure 748: Drilling down in Traceview

The “self” line refers to code that is directly executed in the method, not involving a nested method call, such as variable declarations and returning values. We see the `valueOf()` calls, along with three rows showing references to `StringBuilder`. On the surface, that may seem odd, considering that we are not referring to `StringBuilder` in the source code.

It turns out that the `javac` compiler replaces string concatenation with `append()` calls on a `StringBuilder`, created on the fly for that specific concatenation. So, of the 83.9% of the time taken up in the entire run by the `doTest()` method, 26.7% is taken up by creating these temporary `StringBuilder` objects, 28.8% is consumed by calling `append()` on the `StringBuilder`, and another 18.4% is used by calling `toString()` to get the resulting `String` out of the `StringBuilder`.

This suggests an optimization: we could create our own `StringBuilder` and use it for concatenating the text, thereby saving us creating a few temporary ones and calling `toString()` extra times:

```
package com.commonsware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringBuilderActivity extends BaseActivity {
    StringBuilderTask createTask(TextView msg, View v) {
        return(new StringBuilderTask(msg, v));
    }

    class StringBuilderTask extends BaseTask {
        StringBuilderTask(TextView msg, View v) {
            super(msg, v);
        }

        protected String doTest() {
            StringBuilder result=new StringBuilder("This is a string");
```

FINDING CPU BOTTLENECKS

```
    result.append(" -- that varies --");
    result.append(" and also has ");
    result.append(String.valueOf(4));
    result.append(" hyphens in it");

    return(result.toString());
}
}
```

This implementation of the algorithm runs about twice as fast as the first.

The “Exclusive” and “Excl %” columns show how much time is taken in an individual method itself, not including any children. If you sort on that, you see the specific local spots where time is being taken up. For example, here is a Traceview roster from testing the second algorithm shown above (the `StringPerfBuilder` activity):

Name	Incl %	Inclusive	▲ Excl %	Exclusive	Calls+Recur Calls/Total	Time/Call
▶ 11 java/lang/AbstractStringBuilder.append0 (Ljava/lang/String;)V	42.2%	1437.766	16.6%	564.832	48805+0	0.029
▶ 12 java/lang/String._getChars (II[CI)V	15.7%	533.731	10.6%	360.757	61006+0	0.009
▶ 13 dalvik/system/VMDebug.startGC ()V	10.2%	347.656	10.2%	347.656	11+0	31.605

▶ 19 java/lang/StringBuilder.toString ()Ljava/lang/String;	7.1%	240.708	2.0%	66.408	12201+0	0.020

Figure 749: Traceview, sorted by exclusive time

We see that the top three culprits are all Android/Dalvik methods, which we cannot optimize. Instead, the fact that they are taking up so much time is indicative of the fact that we are calling them a lot, also in evidence by the Calls/Total column. You can examine the parents of a call to see where those calls come from, to see if you can change upstream code to result in fewer such calls:

FINDING CPU BOTTLENECKS

Name	Incl %	Inclusive	Excl %	Exclusive	Calls+Recur Calls/Total	Time/Call
11 java/lang/AbstractStringBuilder.append0 (Ljava/lang/String;)V	42.2%	1437.766	16.6%	564.832	48805+0	0.029
Parents						
10 java/lang/StringBuilder.append (Ljava/lang/String;)Ljava/lang/StringBuilder;	100.0%	1437.735			48804/48805	
32 java/lang/IntegralToString.convertInt (Ljava/lang/AbstractStringBuilder;)Ljava/lang/Strii	0.0%	0.031			1/48805	
Children						

Figure 750: Traceview, showing parents of a method call

Here, we can see that all those `append0()` calls are triggered by calls to `append()` on the `StringBuilder`, which is not terribly surprising.

You can also zoom in to take a very narrow look at the data. Simply click-drag a bar in the timeline to select a region to zoom into. The timeline will switch to show just that range of milliseconds and the calls that take place there:

Figure 751: Traceview, zoomed in on ~230 milliseconds of run time

If you zoom in far enough, you will start seeing solid blocks of color, corresponding to the color-coded methods in the table of results on the bottom half of the screen. You can tap on any block of color to bring up that specific method in the table:

FINDING CPU BOTTLENECKS

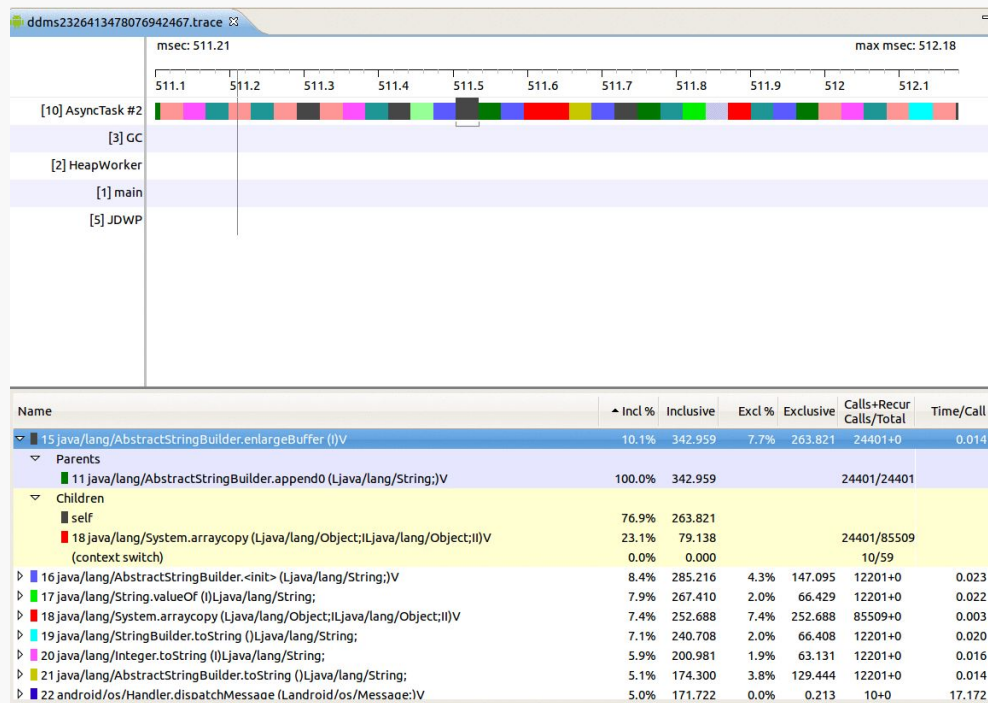

Figure 752: Traceview, zoomed in on ~1 millisecond of run time, highlighting one specific method

Zooming back out, though, is somewhat of a pain. If you drag the timeline itself (not one of the bars, but the “meter stick” showing the milliseconds) from left to right, you will zoom out. Do this enough times, and you can return approximately to the original state.

Other General CPU Measurement Techniques

While Traceview is great for narrowing down a general performance issue to a specific portion of code, it does assume that you know approximately where the problem is, or that you even have a problem in the first place. There are other approaches to help you identify if and (roughly) where you have problems, which you can then attack with Traceview to try to refine.

Logging

Traceview can be useful, if you have a rough idea of where your performance problem lies and need to narrow it down further. If you have a large and complicated application, though, trying to sift through all of it in Traceview may be difficult.

However, there is nothing stopping you from using good old-fashioned logging to get a rough idea of where your problems lie, for further analysis via Traceview. Just sprinkle your code with `Log.d()` calls, logging `SystemClock.uptimeMillis()` with an appropriate label to identify where you were at that moment in time. “Eyeballing” the LogCat output can illustrate areas where unexpected delays are occurring — the areas in which you can focus more time using Traceview.

A useful utility class for this is `TimingLogger`, in the `android.util` package. It will collect a series of “splits” and can dump them to LogCat along with the overall time between the creation of the `TimingLogger` object and the corresponding `dumpToLog()` method call. Note, though, that this will only log to LogCat when you call `dumpToLog()` — all of the calls to `split()` to record intermediate times have their results buffered until `dumpToLog()` is called. Also note that logging needs to be set to `VERBOSE` for this information to actually be logged — use the command `adb shell setprop log.tag.LOG_TAG VERBOSE`, substituting your log tag (supplied to the `TimingLogger` constructor) for `LOG_TAG`.

FPS Calculations

Sometimes, it may not even be strictly obvious how bad the problem is. For example, consider scrolling a `ListView`. Some performance issues, like sporadic “hiccups” in the scrolling, will be visually apparent. However, absent those, it may be difficult to determine whether your particular `ListView` is behaving more slowly than you would expect.

A classic measurement for games is frames per second (FPS). Game developers aim for a high FPS value — 60 FPS is considered to be fairly smooth, for example. However, this sort of calculation can only really be done for applications that are continuously drawing – such as [Romain Guy’s WindowBackground sample application](#). Ordinary Android widget-based UIs are only drawing based upon user interaction or, possibly, upon background updates to data. In other words, if the UI will not even be trying to draw 60 times in a second, trying to measure FPS to get 60 FPS is pointless.

You may be able to achieve similar results, though, simply by logging how long it takes to, say, fling a list (use `setOnScrollListener()` and watch for `SCROLL_STATE_FLING` and other events).

UI “Jank” Measurement

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Sometimes, janky behavior is obvious to all. Sometimes, janky behavior is only noticeable to those sensitive to small hiccups in the UI.

This section will outline what “jank” is and how to determine, concretely, if your UI suffers from it.

What, Exactly, is Jank?

Prior to Android 4.0, it was difficult to come up with a concrete definition of jank. In effect, we were stuck with [“I know it when I see it”](#) ad-hoc analysis, rather than being able to rely on concrete measurements.

Project Butter changed that.

Android 4.0 ties all graphic operations to a 60 frames-per-second “vsync” frequency. If everything is working smoothly, your UI will update 60 times per second, uniformly (versus varying amounts of times between changes).

The converse is also true: if everything is not working smoothly, your UI will not update 60 times per second. This is the source of the term “dropped frames”: when the time came around for an update, you were not ready, and that frame was skipped.

There are two main ways in which you will drop a frame:

1. You spend too much time on the main application thread, preventing Android from processing your requested UI updates in a timely fashion
2. Your UI changes are too complex to be rendered before time runs out for the current frame, causing your changes to spill over into the next frame

Each frame is ~16ms in duration on-screen (1/60th of a second). Hence, if we cause per-frame work to exceed 16ms, we will skip, or “drop”, a frame.

So, what we need is some way to determine if our code is actually delivering frames on time.

Using gfxinfo

To determine if our problem is in the actual rendering of our UI updates, we can use the GPU profiling feature added in Android 4.2.

Enabling Developer Options

To toggle on GPU profiling, you will need to be able to get to the Developer Options portion of your Settings app. If you see this — typically towards the bottom of the list on the initial Settings screen — just tap on the entry.

If, however, Developer Options is missing, then you will need to use the super-secret trick for enabling Developer Options:

1. Tap on “About Phone”, “About Tablet”, or the equivalent at the bottom of your Settings list
2. Tap on the “Build Number” entry seven times in succession
3. Press BACK, and “Developer Options” should now be in the list

Toggling on GPU Profiling

There are two checkboxes in Developer Options that need to be checked for GPU profiling to be enabled.

The first is “Force GPU rendering”, in the Drawing section. As the name suggests, this will force your application to use the GPU for drawing, even if your application may have requested that hardware acceleration be disabled. Since most applications do not force hardware acceleration to be disabled, this checkbox probably will have no real effect on your app. Note that if you disabled hardware acceleration due to specific rendering problems, this checkbox will probably cause those rendering artifacts to re-appear during your testing.

The second is “Profile GPU rendering”, in the Monitoring section. This will cause the device to keep track of graphics performance on a per-process basis, in a way that we can dump later on.

Figure 753: Developer Options, Showing “Force GPU rendering” and “Profile GPU rendering”

If your app was already running, you will need to get rid of its process (e.g., via swiping it off the recent-tasks list) after you check the “Profile GPU rendering” checkbox. At the present time, whether or not this profiling takes effect is determined at process startup time and is not changed on the fly when you toggle the checkbox. Besides, as noted above, starting with a fresh process should give you more accurate results.

Collecting Data

At this point, you can run your app and conduct your specific test, whether manually or via instrumentation (e.g., a targeted [JUnit test suite](#)).

When complete, run `adb shell dumpsys gfxinfo ...` in a terminal window, where ... is replaced by the package name of your app (e.g., `com.commonware.android.anim.threepane`). This will dump a fair amount of information to the terminal display:

```
mmurphy@xps15:~$ adb shell dumpsys gfxinfo com.commonware.android.anim.threepane
Applications Graphics Acceleration Info:
```

Total DisplayList:  4.48 kB
```

We will discuss what this means in just a bit.

Disabling GPU Profiling

When you are done with your test, it is a good idea to undo the settings changes you made, at least “Profile GPU rendering”. That way, the act of collecting this data does not itself add overhead to unrelated tests in the future.

Analyzing the Results

The key bit for our performance analysis is that long table labeled “Profile data in ms:”. This reports, for a series of UI requests, how much time is spent:

- drawing your UI changes (e.g., `onDraw()` calls to various widgets and containers)
- processing the low-level drawing commands created via the draw phase, to create the contents of the frame
- executing the frame, sending it to the compositor to display on the screen

One way to interpret this table is to paste it into your favorite spreadsheet program, then use that program to draw a stacked column chart of the data. You can [download a spreadsheet](#) in ODS format (for use with LibreOffice, OpenOffice, or other tools that can handle that format) that contains the above table along with a stacked column chart:

Figure 754: gfxinfo Output, In Stacked Column Chart

What you are looking for are columns that come close to, or exceed, the 16ms mark, with milliseconds on the Y axis. As you can see, many operations towards the end of the table are near or above 16ms, indicating that we are probably dropping some frames.

Using systrace

Another way we could determine whether or not we are dropping frames is to use systrace to collect system-level tracing information about the entire device, including our app.

systrace is a very powerful tool, one that 20 or 30 people on the planet truly understand, due to cryptic output and limited documentation. Using gfxinfo for detecting dropped frames is simple by comparison. On the other hand, systrace works for Android 4.1 and higher, versus the Android 4.2 requirement of gfxinfo.

Using systrace involves collecting a trace, which is saved in the form of an HTML file. The HTML file is then used to determine what went on during the period of the trace itself.

Enabling and Collecting a Trace: Command-Line

The original means of using systrace was from the command line. There is a systrace.py Python script located in the tools/systrace/ directory of your SDK installation. If you have a Python interpreter (e.g., your development machine does not run Windows), you can use this approach.

To indicate what specific bits of information to collect, on Android 4.2 and higher, you can tap the “Enable traces” entry in the Monitoring section of the Developer Options page in Settings. This displays a multi-select dialog of the possible major categories of information that systrace should collect:

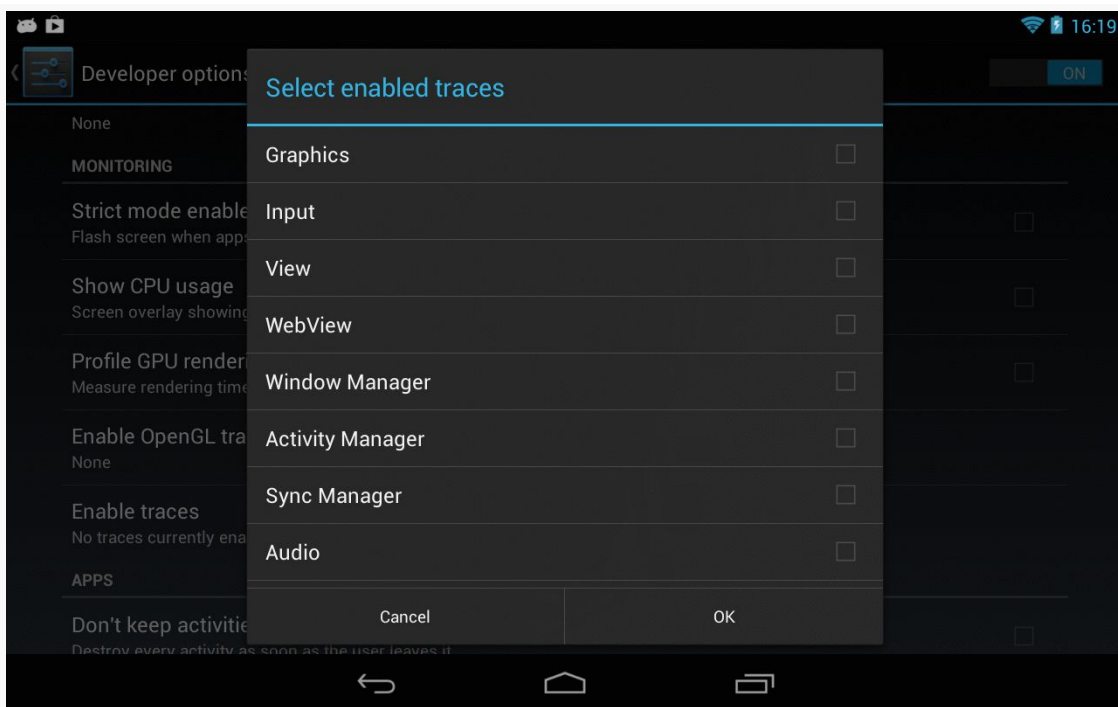

Figure 755: “Enable traces” In Settings

Alternatively, when you run the `systrace.py` script, you can include the `--set-tags` switch, with a comma-delimited list of specific traces (“tags”) that you want to collect. The list of available tag names can be found in [the developer documentation](#).

To actually collect the trace, you run the `systrace.py` script, optionally with `--set-tags` or other command-line switches.

On Android 4.1 and 4.2, this would look like:

```
python systrace.py --set-tags gfx,view,wm
adb shell stop
adb shell start
python systrace.py --time=10 -o trace.html
```

The first `python` command runs `systrace.py` just to set the tags to collect. If you set them using Developer Options in Settings, this would not be required. Restarting `adb shell` is apparently needed, for unclear reasons. The second `systrace.py` run will actually collect the trace, for 10 seconds (`--time=10`), resulting in report written to `trace.html` in the current working directory (`-o trace.html`).

FINDING CPU BOTTLENECKS

The syntax changed for Android 4.3 and higher to simplify matters, combining the two `systrace.py` commands into one:

```
python systrace.py --time=10 -o trace.html gfx view sched wm
```

Note that `--set-tags` is no longer used. Instead, all values not identified by a switch are considered to be tags.

Once you run the script, quickly go to your device and run your test scenario, as the trace starts immediately upon running the script.

Enabling and Collecting a Trace: Eclipse/Monitor

The current version of the ADT plugin for Eclipse also allows you to collect a trace using `systrace`. There is a “Capture system wide trace using `systrace`” button in the toolbar in the Devices view, typically found in the DDMS perspective:

Figure 756: Systrace Toolbar Button in Devices View

This is also available in the same view from the standalone `monitor` utility, and from Android Studio.

Tapping that toolbar button brings up a dialog that allows you to configure the trace you wish to collect, with checkboxes and fields replacing the variety of command-line switches you might use manually with `systrace.py`:

FINDING CPU BOTTLENECKS

Figure 757: Systrace Dialog in Eclipse

Notable settings that you will wish to tailor include:

- Where the trace will be written (by default, as `trace.html` in your home or user directory)
- The duration of the trace
- Which trace tags you wish to use

Clicking OK will then initiate the trace collection, at which point you will want to go to your test device and run through your test scenario.

Choosing the Trace Tags

All of these instructions have been telling you to specify what systrace tags to collect when you collect the trace data. So, what should you collect?

The big four are:

- `sched` for CPU scheduling
- `gfx` for graphics
- `view` for widget rendering

- `wm` for window management

Apps using `WebView` might consider the `webview` tag. There are [a variety of other tags](#) as well that you might find useful for one analysis or another. However, be careful not to request “everything but the kitchen sink”, as it may make your reports difficult to interpret.

Also note that not all devices support all tags. `python systrace.py --list-categories` should tell you what is possible for your connected device.

Augmenting the Trace from Java

You can effectively add your own tag to the output in Java code, to flag key sections of application processing and see where they fall in the report’s timeline. To do this:

- Add calls to `Trace.beginSection()` and `Trace.endSection()` in your API Level 18+ app. Here, `Trace` is `android.os.Trace`, and `beginSection()` takes a `String` parameter that you would like to have logged. Note that these calls can nest, so you can have one section inside of another, but `endSection()` closes the last-begun section. Hence, make sure that your `beginSection()` and `endSection()` calls match up, typically by using `try/finally` exception handling. Also, your `beginSection()` and `endSection()` calls must match up in terms of threads — you cannot begin a section on one thread and end it on another.
- Add the `--app` switch to name your application’s package if you are running `systrace` from the command line. Or, in DDMS, choose your application in the “Enable Application Traces from” drop-down list.

Viewing and Interpreting the Results

What you get as output is an HTML file that can be viewed in the Chrome browser, though you will tend to want to use a development machine for this instead of, say, an Android tablet. That is because the navigation of the Web page is designed for use with a hardware QWERTY keyboard, which most Android devices lack.

You can find [a sample trace](#) from a Nexus 7 online, though note that the HTML is a bit large and may take a few seconds to download. Initially, you will see something like this:

FINDING CPU BOTTLENECKS

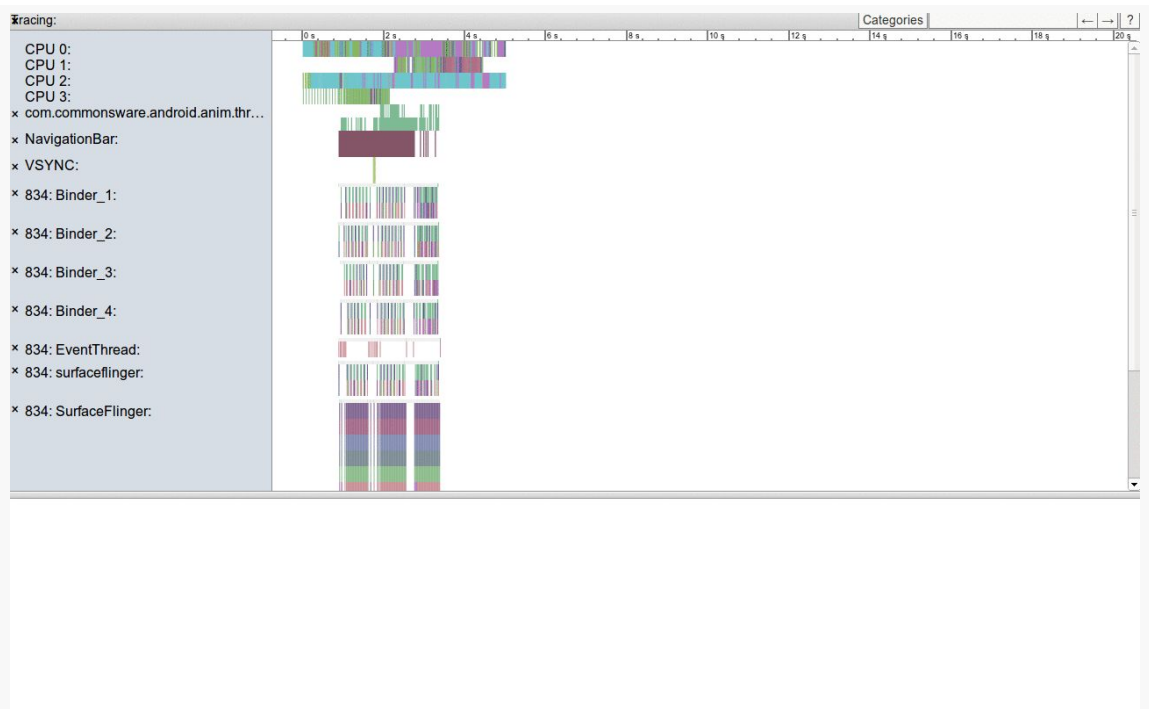

Figure 758: Systrace Output, As Initially Viewed

The left-hand sidebar represents various categories (or “slices” or “tags” or whatever) of data collected by systrace. The main area shows a timeline for the test, with rows corresponding to the sidebar entries for what was occurring at the various times for that particular category. The bottom pane will hold details that will appear when you click on various little blocks within that timeline.

Mostly, your navigation will use the W, A, S, and D keys, presumably chosen to make it appear as though you are playing a video game. Specifically:

- W will zoom in the timeline, while S will zoom out
- A and D will pane the timeline left and right

Jank will show up as gaps in the SurfaceFlinger:

FINDING CPU BOTTLENECKS

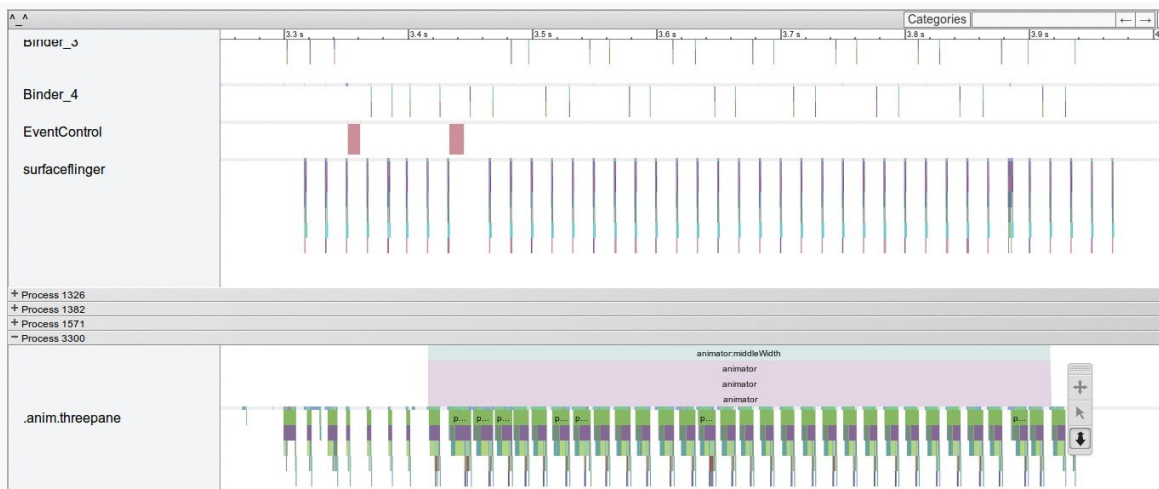

Figure 759: Systrace Output, Zoomed In on 0.7 Seconds of Profiling

Each of the major ticks across the timeline represents 0.1 seconds. There should be six frames in those seconds. However, we can see that in the 3.4–3.5 second range, there is a dropped frame, which shows up as a gap where there should be a pulse of SurfaceFlinger activity.

Zooming in further starts to bring up some detail for the threads in our process, showing methods within the view processing hierarchy that we were working on during this period of time:

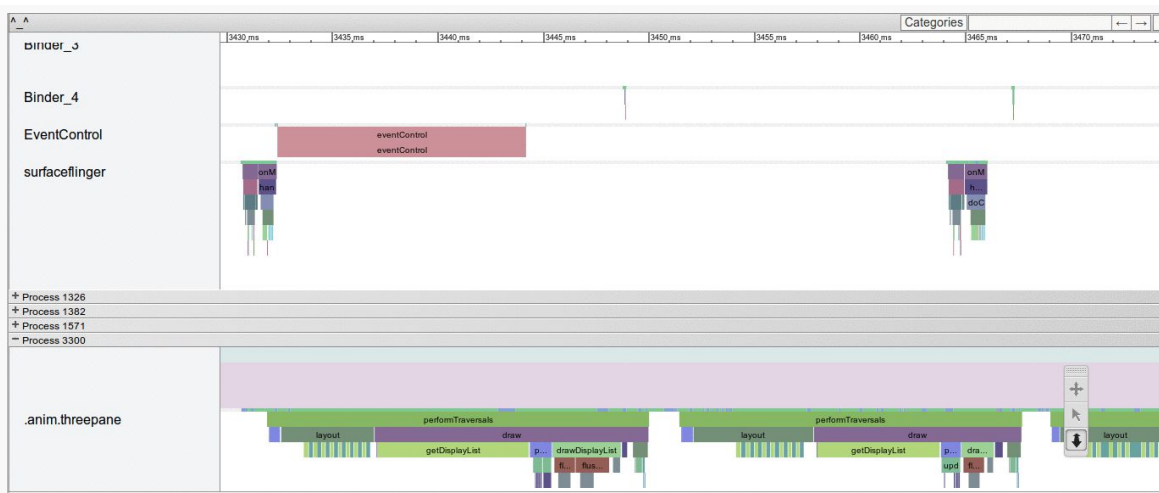

Figure 760: Systrace Output, Zoomed In on 40 Milliseconds of Profiling

In our `gfx/view` slice, we will see various blocks for different major operations in the rendering of our UI. Notably, you will see blocks labeled “performTraversals”, referring to the private `performTraversals()` method on `ViewRootImpl`. It turns out that `performTraversals()` wraps around all of the work shown in the three columns of our `gfxinfo` output: draw, process, and execute. The widths of the “performTraversals” blocks in the `systrace` output shows us how long each of those takes. What we want are nice, short blocks. Instead, panning through our trace, you will see several that are too long. [The chapter on “jank busting”](#) will go into further analysis of where this particular sample application went wrong that caused this behavior.

Focus On: NDK

When Android was first released, many a developer wanted to run C/C++ code on it. There was little support for this, other than by distributing a binary executable and running it via a forked process. While this works, it is a bit cumbersome, and the process-based interface limits how cleanly your C/C++ code could interact with a Java-based UI. On top of all of that, the use of such binary executables is not well supported.

In June 2009, the core Android team released the Native Development Kit (NDK). This allows developers to write C/C++ for Android applications in a supported fashion, in the form of libraries linked to a hosting Java-based application via the Java Native Interface (JNI). This offers a wealth of opportunities for Android development, and this part of the book will explore how you can take advantage of the NDK to exploit those opportunities.

This chapter explains how to set up the NDK and apply it to your project. What it does not do is attempt to cover all possible uses of the NDK — game applications in particular have access to many frameworks, like OpenGL and OpenSL, that are beyond the scope of this book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

This chapter also assumes that you know C/C++ programming.

The Role of the NDK

We start by examining Dalvik's primary limitation — speed. Next, we look at the reasons one might choose the NDK, speed among them. We wrap up with some reasons why the NDK may not be the right solution for every Android problem, despite its benefits.

Dalvik: Secure, Yes; Speedy, Not So Much

Dalvik was written with security as a high priority. Android's security architecture is built around Linux's user model, with each application getting its own user ID. With each application's process running under its own user ID, one process cannot readily affect other processes, helping to contain any single security flaw in an Android application or subsystem. This requires a fair number of processes. However, phones have limited RAM, and the Android project wanted to offer Java-based development. Multiple processes hosting their own Java virtual machines simply could not fit in a phone. Dalvik's virtual machine is designed to address this, maximizing the amount of the virtual machine that can be shared securely between processes (e.g., via “copy-on-write”).

Of course, it is wonderful that Android has security so woven into the fabric of its implementation. However, inventing a new virtual machine required tradeoffs, and most of those are related to speed.

A fair amount of work has gone into making Java fast. Standard Java virtual machines do a remarkable job of optimizing applications on the fly, such that Java applications can perform at speeds near their C/C++ counterparts. This borders on the amazing and is a testament to the many engineers who put countless years into Java.

Dalvik, by comparison, is very young. Many of Java's performance optimization techniques — such as advanced garbage collection algorithms — simply have not been implemented to nearly the same level in Dalvik. This is not to say they will never exist, but it will take some time. Even then, though, there may be limits as to how fast Dalvik can operate, considering that it cannot “throw memory at the problem” to the extent Java can on the desktop or server.

If you need speed, Dalvik is not the answer today, and may not be the answer tomorrow, either.

Going Native

Java-based Android development via Dalvik and the Android SDK is far and away the option with the best support from the core Android team. HTML5 application development is another option that was brought to you by the core Android development team. The third leg of the official Android development triad is the NDK, provided to developers to address some specific problems, outlined below.

Speed

Far and away the biggest reason for using the NDK is speed, pure and simple. Writing in C/C++ for the device's CPU will be a major speed improvement over writing the same algorithms in Java, despite Android's just-in-time (JIT) compiler.

There is overhead in reaching out to the C/C++ code from a hosting Java application, and so for the best performance, you will want a coarse interface, without a lot of calls back and forth between Java and the native opcodes. This may require some redesign of what might otherwise be the “natural” way of writing the C/C++ code, or you may just have to settle for less of a speed improvement. Regardless, for many types of algorithms — from cryptography to game AI to video format conversions — using C/C++ with the NDK will make your application perform much better, to the point where it can enable applications to be successful that would be entirely too slow if written solely in Java.

Bear in mind, though, that much of what you think is Java code in your app really is native “under the covers”. Many of the built-in Android classes are thin shims over native implementations. Again, focus on applying the NDK where you are performing lots of work yourself in Java code that might benefit from the performance gains.

Porting

You may already have some C/C++ code, written for another environment, that you would like to use with Android. That might be for a desktop application. That might be for another mobile platform, such as iOS, where C/C++ is an option. That might be for mobile platform, such as Symbian, where C/C++ is the conventional solution, rather than some other language. Regardless, so long as that code is itself relatively platform-independent, it should be usable on Android.

This may significantly streamline your ability to support multiple platforms for your application, even if down-to-the-metal speed is not really something you necessarily need. This may also allow you to reuse existing C/C++ code written by others, for image processing or scripting languages or anything else.

Knowing Your Limits

Developers love silver bullets. Developers are forevermore seeking The One True Approach to development that will be problem-free. Sisyphus would approve, of course, as development always involves tradeoffs. So while the NDK's speed may make it tantalizing, it is not a solution for general Android application development, for several reasons, explored in this section.

Android APIs

The biggest issue with the NDK is that you have very limited access to Android itself. There are a few libraries bundled with Android that you can leverage, and a few other APIs offered specifically to the NDK, such as the ability to render OpenGL 3D graphics. But, generally speaking, the NDK has no access to the Android SDK, except by way of objects made available to it from the hosting application via JNI.

As such, it is best to view the NDK as a way of speeding up particular pieces of an SDK application — game physics, audio processing, OCR, and the like. All of those are algorithms that need to run on Android devices with data obtained from Android, but otherwise are independent of Android itself.

Cross-Platform Compatibility

While C/C++ *can* be written for cross-platform use, often it is not.

Sometimes, the disparity is one of APIs. Any time you use an API from a platform (e.g., iPhone) or a library (e.g., Qt) not available on Android, you introduce an incompatibility. This means that while a lot of your code — measured in terms of lines — may be fine for Android, there may be enough platform-specific bits woven throughout it that you would have a significant rewrite ahead of you to make it truly cross-platform.

Android itself, though, has a compatibility issue, in terms of CPUs. Android mostly runs on ARM devices today, since Android's initial focus was on smartphones, and ARM-powered smartphones at that. However, the focus on ARM will continue to

waver, particularly as Android moves into other devices where other CPU architectures are more prevalent, such as Atom or MIPS for set-top boxes. While your code may be written in a fashion that works on all those architectures, the binaries that code produces will be specific to one architecture. The NDK gives you additional assistance in managing that, so that your application can simultaneously support multiple architectures.

Right now, the NDK supports ARM, x86, and MIPS CPU architectures. Of these, ARM CPUs power the *vast* majority of Android devices. The first generation of Google TV boxes, and a few other devices, use Intel x86 CPUs (usually Atom-based). MIPS is a relative newcomer to Android, with few devices using such CPUs at this time.

NDK Installation and Project Setup

The Android NDK is blissfully easy to install, in some ways even easier than is the Android SDK. Similarly, setting up an NDK-equipped project is rather straightforward. However, the documentation for the NDK is mostly a set of text files (OVERVIEW.TXT prominent among them). These are well-written but suffer from the limits of the plain-text form factor, plus are focused strictly on the NDK and not the larger issue of Android projects that use the NDK.

This chapter will fill in some of those gaps.

Installing the NDK

As with the Android SDK, the [Android NDK comes in the form of a ZIP or tar .gz file](#), containing everything you need to build NDK-enabled Android applications. Hence, setting up the NDK is fairly trivial, particularly if you are developing on Linux.

Prerequisites

You will need the GNU `make` and GNU `awk` packages installed. These may be part of your environment already. For example, in Ubuntu, run `sudo apt-get install make gawk`, or use the Software Center, to ensure you have these two packages.

While you can do NDK development directly on Linux or OS X, NDK development on Windows can only be done using the [Cygwin](#) environment. This gives you a Linux-style shell and Linux-style tools on a Windows PC. In addition to a base

Cygwin 1.7 (or newer) installation, you will need the make and gawk Cygwin packages installed in Cygwin.

If you encounter difficulties with Cygwin, you may wish to consider whether running Linux in a virtualization environment (e.g., [VirtualBox](#)) might be a better solution for you.

Download and Unpack

The Android NDK per-platform (Linux/OS X/Windows) ZIP files can be downloaded from the [NDK page](#) on the Android Developers site. These ZIP files are not small (~50MB each), because they contain the entire toolchain — that is why there are so few prerequisites.

You are welcome to unpack the ZIP file anywhere it makes sense on your development machine. However, putting it *inside* the Android SDK directory may not be a wise move — a peer directory would be a safer choice. You are welcome to rename the directory if you choose.

Environment Variables

The NDK documentation will cite an NDK environment variable, set to point to the directory in which you unpacked the NDK. This is a documentation convention and does not appear to be required for actual use of the NDK, though it is not a bad idea. You could also consider adding the NDK directory to your PATH, though that too is not required.

Bear in mind that you will be using the NDK tools from the command line, and so being able to conveniently reference this directory is reasonably important.

Setting Up an NDK Project

At its core, an NDK-enhanced Android project is a regular Android project. You still need a manifest, layouts, Java source code, and all the other trappings of a regular Android application. The NDK simply enables you to add C/C++ code to that project and have it included in your builds, referenced from your Java code via the Java Native Interface (JNI).

The examples shown in this section are from the [JNI/WeakBench](#) sample project, which implements a pair of benchmarks in Java and C, to help demonstrate the performance differences between the environments.

Writing Your C/C++ Code

The first step towards adding NDK code to your project is to create a `jni/` directory and place your C/C++ code inside of it. While there are ways to use a different base directory, it is unclear why you would need to. How you organize the code inside of `jni/` is up to you. C++ code should use `.cpp` as file extensions, though this too is configurable.

Your C/C++ code will be made up of two facets:

- The code doing the real work
- The code implementing your JNI interface

If you have never used JNI before, JNI uses naming conventions to tie functions in a C/C++ library to their corresponding hooks in the Java code.

For example, in the WeakBench project, you will find `jni/weakbench.c`:

```
#include <stdlib.h>
#include <math.h>
#include <jni.h>

typedef unsigned char boolean;

static void nsieve(int m) {
    unsigned int count = 0, i, j;
    boolean * flags = (boolean *) malloc(m * sizeof(boolean));
    memset(flags, 1, m);

    for (i = 2; i < m; ++i)
        if (flags[i]) {
            ++count;
            for (j = i << 1; j < m; j += i)
                if (flags[j])
                    flags[j] = 0;
        }

    free(flags);
}

void
Java_com_commonware_android_tuning_weakbench_WeakBench_nsievenative( JNIEnv*
env,
```

```
thiz )
{
    int i=0;
    for (i = 0; i < 3; i++)
        nsieve(10000 << (9-i));
}

double eval_A(int i, int j) { return 1.0/((i+j)*(i+j+1)/2+i+1); }

void eval_A_times_u(int N, const double u[], double Au[])
{
    int i,j;
    for(i=0;i<N;i++)
    {
        Au[i]=0;
        for(j=0;j<N;j++) Au[i]+=eval_A(i,j)*u[j];
    }
}

void eval_At_times_u(int N, const double u[], double Au[])
{
    int i,j;
    for(i=0;i<N;i++)
    {
        Au[i]=0;
        for(j=0;j<N;j++) Au[i]+=eval_A(j,i)*u[j];
    }
}

void eval_AtA_times_u(int N, const double u[], double AtAu[])
{ double v[N]; eval_A_times_u(N,u,v); eval_At_times_u(N,v,AtAu); }

void
Java_com_commonsware_android_tuning_weakbench_WeakBench_specnative( JNIEnv* env,
                                                                    jobject
thiz )
{
    int i;
    int N = 1000;
    double u[N],v[N],vBv,vv;
    for(i=0;i<N;i++) u[i]=1;
    for(i=0;i<10;i++)
    {
        eval_AtA_times_u(N,u,v);
        eval_AtA_times_u(N,v,u);
    }
    vBv=vv=0;
    for(i=0;i<N;i++) { vBv+=u[i]*v[i]; vv+=v[i]*v[i]; }
}
```

Much of the code shown here comes from the [Great Language Benchmarks Game](#), specifically their `nsieve` and `spectral-norm` benchmarks. And, much of the code looks like normal C code.

Two functions, though, serve as JNI entry points:

- `Java_com_commonware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonware_abj_weakbench_WeakBench_specnative`

As will be seen later in this section, these will map to `nsievenative()` and `specnative()` methods on a `com.commonware.abj.weakbench.WeakBench` class. The Java class (with package) and method names are converted into a function call name, so JNI can identify the function at runtime.

The implementation of these methods do not make use of any Java objects, nor do they return anything — they just implement the benchmark.

Writing Your Makefile(s)

To tell the NDK tools how to build your code, you will need one or two makefiles.

Android.mk

This makefile will describe the “module” (library) that you are attempting to add to your Android project by way of the NDK. In it, you will specify the source files that should be compiled and linked into the module. This file, by default, resides in the root of your `jni/` directory.

For example, here is `jni/Android.mk` from the `WeakBench` project:

```
LOCAL_PATH := $(call my-dir)

include $(CLEAR_VARS)

LOCAL_MODULE     := weakbench
LOCAL_SRC_FILES  := weakbench.c

include $(BUILD_SHARED_LIBRARY)
```

Here, we give the module a name (`weakbench`) and identify the source files that go into it (`weakbench.c`).

It is possible for you to have multiple `Android.mk` files, in multiple subdirectories of `jni/`, to create multiple modules. There is an `ANDROID-MK.TXT` file in the NDK documentation directory that provides more detail on how you can configure complex scenarios like this one.

Application.mk

There is a separate, optional, makefile that you can have, `Application.mk`, in your `jni/` directory. This is where you can provide compile flags for the build process, which CPU architectures (ARM, x86, etc.) you wish to support, and so on. By default, if you do not have such a file, the NDK build tools will include all modules defined in your `Android.mk` file(s) in your project, compiled for a generic ARM target with software support for floating-point operations.

For basic NDK applications, skipping `Application.mk` is a reasonable choice. Complex projects, or ones specifically aiming to support other CPU architectures (e.g., ARM-v7 CPUs with hardware floating-point support), will need an `Application.mk` file.

The `WeakBench` project has a one-line `Application.mk` file:

```
APP_ABI := all
```

This tells Android that we want to build the JNI code for all supported CPU architectures. At the time of this writing, that is ARMv5, ARMv7, and x86.

Building Your Library

Any time you modify your C/C++ code, or the makefiles, you will need to build your NDK library. To do that, from a command prompt in your project's root directory, run the `ndk-build` script found in the NDK's root directory. In other words, if you set up an NDK environment variable to point to where you have the NDK installed, execute `$NDK/ndk-build` from your project root.

This will compile and link your C/C++ code into a library (or conceivably several libraries, if you have a complex set of `Android.mk` files). These will wind up in your project's `libs/` directory, in subdirectories based on your CPU architectures indicated by your `Application.mk` file.

For example, if you run `$NDK/ndk-build` from the WeakBench project root, you will wind up with a `libs/armeabi/libweakbench.so` file. The `armeabi` portion is because that is the default CPU architecture that the NDK supports, and WeakBench did not change the defaults via an `Application.mk` file. The “weakbench” portion of `libweakbench.so` is because our `LOCAL_MODULE` value in our `Android.mk` file is `weakbench`. The `lib` prefix is automatically added by the build tools. The `.so` file extension is because our `Android.mk` file indicated that we are building a shared library (via the `BUILD_SHARED_LIBRARY` directive), and `.so` is the standard file extension for shared libraries in Linux (and, hence, Android).

Note that you will also wind up with similar `.so` files in `libs/armeabi-v7a/` and `libs/x86` for those architectures.

You are welcome to add this to your build process, such as adding it to your Ant build script, though it is not automatically included in the build process as defined by Android.

Using Your Library Via JNI

Now that you have your base C/C++ code being successfully compiled by the NDK, you need to turn your attention towards crafting the bridge between the Dalvik VM and the C/C++ code, following in the conventions of the Java Native Interface (JNI).

This section, while explaining the various steps involved in using the JNI, is far from a complete treatise on the subject. If you are going to spend a lot of time working with JNI, you are encouraged to seek additional resources on this topic, such as [Core Java: Volume II](#), which has a chapter on JNI.

We created two C functions for accessing benchmarks:

- `Java_com_commonware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonware_abj_weakbench_WeakBench_specnative`

Those, in turn, need to be defined as static methods on a `com.commonware.abj.weakbench.WeakBench` class. Moreover, these methods will need to have the `native` keyword, indicating that their implementation is not found in Java code, but in native C/C++ code. The naming convention of the C functions allows the Dalvik runtime to identify what function names should be used for those native method implementations.

However, that alone will be insufficient — we need to tell Dalvik where it can find the library in the first place. While naming conventions are good enough for the C function names, there is no corresponding naming convention for the library itself.

To do this, we use the `loadLibrary()` static method on the `System` class. A class implementing native methods should call `loadLibrary()` in a static block, so it is executed when the class is first referenced. For the NDK, all we need to do is supply the name we gave the library in the `Android.mk` file.

Here is the portion of the `WeakBench` class that has the native methods and the `loadLibrary()` call:

```
static {
    System.loadLibrary("weakbench");
}

public native void nsievenative();
public native void specnative();
```

Now, we can call our `nsievenative()` and `specnative()` methods on `WeakBench`, just as if they were regular Dalvik methods on a regular Dalvik class. The fact that they are really going off and invoking C functions is purely “implementation detail” that the consumers of those methods can be blissfully unaware of.

`WeakBench` itself is an `Activity`, invoking both Dalvik and native implementations of these two benchmarks. It uses a series of `AsyncTask` objects for executing the benchmarks on background threads, then updates `TextView` widgets in the UI to show the results:

```
package com.commonware.android.tuning.weakbench;

import android.app.Activity;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.SystemClock;
import android.widget.TextView;

public class WeakBench extends Activity {
    static {
        System.loadLibrary("weakbench");
    }

    public native void nsievenative();
    public native void specnative();

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);
setContentView(R.layout.main);

new JavaSieveTask().execute();
}

/*
 * Code after this point is adapted from the Great Computer Language
 * Shootout. Copyrights are owned by whoever contributed this stuff,
 * or possibly the Shootout itself, since there isn't much information
 * on ownership there. Licensed under a modified BSD license.
 */

private class JavaSieveTask extends AsyncTask<Void, Void, Void> {
    long start=0;
    TextView result=null;

    @Override
    protected void onPreExecute() {
        result=(TextView)findViewById(R.id.nsieve_java);

        result.setText("running...");
    }

    @Override
    protected Void doInBackground(Void... unused) {
        start=SystemClock.uptimeMillis();

        int n=9;
        int m=(1<<n)*10000;
        boolean[] flags=new boolean[m+1];

        nsieve(m, flags);

        m=(1<<n-1)*10000;
        nsieve(m, flags);

        m=(1<<n-2)*10000;
        nsieve(m, flags);

        return(null);
    }

    @Override
    protected void onPostExecute(Void unused) {
        long delta=SystemClock.uptimeMillis()-start;

        result.setText(String.valueOf(delta));
        new JavaSpecTask().execute();
    }
}

private class JavaSpecTask extends AsyncTask<Void, Void, Void> {

    double[] u = new double[n];
    for (int i=0; i<n; i++) u[i] = 1;

    // 20 steps of the power method
    double[] v = new double[n];
    for (int i=0; i<n; i++) v[i] = 0;

    for (int i=0; i<10; i++) {
        MultiplyAtAv(n,u,v);
    }
}
```

```
        MultiplyAtAv(n,v,u);
    }

    // B=AtA      A multiplied by A transposed
    // v.Bv/(v.v)  eigenvalue of v
    double vBv = 0, vv = 0;
    for (int i=0; i<n; i++) {
        vBv += u[i]*v[i];
        vv  += v[i]*v[i];
    }

    return Math.sqrt(vBv/vv);
}

/* return element i,j of infinite matrix A */
private final double A(int i, int j){
    return 1.0/((i+j)*(i+j+1)/2 +i+1);
}

/* multiply vector v by matrix A */
private final void MultiplyAv(int n, double[] v, double[] Av){
    for (int i=0; i<n; i++){
        Av[i] = 0;
        for (int j=0; j<n; j++) Av[i] += A(i,j)*v[j];
    }
}

/* multiply vector v by matrix A transposed */
private final void MultiplyAtv(int n, double[] v, double[] Atv){
    for (int i=0; i<n; i++){
        Atv[i] = 0;
        for (int j=0; j<n; j++) Atv[i] += A(j,i)*v[j];
    }
}

/* multiply vector v by matrix A and then by matrix A transposed */
private final void MultiplyAtAv(int n, double[] v, double[] AtAv){
    double[] u = new double[n];
    MultiplyAv(n,v,u);
    MultiplyAtv(n,u,AtAv);
}
}
```

As with our C implementations of the benchmarks, the Java source code is derived from the [Great Language Benchmarks Game](#).

Building and Deploying Your Project

Given that you have done all of this, the rest is perfectly normal – you build and deploy your Android project no differently than if you did not have any C/C++ code.

Your native library is embedded in your APK file, so you do not have to worry about distributing it separately.

However, bear in mind that the more architectures you choose, the more .so files there are and the bigger your app will be. For tiny bits of C/C++ code, like the code in this app, this increase in file size will not be very noticeable. However, it is something to keep in mind for more elaborate NDK applications. Moreover, there are some ways to help reduce the impact of these extra architectures.

libhoudini and the NDK

libhoudini is a proprietary ARM translation layer for x86-powered Android devices. It allows an app that has NDK binaries for ARM, but not x86, to still run on x86 hardware, albeit not as quickly as it would with native x86 binaries.

Given ARM's current dominance in the Android ecosystem, libhoudini is hugely useful for Intel and hardware vendors interested in using Intel's mobile CPUs. Without it, only apps that ship x86 NDK binaries would be compatible with x86-powered devices like the Samsung Galaxy Tab 3 10.1" tablet. Some developers probably skip x86 NDK binaries, because they are not aware of popular x86-powered devices, or lack one for testing, or are concerned over APK size. The Play Store for x86 would shrink substantially from the million-plus apps available to ARM devices, to those that do not use the NDK or happen to ship x86 binaries. libhoudini makes ARM-only NDK binaries usable on x86, giving x86-powered Android devices access to more of the Play Store catalog.

However, it is slower. A test suite for [SQLCipher for Android](#), run on an ASUS MeMO Pad FHD 10, ran about three times as long when using the ARM binaries and libhoudini, when compared to the same test run using x86 binaries. On the other hand, supporting x86 in addition to ARM adds another 5MB to the app, on top of the 6.5MB spent for ARM and the platform-neutral pieces. Being able to use SQLCipher for Android without the x86 binaries might be useful, particularly for apps bumping up against APK size limits, like the 50MB limit on the Play Store.

You may wish to do your own testing. Testing is easy enough: just temporarily move the x86/ directory from libs/ somewhere else, then recompile and test on libhoudini-equipped hardware. If you do not have your own libhoudini-equipped hardware, you may be able to take advantage of services like [Samsung's Remote Test Lab](#), which recently added the Galaxy Tab 3 10.1 to its lineup.

If you have the space for it, include the x86 binaries for your NDK-compiled libraries. This will give you maximum speed for little incremental engineering cost. However, if space is at a premium, `libhoudini` may allow you to reach many of the same x86 devices, but be sure that your app will run acceptably given the performance overhead.

Gradle and the NDK

Version 0.7 of the Gradle for Android plugin added preliminary support for the NDK. However, this support has its issues, and so you may wish to pursue other approaches, at least in the short term.

Official Support, for Externally-Built Binaries

Sometimes, you may have a project for which you want to use NDK-compiled binaries that somebody else supplies.

For example, at the time of this writing, [SQLCipher for Android](#) is not available as an AAR dependency from any repo. To use it, you need to include a handful of JARs in your project, along with NDK-compiled binaries for the core SQLCipher library and related libraries. Once this is available as an AAR, you could get all of that via a dependency; in the short term, you need to teach Gradle how to pick up the NDK-compiled binaries.

Using 0.7.+ (or higher) of the Gradle for Android plugin, you can have a `jniLibs/` directory in a sourceset. Underneath that directory would go your pre-compiled binaries, in the standard CPU architecture directories (e.g., `jniLibs/x86/`, `jniLibs/armeabi-v7a/`).

The [Gradle/ConstantsSecure](#) sample project is a clone of the same-named project from the SQLCipher for Android chapter, but with the code reorganized into a Gradle sourceset:

```
ConstantsSecure
|— build.gradle
|— libs
|   |— commons-codec.jar
|   |— guava-r09.jar
|   |— sqlcipher.jar
|— local.properties
|— proguard.cfg
|— project.properties
```

FOCUS ON: NDK

```
|— src
  |— main
    |— AndroidManifest.xml
    |— assets
      |— icudt46l.zip
    |— java
      |— com
        |— commonsware
          |— android
            |— sqlcipher
              |— ConstantsBrowser.java
              |— DatabaseHelper.java
              |— Provider.java
    |— jniLibs
      |— armeabi
        |— libdatabase_sqlcipher.so
        |— libsqlcipher_android.so
        |— libstlport_shared.so
      |— x86
        |— libdatabase_sqlcipher.so
        |— libsqlcipher_android.so
        |— libstlport_shared.so
    |— res
      |— drawable-hdpi
        |— ic_launcher.png
      |— drawable-ldpi
        |— ic_launcher.png
      |— drawable-mdpi
        |— add.png
        |— cw.png
        |— delete.png
        |— eject.png
        |— ic_launcher.png
      |— drawable-xhdpi
        |— ic_launcher.png
      |— layout
        |— add_edit.xml
        |— main.xml
        |— row.xml
      |— values
        |— strings.xml
```

(note: above listing includes only files of relevance for the current discussion)

The JARs remain in `libs/`, but the associated NDK `.so` files go in `jniLibs/` of the main sourceset.

When organized this way, the `build.gradle` file needs no changes to incorporate the `.so` files. If you wanted to have the JNI `.so` files in some other directory, you can modify `jniLibs.srcDirs` of your `sourceset` to point to where you want the files to reside.

Official Support, for Building NDK Binaries

To use the official NDK support for invoking the NDK build process from your `build.gradle` file, you need to have a `local.properties` file, defining an `ndk.dir` property, pointing to where your NDK is installed.

You can add an `ndk` closure to your `defaultConfig`, describing how your NDK code can be built:

```
defaultConfig {
    ndk {
        moduleName "anddown"
    }
}
```

In addition to `moduleName`, you can specify:

- `cFlags` for compiler flags
- `ldLibs` for libraries to link in

Your `productFlavors` can also have `ndk` closures with `abiFilter` properties, identifying a particular set of NDK binaries to be included in that flavor. For example, here is a `build.gradle` sample file from [a test project for the Gradle for Android plugin](#):

```
buildscript {
    repositories {
        maven { url ' ../../../../out/host/gradle/repo' }
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:0.7.0-SNAPSHOT'
    }
}
apply plugin: 'android'

android {
    compileSdkVersion 15
    buildToolsVersion "18.0.1"

    defaultConfig {
        ndk {
```

```
        moduleName "sanangeles"
        cFlags "-DANDROID_NDK -DDISABLE_IMPORTGL"
        ldLibs "GLSv1_CM", "dl", "log"
        stl "stlport_static"
    }
}

buildTypes.debug.jniDebugBuild true

productFlavors {
    x86 {
        ndk {
            abiFilter "x86"
        }
    }
    arm {
        ndk {
            abiFilter "armeabi-v7a"
        }
    }
    mips {
        ndk {
            abiFilter "mips"
        }
    }
}
```

Note that this sample is seriously out of date, using Gradle for Android 0.7.0, but it helps to illustrate how the product flavors work.

In here, we define three product flavors, one each for x86, ARM, and MIPS. Each resulting binary will only contain that architecture's version of the compiled NDK code.

Also, you need to tell Gradle for Android where your C/C++ source code resides. The default location is a `jni/` directory in your sourcesets, such as the `main/` sourceset. However, you can override that using `jni.srcDirs` in your configuration of a sourceset.

Example: CWAC-AndDown

[CWAC-AndDown](#) is mentioned in passing in [the chapter on rich text handling](#). It is an Android library that wraps [hoedown](#), a C-based Markdown-to-HTML converter. The hoedown project itself is a fork of sundown, which itself was used by many sites, like GitHub, for their Markdown processing. CWAC-AndDown is great for projects

that take in Markdown and want to render the results in a WebView (though you can use `Html.fromHtml()` to put the results in a TextView if you want).

Since CWAC-AndDown uses hoedown's C code, it has a `jni/` directory containing the JNI wrapper C code, the appropriate makefiles, plus a `src/` subdirectory containing the hoedown source code.

The classic way to build the project was to manually run the `ndk-build` script in the project root, then use Ant to compile the demo. CWAC-AndDown itself is an Android library project, designed to be used by apps like the demo app.

To get this library project to build using Ant and Eclipse, in addition to Gradle, we needed to leave the `jni/` directory in its original spot, alongside the `res/`, `src/`, and related directories and files. Since that is not where Gradle for Android goes looking for C/C++ files, we needed to teach Gradle for Android where our JNI code resides, by configuring `jni.srcDirs` for our main sourceset in `build.gradle`:

```
apply plugin: 'maven'

uploadArchives {
    repositories.mavenDeployer {
        pom.groupId = PUBLISH_GROUP_ID
        pom.artifactId = PUBLISH_ARTIFACT_ID
        pom.version = PUBLISH_VERSION

        repository(url: LOCAL_REPO)
    }
}
```

The CWAC-AndDown `build.gradle` file also contains the `ndk` closure shown earlier in this section, to name the module that we are generating.

Unofficial Support for Makefiles

We also needed to reorganize the CWAC-AndDown source code, due to some fundamental limitations in the current official Android support. Specifically, Gradle for Android *ignores* your own makefiles, preferring instead to generate its own. The generation algorithms are rather limited and make some assumptions about the organization of your code. Having all of your C/C++ source and header files in one big directory seems to work; having other structures may or may not work.

The fact that Gradle for Android ignores your makefiles means that if your makefiles do anything beyond very vanilla stuff, your build may well not work.

FOCUS ON: NDK

The alternative to using the built-in NDK support is to add in your own tasks that use the `ndk-build` command with your original makefiles. One such set of tasks was published by David Weinstein in [a GitHub Gist](#). However, this recipe was written for an early beta version of the Gradle for Android plugin and therefore may require some modification.

Mostly, it involves adding the following to the bottom of your `build.gradle` file:

```
task packageNativeLibs_ARM(type: Jar) {
    baseName 'libtestlib'
    classifier 'armeabi'
    from(file('libs/armeabi/')) {
        include '**/*.so'
    }
    into('lib/armeabi')
    destinationDir(file('libs/'))
}

task packageNativeLibs_x86(type: Jar) {
    baseName 'libtestlib'
    classifier 'x86'
    from(file('libs/x86/')) {
        include '**/*.so'
    }
    into('lib/x86')
    destinationDir(file('libs/'))
}

task packageNativeLibs(description: "package native libraries") {
}

packageNativeLibs.dependsOn 'packageNativeLibs_ARM'
packageNativeLibs.dependsOn 'packageNativeLibs_x86'

task ndkBuild(type: Exec, description: "Task to run ndk-build") {
    commandLine ndkDir + '/ndk-build'
}

packageNativeLibs.dependsOn 'ndkBuild'

tasks.withType(JavaCompile) { compileTask -> compileTask.dependsOn
packageNativeLibs }

clean.dependsOn 'cleanPackageNativeLibs'
```

This task also assumes that you have set an `ndkDir` property. To set properties in Gradle, add a `gradle.properties` file to your project, using the typical properties format:

`ndkDir=/opt/android-ndk`

The Gradle code snippet does several things:

1. It defines two tasks, one each to package the ARM and x86 version of the binaries. If you have a different mix of NDK build targets (e.g., ARMv7, MIPS), you could add or alter these tasks to suit.
2. It defines a `packageNativeLibs` task, that depends upon each of the CPU architecture-specific tasks from the previous point. If you add, change, or remove those architecture-specific tasks, you will need to add, change, or remove the corresponding `packageNativeLibs.dependsUpon` statements.
3. It defines an `ndkBuild` task, that simply executes the `ndk-build` script found in your NDK directory (defined by that `ndkDir` property).
4. It has `packageNativeLibs` depend upon `ndkBuild`.
5. It has all `JavaCompile` tasks in the build depend upon the `packageNativeLibs` task. This ensures that when we compile our Java code, we also compile the NDK code, if it is not already up to date.
6. It adds the auto-generated `cleanPackageNativeLibs` task as a dependency for the `clean` task, so `gradle clean` will clean the NDK build as well as cleaning everything else.

Gradle supports other ways of defining where the NDK directory is, such as depending upon an environment variable, so you have alternatives.

Improving CPU Performance in Java

Knowing that you have CPU-related issues in your app is one thing — doing something about it is the next challenge. In some respects, tuning an Android application is a “one-off” job, tied to the particulars of the application and what it is trying to accomplish. That being said, this chapter will outline some general-purpose ways of boosting performance that may counter issues that you are running into.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

Reduce CPU Utilization

One class of CPU-related problems come from purely sluggish code. These are the sorts of things you will see in Traceview, for example – methods or branches of code that seem to take an inordinately long time. These are also some of the most difficult to have general solutions for, as often times it comes down to what the application is trying to accomplish. However, the following sections provide suggestions for consuming fewer CPU instructions while getting the same work done.

These are presented in no particular order.

Standard Java Optimizations

Most of your algorithm fixes will be standard Java optimizations, no different than have been used by Java projects over the past decade and change. This section outlines a few of them. For more, consider reading *Effective Java* by Joshua Bloch or *Java Performance Tuning* by Jack Shirazi.

Avoid Excessive Synchronization

Few objects in `java.*` namespaces are intrinsically thread-safe, outside of `java.util.concurrent`. Typically, you need to perform your own synchronization if multiple threads will be accessing non-thread-safe objects. However, sometimes, Java classes have synchronization that you neither expect nor need. Synchronization adds unnecessary overhead.

The classic example here is `StringBuffer` and `StringBuilder`. `StringBuffer` was part of Java from early on, and, for whatever reason, was written to be thread-safe — two threads that append to the buffer will not cause any problems. However, most of the time, you are only using the `StringBuffer` from one thread, meaning all that synchronization overhead is a waste. Later on, Java added `StringBuilder`, with the same basic set of methods as has `StringBuffer`, but without the synchronization.

Similarly, in your own code, only synchronize where it is really needed. Do not toss the `synchronized` keyword around randomly, or use concurrent collections that will only be used by one thread, etc.

Avoid Floating-Point Math

The first generation of Android devices lacked a floating-point coprocessor on the ARM CPU package. As a result, floating-point math speed was atrocious. That is why the Google Maps add-on for Android uses `GeoPoint`, with latitude and longitude in integer microdegrees, rather than the standard Android `Location` class, which uses Java double variables holding decimal degrees.

While later Android devices do have floating-point coprocessor support, that does not mean that floating-point math is now as fast as integer math. If you find that your code is spending lots of time on floating-point calculations, consider whether a change in units would allow you to replace the floating-point calculations with integer equivalents. For example, microdegrees for latitude and longitude provide

adequate granularity for most maps, yet allow Google Maps to do all of its calculations in integers.

Similarly, consider whether the full decimal accuracy of floating-point values is really needed. While it may be physically possible to perform distance calculations in meters with accuracy to a few decimal points, for example, in many cases the user will not need that degree of accuracy. If so, perhaps changing to fixed-point (integer) math can boost your performance.

Don't Assume Built-In Algorithms are Best

Years upon years of work has gone into the implementation of various algorithms that underlie Java methods, like searching for substrings inside of strings.

Somewhat less work has gone into the implementation of the Apache Harmony versions of those methods, simply because the project is younger, and it is a modified version of the Harmony implementation that you will find in Android. While the core Android team has made many improvements to the original Harmony implementation, those improvements may be for optimizations that do not fit your needs (e.g., optimizing to reduce memory consumption at the expense of CPU time).

But beyond that, there are [dozens of string-matching algorithms](#), some of which may be better for you depending on the string being searched and the string being searched for. Hence, you may wish to consider applying your own searching algorithm rather than relying on the built-in one, to boost performance. And, this same concept may hold for other algorithms as well (e.g., sorting).

Of course, this will also increase the complexity of your application, with long-term impacts in terms of maintenance cost. Hence, do not assume the built-in algorithms are the worst, either — optimize those algorithms that Traceview or logging suggest are where you are spending too much time.

Support Hardware-Accelerated Graphics

An easy “win” is to add `android:hardwareAccelerated="true"` to your `<application>` element in the manifest. This toggles on hardware acceleration for 2D graphics, including much of the stock widget framework. For maximum backwards compatibility, this hardware acceleration is off, but adding the aforementioned attribute will enable it for all activities in your application.

Note that this is only available starting with Android 3.0. It is safe to have the attribute in the manifest for older Android devices, as they simply will ignore your request.

You also should test your application thoroughly after enabling hardware acceleration, to make sure there are no unexpected issues. For ordinary widget-based applications, you should encounter no problems. Games or other applications that do their own drawing might have issues. If you find that some of your code runs into problems, you can override hardware acceleration on a per-activity basis by putting the `android:hardwareAccelerated` on `<activity>` elements in the manifest.

Minimize IPC

Calling a method on an object in your own process is fairly inexpensive. The overhead of the method invocation is fairly minuscule, and so the time involved is simply however long it takes for that method to do its work.

Invoking behaviors in another process, via inter-process communication (IPC), is considerably more expensive. Your request has to be converted into a byte array (e.g., via the `Parcelable` interface), made available to the other process, converted back into a regular request, then executed. This adds substantial CPU overhead.

There are three basic flavors of IPC in Android:

1. “Directly” invoking a third-party application’s service’s AIDL-published interface, to which you bound with `bindService()`
2. Performing operations on a content provider that is not part of your application (i.e., supplied by the OS or a third-party application)
3. Performing other operations that, under the covers, trigger IPC

Remote Bound Service

Using a remote service is fairly obvious when you do it — it is difficult to mistake copying the AIDL into your project and such. The proxy object generated from the AIDL converts all your method calls on the interface into IPC operations, and this is relatively expensive.

If you are exposing a service via AIDL, design your API to be coarse-grained. Do not require the client to make 1,000 method invocations to accomplish something that can be done in 1 via slightly more complex arguments and return values.

If you are consuming a remote service, try not to get into situations where you have to make lots of calls in a tight loop, or per row of a scrolled `AdapterView`, or anything else where the overhead may become troublesome.

For example, in the [CPU-Java/AIDLOverhead](#) sample project, you will find a pair of projects implementing the same do-nothing method in equivalent services. One uses AIDL and is bound to remotely from a separate client application; the other is a local service in the client application itself. The client then calls the do-nothing method 1 million times for each of the two services. On average, on a Samsung Galaxy Tab 10.1, 1 million calls takes around 170 seconds for the remote service, while it takes around 170 *milliseconds* for the local service. Hence, the overhead of an individual remote method invocation is small (~170 microseconds), but doing lots of them in a loop, or as the user flings a `ListView`, might become noticeable.

Remote Content Provider

Using a content provider can be somewhat less obvious of a problem. Using `ContentResolver` or a `CursorLoader` looks the same whether it is your own content provider or someone else's. However, you know what content providers you wrote; anything else is probably running in another process.

As with remote services, try to aggregate operations with remote content providers, such as:

1. Use `bulkInsert()` rather than lots of individual `insert()` calls
2. Try to avoid calling `update()` or `delete()` in a tight loop – instead, if the content provider supports it, use a more complex “WHERE clause” to update or delete everything at once
3. Try to get all your data back in few queries, rather than lots of little ones... though this can then cause you issues in terms of memory consumption

Remote OS Operation

The content provider scenario is really a subset of the broader case where you request that Android do something for you and winds up performing IPC as part of that.

Sometimes, this is going to be obvious. If you are sending commands to a third-party service via `startService()`, by definition, this will involve IPC, since the third-party

service will run in a third-party process. Try to avoid calling `startService()` lots of times in close succession.

However, there are plenty of cases that are less obvious:

1. All requests to `startActivity()`, `startService()`, and `sendBroadcast()` involve IPC, as it is a separate OS process that does the real work
2. Registering and unregistering a `BroadcastReceiver` (e.g., `registerReceiver()`) involves IPC
3. All of the “system services”, such as `LocationManager`, are really rich interfaces to an AIDL-defined remote service, and so most operations on these system services require IPC

Once again, your objective should be to minimize calls that involve IPC, particularly where you are making those calls frequently in close succession, such as in a loop. For example, frequently calling `getLastKnownLocation()` will be expensive, as that involves IPC to a system process.

Android-Specific Java Optimizations

The way that the Dalvik VM was implemented and operates is subtly different than a traditional Java VM. Therefore, there are some optimizations that are more important on Android than you might find in regular desktop or server Java.

The Android developer documentation has [a roster of such optimizations](#). Some of the highlights include:

1. Getters and setters, while perhaps useful for encapsulation, are significantly slower than direct field access. For simpler cases, such as `ViewHolder` objects for optimizing an `Adapter`, consider skipping the accessor methods and just use the fields directly.
2. Some popular method calls are replaced by hand-created assembler instructions rather than code generated via the JIT compiler. `indexOf()` on `String` and `arraycopy()` on `System` are two cited examples. These will run much faster than anything you might create yourself in Java.

Reduce Time on the Main Application Thread

Another class of CPU-related problem is when your code may be efficient, but it is occurring on the main application thread, causing your UI to react sluggishly. You

might have tuned your decryption algorithm as best as is mathematically possible, but it may be that decrypting data on the main application thread simply takes too much time. Or, perhaps `StrictMode` complained about some disk or network I/O that you are performing on the main application thread.

The following sections recap some commonly-seen patterns for moving work off the main application thread, plus a few newer options that you may have missed.

Generate Less Garbage

Most developers think of having too many allocations as being solely an issue of heap space. That certainly has an impact, and depending on the nature of the allocations (e.g., bitmaps), it may be the dominant issue.

However, garbage has impacts from a CPU standpoint as well. Every object you create causes its constructor to be executed. Every object that is garbage-collected requires CPU time both to find the object in the heap and to actually clean it up (e.g., execute the finalizer, if any).

Worse still, on older versions of Android (e.g., Android 2.2 and down), the garbage collector interrupts the entire process to do its work, so the more garbage you generate, the more times you “stop the world”. Game developers have had to deal with this since Android’s inception. To maintain a 60 FPS refresh rate, you cannot afford *any* garbage collections on older devices, as a single GC run could easily take more than the ~16ms you have per drawing pass.

As a result of all of this, game developers have had to carefully manage their own object pools, pre-allocating a bunch of objects before game play begins, then using and recycling those objects themselves, only allowing them to become garbage after game play ends.

Most non-game Android applications may not have to go to quite that extreme across the board. However, there are cases where excessive allocation may cause you difficulty. For example, avoiding creating too much garbage is one aspect of view recycling with `AdapterView`, which is covered in greater detail [in the next section](#).

If Traceview indicates that you are spending a lot of time in garbage collection, pay attention to your loops or things that may be invoked many times in rapid succession (e.g., accessing data from a custom `Cursor` implementation that is tied to a `CursorAdapter`). These are the most likely places where your own code might be creating lots of extra objects that are not needed. Examining the heap to see what is

all being created (and eventually garbage collected) will be covered in [an upcoming chapter of the book](#).

View Recycling

Perhaps the best-covered Android-specific optimization is view recycling with `AdapterView`.

In a nutshell, if you are extending `BaseAdapter`, or if you are overriding `getView()` in another adapter, please make use of the `View` parameter supplied to `getView()` (referred to here as `convertView`). If `convertView` is not null, it is one of your previous `View` objects you returned from `getView()` before, being offered to you for recycling purposes. Using `convertView` saves you from inflating or manually constructing a fresh `View` every time the user scrolls, and both of those operations are relatively expensive.

If you have been ignoring `convertView` because you have more than one type of `View` that `getView()` returns, your `Adapter` should be overriding `getViewTypeCount()` and `getItemViewType()`. These will allow Android to maintain separate object pools for each type of row from your `Adapter`, so `getView()` is guaranteed to be passed a `convertView` that matches the row type you are trying to create.

A somewhat more advanced optimization — caching all those `findViewById()` lookups — is also possible once your row recycling is in place. Often referred to as “the holder pattern”, you do the `findViewById()` calls when you inflate a new row, then attach the `findViewById()` results to the row itself via some custom “holder” object and the `setTag()` method on `View`. When you recycle the row, you can get your “holder” back via `getTag()` and skip having to do the `findViewById()` calls again.

Background Threads

Of course, the backbone of any strategy to move work off the main application thread is to use background threads, in one form or fashion. You will want to apply these in places where `StrictMode` complains about network or disk I/O, or places where `Traceview` or logging indicate that you are taking too much time on the main application thread during GUI processing (e.g., converting downloaded bitmap images into `Bitmap` objects via `BitmapFactory`).

Sometimes, you will manually dictate where work should be done in the background, either by forking threads yourself or by using `AsyncTask`. `AsyncTask` is a

nice framework, handling all of the inter-thread communication for you and neatly packaging up the work to be done in readily understood methods. However, `AsyncTask` does not fit every scenario — it is mostly designed for “transactional” work that is known to take a modest amount of time (milliseconds to seconds) then end. For cases where you need unbounded background processing, such as monitoring a socket for incoming data, forking your own thread will be the better approach.

Sometimes, you will use facilities supplied by Android to move work to the background. For example, many activities are backed by a `Cursor` obtained from a database or content provider. Classically, you would manage the cursor (via `startManagingCursor()`) or otherwise arrange to refresh that `Cursor` in `onResume()`, so when your activity returns to the foreground after having been gone for a while, you would have fresh data. However, this pattern tends to lead to database I/O on the main application thread, triggering complaints from `StrictMode`. Android 3.0 and the Android Compatibility Library offer a `Loader` framework designed to try to solve the core pattern of refreshing the data, while arranging for the work to be done asynchronously.

Asynchronous BroadcastReceiver Operations

99.44% of the time (approximately) that Android calls your code in some sort of event handler, you are being called on the main application thread. This includes manifest-registered `BroadcastReceiver` components — `onReceive()` is called on the main application thread. So any work you do in `onReceive()` ties up that thread (possibly impacting an activity of yours in the foreground), and if you take more than 10 seconds, Android will terminate your `BroadcastReceiver` with extreme prejudice.

Classically, manifest-registered `BroadcastReceiver` components only live as long as the `onReceive()` call does, meaning you can do very little work in the `BroadcastReceiver` itself. The typical pattern is to have it send a command to a service via `startService()`, where the service “does the heavy lifting”.

Android 3.0 added a `goAsync()` method on `BroadcastReceiver` that can help a bit here. While under-documented, it tells Android that you need more time to complete the broadcast work, but that you can do that work on a background thread. This does not eliminate the 10-second rule, but it does mean that the `BroadcastReceiver` can do some amount of I/O without having to send a command to a service to do it while still not tying up the main application thread.

The [CPU-Java/GoAsync](#) sample project demonstrates `goAsync()` in use, as the project name might suggest.

Our activity's layout consists of two `Button` widgets and an `EditText` widget:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical" android:layout_width="match_parent"
    android:layout_height="match_parent">
    <EditText android:id="@+id/editText1" android:layout_width="match_parent"
        android:layout_height="wrap_content">
    </EditText>
    <Button android:layout_width="match_parent" android:id="@+id/button1"
        android:layout_height="wrap_content" android:text="@string/nonasync"
        android:onClick="sendNonAsync"></Button>
    <Button android:layout_width="match_parent" android:id="@+id/button2"
        android:layout_height="wrap_content" android:text="@string/async"
        android:onClick="sendAsync"></Button>
</LinearLayout>
```

The activity itself simply has `sendAsync()` and `sendNonAsync()` methods, each invoking `sendBroadcast()` to a different `BroadcastReceiver` implementation:

```
package com.commonware.android.tuning.goasync;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class GoAsyncActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void sendAsync(View v) {
        sendBroadcast(new Intent(this, AsyncReceiver.class));
    }

    public void sendNonAsync(View v) {
        sendBroadcast(new Intent(this, NonAsyncReceiver.class));
    }
}
```

The `NonAsyncReceiver` simulates doing time-consuming work in `onReceive()` itself:

```
package com.commonware.android.tuning.goasync;

import android.content.BroadcastReceiver;
```

```
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class NonAsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context arg0, Intent arg1) {
        SystemClock.sleep(7000);
    }
}
```

Hence, if you click the “Send Non-Async Broadcast” button, not only will the button fail to return to its normal state for seven seconds, but the EditText will not respond to user input either.

The AsyncReceiver, though, uses `goAsync()`:

```
package com.commonware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class AsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        final BroadcastReceiver.PendingResult result=goAsync();

        (new Thread() {
            public void run() {
                SystemClock.sleep(7000);
                result.finish();
            }
        }).start();
    }
}
```

The `goAsync()` method returns a `PendingResult`, which supports a series of methods that you might ordinarily fire on the `BroadcastReceiver` itself (e.g., `abortBroadcast()`) but want to do on a background thread. You need your background thread to have access to the `PendingResult` — in this case, via a `final` local variable. When you are done with your work, call `finish()` on the `PendingResult`.

If you click the “Send Async Broadcast” button, even though we are still sleeping for 7 seconds, we are doing so on a background thread, and so our user interface is still responsive.

Saving SharedPreferences

The classic way to save `SharedPreferences.Editor` changes was via a call to `commit()`. This writes the preference information to an XML file on whatever thread you are on — another hidden source of disk I/O you might be doing on the main application thread.

If you are on API Level 9, and you are willing to blindly try saving the changes, use the new `apply()` method on `SharedPreferences.Editor`, which works asynchronously.

If you need to support older versions of Android, or you really want the boolean return value from `commit()`, consider doing the `commit()` call in an `AsyncTask` or background thread.

And, of course, to support both of these, you will need to employ tricks like conditional class loading. You can see that used for saving `SharedPreferences` in the [CPU-Java/PrefsPersist](#) sample project. The activity reads in a preference, puts the current value on the screen, then updates the preference with the help of an `AbstractPrefsPersistStrategy` class and its `persist()` method:

```
package com.commonware.android.tuning.prefs;

import android.app.Activity;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.widget.TextView;

public class PrefsPersistActivity extends Activity {
    private static final String KEY="counter";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(this);
        int counter=prefs.getInt(KEY, 0);

        ((TextView)findViewById(R.id.value)).setText(String.valueOf(counter));

        AbstractPrefsPersistStrategy.persist(prefs.edit().putInt(KEY, counter+1));
    }
}
```

AbstractPrefsPersistStrategy is an abstract base class that will hold a strategy implementation, depending on Android version. On pre-Honeycomb builds, it uses an implementation that forks a background thread to perform the commit():

```
package com.commonware.android.tuning.prefs;

import android.content.SharedPreferences;
import android.os.Build;

abstract public class AbstractPrefsPersistStrategy {
    abstract void persistAsync(SharedPreferences.Editor editor);

    private static final AbstractPrefsPersistStrategy INSTANCE=initImpl();

    public static void persist(SharedPreferences.Editor editor) {
        INSTANCE.persistAsync(editor);
    }

    private static AbstractPrefsPersistStrategy initImpl() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<Build.VERSION_CODES.HONEYCOMB) {
            return(new CommitAsyncStrategy());
        }

        return(new ApplyStrategy());
    }

    static class CommitAsyncStrategy extends AbstractPrefsPersistStrategy {
        @Override
        void persistAsync(final SharedPreferences.Editor editor) {
            (new Thread() {
                @Override
                public void run() {
                    editor.commit();
                }
            }).start();
        }
    }
}
```

On Honeycomb and higher, it uses a separate strategy class that uses the new apply() method:

```
package com.commonware.android.tuning.prefs;

import android.content.SharedPreferences.Editor;

public class ApplyStrategy extends AbstractPrefsPersistStrategy {

    @Override
    void persistAsync(Editor editor) {
```

```
        editor.apply();  
    }  
}
```

By separating the Honeycomb-specific code out into a separate class, we can avoid loading it on older devices and encountering the dreaded `VerifyError`.

Whether using the built-in `apply()` method is worth dealing with multiple strategies, versus simply calling `commit()` on a background thread, is up to you.

Improve Throughput and Responsiveness

Being efficient and doing work on the proper thread may still not be enough. It could be that your work is not consuming excessive CPU time, but is taking too long in “wall clock time” (e.g., the user sits waiting too long at a `ProgressDialog`). Or, it could be that your work, while efficient and in the background, is causing difficulty for foreground operations.

The following sections outline some common problems and solutions in this area.

Minimize Disk Writes

Earlier in this book, we emphasized moving disk writes off to background threads.

Even better is to get rid of some of the disk writes entirely.

A big culprit here comes in the form of database operations. By default, each `insert()`, `update()`, or `delete()`, or any `execSQL()` invocation that modifies data, will occur in its own transaction. Each transaction involves a set of disk writes. Many times, this is not a problem. But, if you are doing a lot of these – such as importing records from a CSV file — hundreds or thousands of transactions will mean thousands of individual disk writes, and that can take some time. You may wish to wrap those operations in your own transaction, using methods like `beginTransaction()`, simply to reduce the number of transactions and, therefore, disk writes.

If you are doing your own disk I/O beyond databases, you may encounter similar sorts of issues. Overall, it is better to do a few larger writes than lots of little ones.

Set Thread Priority

Threads you fork, by default, run at a default priority: `THREAD_PRIORITY_DEFAULT` as defined on the `Process` class. This is a lower priority than the main application thread (`THREAD_PRIORITY_DISPLAY`).

Threads you use via `AsyncTask` run at a lower priority (`THREAD_PRIORITY_BACKGROUND`). If you fork your own threads, then, you might wish to consider moving them to a lower priority as well, to affect how much time they get compared to the main application thread. You can do this via `setThreadPriority()` on the `Process` class.

The lowest possible priority, `THREAD_PRIORITY_LOWEST`, is described as “only for those who really, really don’t want to run if anything else is happening”. You might use this for “idle-time processing”, but bear in mind that the thread will be paused a lot to allow other threads to run.

Lower-priority threads will help ensure that your background work does not affect your foreground UI. Processes themselves are put in a lower-priority class as they move to the background (e.g., you have no activities visible), which further reduces the amount of CPU time you will be using at any given moment.

Also, note that `IntentService` uses a thread at default (*not* background) priority — you may wish to drop the priority of this thread to something that will be lower than your main application thread, to minimize how much CPU time the `IntentService` steals from your UI.

Do the Work Some Other Time

Just because you could do the work now does not mean you should do the work now. Perhaps a better answer is to do the work later, or do part of the work now and part of the work later.

For example, suppose that you have your own database of points of interest for your custom map application. Periodically, you publish a new database on your Web site, which your Android app should download. Odds are decent that the user is not in desperate need for this new database right away. In fact, the CPU time and disk I/O time to download and save the database might incrementally interfere with the foreground application, despite your best efforts.

In this case, not only should you check for and download the database when the user is unlikely to be using the device (e.g., before dawn), but you should check whether the screen is on via `isScreenOn()` on `PowerManager`, and delay the work to sometime when the screen is off. For example, you could have `AlarmManager` set up to have your code check for updates every 24 hours at 4am. If, at 4am, the screen is on, your code could skip the download and wait until tomorrow, or skip the download and add a one-shot alarm to wake you up in 30 minutes, in hopes that the user will no longer be using the device.

At the same time, you may wish to consider having a “refresh” menu choice somewhere, for when the user specifically wants you to go get the update (if available) *now*, for whatever reason.

Finding and Eliminating Jank

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Finding and eliminating the causes of janky behavior (“jank”) is part science, part art, and part throwing darts at a dartboard.

This chapter will outline some techniques for identifying and removing jank from a user interface. The steps shown here originated in [a blog post by Google’s Romain Guy](#), with a few additional twists and turns due to the different nature of the particular case being studied. Mr. Guy’s blog post is essential reading for all advanced Android developers, and the author is deeply indebted to Mr. Guy for his work in this area.

Prerequisites

The only hard prerequisite for this chapter is having read the core chapters and [the chapter on finding CPU bottlenecks](#).

That being said, having read [the chapter on animators](#) would help understand portions of this chapter a bit better.

The Case: ThreePaneDemoBC

In [the chapter on animators](#), we examined an implementation of the Gmail-style three-pane layout with animated transitions (a.k.a., [“The Three-Fragment Problem”](#)). The implementation shown there originated with [a Stack Overflow question](#) with the solution presented in this book offered as [an answer](#).

[A commenter on that answer](#) pointed out that he detected some stutter, even on decent hardware.

This chapter reviews the steps that were taken to determine if we really are doing things incorrectly, what specifically we are doing wrong, and what can be done to fix it.

Are We Janky?

In the eyes of this book's author, the three-pane implementation presented in the chapter on animators was perfectly reasonable on good hardware.

There are two lessons to take from this:

1. It is better to come up with an objective definition for “jank” and test to see if your code meets that definition at various points
2. The author of this book is very tolerant of janky user interfaces

The results shown in [the chapter on CPU measurement](#) for the gfxinfo and systrace tools comes from the three-pane demo code. The gfxinfo and the systrace results both point to the three-pane demo spending too much time doing work and therefore dropping some number of frames. This lines up with the visual report, and indicates that we have some work to do to try to improve matters.

Finding the Source of the Jank

Just because we know that we are janky does not mean that we have any idea what to do about it. We need to conduct some further analysis to determine where, exactly, our jank is coming from.

Traceview

One thing that we can do to help further refine the source of our trouble is to use Traceview. As outlined in [the section on Traceview](#), Traceview reports how many calls were made of various methods in our code (and in the framework code) and how much time was spent there.

Here are some of the results from a Traceview run on the three-pane demo on a Nexus 7:

FINDING AND ELIMINATING JANK

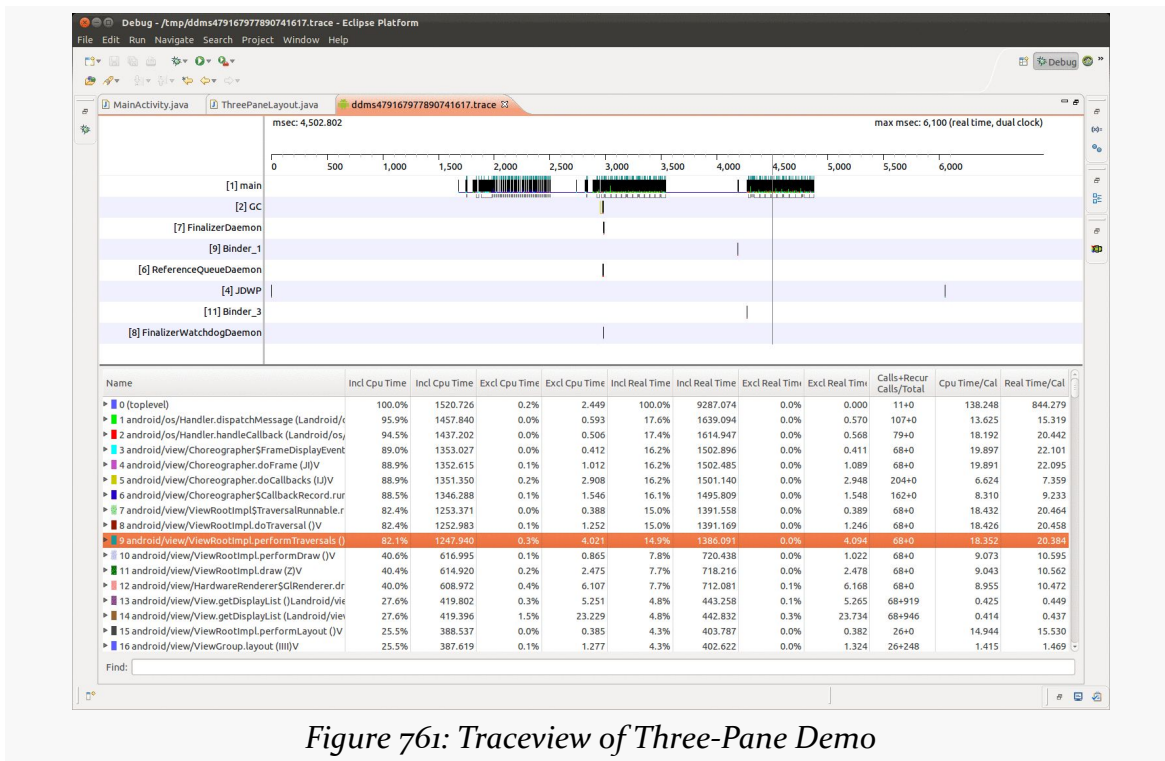

Figure 761: Traceview of Three-Pane Demo

We see that 88.9% of our CPU time is spent in `doFrame()` on `Choreographer` and the calls triggered from it. `doFrame()` is a private method which, as the name suggests, performs the drawing, processing, and executing of a single frame's worth of rendering. More importantly, we see that `doFrame()` was called 68 times during our test run, meaning that our UI changed 68 times during the ~3 seconds of activity during our trace.

Further down the table, we see that `layout()` on `ViewGroup` was called 26 times directly (and 248 more times via recursion), contributing about 25% of the time consumed by `doFrame()`. Since `layout()` is called on less than half of the `doFrame()` calls, the time consumed by `layout()` makes up a fairly significant portion of the `doFrame()` time during those 26 frames.

More importantly, `layout()` is something that we trigger. It implies that we have made some change to our UI content that requires a layout pass of some `ViewGroup`.

Having a layout pass on occasion is perfectly normal, particularly in response to user input. A `layout()` might be triggered by the user tapping on a row in one of our `ListView`s, for example. But we are not doing 26 user input events in our test — all we are doing is tapping one time each on a pair of `ListView` rows, then pressing the

BACK button. This implies that something else in our code is causing `layout()` to be needed.

Unfortunately, at this point, Traceview does not help much, because the calls to `layout()` are asynchronous with respect to our own code, so it will not be all that obvious where the extra calls are coming from. This is where we need some expert help, as we will see [later in this chapter](#).

Overdraw

Another common source of jank is overdraw. Overdraw refers to the act of painting the same pixel several times, due to overlapping components. For example:

- The activity window itself has a background
- You have a container that fills the activity's content, such as a `ListView`, which has a background
- You have children in that container with backgrounds (row), who have their own children with backgrounds and, eventually, content (widgets like `ImageView` and `TextView`)

Places where there is overlap, the OS might set the color of a pixel several times per frame, wasting time.

The easiest way to track down overdraw is to use the “Show GPU overdraw” option in the Developer Options portion of the Settings app:

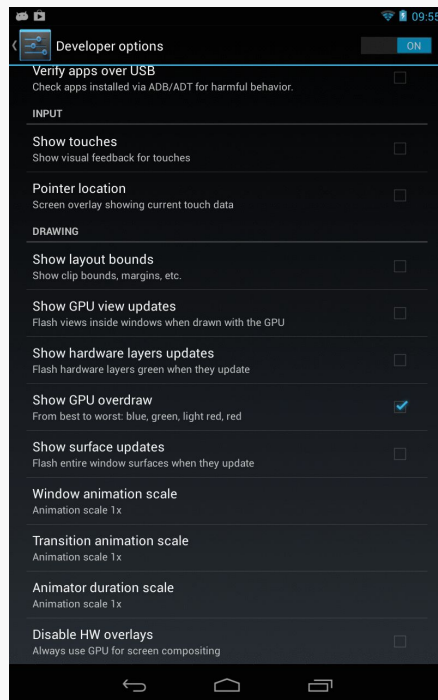

Figure 762: Nexus 7 Developer Options, with “Show GPU overdraw”

This option is only available on Android 4.2 and higher.

When you enable this option, then restart your app’s process (if it was already running), Android will shade pixels that are overdrawn:

- Blue for pixels that are drawn twice
- Green for pixels that are drawn three times
- Pink for pixels that are drawn four times
- Red for pixels that are drawn five or more times

In short: pink and red are bad. Green and blue are OK, though if you have large patches of either shade, you might consider trying to see if there’s a way to get rid of the overdraw.

Of course, the fact that these are shades applied to existing pixel colors may make it a bit difficult to tell exactly where the overdraw is occurring. For example, a red portion of your UI might be red from overdraw... or it might be red because you made it red. Temporarily changing your color scheme to something else (e.g., yellow) will help distinguish what is overdraw and what is just the natural UI coloration.

FINDING AND ELIMINATING JANK

If you enable this option on a Nexus 7 and run the three-pane demo, you will see very little blue or green (beyond the normal blue of the activated state of our ListView rows), and virtually no red:

Figure 763: Three-Pane Demo, As Initially Launched, Showing Overdraw

FINDING AND ELIMINATING JANK

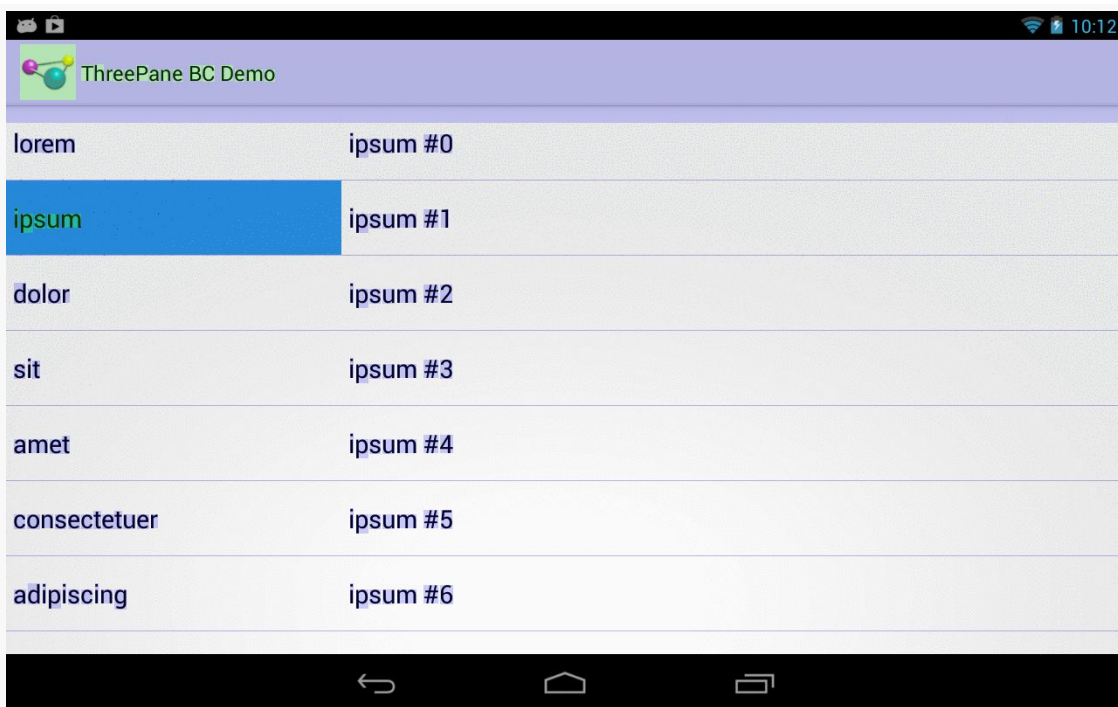

Figure 764: Three-Pane Demo, Left and Middle Panes, Showing Overdraw

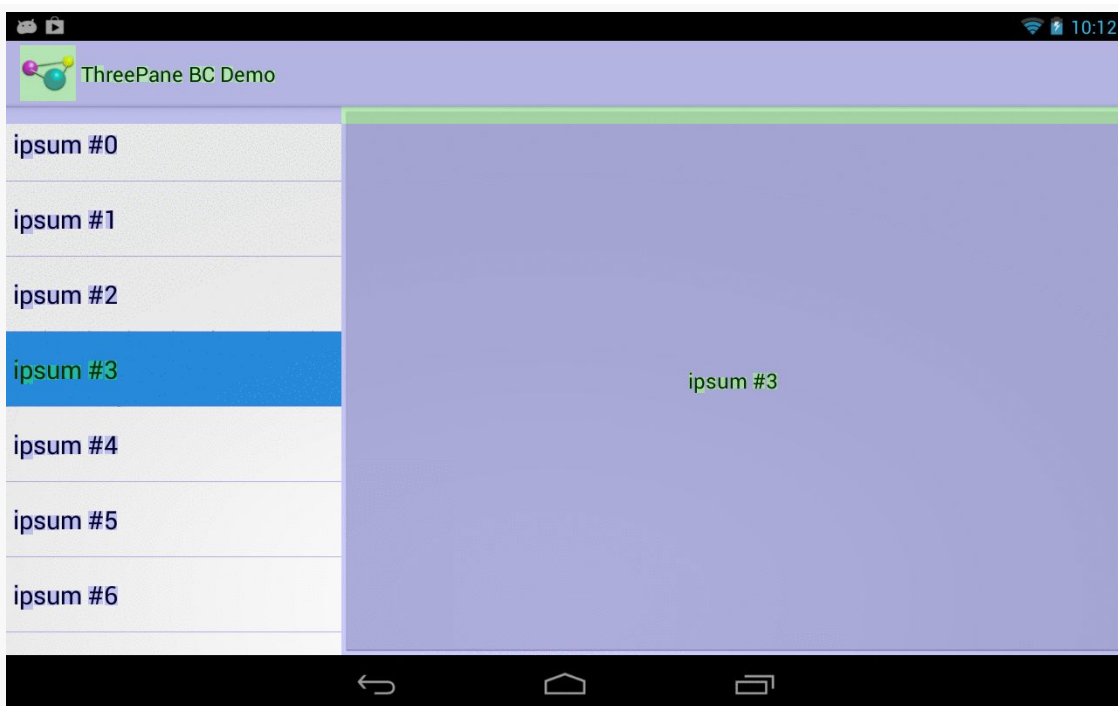

Figure 765: Three-Pane Demo, Middle and Right Panes, Showing Overdraw

FINDING AND ELIMINATING JANK

Figure 766: Three-Pane Demo, Left and Middle Panes Via BACK, Showing Overdraw

On the other hand, bringing up the Contacts app on the same Nexus 7 shows significantly more overdraw:

Figure 767: Contacts App, Showing Overdraw

The good news is that our app is not suffering performance problems due to overdraw.

The bad news is that the Contacts app is.

The good news is that if you are reading this, you are probably not responsible for maintaining the Contacts app.

The Contacts app's major problems come from the contact photos, or placeholders as seen here. Either the `ImageView` has a background, or the `ImageView` fills some container with a background. For example, the `ImageView` might be in some container with a background to provide a bevel effect around the image. Making the portion of the background that is behind the `ImageView` be transparent will eliminate the overdraw.

Note: some GPU architectures can automatically fix overdraw in select places, while others cannot. Notably, the Tegra 3 cannot. Hence, the Tegra 3 is a good test platform for using this overdraw-detection feature of Android.

Extraneous Views

Another related source of jank is having too many extraneous views. Each widget and container contributes to the cost of drawing the overall UI, so having extraneous views adds overhead.

Perhaps the most common scenario for extraneous views is the single-child container. If a container will only ever hold one child, perhaps you can get rid of that container. Not only will this speed up execution at runtime, but it can help [avoid running out of stack space](#).

One likely way to find these extraneous views is to bring up your user interface [in Hierarchy View on an emulator](#) (or possibly on a device by [using ViewServer](#)). In particular, single-child containers are fairly obvious — look for bubbles that have just one child bubble on the right.

There are two such cases in the UI for our three-pane demo, though neither are our fault.

Figure 768: Single-Child FrameLayout in Three-Pane Demo, from Hierarchy View

Here, we have a FrameLayout holding onto just one child, our ThreePaneLayout custom view. We set up ThreePaneLayout as being our activity’s content view. The “content view” of an activity is poured into a FrameLayout, supplied by the Android framework — that is the FrameLayout seen in Hierarchy View. We have no good way to get rid of this FrameLayout. Fortunately, FrameLayout is a very cheap container, in terms of runtime execution speed.

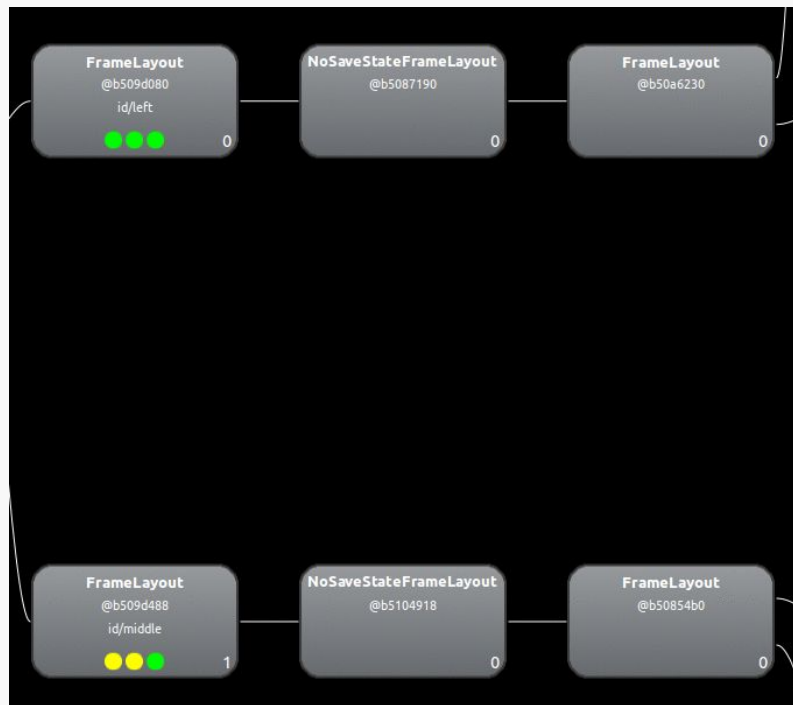

Figure 769: More Single-Child Containers in Three-Pane Demo, from Hierarchy View

Here, we see that our left and middle `FrameLayout` containers, for our left and middle panes, each contain one child, a `NoSaveStateFrameLayout`, which in turn each hold one child, a `FrameLayout`. These containers are added by `ListFragment`, not directly by our code. A `ListFragment` is surprisingly complex, adding several widgets and containers beyond the `ListView` itself:

FINDING AND ELIMINATING JANK

Figure 770: Contents of a ListFragment, from Hierarchy View

Short of writing our own fragment for holding a `ListView`, there is nothing we can do about these extraneous views.

Conclusion: Too Many `layout()` Calls?

Given that overdraw does not seem to be a problem and that we have few extraneous views under our control, it would seem that perhaps we should return our attention to the extra `layout()` calls. While trying to get rid of the `ListFragment` extraneous views would make those `layout()` calls incrementally cheaper, we will get more value by getting rid of the unnecessary calls in the first place, if indeed they are unnecessary.

Where Things Went Wrong

Of course, it doesn't hurt to call in an expert, to try to confirm exactly what is going on.

Chet Haase — Google engineer on Android, [celebrated book author](#), and part-time comedian – [chimed in with an answer](#) to a Stack Overflow question about this three-

pane animation, asked by the person who commented about the dropped frames on the original Stack Overflow question.

The key statement from his answer was:

Sliding things around is fine (translationX/Y), fading things in/out is good (alpha), but actually laying things out on every frame? Just say no.

Specifically, he is referring to our use of `ObjectAnimator` to change the width of the middle pane as we show and hide the right pane. Each time we change the width of the middle pane, we trigger a `layout()` call, to reposition the child widgets within that pane as needed. Our animations are adding ~20 `layout()` calls, introducing overhead that is pushing us over the per-frame limit on the Nexus 7.

Removing the Jank

To remove the jank, we need to remove the `ObjectAnimator` changing the width of the middle pane on the fly. You can see the results of this in the [Jank/ThreePaneBC](#) sample app.

Now, our `showLeft()` and `hideLeft()` methods immediately change the width of the middle pane, rather than arranging its animation:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);
    setMiddleWidth(leftWidth);
}

public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);
    setMiddleWidth(middleWidthNormal);
}

private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
```

FINDING AND ELIMINATING JANK

This does not provide nearly as good of a UI as the original. However, the revised solution does reduce the jank, as seen in this gfxinfo output:

There are probably ways to improve upon the revised jank-free implementation. Lacking that, it is up to you to decide if the amount of jank found in the original implementation is worth the improved animation or not.

Issues with Bandwidth

As anyone who owned an Apple Newton or Palm V PDA back in the 1990's knows, handheld devices have been around for quite some time. For a very long time, they were a niche product, associated with geeks, nerds, and the occasional business executive.

Internet access changed all of that.

Blackberry for enterprise messaging — an outgrowth of its original two-way paging approach — blazed part of the trail, but the concept “crossed the chasm” to ordinary people with the advent of the iPhone, Android devices, and similar equipment.

Therefore, it is not terribly surprising when Android developers want to add Internet capabilities to their apps. To the contrary, it is almost unusual when you encounter an app that does *not* want to use the Internet for something or another.

However, mobile Internet access inherits all of the classic problems of Internet access (e.g., “server not found”) and adds new and exciting challenges, all of which can leave a developer with an app that has performance issues.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You're Using Too Much of the Slow Stuff

To paraphrase America's Founding Fathers, "all Internet connections are not created equal".

One form of inequality is speed. Different classes of connection have different theoretical upper bounds. WiMAX and other "4G" connections are theoretically faster than 3G connections, which are theoretically faster than 2G or EDGE connections. WiFi — typically 802.11g in today's devices — is theoretically ridiculously fast though it is typically limited by the ISP connection, and ISP connections can run the gamut from really fast to merely good.

However, "theoretical" bounds tend to run afoul of reality. There are plenty of places where high-speed mobile data connections are non-existent, despite what the carriers' coverage maps claim. 2G mobile data works, but is not especially speedy. This layers on top of the typical Internet congestion issues, along with typically transitory problems (e.g., trying to get connectivity while attending a technology conference keynote presentation).

Hence, what runs quickly in the lab may run much more slowly in users' hands.

If you followed the instructions in previous chapters on CPU bottlenecks, the limited bandwidth will not cause your UI to become "janky", in that it will be responsive to touches and taps. However, poor connectivity will mean that you are simply slow to respond to user requests. For example, clicking the "check for new email" menu button has no immediate effect. If you feel that you need a splash screen or progress indicator to tell the user that "we are really checking for new email, honest", then you know that your Internet access is slower than is ideal.

Obviously, some of this is unavoidable. However, the objective of the chapters in this part of the book is to give you an idea of ways to reduce your bandwidth consumption, making those delays be that much less annoying for your users.

You're Using Too Much of the Expensive Stuff

Mobile data tends to come with more strings attached than does WiFi.

In the US, it used to be that mobile data connections included unlimited usage. Now, at best, a mobile data plan has "unlimited" usage for a curious definition of the term "unlimited". More and more carriers are moving towards a hard cap — go above

the cap, and you either cannot use more bandwidth, have your speeds curtailed, or pay significantly for additional bandwidth.

Outside of the US, the “pay significantly for bandwidth” approach is fairly typical. So-called “metered” data plans simply charge you such-and-so per MB or GB of bandwidth.

And, to top it off, roaming almost always is a metered plan. So, a US resident traveling overseas, even with a SIM and phone that supports international usage, would pay a ridiculous sum for bandwidth. Stories of phone bills in the tens of thousands of dollars abound, where people simply used their phone as they normally would when they were outside of their home network.

Hence, if you use a fair bit of bandwidth, it would be really nice if you offered users means to consume less of it when they are on mobile data compared to WiFi (which is typically unmetered). You could elect to poll your server less frequently, for example, giving the users the ability to specify separate polling periods depending on which type of connection they have.

And, of course, there are other “costs” for using bandwidth besides direct monetary costs. For example, downloading data over a slower mobile data connection may consume more power than downloading the same data over WiFi — while the WiFi radio might consume additional power, the time difference might account for more power consumption, if the CPU could be powered down for the rest of that time.

These chapters will show you how you can react to changes in connectivity and approaches for how to use that information to reduce costs for the user.

You’re Using Too Much of Somebody Else’s Stuff

It is easy for developers to think that they alone are using a user’s device. Alas, this is infrequently the case, particularly when it comes to background Internet access.

While your application is busily downloading stuff, some other application might be busily downloading stuff. In principle, this should not be an issue, as multiple applications can access the Internet simultaneously. However, bandwidth can become an issue. If you are in the background, and the other application is in the foreground, the user might notice that bandwidth is an issue. For example, users might be unhappy if your downloads are impeding their ability to watch streaming video, or play their favorite Android-based MMORPG, or whatever.

A polite Android application will test to see whether the foreground application is heavily using the Internet and will curtail its own Internet use while that is going on. This chapter will help you learn how to make that determination and how to respond.

You're Using Too Much... And There Is None

Not only might location dictate how much bandwidth you have, but whether you have any bandwidth at all.

While some people think that the entire planet has connectivity, reality once again dictates otherwise. Major metropolitan areas have connectivity... at least, so long as the carriers have not melted down due to overuse, as AT&T tended to do during the early months of the iPhone Invasion. Outlying areas are much more hit-or-miss. Voice is sometimes a challenge, let alone data. And it only *seems* as though there is a Starbucks every 100 meters, which might actually provide blanket WiFi coverage.

Then, of course, there are planes (most do not offer in-flight WiFi at this time), international travel without an international-capable phone plan, and so on.

Some Android applications have the potential to still offer near-complete functionality despite this, with a bit of user assistance. For example, Google Maps for Android now has an offline caching feature, which will download data for a 10-mile radius from a given point, for use while the device is otherwise offline.

Here, the issue becomes less one of bandwidth (other than detecting that you have no connection) and more one of caching and storage. The space-related issues that these techniques can raise will be covered elsewhere in this book.

Focus On: TrafficStats

To be able to have more intelligent code — code that can adapt to Internet activity on the device — Android offers the `TrafficStats` class. This class really is a gateway to a block of native code that reports on traffic usage for the entire device and per-application, for both received and transmitted data. This chapter will examine how you can access `TrafficStats` and interpret its data.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

TrafficStats Basics

The `TrafficStats` class is not designed to be instantiated — you will not be invoking a constructor by calling `new TrafficStats()` or something like that. Rather, `TrafficStats` is merely a collection of static methods, mapped to native code, that provide access to point-in-time traffic values. No special permissions are needed to use any of these methods. Most of the methods were added in API Level 8 and therefore should be callable on most Android devices in use today.

Device Statistics

If you are interested in overall traffic, you will probably care most about the `getTotalRxBytes()` and `getTotalTxBytes()` on `TrafficStats`. These methods return received and transmitted traffic, respectively, measured in bytes.

You also have:

1. `getTotalRxPackets()` and `getTotalTxPackets()`, if for your case measuring IP packets is a better measure than bytes
2. `getMobileRxBytes()` and `getMobileTxBytes()`, which return the traffic going over mobile data (also included in the total)
3. `getMobileRxPackets()` and `getMobileTxPackets()`, which are the packet counts for the mobile data connection

Per-Application Statistics

Technically, `TrafficStats` does not provide per-application traffic statistics. Rather, it provides per-UID traffic statistics. In most cases, the UID (user ID) of an application is unique, and therefore per-UID statistics map to per-application statistics. However, it is possible for multiple applications to share a single UID (e.g., via the `android:sharedUserId` manifest attribute) — in this case, `TrafficStats` would appear to provide traffic data for all applications sharing that UID.

There are per-UID equivalents of the first four methods listed in the previous section, replacing “Total” with “Uid”. So, to find out overall traffic for an application, you could use `getUidRxBytes()` and `getUidTxBytes()`. However, these are the only two UID-specific methods that were implemented in API Level 8. Equivalents of the others (e.g., `getUidRxPackets()`) were added in API Level 12. API Level 12 also added some TCP-specific methods (e.g., `getUidTcpTxBytes()`). Note, though, that the mobile-only method are only available at the device level; there are no UID-specific versions of those methods.

Interpreting the Results

You will get one of two types of return value from these methods.

In theory, you will get the value the method calls for (e.g., number of bytes, number of packets). The documentation does not state the time period for that value, so while it is possible that it is really “number of bytes since the device was booted”, we do not know that for certain. Hence, `TrafficStats` results should be used for comparison purposes, either comparing the same value over time or comparing multiple values at the same time. For example, to measure bandwidth consumption, you will need to record the `TrafficStats` values at one point in time, then again later — the difference between them represents the consumed bandwidth during that period of time.

In practice, while the “total” methods seem reliable, the per-UID methods often return -1. The official explanation for this is that the particular traffic metric is unavailable on that device, and this does explain some of the -1 values that are returned. For example, a Nexus One running Android 2.3 returns -1 for all the per-UID methods, while a Nexus S running Android 2.3 will return a positive value for *some* UIDs. It is unclear what the other -1 values mean. Two possible meanings are:

1. There has been no traffic of that type on that UID since boot, or
2. You do not have permission to know the traffic of that type on that UID

Hence, the per-UID values are a bit “hit or miss”, which you will need to take into account.

Example: TrafficMonitor

To illustrate the use of `TrafficStats` methods and analysis, let us walk through the code associated with the [Bandwidth/TrafficMonitor](#) sample application. This is a simple activity that records a snapshot of the current traffic levels on startup, then again whenever you tap a button. On-screen, it will display the current value, previous value, and difference (“delta”) between them. In LogCat, it will dump the same information on a per-UID basis.

TrafficRecord

It would have been nice if `TrafficStats` were indeed an object that you would instantiate, that captured the traffic values at that moment in time. Alas, that is not how it was written, so we need to do that ourselves. In the `TrafficMonitor` project, this job is delegated to a `TrafficRecord` class:

```
package com.commonware.android.tuning.traffic;

import android.net.TrafficStats;

class TrafficRecord {
    long tx=0;
    long rx=0;
    String tag=null;

    TrafficRecord() {
        tx=TrafficStats.getTotalTxBytes();
        rx=TrafficStats.getTotalRxBytes();
    }

    TrafficRecord(int uid, String tag) {
```

```
        tx=TrafficStats.getUidTxBytes(uid);
        rx=TrafficStats.getUidRxBytes(uid);
        this.tag=tag;
    }
}
```

There are two separate constructors, one for the total case and one for the per-UID case. The total case just logs `getTotalRxBytes()` and `getTotalTxBytes()`, while the per-UID case uses `getUidRxBytes()` and `getUidTxBytes()`. The per-UID case also stores a “tag”, which is simply a `String` identifying the UID for this record — as you will see, `TrafficMonitor` uses this for a package name.

TrafficSnapshot

An individual `TrafficRecord`, though, is insufficient to completely capture the traffic figures at a moment in time. We need a collection of `TrafficRecord` objects, one for the device (“total”) and one per running UID. The work to collect all of that is handled by a `TrafficSnapshot` class:

```
package com.commonware.android.tuning.traffic;

import java.util.HashMap;
import android.content.Context;
import android.content.pm.ApplicationInfo;

class TrafficSnapshot {
    TrafficRecord device=null;
    HashMap<Integer, TrafficRecord> apps=
        new HashMap<Integer, TrafficRecord>();

    TrafficSnapshot(Context ctxt) {
        device=new TrafficRecord();

        HashMap<Integer, String> appNames=new HashMap<Integer, String>();

        for (ApplicationInfo app :
            ctxt.getPackageManager().getInstalledApplications(0)) {
            appNames.put(app.uid, app.packageName);
        }

        for (Integer uid : appNames.keySet()) {
            apps.put(uid, new TrafficRecord(uid, appNames.get(uid)));
        }
    }
}
```

The constructor uses `PackageManager` to iterate over all installed applications and builds up a `HashMap`, mapping the UID to a `TrafficRecord` for that UID, tagged with

the application package name (e.g., `com.commonware.android.tuning.traffic`). It also creates one `TrafficRecord` for the device as a whole.

TrafficMonitorActivity

`TrafficMonitorActivity` is what creates and uses `TrafficSnapshot` objects. This is a fairly conventional activity with a `TableLayout`-based UI:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/table"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <Button
        android:onClick="takeSnapshot"
        android:text="Take Snapshot"/>

    <TableRow>

        <TextView
            android:layout_column="1"
            android:layout_gravity="right"
            android:text="@string/received"
            android:textSize="20sp"/>

        <TextView
            android:layout_gravity="right"
            android:text="@string/sent"
            android:textSize="20sp"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:text="@string/latest"
            android:textSize="20sp"
            android:textStyle="bold"/>

        <TextView
            android:id="@+id/latest_rx"
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:textSize="20sp"/>

        <TextView
            android:id="@+id/latest_tx"
            android:gravity="right"
            android:textSize="20sp"/>
    </TableRow>
</TableLayout>
```

```
</TableRow>

<TableRow>

    <TextView
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:text="@string/previous"
        android:textSize="20sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/previous_rx"
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:textSize="20sp"/>

    <TextView
        android:id="@+id/previous_tx"
        android:gravity="right"
        android:textSize="20sp"/>
</TableRow>

<TableRow>

    <TextView
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:text="@string/delta"
        android:textSize="20sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/delta_rx"
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:textSize="20sp"/>

    <TextView
        android:id="@+id/delta_tx"
        android:gravity="right"
        android:textSize="20sp"/>
</TableRow>

</TableLayout>
```

The activity implementation consists of three methods. There is your typical `onCreate()` implementation, where we initialize the UI, get our hands on the `TextView` widgets for output, and take the initial snapshot:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
```

FOCUS ON: TRAFFICSTATS

```
setContentView(R.layout.main);

latest_rx=(TextView)findViewById(R.id.latest_rx);
latest_tx=(TextView)findViewById(R.id.latest_tx);
previous_rx=(TextView)findViewById(R.id.previous_rx);
previous_tx=(TextView)findViewById(R.id.previous_tx);
delta_rx=(TextView)findViewById(R.id.delta_rx);
delta_tx=(TextView)findViewById(R.id.delta_tx);

takeSnapshot(null);
}
```

The `takeSnapshot()` method creates a new `TrafficSnapshot` (held in a latest data member) after moving the last `TrafficSnapshot` to a previous data member. It then updates the `TextView` widgets for the latest data and, if the previous data member is not null, also for the previous snapshot and the difference between them. This alone is sufficient to update the UI, but we also want to log per-UID data to LogCat:

```
public void takeSnapshot(View v) {
    previous=latest;
    latest=new TrafficSnapshot(this);

    latest_rx.setText(String.valueOf(latest.device.rx));
    latest_tx.setText(String.valueOf(latest.device.tx));

    if (previous!=null) {
        previous_rx.setText(String.valueOf(previous.device.rx));
        previous_tx.setText(String.valueOf(previous.device.tx));

        delta_rx.setText(String.valueOf(latest.device.rx-previous.device.rx));
        delta_tx.setText(String.valueOf(latest.device.tx-previous.device.tx));
    }

    ArrayList<String> log=new ArrayList<String>();
    HashSet<Integer> intersection=new HashSet<Integer>(latest.apps.keySet());

    if (previous!=null) {
        intersection.retainAll(previous.apps.keySet());
    }

    for (Integer uid : intersection) {
        TrafficRecord latest_rec=latest.apps.get(uid);
        TrafficRecord previous_rec=
            (previous==null ? null : previous.apps.get(uid));

        emitLog(latest_rec.tag, latest_rec, previous_rec, log);
    }

    Collections.sort(log);

    for (String row : log) {
        Log.d("TrafficMonitor", row);
    }
}
```

```
}  
}
```

One possible problem with the snapshot system is that the process list may change between snapshots. One simple way to address this is to only log to LogCat data where the application's UID exists in both the previous and latest snapshots. Hence, `takeSnapshot()` uses a `HashSet` and `retainAll()` to determine which UIDs exist in both snapshots. For each of those, we call an `emitLog()` method to record the data to an `ArrayList`, which is then sorted and dumped to LogCat.

The `emitLog()` method builds up a line with the package name and bandwidth consumption information, assuming that there is bandwidth to report (i.e., we have a value other than -1):

```
private void emitLog(CharSequence name, TrafficRecord latest_rec,  
                    TrafficRecord previous_rec,  
                    ArrayList<String> rows) {  
    if (latest_rec.rx > -1 || latest_rec.tx > -1) {  
        StringBuilder buf = new StringBuilder(name);  
  
        buf.append("=");  
        buf.append(String.valueOf(latest_rec.rx));  
        buf.append(" received");  
  
        if (previous_rec != null) {  
            buf.append(" (delta=");  
            buf.append(String.valueOf(latest_rec.rx - previous_rec.rx));  
            buf.append(")");  
        }  
  
        buf.append(", ");  
        buf.append(String.valueOf(latest_rec.tx));  
        buf.append(" sent");  
  
        if (previous_rec != null) {  
            buf.append(" (delta=");  
            buf.append(String.valueOf(latest_rec.tx - previous_rec.tx));  
            buf.append(")");  
        }  
  
        rows.add(buf.toString());  
    }  
}
```

Since the lines created by `emitLog()` start with the package name, and since we are sorting those before dumping them to LogCat, they appear in LogCat in sorted order by package name.

Using TrafficMonitor

Running the activity gives you the initial received and sent counts (in bytes):

Figure 772: The TrafficMonitor sample application, as initially launched

Tapping Take Snapshot grabs a second snapshot and compares the two:

FOCUS ON: TRAFFICSTATS

	<u>Received</u>	<u>Sent</u>
Latest	254328236	126647372
Previous	254326126	126645374
Delta	2110	1998

Figure 773: The TrafficMonitor sample application, after Take Snapshot was clicked

Also, LogCat will show how much was used by various apps:

```

```

Other Ways to Employ TrafficStats

Of course, there are more ways you could use TrafficStats than simply having an activity to report them on a button click. TrafficMonitor is merely a demonstration of using the class and providing a lightweight way to get value out of that data. Depending upon your application's operations, though, you may wish to consider using TrafficStats in other ways, in your production code or in your test suites.

In Production

If your app is a bandwidth monitor, the need to use TrafficStats is obvious. However, even if your app does something else, you may wish to use TrafficStats to understand what is going on in terms of Internet access within your app or on the device as a whole.

For example, you might want to consider bandwidth consumption to be a metric worthy of including in the rest of the “analytics” you generate from your app. If you are using services like [Flurry](#) to monitor which activities get used and so on, you might consider also logging the amount of bandwidth your application consumes. This not only gives you much more “real world” data than you will be able to collect on your own, but it may give you ideas of how users are using your application beyond what the rest of your metrics are reporting.

Another possibility would be to include your app's bandwidth consumption in error logs reported via libraries like [ACRA](#). Just as device particulars can help identify certain bug report patterns, perhaps certain crashes of your app only occur when users are using a lot of bandwidth in your app, or using a lot of bandwidth elsewhere and perhaps choking your own app's Internet access.

The [chapter on bandwidth mitigation strategies](#) will also cover a number of uses of `TrafficStats` for real-time adjustment of your application logic.

During Testing

You might consider adding `TrafficStats`-based bandwidth logging for your application in your test suites. While individual tests may or may not give you useful data, you may be able to draw trendlines over time to see if you are consuming more or less bandwidth than you used to. Take care to factor in that you may have changed the tests, in addition to changing the code that is being tested.

From a JUnit-based unit test suite, measuring bandwidth consumption is not especially hard. You can bake it into the `setUp()` and `tearDown()` methods of your test cases, either via inheritance or composition, and log the output to a file or `LogCat`.

From an external test engine, like [monkeyrunner](#) or [NativeDriver](#), recording bandwidth usage is more tricky, because your test code is not running on the device or emulator. You may have to include a `BroadcastReceiver` in your production code that will log bandwidth usage and trigger that code via the `am broadcast shell` command.

Measuring Bandwidth Consumption

The first step towards addressing bandwidth concerns is to get a better picture of how much bandwidth you are actually consuming, when, and under what conditions. Only then will you be able to determine where your efforts need to be applied and whether those efforts are actually giving you positive results. This chapter will examine a handful of ways you can determine how much bandwidth you are really using in your application.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

On-Device Measurement

Many times, you are best served by measuring your bandwidth consumption right on the device itself:

1. This is your only option for gathering bandwidth metrics from copies of your app in end users' hands, unless they invite you to their home or office and have you sniff on their personal network, which seems unlikely
2. This is your only option for gathering bandwidth metrics when you are using mobile data plans (e.g., 3G) instead of WiFi, since you probably do not control the wireless telecommunications infrastructure in your area
3. This is your simplest option for tying bandwidth metrics to events within your app or occurring on the device

4. This is your only option for using bandwidth metrics to adjust your application behavior in real time, in addition to using the metrics to learn how best to adjust your code in future updates to the app

Hence, in addition to perhaps other off-device techniques, you really should consider one of the on-device approaches outlined in the following sections.

Yourself, via TrafficStats

The [preceding chapter](#) outlined how to use the TrafficStats class to collect metrics on the bandwidth consumed by applications (including yours) and for the device as a whole. This gives you the most flexibility, because you can write your own code to collect whatever portion of this data you need. It can address all of the bullets shown above, for example.

It is not perfect, though:

1. It requires you to write your own code, adding yet more work to your plate
2. Per-UID traffic data may or may not be available, depending upon the device

Existing Android Applications

If you do not want to write code to use TrafficStats, there are various applications on the Play Store that can report that data to you, much along the lines of how TrafficMonitor does. Here are some notes about a few free ones tested by the author:

1. [Network Traffic Detail](#) (v. 1.3) works, but does not consider that bandwidth is only reported per UID, not per application. As a result, it reports the same traffic multiple times, one for each application sharing a UID.
2. [Traffic Monitor](#) (v. 2.4.2) advertises itself as an application, but does not put an icon in the launcher for it, forcing you to install an app widget instead in order to get to the actual application. While it reports device-level bandwidth, and it has a task manager, the task list does not report bandwidth for those tasks.
3. [Bandwidth Monitor](#) (v. 1.0.6) works and is perhaps incrementally easier to use than the other alternatives, though its touted bar chart of bandwidth consumption lacks any indicator of the value of the Y axis.

There are certainly others on the Market today and more will show up over time. For your own use, these sorts of apps may be very helpful. However, since you control

nothing over what is collected and how (and, in the case of some, even when it is collected), it may be difficult for you to get a solid grasp on where your code is consuming bandwidth this way.

There are also various apps that provide more in the way of packet-sniffing capability. However, these require you to root your phone and run the app with root privileges.

Off-Device Measurement

The biggest limitation of `TrafficStats` is that it only gives you gross metrics: numbers of bytes, packets, and so on. Sometimes, that is not enough to help you understand why those bytes, packets, and so on are actually being sent or received. Sometimes, it would be nice to understand the traffic in more detail, from the ports and IP addresses to perhaps the actual data being transmitted. For obvious security reasons, this is not something an ordinary Android SDK application can do. However, there are techniques for accomplishing this, mostly for use over WiFi in your own home or office network. Some of these are outlined in the following sections.

Wireshark

[Wireshark](#), formerly known as Ethereal, is perhaps the world's leading open source network traffic analyzer and packet inspector. Using it, you can learn in great detail what is going on with your local network. And, Android provides additional options for you to leverage Wireshark to make sense of application behavior. Wireshark is available for Linux, OS X, and Windows.

There is a lightly-documented `-tcpdump` switch available on the Android emulator. If you launch the emulator from the command line with that switch (plus `-avd` to identify the AVD file you want to use), all network access is dumped to your specified log file. You can then load that data into Wireshark for analysis, via File|Open from the main menu.

For example, here is a screenshot of Wireshark examining data from such an emulator dump file, in which the emulator was used to conduct a Google search:

MEASURING BANDWIDTH CONSUMPTION

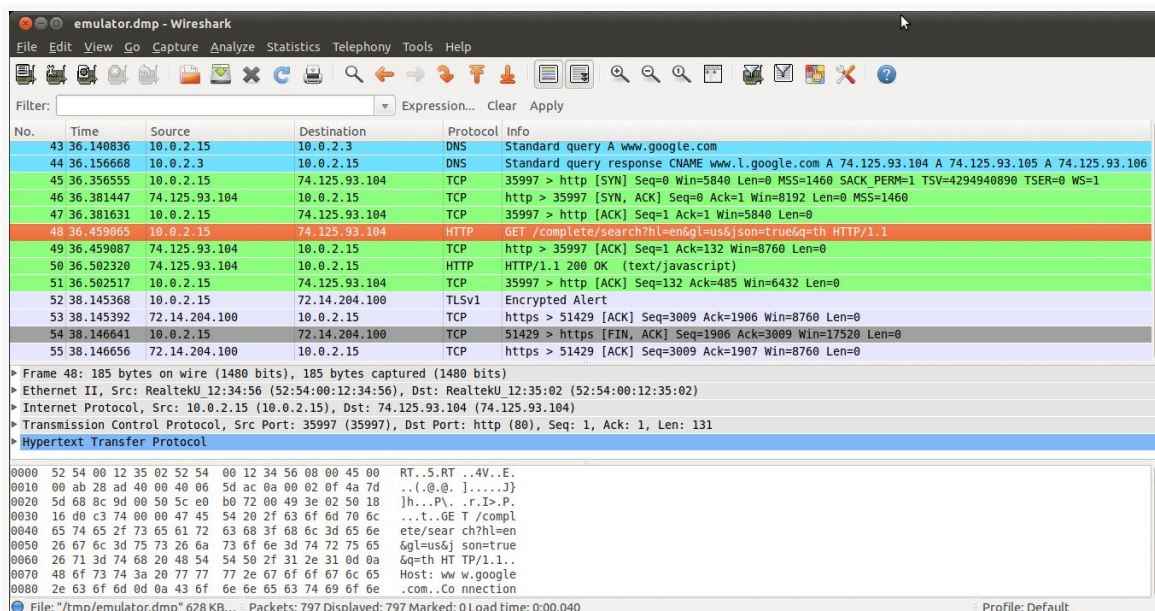

Figure 774: Wireshark examining captured emulator packets

This screenshot shows an HTTP request in the highlighted line in the list, with the hex and ASCII contents of the request shown in the bottom pane.

In terms of using Wireshark to monitor traffic from actual hardware, that is indubitably possible. However, WiFi packet collection is a tricky process with Wireshark, being very dependent upon operating system and possibly even the WiFi adapter chipset. You also get much lower-level information, making it a bit more challenging to figure out what is going on. Attempting to cover all of this is well beyond the scope of this book and the author's Wireshark expertise.

Networking Hardware

Sophisticated firewalls sometimes have packet tracing/sniffing capability. In this case, “sophisticated” does not necessarily mean “expensive”, as open source router/firewall distributions, like OpenWrt, can be used for this sort of work. In this case, the router captures the packets and, in many cases, routes them to Wireshark for analysis. Some might offer on-board analysis (e.g., Web interface to packet capture logs).

This is particularly useful on a Windows wireless network. Wireshark has limits, imposed by Windows, that cause some problems when trying to capture WiFi

packets. By offloading the packet capture to networking hardware, those limits can be bypassed.

Tactical Measurement in DDMS

TrafficStats is great for measuring gross bandwidth consumption over some period of time. However, it requires coding, logging, and your own analysis mechanism.

Another approach is to use the new Network Statistics view available as part of DDMS. This view will report, in real time, what your receiving and transmitting bandwidth usage is, in the form of a line chart. This tool was added to the r17 edition of the Android tools.

To use this view, you will need a device running Android 4.0.3 or higher. It does not work with the emulator or older devices, unfortunately.

If you have such a device though, when you run your app on it, you can:

- Open the Network Statistics view in Eclipse (or the equivalent in the standalone monitor tool)
- Run your app and get it ready for testing
- Click on your debuggable process in the Devices view
- Choose a refresh speed for the line chart (100ms, 250ms, or 500ms) in the Network Statistics view
- Click the Start button adjacent to the speed drop-down
- Do something in your app to trigger network I/O
- Click the Stop button to freeze the updates to the line chart

What you will get, out of the box, is something like this:

MEASURING BANDWIDTH CONSUMPTION

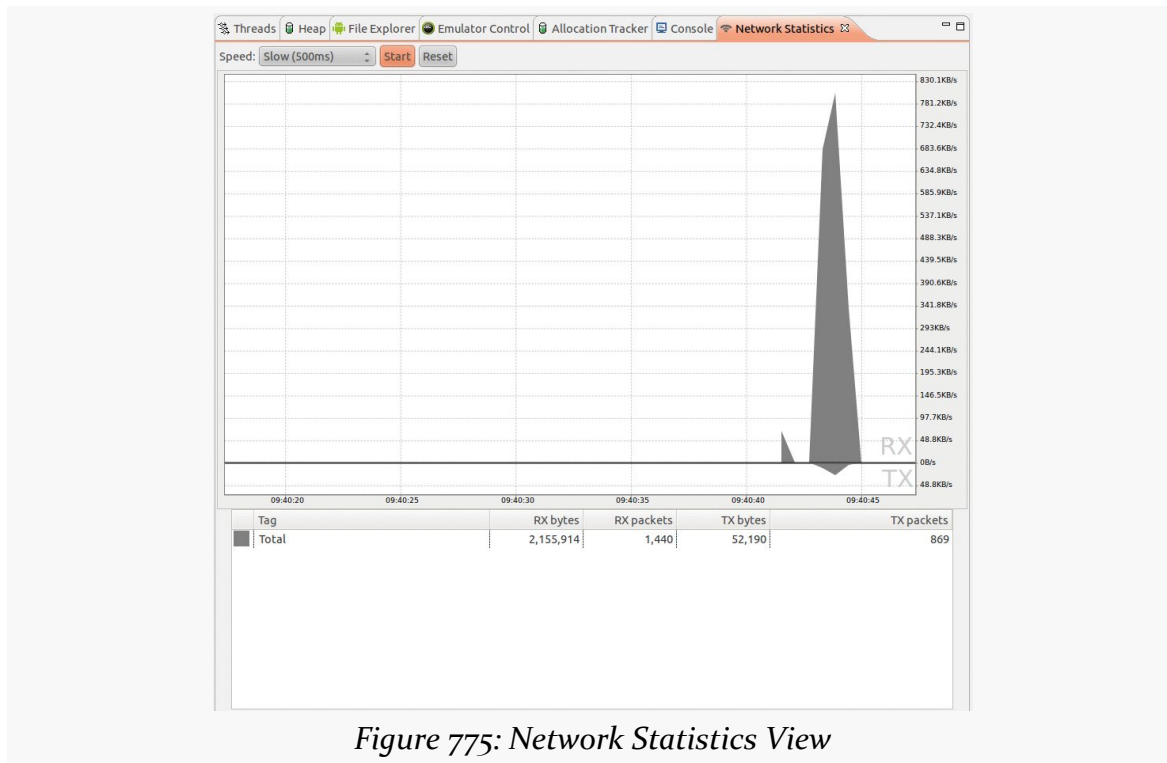

Figure 775: Network Statistics View

This particular output came from a run of the DownloadItYourself demo app from earlier in the book. The table at the bottom shows the total amount of bandwidth consumed during the test run, and the line chart at the top helps to illustrate when we consumed that bandwidth. Received bandwidth appears above the baseline; transmitted bandwidth appears below the baseline.

For fairly simple cases, this is all you will need. If, however, you have lots of things going on, you might want to track individual bits of network I/O. Android supports a tagging concept that will help with this, allowing you to associate a tag with the current thread.

In most cases, if you are using higher-level libraries like `URLConnection` or `HttpClient`, you would use `setThreadStatsTag()`, a static method added to `TrafficStats` in API Level 14. You supply an integer “tag”, which will be associated with network I/O performed on that tag from those libraries. If you are working with raw sockets, you will also need to use `tagSocket()` and `untagSocket()` to associate the work for that socket with the tag for the current thread.

This will then give you a much more detailed set of output, showing not only total network I/O but per-tag network I/O:

MEASURING BANDWIDTH CONSUMPTION

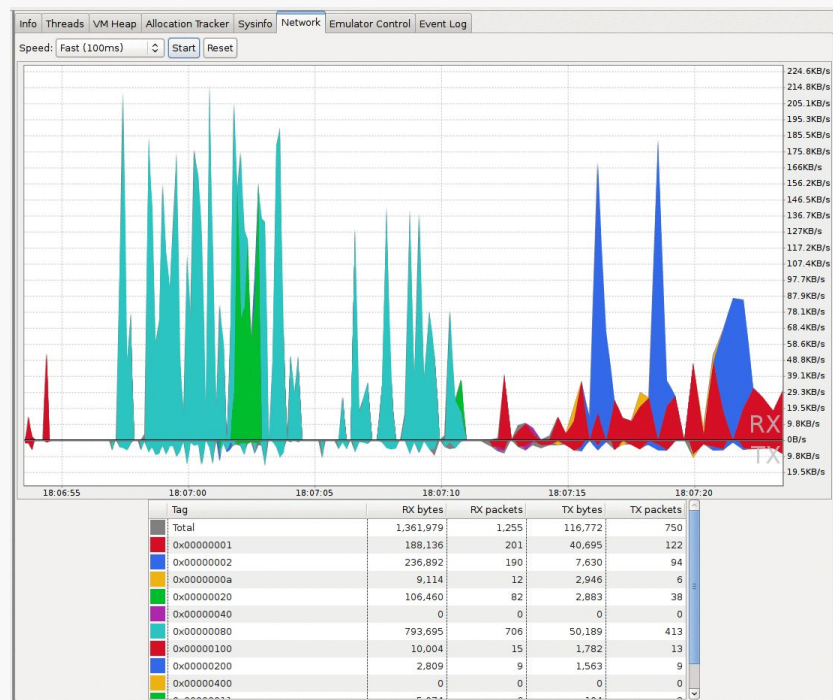

Figure 776: Network Statistics Detailed View (image courtesy of Android Open Source Project)

Clicking the Reset button, to the right of the Start button, clears the graph and table, to give you fresh results for your next test.

Being Smarter About Bandwidth

Given that you are [collecting metrics about bandwidth consumption](#), you can now start to determine ways to reduce that consumption. You may be able to permanently reduce that consumption (at least on a per-operation basis). You may be able to shunt that consumption to times or networks that the user prefers. This chapter reviews a variety of means of accomplishing these ends.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Internet access](#).

Bandwidth Savings

The best way to reduce bandwidth consumption is to consume less bandwidth.

(in other breaking news, water is wet)

In recent years, developers have been able to be relatively profligate in their use of bandwidth, pretty much assuming everyone has an unlimited high-speed Internet connection to their desktop or notebook and the desktop or Web apps in use on them. However, those of us who lived through the early days of the Internet remember far too well the challenges that dial-up modem accounts would present to users (and perhaps ourselves). Even today, as Web apps try to “scale to the Moon and back”, bandwidth savings becomes important not so much for the end user, but for the Web app host, so its own bandwidth is not swamped as its user base grows.

Fortunately, widespread development problems tend to bring rise to a variety of solutions — a variant on the “many eyes make bugs shallow” collaborative development phenomenon. Hence, there are any number of tried-and-true techniques for reducing bandwidth consumption that have had use in Web apps and elsewhere. Many of these are valid for native Android apps as well, and a few of them are profiled in the following sections.

Classic HTTP Solutions

Trying to get lots of data to fit on a narrow pipe — whether that pipe is on the user’s end or the provider’s end — has long been a struggle in Web development. Fortunately, there are a number of ways you can leverage HTTP intelligently to reduce your bandwidth consumption.

GZip Encoding

By default, HTTP requests and response are uncompressed. However, you can enable GZip encoding and thereby request that the server compress its response, which is then decompressed on the client. This trades off CPU for bandwidth savings and therefore needs to be done judiciously.

Enabling GZip compression is a two-step process:

- Adding the Accept-Encoding: gzip header to the HTTP request
- Determine if the response was compressed and, if so, decompressing it

Bear in mind that the Web server may or may not honor your GZip request, for whatever reason (e.g., response is too small to make it worthwhile).

For example, using the HttpClient library in Android, you could add the header on the request:

```
HttpGet get=new HttpGet(url);  
get.addHeader("Accept-Encoding", "gzip");  
  
// rest of configuration here, if any  
  
// execute the request given an HttpClient object named client  
HttpResponse response=client.execute(get);
```

Then, you can check the response and get a valid InputStream for either the compressed or the not-compressed cases:

```
// assumes HttpResponse response as in above code snippet

InputStream stream=response.getEntity().getContent();
Header enc=response.getFirstHeader("Content-Encoding");

if (enc!=null && enc.getValue().equalsIgnoreCase("gzip")) {
    stream=new GZIPInputStream(stream);
}

// at this point, stream will work for either encoding
```

Equivalents exist for using `URLConnection`, if you prefer to use that HTTP API in Android.

If-Modified-Since / If-None-Match

Of course, avoiding a download offers near-100% compression. If you are caching data, you can take advantage of HTTP headers to try to skip downloads that are the same content as what you already have, specifically `If-Modified-Since` and `If-None-Match`.

An HTTP response can contain either a `Last-Modified` header or an `ETag` header. The former will contain a timestamp and the latter will contain some opaque value. You can store this information with the cached copy of the data (e.g., in a database table). Later on, when you want to ensure you have the latest version of that file, your HTTP GET request can include an `If-Modified-Since` header (with the cached `Last-Modified` value) or an `If-None-Match` header (with the cached `ETag` value). In either case, the server should return either a 304 response, indicating that your cached copy is up to date, or a 200 response with the updated data. As a result, you avoid the download entirely (other than HTTP headers) when you do not need the updated data.

For example, using `HttpClient`, you can check for the existence of an `ETag` header in an HTTP response:

```
HttpGet get=new HttpGet(url);

// execute the request given an HttpClient object named client
HttpResponse response=client.execute(get);
Header etag=response.getFirstHeader("ETag");

if (etag!=null) {
    // cache this
}

// process the download
```

On subsequent requests, you can add the If-None-Match header and handle both cases:

```
HttpGet get=new HttpGet(url);

get.addHeader("If-None-Match", etag);

// execute the request given an HttpClient object named client
HttpResponse response=client.execute(get);
int sc=response.getStatusLine().getStatusCode();

if (sc!=HttpStatus.SC_NOT_MODIFIED) {
    // cache invalid, so process the download and, perhaps, grab fresh
    // ETag
}
```

Using Last-Modified and If-Modified-Since is mostly a matter of switching headers. And, once again, there are equivalent ways to use these headers with `URLConnection`.

Binary Payloads

While XML and JSON are relatively easy for humans to read, that very characteristic means they tend to be bloated in terms of bandwidth consumption. There are a variety of tools, such as Google's [Protocol Buffers](#) and Apache's [Thrift](#), that allow you to create and parse binary data structures in a cross-platform fashion. These might allow you to transfer the same data that you would in XML or JSON in less space. As a side benefit, parsing the binary responses is likely to be faster than parsing XML or JSON. Both of these tools involve the creation of an IDL-type file to describe the data structure, then offer code generators to create Java classes (or equivalents for other languages) that can read and write such structures, converting them into platform-neutral on-the-wire byte arrays as needed.

Minification

If you are loading JavaScript or CSS into a `WebView`, you should consider standard tricks for compressing those scripts, collectively referred to as “[minification](#)”. These techniques eliminate all unnecessary whitespace and such from the files, rename variables to be short, and otherwise create a syntactically-identical script that takes up a fraction of the space. There are services like [box.js](#) that can even aggregate several scripts into one file and minify them, to further reduce HTTP overhead.

Push versus Poll

Another way to consume less bandwidth is to only make the requests when it is needed. For example, if you are writing an email client, the way to use the least bandwidth is to download new messages only when they exist, rather than frequently polling for messages.

Off the cuff, this may seem counter-intuitive. After all, how can we know whether or not there are any messages if we are not polling for them?

The answer is to use a low-bandwidth push mechanism. The quintessential example of this is GCM, the Google Cloud Messaging system, available for Android 2.2 and newer. This service from Google allows your application to subscribe to push notifications sent out by your server. Those notifications are delivered asynchronously to the device by way of Google's own servers, using a long-lived socket connection. All you do is register a `BroadcastReceiver` to receive the notifications and do something with them.

For example, Remember the Milk — a task management Web site and set of mobile apps — uses GCM to alert the device of task changes you make through the Web site. Rather than the Remember the Milk app having to constantly poll to see if tasks were added, changed, or deleted, the app simply waits for GCM events.

You could create your own push mechanism, perhaps using a `WebSocket` or Comet-style long-poll technique. The downside is that you will need a service in memory all of the time to manage the socket and thread that monitors it. If you only need this while your service is in memory for other reasons, that is fine. However, keeping a service in memory 24x7 has its own set of issues, not the least of which is that users will tend to smack it down using a “task killer” or the Manage Services screen in the Settings app.

Thumbnails and Tiles

A general rule of thumb is: don't download it until you really need it.

Sometimes, you do not know if you really need a particular item until something happens in the UI. Take a `ListView` displaying thumbnails of album covers for a music app. Assuming the album covers are not stored locally, you will need to download them for display. However, which covers you need varies based upon scrolling. Downloading a high-resolution album cover that might get tossed in a

matter of milliseconds (after an expensive rescale to fit a thumbnail-sized space) is a waste of bandwidth.

In this case, either the album covers are something you control on the server side, or they are not. If they are, you can have the server prepare thumbnails of the covers, stored at a spot that the app can know about (e.g., `.../cover.jpg` it is `.../thumbnail.jpg`). The app can then download thumbnails on the fly and only grab the full-resolution cover if needed (e.g., user clicks on the album to bring up a detail screen). If you do not control the album covers, this option might still be available to you if you can run your own server for the purposes of generating such thumbnails.

You can see a similar effect with the map tiles in Google Maps. When zooming out, the existing map tiles are scaled down, with placeholders (the gridlines) for the remaining spots, until the tiles for those spots are downloaded. When zooming in, the existing map tiles are scaled up with a slight blurring effect, to give the user some immediate feedback while the full set of more-detailed tiles is downloaded. And, if the user pans, you once again get placeholders while the tiles for the newly uncovered areas are downloaded. In this fashion, Google Maps is able to minimize bandwidth consumption by giving users partial results immediately and back-filling in the final results only when needed. This same sort of approach may be useful with your own imagery.

Collaborative Bandwidth

For some common services, perhaps sharing is the best option to reduce bandwidth usage.

For example, consider Twitter. It is entirely possible that a user might have multiple applications all polling and downloading the user's timeline:

1. A built-in Twitter app that the user does not like, but cannot uninstall
2. A regular Twitter app that the user employs for normal stuff
3. A separate Twitter app widget, because the other Twitter apps on the device either lack an app widget or the user does not like it
4. Yet another application that uses Twitter as one of several data sources (e.g., monitoring for references to certain keywords, such as a company name, across multiple social networks)

In an ideal world, all of these apps would use one common engine that handles collecting the tweets and making them available — securely — to the other

applications. This would dramatically cut bandwidth by eliminating redundant polling.

If your data source is used by other applications, consider reaching out to those developers and creating a common engine, perhaps using a `ContentProvider` for data sharing, an `IntentService` or sync provider for collecting the data, plus common activities for preferences. Distribute the code to all of the development teams as an Android library project. Ship these components disabled in your manifest, enabling them if you cannot find another implementation on the device, indicating that you are the only one of this “application family” installed. If you do find another implementation, use that one instead of your own. There are certainly issues to be dealt with here (e.g., what if the user uninstalls the app that the others are depending upon), but it is worth considering for shared development costs as well as shared bandwidth.

Bandwidth Shaping

Sometimes, you have no ability to reduce the bandwidth itself. Perhaps you do not control both ends of the communications pipeline. Perhaps the data you are trying to exchange is already compressed (e.g., downloading an MP4 video). Perhaps some of the techniques in the preceding section were unavailable to you (e.g., cannot route data through third-party servers like Google’s for [GCM](#)).

There still may be ways for you to help your users, by shaping your bandwidth use. Rather than just blindly doing whatever you want whenever you want, you learn what the *user* wants and what *other applications* want and tailor your bandwidth use on the fly to match those needs. The following sections outline some ways of achieving this.

Driven by Preferences

If you are consuming enough bandwidth that this chapter is relevant to you, you probably are consuming enough bandwidth that you should be asking the user how best to consume that bandwidth. After all, they are the one paying the price — in time as well as money – for that consumption.

The following sections present some possible strategies for preference-based bandwidth shaping.

Budgets

One strategy is for the user to give you a budget (e.g., 20MB/day) and for you to stick within that budget.

Collecting the budget is fairly easy — just use `SharedPreferences`. Either use a `ListPreference` with likely budget value or an `EditTextPreference` and a bit of validation for a free-form budget amount.

Next, you will need to have some idea how much bandwidth any given network operation will consume. For some things, this might be an estimate based on your experiments as a developer, or perhaps it is based on historical averages for this user and type of operation. For example, a “podcatcher” (feed reader designed to download podcast episodes) should have some idea how big a given RSS or Atom feed download should be. In some cases, it might be worthwhile to get a better estimate — for example, the podcatcher might use an HTTP HEAD request to determine the size of the MP3 or OGG file before deciding whether to download it.

Then, you need to be keeping track of your budget. This could be a simple flat file with the initial `TrafficStats` bandwidth values for your process. Re-initialize that file on the first network operation of the day (or whatever period you chose for your budget). Before doing another network operation, compare the current `TrafficStats` values with the initial ones and see how close you are to the budget. If the new network operation will exceed the budget, skip the operation, perhaps putting it in a work queue to perform in the next budget. You might even hold a reserve for certain types of operations. For example, the podcatcher might ensure there is at least 10% of the budget available for downloading the feeds, even if it means putting a podcast on the queue for download tomorrow. That way, you can present to the user the latest podcast information, with icons indicating which are downloaded and which are queued for download — the user might be able to then request to override the budget and download something on demand.

For devices that lack per-UID `TrafficStats` support, you will have to “fake it” a bit. Use your own calculations of how much bandwidth each operation consumes and track that information, even if you wind up missing out on some bytes here or there.

Connectivity

If the user might not care how much bandwidth you consume, so long as it is unmetered bandwidth, you might include a `CheckBoxPreference` to indicate if large network operations should be limited to WiFi and avoid mobile data.

You could then use `ConnectivityManager` and `getActiveNetworkInfo()` to see what connection you have before performing a network operation. If it is a background operation (e.g., the podcatcher checking for new podcasts every hour), if the network is not the desired one, you can skip the operation or put it on a work queue for re-trying later. If it is a foreground operation (e.g., the user clicked a “refresh” menu choice), you could pop up a confirmation `AlertDialog` to warn the user that they are on mobile data — perhaps this time they are interested in doing the operation anyway.

Another approach for handling the background operations is to register a `BroadcastReceiver` for the `CONNECTIVITY_ACTION` broadcast (defined on `ConnectivityManager`). If the connectivity switches to mobile data, cancel your outstanding `AlarmManager` alarms; if connectivity switches to WiFi, re-enable those alarms.

Of course, you should also consider monitoring the background data setting — the global Settings checkbox indicating whether background network operations are allowed. On `ConnectivityManager`, `getBackgroundDataSetting()` tells you the state of this checkbox, and `ACTION_BACKGROUND_DATA_SETTING_CHANGED` allows you to set up a `BroadcastReceiver` to watch for changes in its state.

Windows

If your user is less concerned about the bandwidth or the network, but does care about the time of day (e.g., does not want your application consuming significant bandwidth when they might be getting a VOIP call), you could offer preferences for that as well. Cook up a `TimePreference` and use that to collect start and stop times for the high-bandwidth window. Then, set up alarms with `AlarmManager` for those points in time. The alarm for the start time of the window sets up a third alarm with your regular polling interval. The alarm for the stop time of the window cancels the polling interval alarm.

Driven by Other Usage

If your network I/O is part of a foreground application, one presumes that you are the most important thing in the user's life right now. Or, at least, the most important thing on the user's phone right now. Hence, what other applications might want to do with the Internet connection is not a major concern.

If, however, your network I/O is part of a background operation, it might be nice to try to avoid doing things that might upset the user. If the user is watching streaming video or is on a VOIP call or otherwise is aware of bandwidth changes, the bandwidth you use might impact the user in ways that the user will not appreciate very much. This is unlikely to be a big problem for small operations (e.g., downloading a 1KB JSON file), but larger operations (e.g., downloading a 5MB podcast) might be more noticeable.

You can use `TrafficStats` to help here. Before doing the actual network I/O, grab the current traffic data, wait a couple of seconds, and compare the latest to the previous values. If little to no bandwidth was consumed during that period, assume it is safe and go ahead and do your work. If, however, a bunch of bandwidth was consumed, you might want to consider:

1. Skipping this polling cycle and trying again later, or
2. Adding a one-off alarm using `set()` on `AlarmManager` to give you control again in a minute, with the current traffic data packaged as an extra on the `Intent`, so you can make a decision after a bigger sample size of bandwidth consumption, or
3. Adding an entry in a persistent work queue, so you know later on to try again if bandwidth contention has improved

You could try to get more sophisticated, by using `ActivityManager` and the per-UID values from `TrafficStats` to see if it is a foreground application that is the one consuming the bandwidth. It is unclear how reliable this will be, both in determining who is consuming the bandwidth (again, per-UID traffic is not available on many devices) and in avoid user angst. It may be simpler just to assume the worst and side-step your I/O until the other apps have quieted down.

Avoiding Metered Connections

Android 4.1 (a.k.a., Jelly Bean) added `isActiveNetworkMetered()` as a method on `ConnectivityManager`. In principle, this will return `true` if Android thinks that the

BEING SMARTER ABOUT BANDWIDTH

current data connection may involve bandwidth charges. You can examine this value and steer your bandwidth consumption accordingly.

Issues with Application Heap

RAM. Developers nowadays are used to having lots of it, and a virtual machine capable of using as much of it as exists (and more, given swap files and page files).

“Graybeards” — like the author of this book — distinctly remember a time when we had 16KB of RAM and were happy for it. Such graybeards would also appreciate it if you would get off their respective lawns.

Android comes somewhere in the middle. We have orders of magnitude more RAM than, say, the TRS-80 Model III. We do not have as much RAM as does the modern notebook, let alone a Web server. As such, it is easy to run out of RAM if you do not take sufficient care.

There are two facets of memory issues with Android:

- What are the problems we encounter inside our own app, in terms of our application heap?
- What problems can we encounter with system RAM overall, and how can we resolve them?

This part of the book examines memory-related issues, with this chapter focusing on the application heap. Another chapter will deal with [system RAM issues](#). These are not to be confused with any memory-related issues inherent to graybeards.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#).

You Are in a Heap of Trouble

When we think of “memory” and Java-style programming, the primary form of memory is the heap. The heap holds all of our Java objects – from an Activity to a widget to a String.

Traditional Java applications have an initial heap size determined by the virtual machine, possibly configured via command-line options when the program was run. Traditional Java applications can also request additional memory from the OS, up to some maximum, also configurable.

Android applications have the same basic structure, with very limited configurability and much lower maximums than you might expect.

Older Android devices, particularly those with HVGA screens like the T-Mobile G1, tend to have a maximum of 16MB of heap space. Newer Android phones with higher-resolution screens might have 24MB (Motorola DROID) or 32MB (Nexus One) of heap space. Tablets might have 48MB of heap space.

This heap limit can be problematic. For example, each widget or layout manager instance takes around 1KB of heap space. This is why AdapterView provides the hooks for view recycling — we cannot have a ListView with literally thousands of row views without potentially running out of heap.

API Level 11+ supports applications requesting a “large heap”. This is for applications that specifically need tons of RAM, such as an image editor to be used on a tablet. This is not for applications that run out of heap due to leaks or sloppy programming. Bear in mind that users will feel effects from large-heap applications, in that their other applications will be kicked out of memory more quickly, possibly irritating them. Also, garbage collection on large-heap applications runs more slowly, consuming more CPU time. To enable the large heap, add `android:largeHeap="true"` to the `<application>` element of your manifest.

Determining Your Heap Size At Runtime

To get a sense for how much heap you will be able to potentially grow to, you can call `getMemoryClass()` on an `ActivityManager`. This will return your per-process heap limit in megabytes.

If you requested `android:largeHeap="true"` in the manifest, use `getLargeMemoryClass()` on `ActivityManager` to learn how large your “large heap” actually is. Note that it is entirely possible that the “large heap” is not all that large, or potentially is no bigger than the standard heap, depending upon how much RAM is physically present on the device.

Fragments of Memory

The Dalvik garbage collector is a non-compacting implementation, which makes `OutOfMemoryError` messages somewhat more likely than you would find on traditional Java environments.

Here, “non-compacting” means that Dalvik does not try to move objects around in physical memory to “compact” the use of physical memory, leaving a large contiguous block of free physical memory for future allocations.

For example, suppose that we allocate three 1K byte arrays, named A, B, and C. As it turns out, they were allocated using adjacent portions of physical memory, so that the last byte of A immediately precedes the first byte of B, and so on. Hence, we consumed 3K of available heap space to create these three 1K blocks.

If we release all references to A and B, they can be garbage-collected. Dalvik, like Java, will see that A and B are adjacent and will free up their physical memory, such that the memory is available as one contiguous 2K block for future allocations.

If, however, released all references to A and C instead of A and B, Dalvik would be unable to make their blocks be contiguous, and so our heap would have two free 1K blocks, in addition to whatever other free memory that the heap already had.

Hence, allocating memory not only ties up that memory while it is in use, but it may *fragment* the memory even when it is released, such that our formerly pristine heap is now comprised of lots of little free blocks of space, separated from other such blocks by in-use objects. When we try to make a large allocation, such as setting up a byte array for a large image, it may be that while we have enough *total* heap available for the request, there is no single block that would meet our request, and so we get an `OutOfMemoryError`.

One technique to help address this is to pre-allocate any large buffers that you know you need, up front when your process starts up, such as via a custom `Application` subclass. Then, use an “object pool” approach to obtain, use, and reuse these pre-

allocated buffers, rather than having them be garbage-collected and have to be re-allocated later.

Getting a Trim

It would be nice if we knew when a good time would be to cut back on our heap usage. For example, if we are caching a lot of data in our process, to save on future disk I/O, we could free up those caches at some point to help minimize our heap usage.

Fortunately, Android has some hooks for doing just that.

onTrimMemory() Callbacks

Starting in API Level 14, your activities, services, content providers, and custom Application classes all offer an `onTrimMemory()` method that you can override. This will be called from time to time to let you know about changes in the state of your app that might indicate it is time to free up some caches or otherwise cut back on memory consumption.

`onTrimMemory()` is passed a “level”, indicating how serious the memory crunch is. At the present time, there are seven such levels, but others may be added in future versions of Android. However, these levels are in priority order, and the documentation indicates that Google will ensure that future levels are slotted into the order as appropriate. Hence, you can watch for levels of a certain severity or *higher* and take appropriate action at those points in time.

The seven levels are all defined as constants on the `ComponentCallbacks2` interface that defines `onTrimMemory()`. Four were defined in API Level 14, while the remaining three were defined in API Level 16. They are (in order of increasing severity):

- `TRIM_MEMORY_RUNNING_MODERATE` (added in API Level 16)
- `TRIM_MEMORY_RUNNING_LOW` (added in API Level 16)
- `TRIM_MEMORY_RUNNING_CRITICAL` (added in API Level 16)
- `TRIM_MEMORY_UI_HIDDEN` (added in API Level 14)
- `TRIM_MEMORY_BACKGROUND` (added in API Level 14)
- `TRIM_MEMORY_MODERATE` (added in API Level 14)
- `TRIM_MEMORY_COMPLETE` (added in API Level 14)

In particular, `TRIM_MEMORY_BACKGROUND` (or higher) indicates that your process is now on the list of processes to terminate to free up memory, and so the more memory you can free up, the less likely it is that your process will be terminated. Also, at `TRIM_MEMORY_UI_HIDDEN` or higher, your UI is no longer visible to the user, and so this is a fine time to free up UI-related memory that is safe to release, such as perhaps widget hierarchies that you would be rebuilding in `onResume()` later on anyway.

Note that while the focus tends to be on activities implementing `onTrimMemory()` to clean up UI-related resources, you are welcome to implement `onTrimMemory()` in services, content providers, and any custom `Application` subclass, so that you can free up memory that those may be managing as caches.

In the chapter on system RAM, we will get into why freeing up memory may help keep your process around, as we discuss [the relationship between your application heap and available system RAM](#).

Warning: Contains Graphic Images

However, the most likely culprit for `OutOfMemoryError` messages are bitmaps. Bitmaps take up a remarkable amount of heap space. Developers often look at the size of a JPEG file and think that “oh, well, that’s only a handful of KB”, without taking into account:

1. the fact that most image formats, like JPEG and PNG, are compressed, and Android needs the uncompressed image to know what to draw
2. the fact that each pixel may take up several bytes (2 bytes per pixel for `RGB_565`, 3 bytes per pixel for `RGB_888`)
3. what matters is the resolution of the bitmap in its original form, as much (if not more) than the size in which it will be rendered – an `800x480` image displayed in an `80x48` `ImageView` still consumes `800x480` worth of pixel data
4. there are an awful lot of pixels in an image — 800 times 480 is 384,000

Android can make some optimizations, such as only loading in one copy of a `Drawable` resource no matter how many times you render it. However, in general, each bitmap you load takes a decent sized chunk of your heap, and too many bitmaps means not enough heap. It is not unheard of for an application to have more than half of its heap space tied up in various bitmap images.

Compounding this problem is that bitmap memory, before Honeycomb, was difficult to measure. In the actual Dalvik heap, a Bitmap would need ~80 bytes or so, regardless of image size. The actual pixel data was held in “native heap”, the space that a C/C++ program would obtain via calls to `malloc()`. While this space was still subtracted from the available heap space, many diagnostic programs — such as MAT, to be examined in the next chapter — will not know about it. Android 3.0 (code-named “Honeycomb”) moved the pixel data into the Dalvik heap, which will improve our ability to find and deal with memory leaks or overuse of bitmaps.

Bitmap Caching

Many Android libraries, like [Picasso](#), offer bitmap caching. Using an existing caching implementation is a lot easier than is rolling your own.

However:

- Make sure that the library is intelligently sizing the cache based upon possible heap space, such as via `getMemoryClass()` as is noted earlier in this answer.
- Where possible, tie your cache to `onTrimMemory()` so that you can flush that cache when appropriate.
- Be careful about using *multiple* libraries, each of which might implement its own cache, that you do not wind up caching too much overall. Each library tends to think that it is The One True Cache for your app and will be oblivious to any other caches — bitmap or otherwise — that you may have in your app. Ideally, the library will have a way for you to set the maximum cache size.

Bitmap Sizing

Sometimes, you do not need a full-size image. For example, if you are showing thumbnails of images in a `ListView`, but only expect to show the full-size image for a few (e.g., rows that the user clicks upon), it is wasteful to load the full-size image for everything in the list.

`BitmapFactory.Options` offers `inSampleSize`, which tells the framework to sample the image as it is loaded, to result in a smaller image. `inSampleSize` of 2 will result in an image that is half the width and half the height; `inSampleSize` of 4 will result in an image that is a quarter the width and a quarter the height; etc. Note that `inSampleSize` is limited to powers of 2 and will round as needed.

If you know ahead of time the size of the image, you can calculate an appropriate `inSampleSize` to use. Otherwise, for local content, you can use `BitmapFactory` twice:

- Once with a `BitmapFactory.Options` set with `inJustDecodeBounds` set to `true`, which will merely tell you how big the image is via `outHeight` and `outWidth` on the `BitmapFactory.Options` itself
- Once with a `BitmapFactory.Options` set with `inSampleSize` set to your desired value and `inJustDecodeBounds` set to `false`, to really load the image, but downsampled to consume less memory

This approach does not work well for images being downloaded directly from the Internet, as you do not want to download the image twice, once just to figure out how big it is. Instead, download the image *without* using `BitmapFactory` to a local file, then use `BitmapFactory` to load in the image. If you are electing to use a two-level cache (memory plus disk), you might download the image to the disk cache, for example.

For example, let's look at the [Bitmaps/InSampleSize](#) sample project, which demonstrates the memory impact (and visual impact) of loading bitmaps at varying sample sizes.

In the `assets/` directory, we have a ~70KB JPEG file of a flower (courtesy of [the Wikimedia Project](#)) and a ~50KB PNG of the CommonsWare logo. Both images are 672 pixels square, which makes them relatively large images. These are in `assets` to ensure that Android will not attempt any sort of density-based conversion of the images, if they were to be in a drawable resource directory.

The `MainActivity` of the project simply loads up a `ViewPager` and attaches it to a `SampleAdapter`:

```
package com.commonware.android.bitmap.iss;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);
```

```
    pager.setAdapter(buildAdapter());
}

private PagerAdapter buildAdapter() {
    return(new SampleAdapter(this, getFragmentManager()));
}
}
```

SampleAdapter, in turn, populates the ViewPager with four instances of a BitmapFragment, where we supply the newInstance() factory method of BitmapFragment with a value of 1, 2, 4, or 8 ($1 \ll \text{position}$), indicating the inSampleSize value we want to use for that fragment instance:

```
package com.commonware.android.bitmap.iss;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(4);
    }

    @Override
    public Fragment getItem(int position) {
        return(BitmapFragment.newInstance(1 << position));
    }

    @Override
    public String getPageTitle(int position) {
        return(BitmapFragment.getTitle(ctxt, 1 << position));
    }
}
```

BitmapFragment then:

- Inflates a layout consisting of four ImageView widgets, two at 672dp square for the “natural” size (scaling only for density), and two at 128dp square to illustrate how the images appear when constrained to a smaller space:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="vertical">

        <TextView
            android:id="@+id/byte_count"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_horizontal"
            android:layout_marginBottom="16dp"
            android:textSize="20sp"
            android:textStyle="bold"/>

        <ImageView
            android:id="@+id/flower_large"
            android:layout_width="672dp"
            android:layout_height="672dp"
            android:layout_gravity="center_horizontal"
            android:layout_marginBottom="16dp"
            android:contentDescription="@string/flower_large"
            android:scaleType="fitCenter"/>

        <ImageView
            android:id="@+id/logo_large"
            android:layout_width="672dp"
            android:layout_height="672dp"
            android:layout_gravity="center_horizontal"
            android:layout_marginBottom="16dp"
            android:contentDescription="@string/logo_large"
            android:scaleType="fitCenter"/>

        <ImageView
            android:id="@+id/flower_small"
            android:layout_width="128dp"
            android:layout_height="128dp"
            android:layout_gravity="center_horizontal"
            android:layout_marginBottom="16dp"
            android:contentDescription="@string/flower_small"
            android:scaleType="fitCenter"/>

        <ImageView
            android:id="@+id/logo_small"
            android:layout_width="128dp"
            android:layout_height="128dp"
            android:layout_gravity="center_horizontal"
            android:contentDescription="@string/logo_small"
            android:scaleType="fitCenter"/>
    </LinearLayout>
```

</ScrollView>

- Uses a private load() method to load the images at the desired inSampleSize using a BitmapFactory.Options object
- Pours the images each into two ImageView widgets, one large and one small
- Updates some TextView widgets in the fragment to show how much memory those images are consuming

```
package com.commonware.android.bitmap.iss;

import android.annotation.TargetApi;
import android.app.Fragment;
import android.content.Context;
import android.content.res.AssetManager;

private int byteCount(Bitmap b) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        return(b.getAllocationByteCount());
    }

    return(b.getByteCount());
}
}
```

ISSUES WITH APPLICATION HEAP

If you run this on a device, you will see the images at the various sample sizes, one sample size per page of the ViewPager. While the quality of the loaded images decreases as `inSampleSize` increases, the smaller `ImageView` widgets are still usable for the flower JPEG, though the line-art PNG suffers.

NOTE: The following screenshots will themselves be modified as part of the publishing process of the book and are here only for illustration purposes. You will want to run the demo and see the results first-hand.

Figure 777: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, Flower JPEG, Full Size

Figure 778: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, CW Logo PNG (Full Size) and Smaller Sizes

ISSUES WITH APPLICATION HEAP

Figure 779: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 8, Flower JPEG, Full Size

The key, though, is the reduced memory footprint. The images loaded without sampling (`inSampleSize` of 1) take up 1,806,336 bytes of heap space (672 x 672 x 4 bytes per pixel). The `inSampleSize` of 8, by contrast, take up 28,244 bytes of heap space, less than 2% of the original.

You should consider experimenting with `inSampleSize` and determine an appropriate sampling level for the types of images you will receive (photos work better than line art) and the sizes you intend to use them in.

Bitmap Color Space

`BitmapFactory` will load images as `ARGB_8888` by default. That means that each pixel takes up four bytes, one each for the red, green, and blue color channels, plus a byte for the alpha channel (transparency).

However, particularly for thumbnails of photographs, where transparency probably does not exist and the image is small when viewed by the user, four bytes per pixel may be overkill.

Instead, you can set `inPreferredConfig` of the `BitmapFactory.Options` to `RGB_565`, which uses only two bytes (five bits for red, six bits for green, five bits for blue, and no transparency). This will cut your memory consumption for the bitmap in half, with no loss of resolution (as you get with `inSampleSize`).

Bitmap Reuse

If you will be doing a lot of work with bitmaps, particularly bitmaps of the same size, an object pool can be of tremendous help to minimize heap fragmentation. You can reuse the same `Bitmap` over and over again, by supplying it via `inBitmap` in the `BitmapFactory.Options` object. If the `Bitmap` is compatible with what you are looking to decode, it will be reused, rather than have a new `Bitmap` (backed by a new hunk of heap space) be created.

Here, “compatible” means:

- The image is the same bit depth configuration (`ARGB_8888` versus `RGB_565`)
- For API Level 18 and below, the resolution is identical; for API Level 19+, the `inBitmap` resolution is the same as or higher than the bitmap to be loaded

Releasing SQLite Memory

SQLite maintains a “page cache” of loaded pages from your database files. Curiously, it does so on a static basis, not on a per-`SQLiteDatabase` basis. Hence, even after you have closed your databases, you might still be consuming more memory than you need to, due to this cache.

From `onTrimMemory()`, you can call the static `releaseMemory()` method on `SQLite`, to try to free up some of this memory. This should not cause any database errors, but it may slow down the next few database accesses, as the necessary pages may no longer be cached and may have to be loaded again from disk.

In Too Deep (on the Stack)

Heap, however, is not the only possible source of memory errors. It is also possible to get a `StackOverflowError`, indicating that you have run out of stack space (or possibly that the [leading Android developer support resource](#) is down for maintenance).

In stack-based programming languages like Java, each time you call a method, some stack space is consumed. While method parameters are objects that live on the heap, the parameter references are stored on the stack, as is information about the method being invoked. References to local data members to the method or blocks inside of it are also stored on the stack.

Since these references only take up ~4 bytes each, you would think it might take a minor eternity to run out of stack space. However, the main application thread in your Android application has an 8KB stack (at least on older devices), which means you can run out of stack space with only a couple of thousand objects on it.

Even still, it would take hundreds and hundreds of nested method invocations to put a couple of thousand objects onto the stack. In normal programming, you might only encounter this with a runaway bit of recursion, in which case no amount of stack would save you.

However, Android GUIs are fairly stack-driven. You can run out of stack space if your UI becomes too complex. More specifically, you might run out of stack space if your view hierarchy — from the root container of the Android window to the widgets inside of the containers inside of your rows inside of your `ListView` inside of your `TabHost` — gets too deep. A depth of 15 or so makes you very likely to run out of stack space somewhere along the line. So if you get the stack-space exception and the stack trace seems to be all in Android UI rendering code, your view hierarchy is probably too complex. In this part of the book, we will examine how to measure your view hierarchy depth and ways of trying to simplify it.

Finding Memory Leaks with MAT

The Eclipse Memory Analyzer (MAT) is your #1 tool for identifying memory leaks and the culprits behind running out of heap space. Particularly when used with Honeycomb or newer versions of Android, MAT can identify:

1. Who are the major sources of memory consumption, both directly (e.g., bitmaps) or indirectly (e.g., leaked activities holding onto lots of widgets)
2. What is keeping objects in memory unexpectedly, defying standard garbage collection — the way that you leak memory in a managed runtime environment like Dalvik

This chapter will identify how to collect heap data for use with MAT and how to use MAT to make sense of what the heap is trying to tell us about what is going on inside of your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading [the introductory chapter to this trail](#) might be nice.

Setting Up MAT

MAT is an official Eclipse project, [hosted on the Eclipse Web site](#). It comes in two flavors:

1. A plug-in for Eclipse itself, providing a new “Memory Analysis” perspective and related tools
2. A standalone version, running in the Eclipse RCP framework

Developers who use Android Studio, or any non-Eclipse IDE, will need to use the standalone version. Some Eclipse users may prefer the standalone version, because they run into problems when their Eclipse workspaces have too many plugins. Some developers may prefer the integrated version, because two Eclipse-based apps would consume too much RAM.

There is a traditional [download link](#) to get the standalone edition. As with other Eclipse plug-ins, you will need to add the MAT update site to Eclipse — for example, in Eclipse Galileo:

1. Choose Help|Install New Software... from the main menu
2. Click the Add... button in the upper-right corner of the dialog, fill in `http://download.eclipse.org/mat/1.1/update-site/` as the Location and whatever name you want, then click OK
3. Choose Memory Analyzer for Eclipse IDE and complete the rest of the new-software wizard

Getting Heap Dumps

The first step to analyzing what is in your heap is to actually get your hands on what is in your heap. This is referred to as creating a “heap dump” — what amounts to a log file containing all your objects and who points to what.

There are multiple ways of obtaining a heap dump, depending on your tools and use cases. Note that you will find some blog post and the like indicating you can create a heap dump via the `adb shell kill` command, but this has been disabled in newer versions of Android.

From DDMS

You can get a heap dump any time you want from DDMS, using either the Android/DDMS view in Android Studio, the DDMS perspective in Eclipse or via the Android Device Monitor.

Android Studio

In the Android/DDMS view in Android Studio, when you have selected a process in the list, a “Dump Java Heap” toolbar button will be enabled:

Figure 781: “Dump Java Heap” Toolbar Button in Android Studio

Tapping that, and waiting a few moments, will pop up a dialog where you can specify where you want the heap dump file to be written to. You may wish to use the .hprof extension for this file. Also, the dialog will have a checkbox asking if you want to “Convert to standard HPROF format” — please ensure that this checkbox is checked.

Eclipse

In the device-and-process tree (the Devices tool in Eclipse), you will find a toolbar button that looks like a half-empty can with a downward-pointing arrow:

Figure 782: “Dump HPROF File” Toolbar Button Icon

Clicking this — after choosing your desired process — DDMS will create a heap dump for you. However, the process varies at this point, depending on whether you are using the DDMS perspective in Eclipse or standalone DDMS.

Once you click the toolbar button for the heap dump, DDMS will create the dump for you, in a file generated in your development machine's temporary-files directory (e.g., /tmp). If you wish to save this dump for some reason, you will want to rename it and move it to some other location.

Android Device Monitor

The process for generating a heap dump from DDMS in the Android Device Monitor goes through the same steps as is described for Eclipse above.

Then, however, you will need to run the `hprof-conv` utility, from the `tools/` directory of your SDK, to convert the heap dump into the format that MAT will use. This is automatic if you use the DDMS perspective in Eclipse or have the “convert” checkbox checked in the save-file dialog in Android Studio.

From Code

Another possibility is to trigger the heap dump yourself from code. The `dumpHprofData()` static method on the `Debug` class (in the `android.os` package) will write out a heap dump to the file you indicate. Since these files can be big, and since you will need to transfer them off the device or emulator, it will be best to specify a path to a file on external storage, which means that your project will need the `WRITE_EXTERNAL_STORAGE` permission.

To view the results in MAT, you will need to transfer the file to your development machine (e.g., DDMS File Manager, `adb pull`, using MTP-mounted external storage on Android 3.0+).

Automating Heap Dumps in Testing

One problem with using `dumpHprofData()` is that there is no logical reason to have that code in your production app. Fortunately, you can use it from a JUnit test suite that uses the Android instrumentation framework. However, the main project, not the test project, is the one that needs `WRITE_EXTERNAL_STORAGE` — with luck, your app needs this permission anyway.

The problem then becomes a matter of figuring out where in the JUnit test suite to call `dumpHprofData()`. One strategy is simply to add it to specific test methods or test cases, if you want to have a dump at specific points. If, however, you want a

dump at the end of the complete battery of tests, you will need to create your own test runner.

For example, in the [MAT/Spinners](#) sample project, you will find a near-identical clone of the same project from elsewhere in this book. It simply runs through a pathetic little test suite for an app that displays contact data in a `ListView`, driven by a `Spinner` to select what data you want to see.

The augmented version of this project adds an `HprofTestRunner` that will dump the heap at the end of the run:

```
package com.commonware.android.contacts.spinners;

import java.io.File;
import java.io.IOException;
import android.os.Bundle;
import android.os.Debug;
import android.os.Environment;
import android.test.InstrumentationTestRunner;

public class HprofTestRunner extends InstrumentationTestRunner {
    @Override
    public void finish(int resultCode, Bundle results) {
        try {
            Debug.dumpHprofData(new File(Environment.getExternalStorageDirectory(),
                "hprof.dmp").getAbsolutePath());
        }
        catch (IOException e) {
            e.printStackTrace();
        }

        super.finish(resultCode, results);
    }
}
```

To add code at the end of a test run, simply override the `finish()` method, do your work, then chain to the superclass. Here, we create an `hprof.dmp` file out in the root of external storage. Note that the runner does not log to `LogCat`, which is why this code uses the classic `printStackTrace()` to dump any exceptions to the test runner's own error log.

To use the `HprofTestRunner`, you need to update the `android:name` attribute in the `<instrumentation>` element in your manifest to reference this runner class:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- package name must be unique so suffix with "tests" so package loader
doesn't ignore us -->
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
```

FINDING MEMORY LEAKS WITH MAT

```
    package="com.commonware.android.contacts.spinners.tests"
    android:versionCode="1"
    android:versionName="1.0">
    <!-- We add an application tag here just so that we can indicate that
         this package needs to link against the android.test library,
         which is needed when building test cases. -->
    <application>
        <uses-library android:name="android.test.runner" />
    </application>
    <!--
        This declares that this application uses the instrumentation test runner
        targeting
        the package of com.commonware.android.contacts.spinners. To run the tests
        use the command:
        "adb shell am instrument -w com.commonware.android.contacts.spinners.tests/
        android.test.InstrumentationTestRunner"
    -->
    <instrumentation
        android:name="com.commonware.android.contacts.spinners.HprofTestRunner"

        android:targetPackage="com.commonware.android.contacts.spinners"
        android:label="Tests for
        com.commonware.android.contacts.spinners"/>
</manifest>
```

Also, in your build.xml file for Ant, you will need to add the test.runner property, identifying the same class, before the final <import/> tag:

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="SpinnersTests" default="help">

    <!-- The local.properties file is created and updated by the 'android' tool.
         It contains the path to the SDK. It should *NOT* be checked into
         Version Control Systems. -->
    <property file="local.properties" />

    <!-- The ant.properties file can be created by you. It is only edited by the
         'android' tool to add properties to it.
         This is the place to change some Ant specific build properties.
         Here are some properties you may want to change/update:

         source.dir
             The name of the source directory. Default is 'src'.
         out.dir
             The name of the output directory. Default is 'bin'.

         For other overridable properties, look at the beginning of the rules
         files in the SDK, at tools/ant/build.xml

         Properties related to the SDK location or the project target should
         be updated using the 'android' tool with the 'update' action.

         This file is an integral part of the build system for your
```

FINDING MEMORY LEAKS WITH MAT

```
application and should be checked into Version Control Systems.

-->
<property file="ant.properties" />

<!-- if sdk.dir was not set from one of the property file, then
get it from the ANDROID_HOME env var.
This must be done before we load project.properties since
the proguard config can use sdk.dir -->
<property environment="env" />
<condition property="sdk.dir" value="${env.ANDROID_HOME}">
  <isset property="env.ANDROID_HOME" />
</condition>

<!-- The project.properties file is created and updated by the 'android'
tool, as well as ADT.

This contains project specific properties such as project target, and
dependencies. Lower level build properties are stored in ant.properties
(or in .classpath for Eclipse projects).

This file is an integral part of the build system for your
application and should be checked into Version Control Systems. -->
<loadproperties srcFile="project.properties" />

<!-- quick check on sdk.dir -->
<fail
  message="sdk.dir is missing. Make sure to generate local.properties
using 'android update project' or to inject it through the ANDROID_HOME
environment variable."
  unless="sdk.dir"
/>

<!--
  Import per project custom build rules if present at the root of the
project.
  This is the place to put custom intermediary targets such as:
    -pre-build
    -pre-compile
    -post-compile (This is typically used for code obfuscation.
                     Compiled code location: ${out.classes.absolute.dir}
                     If this is not done in place, override
${out.dex.input.absolute.dir})
    -post-package
    -post-build
    -pre-clean
-->
<import file="custom_rules.xml" optional="true" />

<!-- Import the actual build file.

To customize existing targets, there are two options:
- Customize only one target:
```

```
- copy/paste the target into this file, *before* the
  <import> task.
- customize it to your needs.
- Customize the whole content of build.xml
  - copy/paste the content of the rules files (minus the top node)
    into this file, replacing the <import> task.
  - customize to your needs.

*****
***** IMPORTANT *****
*****
In all cases you must update the value of version-tag below to read
'custom' instead of an integer,
in order to avoid having your file be overridden by tools such as
"android update project"
-->
<!-- version-tag: custom -->
<property name="test.runner"
value="com.commonware.android.contacts.spinners.HprofTestRunner" />
<import file="${sdk.dir}/tools/ant/build.xml" />

</project>
```

Then, running the tests via `ant debug install test` will use your runner and will dump the HPROF file at the end of the run. You could also elect to automate retrieving the HPROF file by adding an Ant task that will use `adb pull` to retrieve the file from where it is stored.

If you wish to run your tests through Eclipse, you will need to change the Instrumentation property of your test projects to point to your custom InstrumentationTestRunner subclass.

Basic MAT Operation

Once you have MAT installed and you have obtained a heap dump, you can start doing some analysis.

Loading Your Dump

If you used the DDMS perspective in Eclipse to create the heap dump, it should automatically pop you into MAT:

FINDING MEMORY LEAKS WITH MAT

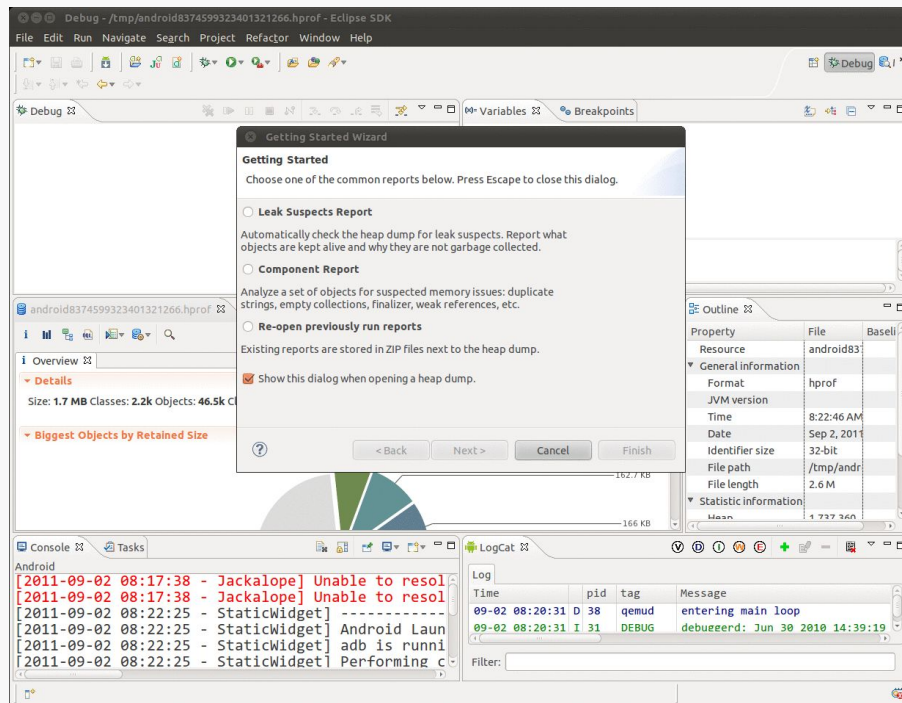

Figure 783: The MAT Eclipse perspective, as initially opened

If you used Android Studio and checked the “convert” checkbox, you can use the File menu in the standalone MAT edition to open up the heap dump that you saved.

If you used the Android Device Monitor or the code-based way of getting a heap dump, after using `hprof-conv` to create a MAT-compatible version of your dump, you can open it using the File|Open Heap Dump... menu from the Eclipse (or standalone MAT) main menu.

The first time you run MAT, you may be presented with the “Getting Started Wizard” (see above screenshot), which you can use or dismiss as you see fit.

The Overview tool gives you, well, an overview of the contents of the heap dump:

FINDING MEMORY LEAKS WITH MAT

Figure 784: The Overview tool inside the MAT Eclipse perspective

The Overview tool also has links and toolbar buttons to get you to the other major functional areas within MAT.

Finding Your Objects

If you want to see if instances of your own classes are being kept in memory despite garbage collection, you can search for objects based upon a regular expression on the fully-qualified class name.

One way to access this is via the Histogram, reachable via a link in the Overview's Actions area or via a toolbar button:

FINDING MEMORY LEAKS WITH MAT

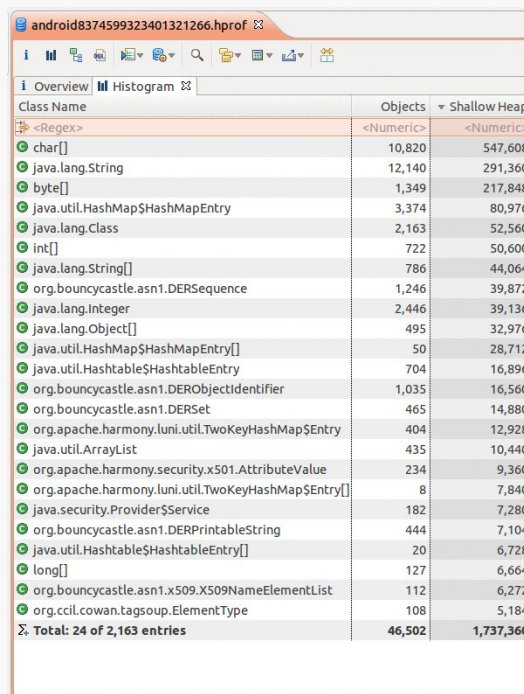

Figure 785: The icon used for the Histogram toolbar button

The histogram initially displays the top culprits in terms of “shallow heap” — the amount of memory those objects hold onto directly:

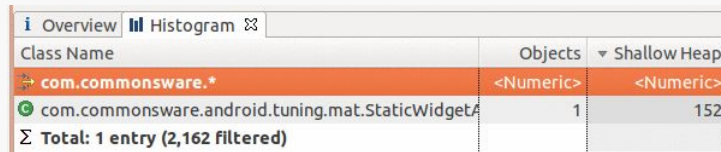

Class Name	Objects	Shallow Heap
<Regex>	<Numeric>	<Numeric>
char[]	10,820	547,608
java.lang.String	12,140	291,360
byte[]	1,349	217,848
java.util.HashMap\$HashMapEntry	3,374	80,976
java.lang.Class	2,163	52,560
int[]	722	50,600
java.lang.String[]	786	44,064
org.bouncycastle.asn1.DERSequence	1,246	39,872
java.lang.Integer	2,446	39,136
java.lang.Object[]	495	32,976
java.util.HashMap\$HashMapEntry[]	50	28,712
java.util.Hashtable\$HashtableEntry	704	16,896
org.bouncycastle.asn1.DERObjectIdentifier	1,035	16,560
org.bouncycastle.asn1.DERSet	465	14,880
org.apache.harmony.luni.util.TwoKeyHashMap\$Entry	404	12,928
java.util.ArrayList	435	10,440
org.apache.harmony.security.x501.AttributeValue	234	9,360
org.apache.harmony.luni.util.TwoKeyHashMap\$Entry[]	8	7,840
java.security.Provider\$Service	182	7,280
org.bouncycastle.asn1.DERPrintableString	444	7,104
java.util.Hashtable\$HashtableEntry[]	20	6,728
long[]	127	6,664
org.bouncycastle.asn1.x509.X509NameElementList	112	6,272
org.ccil.cowan.tagsoup.ElementType	108	5,184
Total: 24 of 2,163 entries	46,502	1,737,360

Figure 786: The Histogram tab inside the MAT Eclipse perspective

To see what objects of yours might still be in the heap, you can type in a regular expression (e.g., `com.commonsware.*`) in the Regex row at the top of the table, then press [Enter] to view a filtered list of objects based upon that regular expression:

FINDING MEMORY LEAKS WITH MAT

Class Name	Objects	Shallow Heap
com.commonware.*	<Numeric>	<Numeric>
com.commonware.android.tuning.mat.StaticWidgetA	1	152
Σ Total: 1 entry (2,162 filtered)		

Figure 787: A filtered histogram, showing `com.commonware.*` objects

Here, we see one instance of a `com.commonware` class is still lurking around a heap dump.

Getting Back to Your Roots

However, just because we see an object in MAT does not necessarily mean that it has been leaked. For example, this is an activity – just looking at the above screenshot does not indicate whether that activity was in the foreground, was in the background for normal reasons, or is actually leaked.

To help determine what is keeping the object in memory, you will need to trace back to the “GC roots” — the objects that are preventing our activity from being garbage collected.

To do this, you will right-click over the object in question and choose the “GC Roots” context menu choice (in the Histogram, it is “Merge Shortest Paths to GC Roots”). This will usually bring up a flyout sub-menu where you can further constrain what is reported as a root:

FINDING MEMORY LEAKS WITH MAT

Figure 788: A filtered histogram, showing *com.commonware.** objects

The big filters are for “soft references” and “weak references”. These refer to the `SoftReference` and `WeakReference` classes in Java, respectively. Both are ways to hold onto an object yet still allow it to be garbage collected when needed. The big difference is that an object only referenced by `WeakReference` objects can be garbage collected immediately, while an object referenced only by `SoftReference` objects (or a mix of `SoftReference` and `WeakReference` objects) should be kept around until the Dalvik VM is low on memory. Usually, you can ignore weak references, as those just indicate objects that the garbage collector has not quite detected are eligible for reclamation. Whether you want to also filter out soft references would depend a bit on the objects in question — for example, if you are using `SoftReference` with a cache, you might filter out soft references as well to confirm that nothing *other than* your cache is holding onto these objects.

Filtering out weak references (or whatever) brings up another tab containing the GC roots preventing our activity from being garbage collected:

Figure 789: The GC roots holding onto an activity

This is showing that the *class* for our activity has a data member (`doNotDoThisPlease`) that has a *View*, and that in turn is holding onto our activity via an *mContext* data member. Static data members (i.e., data members of class objects) are classic sources of memory leaks in Java. The Retained Heap column on the far right shows how much memory that individual object (and everything it points to) is keeping around — in this case, about 2.5KB.

Identifying What Else is Floating Around

This helps us find where your own objects are being leaked. What happens if you are leaking other things, though?

One possibility is to examine the rest of the Histogram tab, as it will point out the classes (and primitives) that have the most outstanding instances or hold the most aggregate shallow heap. If you applied a regular expression, you can click on the regular expression and delete it to return to the non-filtered roster. The Histogram tends to report a lot of primitives (e.g., char array), and it will take some experience to learn what is standard Android application “noise” and what might represent problems.

Another way to find leaks is to examine the “dominator tree”. The term “dominator tree” comes from graph theory — object A “dominates” object B if the only paths to get to B go through A. In MAT, the dominator tree will bubble up those objects whose retained heap — the total memory the object is responsible for, including objects it links to — are high. Or, as MAT describes it, it lists “the biggest objects”.

To get to the dominator tree, you can click its link on the Overview tab, or you can click the corresponding toolbar button:

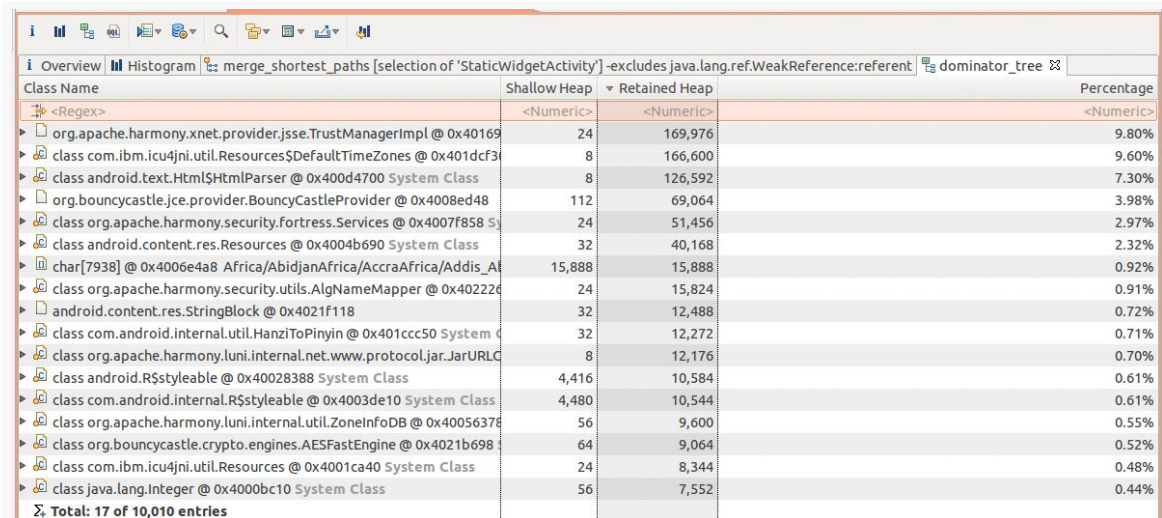

Figure 790: The icon used for the Dominator Tree toolbar button

FINDING MEMORY LEAKS WITH MAT

This will open up another tab in the same tool, showing “the biggest objects” by retained heap:

The screenshot shows the MAT Dominator Tree tab. The table lists various classes and their memory usage. The columns are Class Name, Shallow Heap, Retained Heap, and Percentage. The total memory usage is 17 of 10,010 entries.

Class Name	Shallow Heap	Retained Heap	Percentage
<Regex>	<Numeric>	<Numeric>	<Numeric>
org.apache.harmony.xnet.provider.jsse.TrustManagerImpl @ 0x40169	24	169,976	9.80%
class com.ibm.icu4jni.util.Resources\$DefaultTimeZones @ 0x401dcf3	8	166,600	9.60%
class android.text.Html\$HtmlParser @ 0x400d4700 System Class	8	126,592	7.30%
org.bouncycastle.jce.provider.BouncyCastleProvider @ 0x4008ed48	112	69,064	3.98%
class org.apache.harmony.security.fortress.Services @ 0x4007f858 Sy	24	51,456	2.97%
class android.content.res.Resources @ 0x4004b690 System Class	32	40,168	2.32%
char[7938] @ 0x4006e4a8 Africa/AbidjanAfrica/AccraAfrica/Addis_A	15,888	15,888	0.92%
class org.apache.harmony.security.utils.AlgNameMapper @ 0x402226	24	15,824	0.91%
android.content.res.StringBlock @ 0x4021f118	32	12,488	0.72%
class com.android.internal.util.HanziToPinyin @ 0x401ccc50 System C	32	12,272	0.71%
class org.apache.harmony.luni.internal.net.www.protocol.jar.JarURLC	8	12,176	0.70%
class android.R\$styleable @ 0x40028388 System Class	4,416	10,584	0.61%
class com.android.internal.R\$styleable @ 0x4003de10 System Class	4,480	10,544	0.61%
class org.apache.harmony.luni.internal.util.ZoneInfoDB @ 0x40056378	56	9,600	0.55%
class org.bouncycastle.crypto.engines.AESFastEngine @ 0x4021b698	64	9,064	0.52%
class com.ibm.icu4jni.util.Resources @ 0x4001ca40 System Class	24	8,344	0.48%
class java.lang.Integer @ 0x4000bc10 System Class	56	7,552	0.44%
Σ Total: 17 of 10,010 entries			

Figure 791: The MAT Dominator Tree tab

You can display more by right-clicking over the Total row at the bottom and choosing “Next 25”.

Here too, the roster will mostly be system objects (e.g., `org.bouncycastle` for the `javax.crypto` implementation). What you would be looking for are objects that you might be interacting with more directly that perhaps you are leaking, such as a `Bitmap`.

If you find something of interest, right-clicking over the object and choosing “Path to GC Roots” or “Merge Shortest Paths to GC Roots” will help you track down what is holding onto the object, akin to the similar feature in the Histogram.

Some Leaks and Their MAT Analysis

Let’s now take a look at some common leak scenarios in Android and see how we find out whether we have a leak and what is causing it. All of the projects demonstrated below are in the MAT directory of the book’s source code.

Widget in Static Data Member

The screen shots from above are mostly taken from the [MAT/StaticWidget](#) sample project, where we do something naughty:

```
package com.commonware.android.tuning.mat;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;

public class StaticWidgetActivity extends Activity {
    @SuppressWarnings("unused")
    static private View doNotDoThisPlease;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        doNotDoThisPlease=findViewById(R.id.make_me_static);
    }
}
```

We take a widget (specifically the auto-generated `TextView`) and put it in a static data member, and never replace it with null.

As a result, even if the user presses BACK to get out of the activity, the static data member holds onto `TextView`, which itself has a reference back to our Activity.

Usually, you will pick this sort of leak up by scanning on your own application's package, as your activity will appear in there. If you are using multiple packages in your application (e.g., yours and a third-party activity), you might need to also check the third-party package to see if any of its objects are being leaked. Whether those leaks are the fault of your code or the third party's own code will vary, of course.

Leaked Thread

You can see similar results when you leak a thread, such as in the [MAT/LeakedThread](#) sample project:

```
package com.commonware.android.tuning.mat;

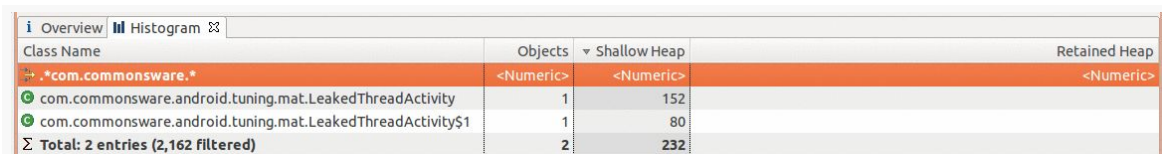

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
```

FINDING MEMORY LEAKS WITH MAT

```
public class LeakedThreadActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        new Thread() {
            public void run() {
                while(true) {
                    SystemClock.sleep(100);
                }
            }
        }.start();
    }
}
```

Here, if we filter on `com.commonware` in the Histogram, we see two entries:

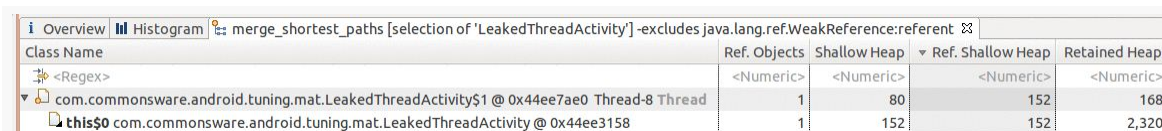

Class Name	Objects	Shallow Heap	Retained Heap
com.commonware.	<Numeric>	<Numeric>	<Numeric>
com.commonware.android.tuning.mat.LeakedThreadActivity	1	152	
com.commonware.android.tuning.mat.LeakedThreadActivity\$1	1	80	
Σ Total: 2 entries (2,162 filtered)	2	232	

Figure 792: The *LeakedThreadActivity* Histogram

As with other places in Java (e.g., stack traces), the `$` syntax in a class name refers to an inner class, and `$1` refers to the first anonymous inner class.

If we look at the GC roots for the activity, we see:

Class Name	Ref. Objects	Shallow Heap	Ref. Shallow Heap	Retained Heap
<Regex>	<Numeric>	<Numeric>	<Numeric>	<Numeric>
com.commonware.android.tuning.mat.LeakedThreadActivity\$1 @ 0x44ee7ae0 Thread-8 Thread	1	80	152	168
this\$0 com.commonware.android.tuning.mat.LeakedThreadActivity @ 0x44ee3158	1	152	152	2,320

Figure 793: The GC roots for *LeakedThreadActivity*

The root is a thread, as denoted by the “Thread” annotation on the end of the root entry. We see that the Thread object itself is our `$1` inner class instance, and it holds onto the activity via the implicit reference every non-static inner class has to its outer class instance (`this$0`).

Any running thread will cause anything it can reach to remain in the heap and not get garbage collected. An inner class implementation of the Thread — which most code examples will use, in one form or fashion — will leak the outer class instance. Hence, the lessons to be learned here are:

1. Leaking threads leaks memory
2. Consider using static inner classes, or separate classes, rather than non-static inner classes, so you do not cause objects to be held onto unnecessarily and unexpectedly

All Sorts of Bugs

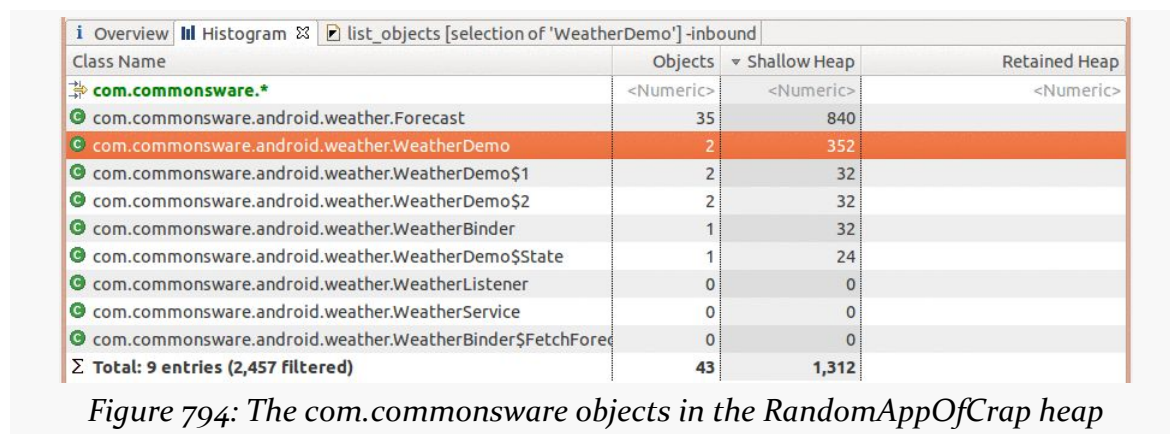

Let's now examine the [MAT/RandomAppOfCrap](#) sample application. This is a variation on an example from elsewhere in this book, showing using a bound service that connects to a Web service — in this case, the US National Weather Service. In this modified version, a number of leak-related bugs were introduced.

Leaks Via Configuration Changes

The WeatherDemo activity implements `onRetainNonConfigurationInstance()`, returning a State object. State is an inner class of WeatherDemo, but not a static inner class.

This is not a good idea.

When you search the Histogram for `com.commonware` after loading a weather forecast (e.g., run the app and use DDMS to push over a location fix) and rotating the screen, you see that there are two instances of WeatherDemo floating around the heap:

To figure out what those objects are, you can right-click over a class in the Histogram and choose “List Objects” from the context menu. The fly-out sub-menu will let you choose to show incoming references (who points to these objects) or

FINDING MEMORY LEAKS WITH MAT

outgoing references (what these objects point to). In this case, showing incoming references will bring up the following:

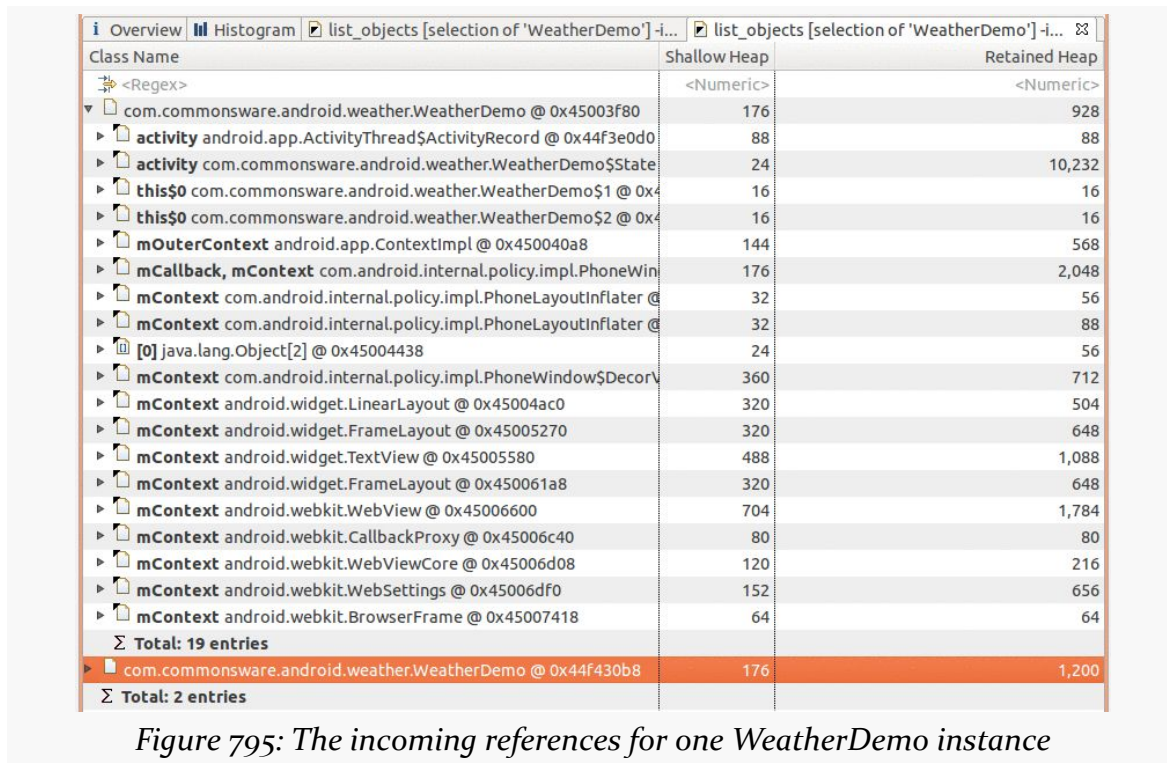

Figure 795: The incoming references for one WeatherDemo instance

FINDING MEMORY LEAKS WITH MAT

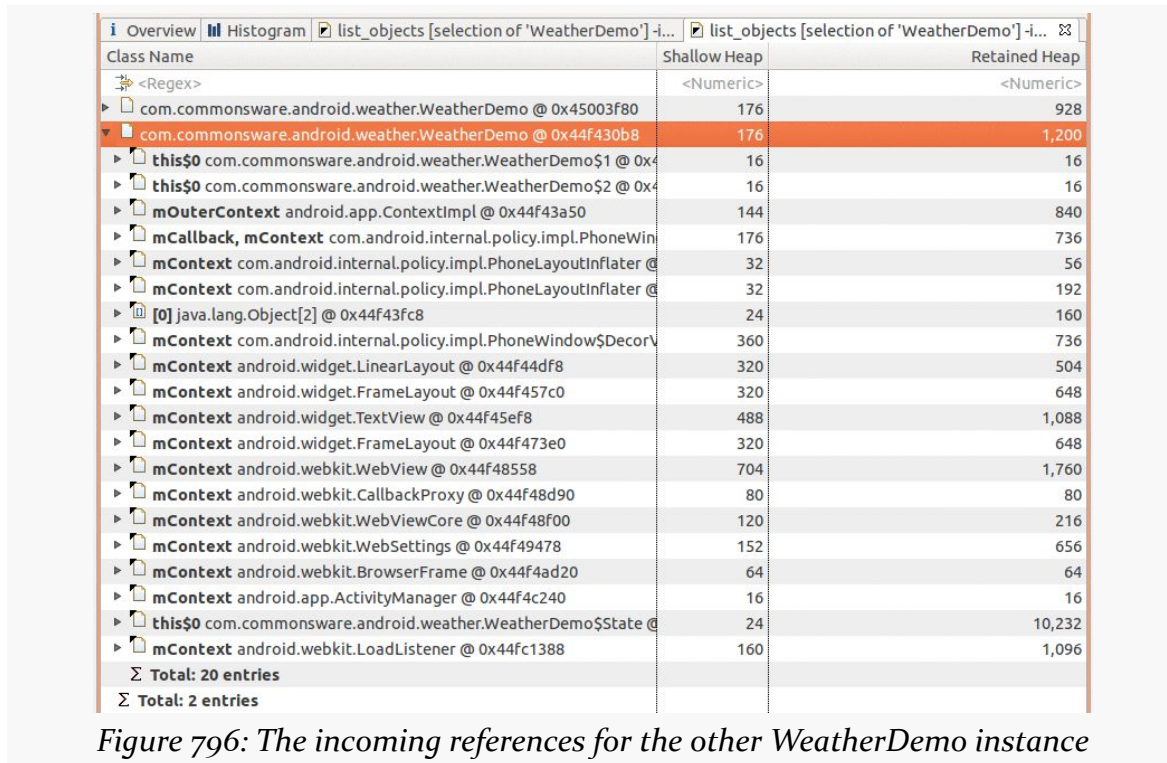

Figure 796: The incoming references for the other `WeatherDemo` instance

The eight-digit hex numbers shown after the @ sign are the object identifiers for each of the referred-to objects. You can use this to distinguish which objects are the same.

What you will notice is that both `WeatherDemo` instances are pointed to by the `State` object. In one, it is referred to by the activity data member. In the other, it is referred to by `this$0` — the implicit reference an inner class instance has on the outer class instance. Since both `WeatherDemo` instances hold onto the `State` via the state data member, this means that one `WeatherDemo` instance (the foreground one) is holding an indirect reference, via the `State`, to the other now-destroyed `WeatherDemo` instance. This is a leak.

The solution for this would be to use a static inner class for `State`, eliminating the implicit reference and breaking this connection.

Leaks from Unregistered System Listeners

We also see from our filtered Histogram that we have two retained instances of the `$1` inner class. Displaying incoming references to those objects shows us that those are the `LocationListener` objects we are using to get our GPS fixes:

FINDING MEMORY LEAKS WITH MAT

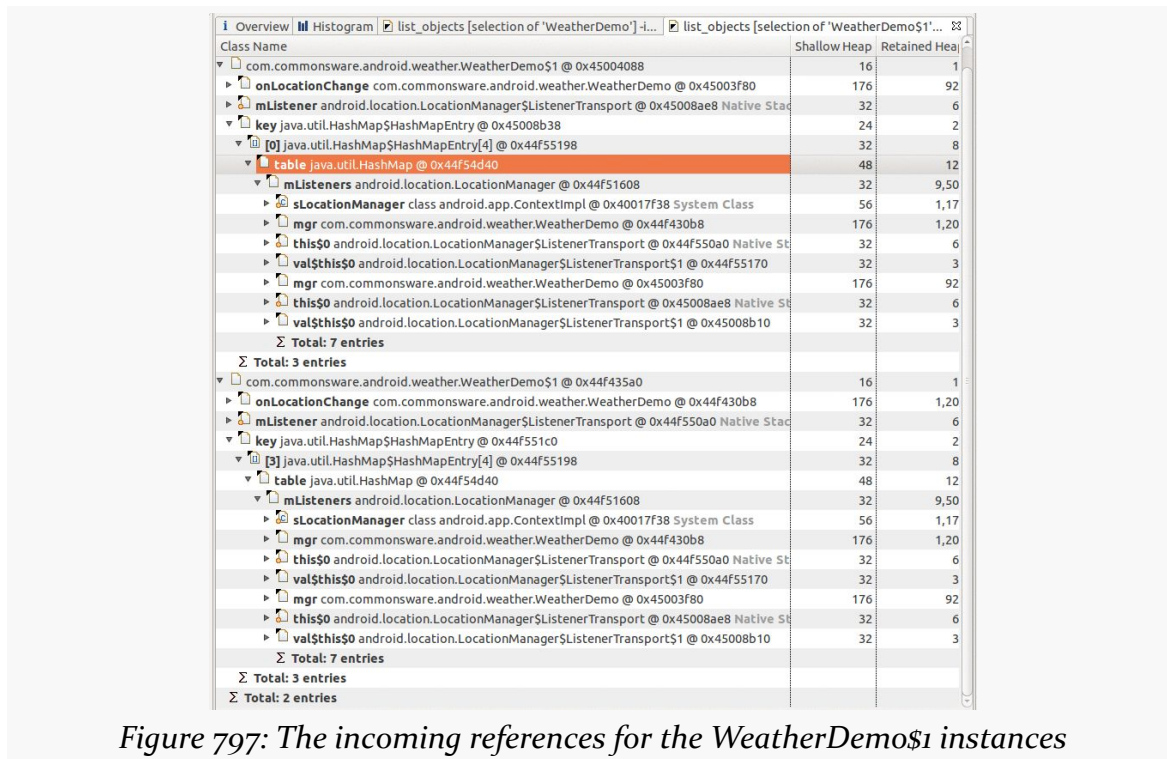

Figure 797: The incoming references for the WeatherDemo\$1 instances

Tracing through the incoming references, we see that the ContextImpl class holds a static reference to the LocationManager system service in our process, and LocationManager has an mListeners data member which is a list of all registered LocationListener instances.

Alas, in WeatherDemo, we are registering a LocationListener and never unregistering it. Since our LocationListener is an inner class, not only is the LocationListener itself leaked, but it prevents our destroyed WeatherDemo object from being garbage collected.

This same pattern can be seen for many of the system services — if you register a listener, you must ensure that you unregister it to prevent leaks.

What MAT Won't Tell You

MAT is not a universal solution. It may not tell you of all possible leaks.

For example, if you bind to a service, the ServiceConnection object you create is held onto, indirectly, by the OS itself. That is how you can use the ServiceConnection to unbind from the service later on. However, if you examine

FINDING MEMORY LEAKS WITH MAT

MAT, you will see no evidence of this, as MAT is limited to examining *your own* process and cannot report about references that are triggered by other processes.

MAT also will not report anything that is part of the native heap (i.e., what you get with a C `malloc()` call) — it only reports on the Dalvik heap. Hence, MAT will not reflect the actual memory consumption of bitmap images on Gingerbread and earlier environments. You may wish to do some testing of your app on Honeycomb, not just for any tablet support you may offer, but to get more complete results from MAT.

Issues with System RAM

Your application heap is your little corner of the system RAM on the device that you focus on in your Java development. However, there are other things that you might do that consume system RAM, such as use the NDK to add C/C++ code to your app. How much system RAM you consume overall will have an impact on user acceptance of your app, as the more RAM you use, the more frequently the user's other apps are terminated to make room for you. And, as a result, the more system RAM you use, the more likely it is that *your* process will be terminated when you are not in the foreground, to free up RAM for other apps. Hence, while system RAM is not something you necessarily think about as often as you do your application heap, it *is* something that you should pay attention to, at least a little bit.

This chapter will explain a bit more about the relationship between your app and system RAM, how you can measure how much system RAM your app is consuming, and how you can reduce that consumption.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading the chapter on [issues with the application heap](#) is also a good idea.

Can't We All Just Get Along?

Alas, we have not invented the device with infinite RAM, nor the application that takes zero memory. In fact, our devices have fairly limited RAM (e.g., 1GB), and our apps therefore fight over that memory. That includes both apps that the user runs

explicitly (e.g., via the home screen launcher) and apps that run based upon external factors (e.g., the app that receives a [GCM push event](#) and uses that trigger to update some data).

The good news is that the user tends to be a bit oblivious to all of the comings and goings of apps. Android keeps process around while it can and terminates them as needed to free up system RAM for other processes, without the user's explicit involvement. Of course, power users might try to employ "task managers" and the like to be more involved in decision-making, but that's something they opted into, not something that was forced upon them, the way that older mobile operating systems like Windows Mobile required.

However, there is a fundamental assumption in Android that apps play fair. The per-process heap limits — and the fact that apps do not necessarily have to use all the way up to those limits — means that a given Android device can power many processes at once. That starts to break down when apps do various things to consume an excessive amount of system RAM, more than what the per-process heap limit would normally constrain them to. Hence, it is a good idea to keep tabs on how much you use of system RAM, so that you can be a "good citizen" and not cause the user undue angst or force them to employ task managers to try to keep you in line.

Contributors to System RAM Consumption

There are many factors that contribute towards your system RAM consumption, including:

- Your heap usage, up to the per-process heap limit, for each process that you are running
- Your native libraries (.so files) from the NDK
- The system RAM allocated by that native code, which does not count against your per-process heap usage

In addition, the reporting tools usually allocate a portion of shared RAM to your app. Your app's process is forked from the zygote process, which contains the Dalvik runtime environment, framework JAR (for all those `android.*` classes), and related libraries. Your app shares that memory with all other processes forked from the zygote. However, to reflect the fact that there is this overhead, your app's share of it (roughly calculated as the amount of shared RAM divided by the number of processes) tends to get added to your memory consumption totals.

Measuring System RAM Consumption: Tools

Figuring out how much RAM your application is using is not easy. Or, as [Dianne Hackborn](#) put it:

Note that memory usage on modern operating systems like Linux is an extremely complicated and difficult to understand area. In fact the chances of you actually correctly interpreting whatever numbers you get is extremely low. (Pretty much every time I look at memory usage numbers with other engineers, there is always a long discussion about what they actually mean that only results in a vague conclusion.)

Fortunately, particularly in Android 4.4, a fair bit of work has gone into trying to help us determine how much our apps impact system RAM.

Process Stats in Settings

On Android 4.4, in Settings > Developer Options, you will find:

Process Stats: Geeky stats about running processes

(here, “geeky” is presumably used as a term of endearment)

ISSUES WITH SYSTEM RAM

Figure 798: Developer Options in Android 4.4, Showing “Process Stats”

Tapping on that entry brings up a screen that describes the current state of the system, with respect to RAM:

ISSUES WITH SYSTEM RAM

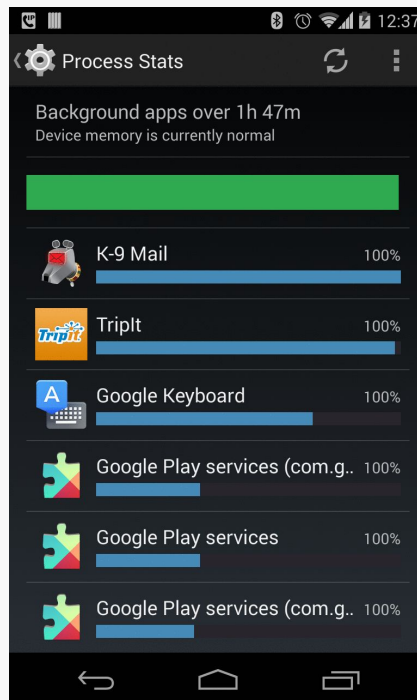

Figure 799: Process Stats in Android 4.4

While it may look simple, this screen, and its child screens, are remarkably complex, particularly once you start playing around with various options from the action bar overflow.

The Summary

At the top, you will see:

- How much history is being reported in this screen (“1h 47m”)
- What the current status of the system is with respect to RAM (“currently normal”)
- What the status of the system has been over that range of time, as illustrated by the bar, where green is “normal”

The bar is not so much a timeline as a stacked bar chart, where the mix of red and yellow indicates the amount of time the device was in a low-memory state, contrasted with the green “normal” state.

Usually, your device should be “normal” with a mostly-green or completely-green bar.

The Roster

The list beneath the summary shows some running processes. What is included in this list depends on what mode Process Stats is running in. The summary indicates that our mode is “Background apps”. There are three major categories for apps:

1. Foreground, which includes whatever app is truly in the visible foreground, plus any apps that have a foreground service
2. Background, which is pretty much everything else with a service
3. Cached, which are all apps that still have running processes but do not have a service

By default, Process Stats will show background processes.

Each row in the list shows details for a specific process:

- the application label for the app that owns the process (e.g., “K-9 Mail”)
- the percentage of time, for the time period Process Stats is reporting, that this process was running (e.g., “100%”)
- the “relative computed memory load” of that process, as is indicated by the blue bar, with longer blue bars indicating greater load

The list is sorted in order of “relative computed memory load”.

Many background apps will have a running percentage of 100%, indicating that they have an always-running service. Those with a percentage less than 100% indicate an app that had a service running at the point in time of the Process Stats snapshot that you are examining, but did not necessarily have a service running for the entire timeframe (e.g., periodic IntentService doing background work)

Refresh and Duration

There is a “refresh” icon in the action bar that will update the current view to reflect changes since you last opened or refreshed the screen.

How long the timeframe is depends a bit upon device operation and also on the “Duration” entry in the overflow menu:

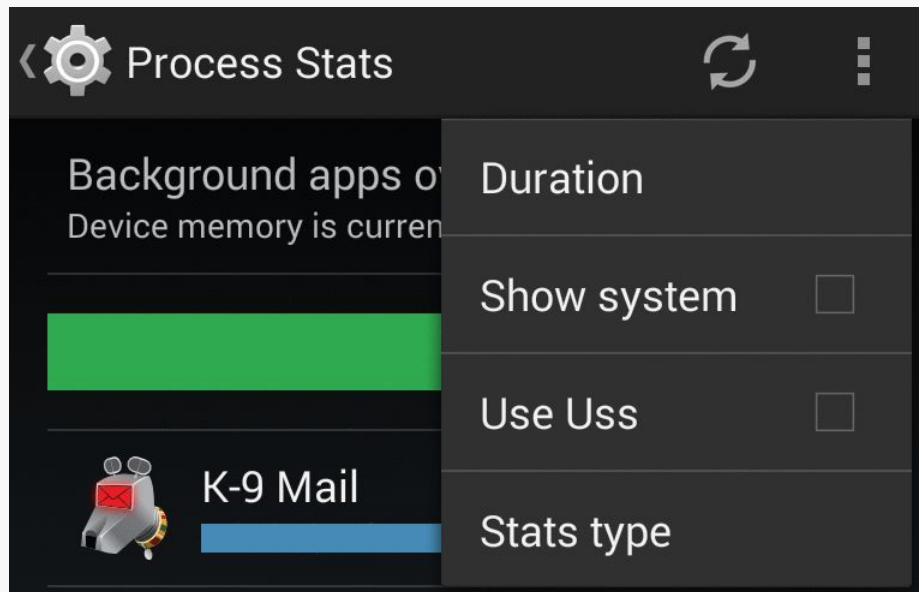

Figure 800: Process Stats Overflow in Android 4.4

Tapping that gives you a roster of available timeframes:

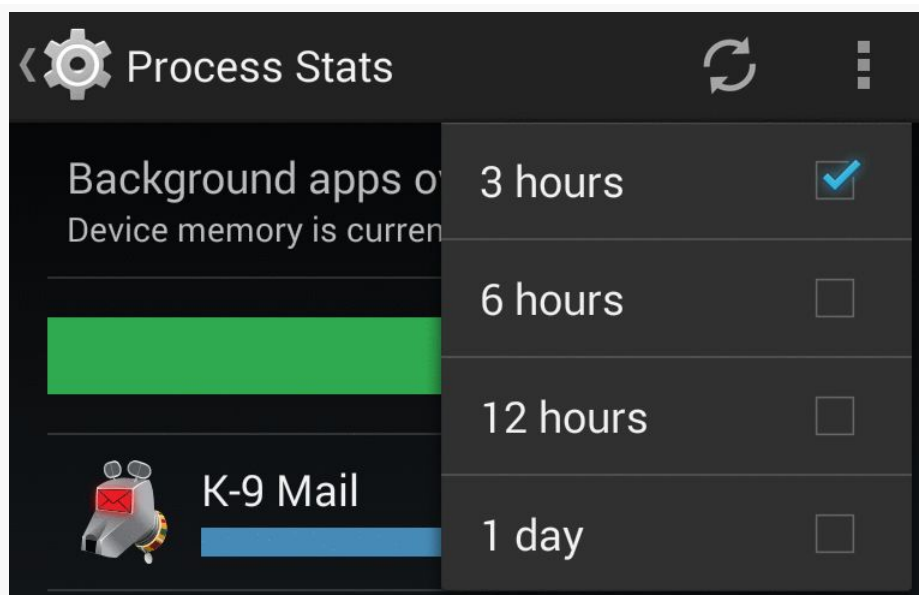

Figure 801: Process Stats Duration Options in Android 4.4

Even though these items render with checkboxes, they function as radio buttons, so whatever you tap on becomes the new duration. Upon making a change, the summary area will reflect the newly-chosen duration. Note that this choice is not

persistent, as exiting Process Stats via the BACK button and re-entering it returns you to a three-hour duration.

Controlling What is Shown

If your application is not showing up in the background roster, it may be classified as “foreground” (e.g., if you have a foreground service) or “cached” (if not). The “Stats type” overflow option will let you toggle between these categories, to see what processes are reported in each.

Note that an app can appear in more than one roster, since the roster is by *process*. For example, at the time of this writing, Evernote appears in the author’s Nexus 4 both in “foreground” and in “cached”, for separate processes.

As with the duration, the choice of category is not persistent, and you will be returned to the background process roster if you exit Process Stats via the BACK button and later return to it.

Drilling Down Into an App

Tapping on an item in the list will bring up details about that particular app and process:

ISSUES WITH SYSTEM RAM

Figure 802: Process Stats Details for K-9 Mail

The “Average RAM use” value shows how much system RAM is attributed to your app. This will include:

- All system RAM used uniquely by your app (e.g., your heap)
- A portion of system RAM shared by your app and others (e.g., the Dalvik runtime)

This is known as “Proportional Set Size” or “PSS” in Linux, and is a common way of coming up with a simple number for the amount of RAM that a particular process is responsible for.

The blue bar is based off of this average RAM use (or PSS) value, multiplied by the percentage of the time that the process was running.

The “Maximum RAM use” value is the highest PSS associated with your process during the period under examination.

Also listed are the services of your app and the percentage of time that they were in a running state. Everlasting services will show up as 100%, while transient services (e.g., IntentService) will show up with a much smaller percentage.

How You Want Your App to Appear

Ideally:

- Your app spends most of its time in the “cached” process list, not the “background” or “foreground” list
- Your app has a low percentage of time spent running
- Your app has a low “relative computed memory load” and, ideally, a low “Average RAM use” value

The better you are in these areas, the more likely it is that you are not seriously impacting system RAM.

procstats

The data that powers the Process Stats screen in Settings is also available as human-readable text output, using the `adb shell dumpsys procstats` command, against your Android 4.4 device or emulator.

Running that command will give you three blocks of information:

- Process memory usage, aggregated over the last 24 hours
- Process memory usage, aggregated over the last 3 hours
- A snapshot of the current memory usage, at the time you ran the command

This can be a long report, even for just one of those blocks. For example, here is the last-3-hours block, run on the author’s personal Nexus 4:

```

```

Unfortunately, it is rather cryptic and rather long.

There are various command-line switches you can add to help manage the output. Use the `-h` switch to see the full roster. Some notable options:

- `-csv` switches the output to be in CSV format, for importing into a spreadsheet or running through an analysis tool, with other switches (e.g., `-csv-proc`) to control what is included in the CSV output
- `--current` will only report the current snapshot
- `--hours NNN` will only report the aggregate over the stated number of hours
- `--full-details` provides a somewhat more documented report, at the cost of greatly increasing its verbosity

Also, including a package name (e.g., `com.commonware.android.sample`) at the end of the command line will constrain the output to solely that package, which is useful if you are only looking to examine your own app's data.

The numbers in parentheses (e.g., `(4.7MB-4.7MB-4.7MB/3.8MB-3.8MB-3.8MB over 2)`) report:

- the minimum proportional set size (PSS) seen
- the average PSS seen
- the maximum PSS seen
- the minimum unique set size (USS) seen, where this is the amount of memory consumed by your app that is *not* shared with other processes (i.e., it is how much memory that would be freed if your process were terminated)
- the average USS seen
- the maximum USS seen
- the number of samples taken of the memory during the timeframe being analyzed

The listing also shows the percentage of time your process was in various states (e.g., cached vs. service vs. “important foreground”)

meminfo

Older devices that do not support `procrank` can support `meminfo`, accessed via `adb shell dumsys meminfo`. Run as-is, it will generate a report of all processes and their PSS, plus the same roster broken down into various process categories (e.g., foreground, cached), and other summary data. The report for the same Nexus 4 that generated the `procrank` shown earlier in this chapter is:

```

This can show you:

- How much memory is being consumed by your Dalvik bytecode (.dex mmap), native libraries used directly by you or by framework components (.so mmap), etc.
- How many objects of various types are in the Dalvik heap, such as views and activities
- How much memory is used by SQLite for its page cache and related process-level buffers, plus which databases you have open that are contributing to memory consumption

Note that the combination of the `Private Dirty` and `Private Clean` columns is roughly analogous to the `USS` reported by `procstats`, in that it represents the amount of memory private to your process and that would be released should your process be terminated.

Measuring System RAM Consumption: Runtime

Some of the same information that the aforementioned reports contain is available at runtime via `ActivityManager` and other framework classes.

`getMemoryInfo()`

`getMemoryInfo()` on `ActivityManager` will fill in a supplied `ActivityManager.MemoryInfo` object. This will report to you:

- The total memory on the device (`totalMem`)

- The “available memory” (whose definition is a bit unclear) (`availMem`)
- What level of “available memory” is considered “low” and should trigger Android to start terminating processes beyond those that are cached, such as ones with running services (`threshold`)
- Whether we are presently in such a low-memory state (`lowMemory`)

getMyMemoryState()

`ActivityManager` also has a `getMyMemoryState()` method, on API Level 16+, that will populate an `ActivityManager.RunningAppProcessInfo` object with information about your process. While not everything in this object will be filled in, you will be able to get:

- The last trim level reported to your activities and Application via `onTrimMemory()` (`lastTrimLevel`)
- What importance level the OS considers your process to be in (`importance`), such as `IMPORTANCE_FOREGROUND` and `IMPORTANCE_EMPTY`
- For processes in the `IMPORTANCE_BACKGROUND` category — meaning the process has outstanding activities but is not in the foreground and has no service — the relative standing of the process compared to other background processes from a least-recently-used standpoint (`lru`), where lower numbers mean more recent usage

getProcessMemoryInfo()

The `getProcessMemoryInfo()` method on `ActivityManager` returns an array of `Debug.MemoryInfo` objects corresponding to the array of `int` process IDs (`pids`) that you pass in. The `Debug.MemoryInfo` objects report how much memory those identified processes are consuming. Of particular note, `getTotalPss()` returns the PSS for that process.

To get the `Debug.MemoryInfo` for your own process, you can use `getMemoryInfo()` on the `Debug` class, rather than find your own process ID and use `getProcessMemoryInfo()`. Or, on API Level 14+, you can simply call `getPss()` on `Debug` directly to find out your PSS.

Learn To Let Go (Of Your Heap)

Part of the reason for worrying a bit about your system RAM consumption is simply to “play nice” with the other apps that the user wants to use. However, since part of

Android's decision-making about what processes to terminate tie into how much RAM those processes take up, the lower your system RAM footprint, the more likely it is that you can hang around for a while.

Part of reducing your system RAM consumption involves cleaning up your heap.

The reason the framework calls callback methods like `onTrimMemory()` is to help you reduce your heap usage to avoid `OutOfMemoryError` exceptions. However, allowing objects to be garbage-collected not only gives you more heap space, but it *also may reduce your system RAM footprint*.

To limit your system RAM usage, your process is not allocated all of its possible heap when the process is started up. Instead, the heap starts small and expands as you allocate more and more memory. However, the reverse is also true: if you release memory, the heap can shrink, returning RAM to the system. Android expands the heap on a “paged” basis, allocate more system RAM to add more pages to the heap. If, as a result of garbage collection, Dalvik sees that there are too many totally empty pages, Dalvik can free up those pages, returning them to the OS for use by other processes.

As noted in [the chapter on the application heap](#), Dalvik's garbage collector is [non-compacting](#), meaning that it does not move objects around to try to clean up pages or otherwise coalesce free memory blocks. Hence, a fragmented heap not only limits how well you can allocate new memory, but it also inhibits Dalvik's ability to reduce your system RAM usage.

Issues with Battery Life

Most Android devices are powered by batteries — Android TV is the biggest class of device that is not. Batteries are wonderful gizmos with one major problem: they are *always* running out of power.

Hence, users are very sensitive to battery consumption. Their ability to use their phones as actual *phones*, let alone for Android apps, depends on having enough battery power. The more apps drain the battery, the more frequently the user has to find a way to recharge the phone, and the more frequently the user fails and their phone shuts down.

The catch is that you may not notice the battery issues in your day-to-day development. The Android emulator's emulated battery does not drain based on you running your app. Your devices are often connected to your development machine via USB for testing and debugging, meaning they are perpetually being charged. Unless you are a regular user of your own app, you might not notice any increased power drain.

This part of the book is focused on helping you understand what is draining power and what you can do to be kinder and gentler on your users' batteries.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You're Getting Blamed

Users, for better or worse, have limited ability to determine what is responsible for draining the battery of their phone. Their #1 tool for this is the “Power Usage Summary” screen in the Settings app, sometimes referred to as the “battery blame screen”.

Figure 8o3: Battery Screen from Settings App

This lists both device features (e.g., the display) and applications. Android incrementally improves the accuracy of this screen with each passing release, trying to make sure the user understands what specifically is consuming the power.

If your application starts appearing on this screen, and the user does not feel that it is justified, the user is likely to become irritated with you.

Now, your appearance on this list might be perfectly reasonable. If you have written a video player app, and the user has just watched a few hours' worth of video, it is very likely that you will appear on this list and will be justified in your battery consumption.

However, anything that you can do to not appear on this screen, or appear lower in the list, will help with user acceptance of your app.

This part of the book will show you how to measure your power usage and ways of trying to use less of it.

Not All Batteries Are Created Equal

Roughly speaking, battery capacity is proportional to screen size. Larger screens mean physically larger devices, and since the rest of the components (e.g., CPU) tend to be the same size, a larger device offers more room for a larger battery. This is good, as the screen is one of the major power draws on a device, and bigger screens draw more power.

Conversely, the battery on a “wearable” — whether eyewear like Google Glass, a smartwatch, or other form factors — tends to be much smaller than average, just because the wearables are physically smaller. A wearable is likely to have a battery with less than a third of the capacity of a phone, which in turn may have a battery with less than a third of the capacity of a large tablet.

Hence, depending upon where your app will be running, the amount of battery available in total will vary widely. What might be considered acceptable battery consumption on a tablet would be considered excessive on a wearable.

Stretching Out the Last mWh

Sometimes, what the user wants your app to do in one case is not what the user wants your app to do in other cases. Serious power-draining might be reserved for when the device is plugged in, or when the device has at least such-and-so power remaining. The user may value the last milliwatt-hours (mWh) more than others and want your application to use less power in those circumstances.

Hence, if your application polls the Internet, you might offer a feature to poll less frequently, or perhaps not at all, when power is low. If your application uses GPS to find a location (e.g., automatic “check-ins” to social networks like Foursquare), you might offer to skip such actions when the battery is low. You might want to signal to the user when the battery gets low during playback of a video, or during the game they are in. And so on.

ISSUES WITH BATTERY LIFE

This part of the book will help you identify when the battery is low and strategies for making use of that information.

Power Measurement Options

As with any situation where you are trying to reduce your use of some system resource, you need to be able to accurately measure how much you are using that resource. Otherwise, you will have no idea whether your attempts to reduce usage are helping. It is possible that what you think will consume less of the resource actually consumes *more*, because of unanticipated side-effects. And, if nothing else, if the change makes your code more complicated and does not help much with resource consumption, you may be better served sticking with the original, simpler implementation.

So, when it comes to power usage, it helps to know how much power you are consuming, to determine if your attempts to use less power actually do help.

Unfortunately, compared to things like RAM and bandwidth, power measurement is a significant challenge. You really need to have hardware specifically instrumented to report power consumption for pieces of that hardware (CPU versus screen versus GPS versus mobile data radio versus ...). Even if you cannot get power usage per component, just having accurate power consumption overall is not something you can necessarily get from any Android device. Alas, getting that level of power usage knowledge can be troublesome in its own right, for a variety of reasons.

This chapter will explore a few ways of measuring power usage, along with the pros and cons of that approach.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

batterystats and the Battery Historian

Android 5.0 brought us “Project Volta”, an initiative to reduce the amount of power consumed by apps, the framework classes, and the OS itself.

Part of what we got from Project Volta is batterystats, a dump of data pertaining to power consumption. Since that data dump can be large and inscrutable, we also have the Battery Historian, a Python script that can convert key batterystats output into a timeline of events.

However, none of this is especially well-documented at this time, and so the usefulness of these utilities is limited at present. The following sections provide some basic guidance for trying to use these tools.

Running a Test

First, since batterystats is obtained via `adb shell dumpsys`, you will want `adb` to be in your `PATH`, by adding your SDK installation’s `platform-tools/` directory to your `PATH` environment variable.

Then, in a terminal, run:

```
adb shell dumpsys batterystats --enable full-wake-history
adb shell dumpsys batterystats --reset
```

This will ensure that batterystats captures all relevant information about WakeLock behavior, and it resets all of the logs.

At this point, run your tests. Ideally, you would do so in a fairly power-neutral environment, such as not using a micro USB cable for an `adb` connection (as that charges the device).

When your test scenario is complete, run `adb shell dumpsys batterystats`, redirecting the output to some file:

```
adb shell dumpsys batterystats > /tmp/bs.txt
```

You can optionally supply your `applicationId` as part of the `batterystats` command, which will restrict the output to events pertaining to your app. However, some events that are from other processes, like the Play Services Framework, may be

of interest to you. You will need to experiment to determine which mode (full or filtered for your app) will work best for you.

Interpreting the Text Output

Depending on how long your test runs, the information included in the batterystats output can be anywhere from tens of KB to tens of MB in size.

Battery History

The file will lead off with the “Battery History” section:

```
Battery History (13% used, 35KB used of 256KB, 68 strings using 4232):

.
.
.
```

This contains information about how much the battery was drained during the test run, along with a detailed roster of the power-related events that occurred during the test run. The timestamps on those roster entries are relative to the first entry in the roster. Beyond that, there is little explanation of what the roster entries mean.

Per-PID Stats

Next, there will be a short stanza labeled “Per-PID Stats” and “Discharge step durations”:

Per-PID Stats:

```
PID 0 wake time: +134ms
PID 536 wake time: +1m35s993ms
PID 0 wake time: +10s842ms
PID 881 wake time: +301ms
PID 536 wake time: +70ms
PID 989 wake time: +23s167ms
PID 1136 wake time: +2s974ms
PID 1193 wake time: +230ms
PID 0 wake time: +1s123ms
PID 617 wake time: +187ms
PID 536 wake time: +18ms
PID 536 wake time: +13ms
PID 627 wake time: +586ms
PID 536 wake time: +184ms
PID 3690 wake time: +9m42s965ms
```

Discharge step durations:

```
#0: +4h8m36s976ms to 97 (screen-off, power-save-off)
#1: +3h7m47s132ms to 98 (screen-off, power-save-off)
```

If you determine your process’ PID, you will see how long the process’ “wake time” was. The precise definition of “wake time” is undocumented.

“Statistics since last charge” Summary

Next up will be a “Statistics since last charge” header, with a few summary blocks of data:

Statistics since last charge:

```
System starts: 0, currently on battery: false
Time on battery: 11h 30m 29s 177ms (99.9%) realtime, 16m 13s 306ms (2.3%)
uptime
Time on battery screen off: 11h 30m 7s 940ms (99.9%) realtime, 15m 52s 69ms
(2.3%) uptime
Total run time: 11h 30m 55s 300ms realtime, 16m 39s 430ms uptime
Start clock time: 2014-10-25-19-54-07
Screen on: 21s 237ms (0.1%) 2x, Interactive: 20s 191ms (0.0%)
Screen brightnesses:
  dark 21s 237ms (100.0%)
Total partial wakelock time: 10m 22s 877ms
Mobile total received: 0B, sent: 0B (packets received 0, sent 0)
Phone signal levels:
  none 11h 30m 29s 177ms (100.0%) 0x
```

POWER MEASUREMENT OPTIONS

```
Signal scanning time: 9s 0ms
Radio types:
  none 11h 30m 29s 177ms (100.0%) 0x
Mobile radio active time: 0ms (0.0%) 0x
Wi-Fi total received: 0B, sent: 0B (packets received 0, sent 0)
Wifi on: 11h 30m 29s 177ms (100.0%), Wifi running: 11h 30m 29s 177ms (100.0%)
Wifi states: (no activity)
Wifi supplicant states:
  group-handshake 16ms (0.0%) 12x
  completed 11h 30m 29s 161ms (100.0%) 12x
Wifi signal levels:
  level(4) 11h 30m 29s 177ms (100.0%) 1x
Bluetooth on: 0ms (0.0%)
Bluetooth states: (no activity)

Device battery use since last full charge
  Amount discharged (lower bound): 2
  Amount discharged (upper bound): 3
  Amount discharged while screen on: 0
  Amount discharged while screen off: 3

Estimated power use (mAh):
  Capacity: 3448, Computed drain: 107, actual drain: 69.0-103
  Idle: 40.3
  Wifi: 36.4
  Uid u0a58: 14.8
  Uid 0: 12.8
  Uid 1000: 1.75
  Uid u0a20: 0.521
  Uid u0a7: 0.389
  Screen: 0.375
  Uid 1013: 0.0775
  Uid 1001: 0.0219
  Uid u0a42: 0.0168
  Uid u0a12: 0.0138
  Uid 1027: 0.0110
  Uid u0a5: 0.00866
  Uid u0a33: 0.00253
  Uid u0a16: 0.000867
  Uid u0a3: 0.000815
  Uid u0a29: 0.000523
  Uid u0a2: 0.000474
  Over-counted: 4.04
```

The first block has useful data about how much various radios were on, how much data they transmitted, how long the screen was on, how long the device had an outstanding partial WakeLock, etc.

Also, the “Estimated power use (mAh)” block is basically the data that underlies the “battery blame screen” in Settings. You will see how many milliamp-hours (mAh) were attributed to your process.

WakeLock Summary

Next up is a summary of WakeLock events:

All kernel wake locks:

```
Kernel Wake lock PowerManagerService.WakeLocks: 10m 23s 46ms (717 times) realtime
Kernel Wake lock qcom_rx_wakelock: 9m 9s 836ms (1537 times) realtime
Kernel Wake lock alarm_rtc: 55s 327ms (717 times) realtime
Kernel Wake lock sns_async_ev_wakelock: 16s 525ms (9 times) realtime
Kernel Wake lock power-supply: 15s 730ms (1448 times) realtime
Kernel Wake lock event0-536: 11s 822ms (1484 times) realtime
Kernel Wake lock event2-536: 10s 686ms (1509 times) realtime
Kernel Wake lock event4-536: 10s 234ms (1509 times) realtime
Kernel Wake lock alarm: 7s 972ms (1239 times) realtime
Kernel Wake lock wlan: 1s 608ms (2 times) realtime
Kernel Wake lock PowerManagerService.Display: 611ms (2 times) realtime
Kernel Wake lock main: 608ms (0 times) realtime
Kernel Wake lock KeyEvents: 136ms (1548 times) realtime
Kernel Wake lock mmc0_detect: 38ms (1507 times) realtime
Kernel Wake lock deleted_wake_locks: 28ms (170 times) realtime
Kernel Wake lock event5-536: 20ms (2 times) realtime
```

All partial wake locks:

```
Wake lock u0a58 wake:com.commonware.android.job/.DemoScheduledService: 9m 0s
153ms (671 times) realtime
Wake lock 1000 *alarm*: 44s 114ms (683 times) realtime
Wake lock u0a7 Checkin Service: 16s 572ms (4 times) realtime
Wake lock 1000 NetworkStats: 7s 347ms (338 times) realtime
Wake lock 1013 AudioMix: 5s 833ms (2 times) realtime
Wake lock 1000 DHCP: 4s 953ms (12 times) realtime
Wake lock u0a7 *net_scheduler*: 1s 504ms (82 times) realtime
Wake lock u0a7 Event Log Service: 1s 98ms (18 times) realtime
Wake lock u0a42 DownloadManager: 322ms (1 times) realtime
Wake lock u0a7 Config Service fetch: 235ms (1 times) realtime
Wake lock u0a7 Icing: 197ms (5 times) realtime
Wake lock u0a7 Event Log Handoff: 143ms (18 times) realtime
Wake lock u0a58 *alarm*: 120ms (24 times) realtime
Wake lock u0a7 GCM_CONN: 61ms (36 times) realtime
Wake lock u0a7 GmsDownloadService: 47ms (1 times) realtime
Wake lock u0a7 *alarm*: 42ms (10 times) realtime
Wake lock u0a7 Wakeful StateMachine: GeofencerStateMachine: 35ms (8 times)
realtime
Wake lock 1000 SyncManagerHandleSyncAlarm: 34ms (6 times) realtime
Wake lock u0a7 GCM_HB_ALARM: 34ms (36 times) realtime
Wake lock u0a7 Checkin Handoff: 12ms (4 times) realtime
Wake lock 1000 SyncLoopWakeLock: 8ms (4 times) realtime
Wake lock u0a33 *alarm*: 7ms (4 times) realtime
Wake lock u0a42 *alarm*: 4ms (3 times) realtime
Wake lock u0a7 GCoreFlp: 2ms (5 times) realtime
```

Your code will tend to show up in the “All partial wake locks” section, showing how many WakeLocks you acquired and for how long overall.

And, if you show up here, you can definitely find out your app's PID — for example, u0a58 is associated with the `com.commonware.android.job` package.

Per PID Summary

Next up are summaries of information per process. Your process will show up somewhere in the list:

```
.
.
.
u0a58:
  Wake lock wake:com.commonware.android.job/.DemoScheduledService: 9m 0s 153ms
  partial (671 times) realtime
  Wake lock *alarm*: 120ms partial (24 times) realtime
  TOTAL wake: 9m 0s 273ms partial realtime
  Foreground activities: 7s 817ms realtime (1 times)
  Foreground for: 12s 959ms
  Active for: 3h 58m 47s 853ms
  Running for: 11h 30m 29s 177ms
  Proc com.commonware.android.job:
    CPU: 1m 4s 370ms usr + 21s 140ms krn ; 400ms fg
  Proc *wakelock*:
    CPU: 43s 690ms usr + 1m 19s 590ms krn ; 0ms fg
  Apk com.commonware.android.job:
    672 wakeup alarms
    Service com.commonware.android.job.DemoScheduledService:
      Created for: 11m 14s 174ms uptime
      Starts: 647, launches: 647
.
.
.
```

As usual, the exact definitions of the information here is largely undocumented.

Installing and Running the Battery Historian

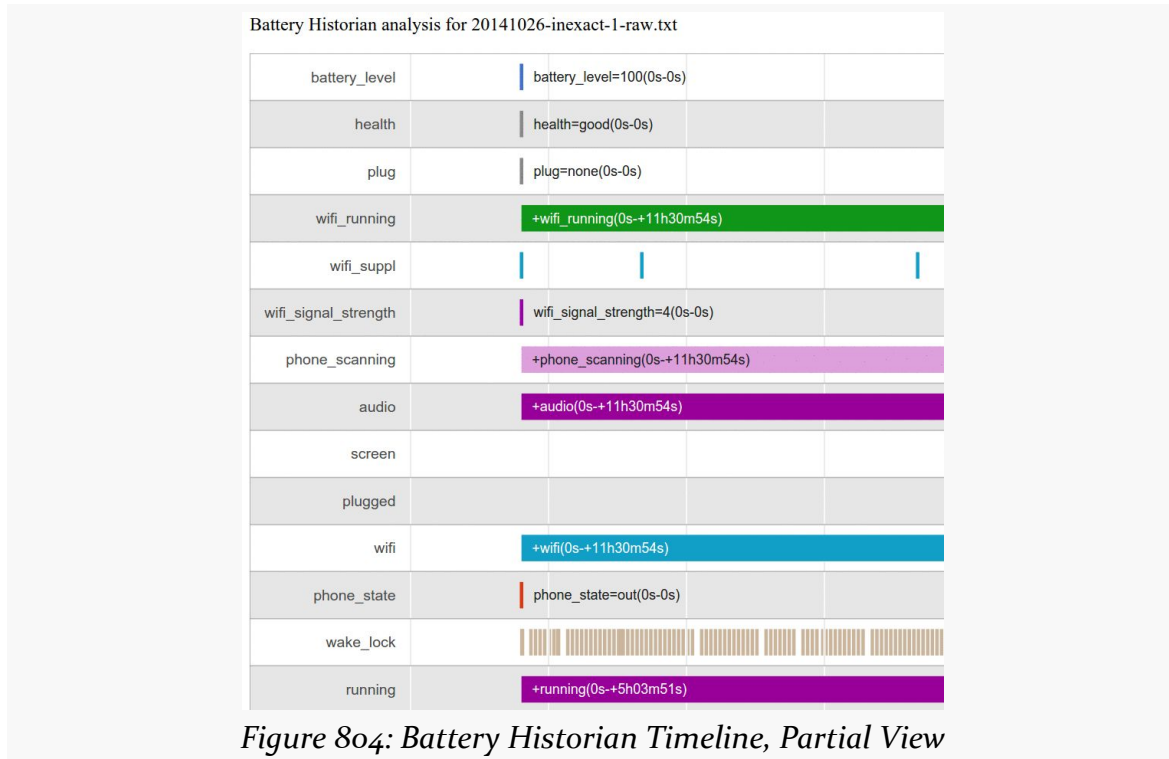

While `batterystats` is part of the Android 5.0 runtime environment, and tools like `adb` are part of the Android SDK, the Battery Historian is neither. Instead, it is a Python script that you have to download to your development machine from [its GitHub project](#).

Given that, you can run the Python script, supplying it with the output of your `batterystats` run, and redirecting the script's output to an HTML file:

```
python historian.py /tmp/bs.txt > /tmp/bs-report.html
```

Interpreting the Historian Output

You can then load that HTML into a Web browser (Chrome-flavored ones are probably a good choice, given that it is Google-generated HTML). This will give you a timeline across the horizontal axis, with event categories culled from the “Battery History” section of the batterystats output on the vertical axis:

POWER MEASUREMENT OPTIONS

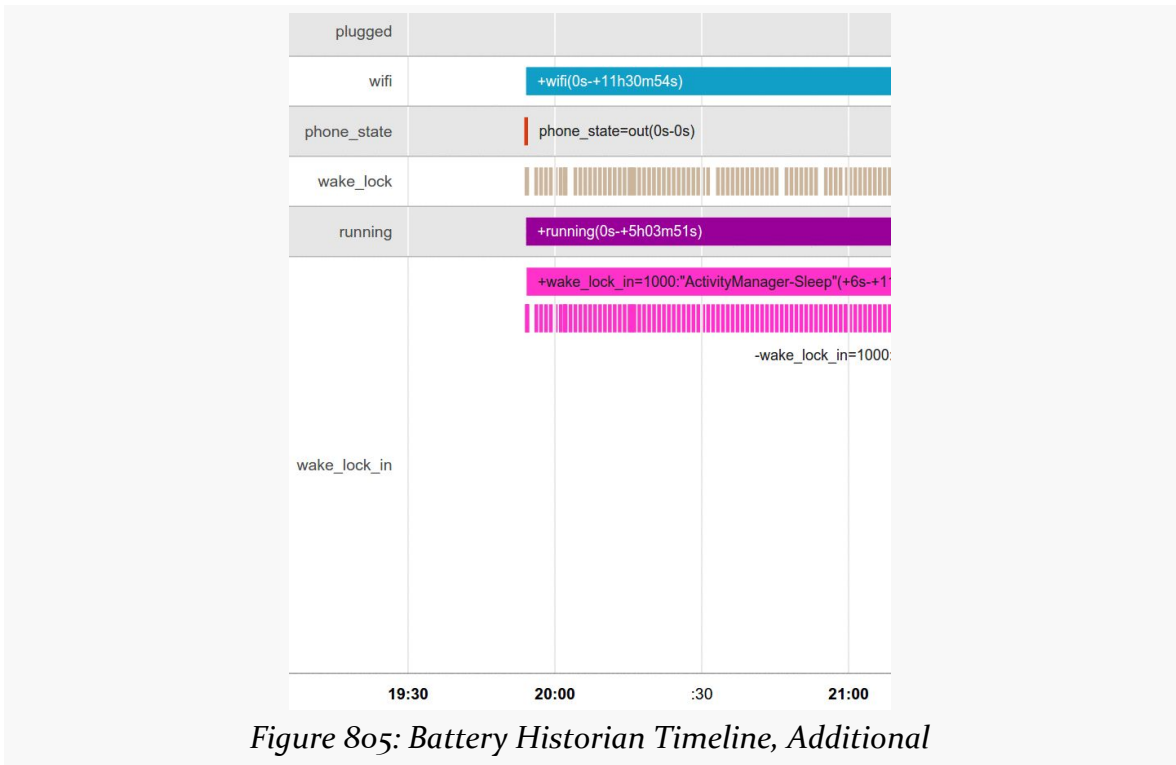

Figure 805: Battery Historian Timeline, Additional

The length of the bar shows the approximate duration of the event, though really short events have a *de minimus* length to give you something to see. Hovering your mouse over one of the bars brings up a pop-up with more details about that event:

POWER MEASUREMENT OPTIONS

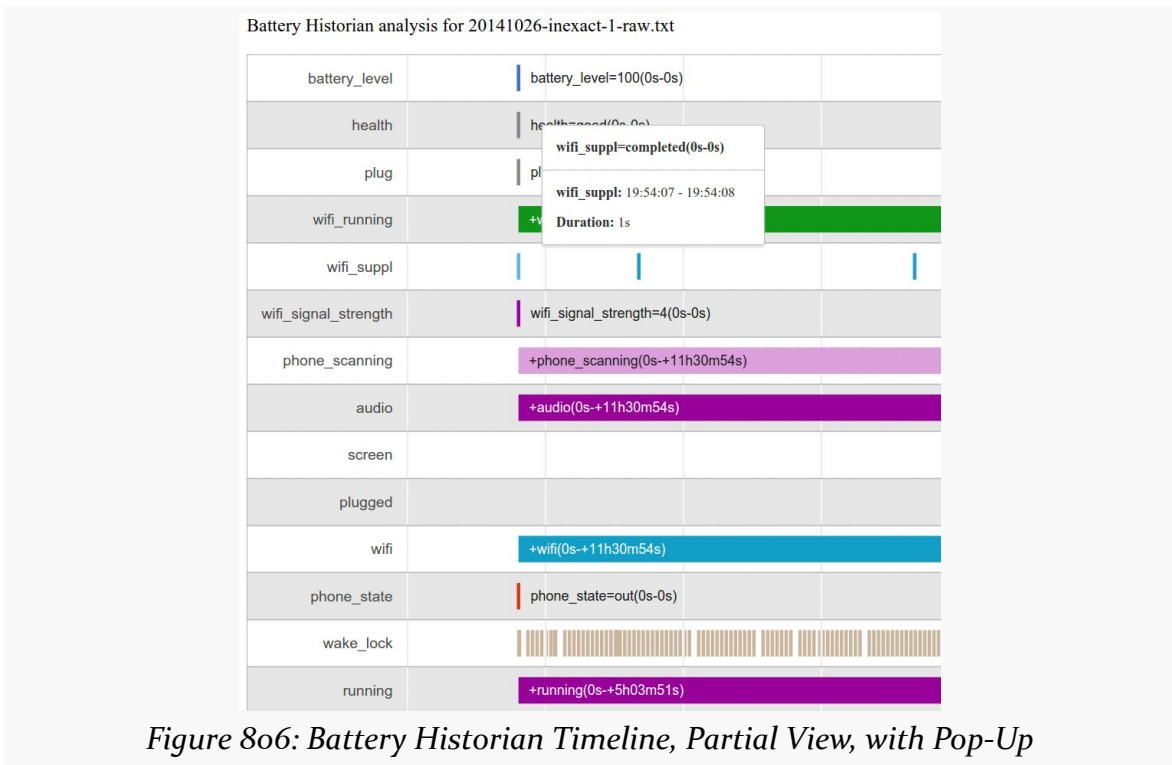

Figure 8o6: Battery Historian Timeline, Partial View, with Pop-Up

If the bar is really long, you may need to scroll your browser horizontally to see the pop-up, as the rendering of the pop-up location does not seem to pay attention to the browser viewport very well.

Below the main chart is a “Zoom” field that you can use to change the scale of the horizontal axis, along with an “Event summary”:

POWER MEASUREMENT OPTIONS

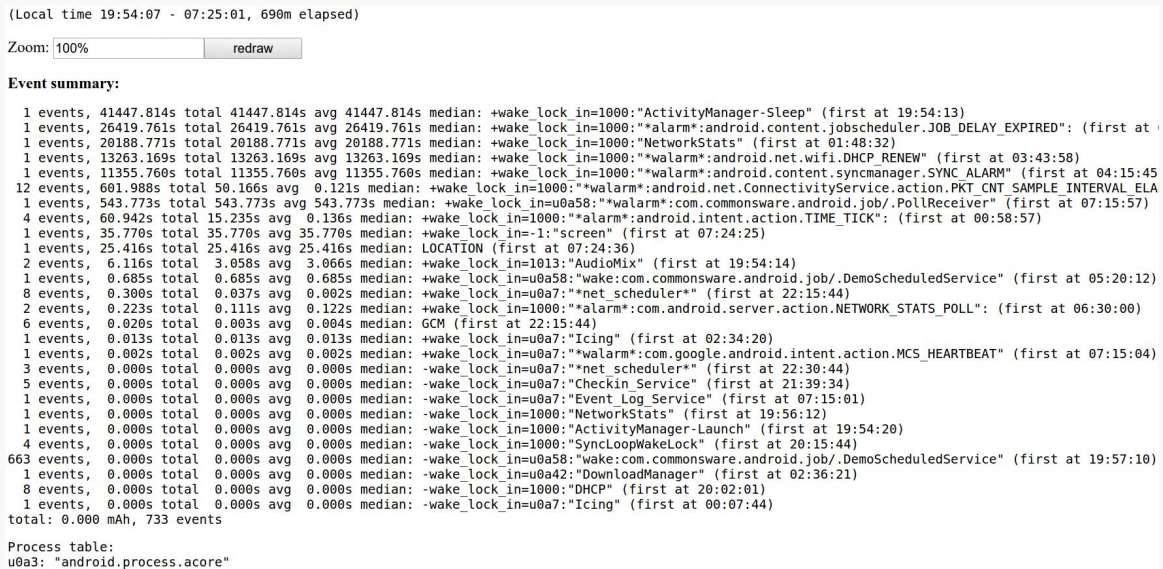

Figure 807: Battery Historian Timeline, Zoom and "Event summary"

Again, this is largely undocumented.

The Qualcomm Tool (That Must Not Be Named)

Qualcomm makes the chipsets that drive a substantial percentage of Android devices. Qualcomm also offers a number of things to further help Android developers, such as open source libraries like AllJoyn (P2P communications).

Qualcomm makes a tool that can help you measure power consumption. There are two versions of this tool:

1. The best version is designed to run on [the Qualcomm MDP series of reference hardware](#), and takes advantage of specific capabilities of that hardware to provide excellent power consumption data
2. Another version can be used with other Android devices powered by Qualcomm chipsets, providing information about power usage, though not quite as much as you get from the first version

Alas, this book does not cover this tool.

The current versions of this tool have a license agreement containing crudely-implemented non-disclosure terms:

You shall not to disclose or permit the disclosure of the Materials in any form or any information relating to the Materials (including without limitation the results of use or testing) to any third party without QTI's prior written permission... You further acknowledge and agree that if QTI, in its sole discretion, chooses to provide any form of support or information relating to the Materials, such support and information shall be deemed confidential and proprietary to QTI and shall be protected in accordance with this Section 4.

In this case, "Materials" refers to the two versions of the tool, plus accompanying documentation, and QTI is Qualcomm Technologies.

The non-disclosure terms do not come with the normal "you can talk about anything that has been already publicly disclosed" caveats. Hence, even the Qualcomm public Web site regarding this tool falls under the "any form of support or information".

Regardless, you may be interested in visiting [Qualcomm's developer support site](#) in hopes that you can find this unnamed tool.

PowerTutor

Perhaps the best-known third-party power analyzer is [PowerTutor](#). PowerTutor is the outcome of a research project from the University of Michigan, with a bit of assistance from Google. In principle, PowerTutor is capable of letting you know power consumption on a device, much along the lines of what Trepn can record on a Qualcomm MDP. In practice, PowerTutor is significantly less powerful and sophisticated.

PowerTutor was created with the HTC Dream (T-Mobile G1), HTC Magic (T-Mobile G2), and Nexus One in mind. Its power output values will be as accurate as they could make it for those devices. If you run PowerTutor on other hardware, the results will be less accurate.

You can obtain PowerTutor from the Play Store, or from the PowerTutor Web site, or you can [compile it from source](#).

PowerTutor is not tied to testing a particular application. As such, you can simply run PowerTutor whenever you want from its launcher icon, then press "Start Power Profiler" in the main activity:

POWER MEASUREMENT OPTIONS

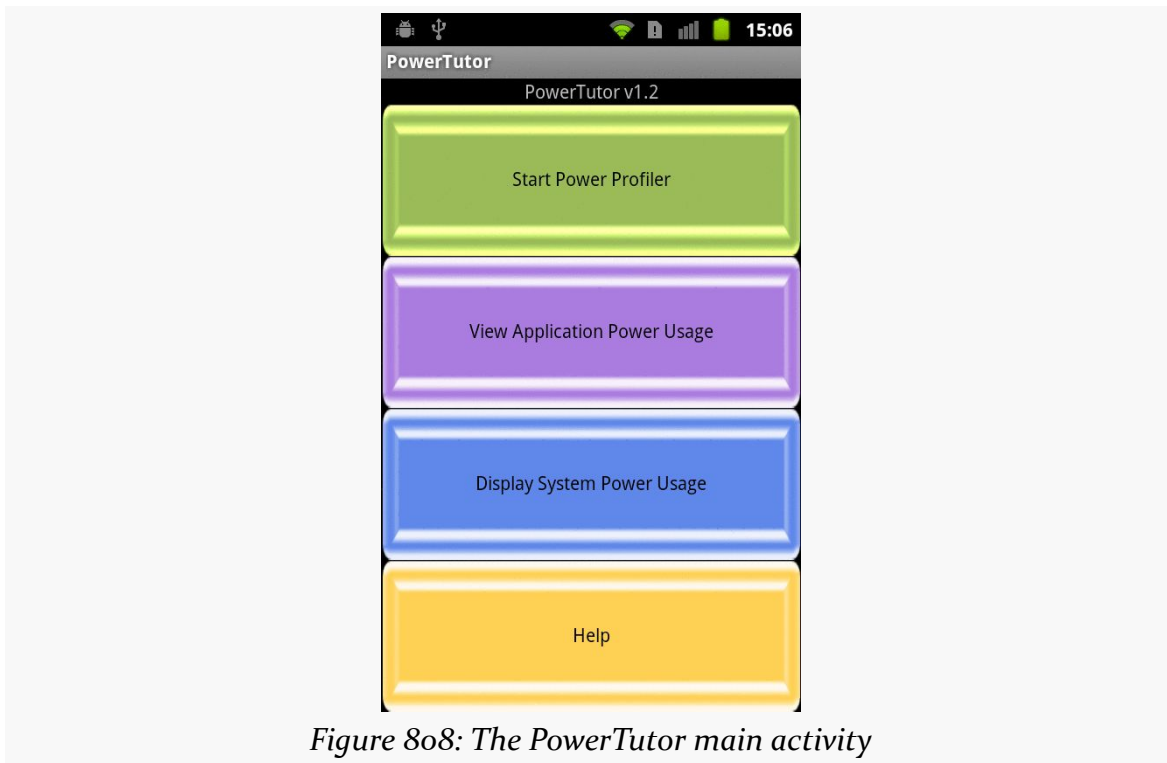

Figure 8o8: The PowerTutor main activity

At this point, you can start playing with your application, or running your unit test suite, or whatever. When you want to get an idea of how much power you have been consuming, you can switch back to the PowerTutor activity and choose “View Application Power Usage”. This brings up a list of processes and toggle buttons to show various power consumption values for each:

POWER MEASUREMENT OPTIONS

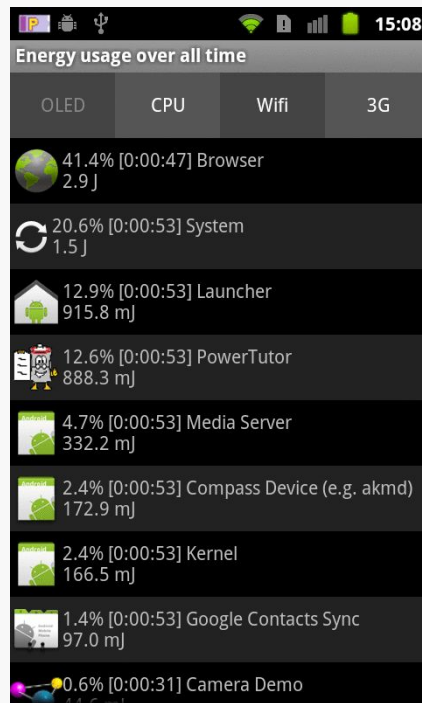

Figure 809: The PowerTutor application roster

Tapping the list entry brings up a graph for that particular process, though since this information is only available while PowerTutor is recording new data, the graph is usually empty unless you have logic running in the background:

POWER MEASUREMENT OPTIONS

Figure 810: The PowerTutor live charts for a single process current power consumption

You can also bring up a chart showing what portion of your power consumption came from various sources for the whole device, such as a pie chart of current consumption:

Figure 811: The PowerTutor pie chart for current overall power consumption

Given that the source code is available, one might augment PowerTutor to:

1. Saving results, both as data files for offline analysis (akin to Trepn's CSV files) or for viewing charts and tables on the device when data is not being actively collected
2. Allowing one to record application states, akin to Trepn, to better correlate application functionality to saved power results

Battery Screen in Settings Application

Of course, what developers tend to focus on most with power is the battery consumption screen in the Settings application, as shown in [a previous chapter](#):

POWER MEASUREMENT OPTIONS

Figure 812: Battery Screen from Settings App

After all, this is what users will tend to focus on — anything showing up in here is a source of blame for whatever power woes the user believes she is experiencing. Conversely, if your application does not show up in this screen during normal operation, then there is no compelling reason for you to do further analysis, as users will tend to be oblivious to your actual power consumption.

If you do show up in the list, tapping on your entry can give you some more details of what power you consumed and why:

POWER MEASUREMENT OPTIONS

Figure 813: Battery Details Screen from Settings App

However, the information contained in here is mostly guesswork, using a more refined version of the same approach that PowerTutor uses. Ordinary Android hardware simply lacks enough fine-grained power measurement instrumentation to do an accurate job of apportioning power usage among different processes. So, the details of how long you kept the CPU powered on may be accurate, but the percentage of battery consumption associated with your app is just an estimate.

BatteryInfo Dump

Yet another possibility is to use the `adb shell dumpsys batteryinfo` command from your command prompt or terminal on your development workstation. This will emit a fair amount of data that probably means something to somebody, such as general device information:

```
Battery History:
-1h00m56s463ms 096 20030002 status=discharging health=good
plug=none temp=191 volt=4060 +screen +wake_lock +sensor

Device battery use since last full charge
  Amount discharged (lower bound): 0
  Amount discharged (upper bound): 1
  Amount discharged while screen on: 1
  Amount discharged while screen off: 0
```

POWER MEASUREMENT OPTIONS

(... and lots more...)

and per-process information (here, showing power used by PowerTutor itself):

```
#10058:
Wake lock window: 5s 71ms window (1 times) realtime
Proc edu.umich.PowerTutor:
  CPU: 11s 750ms usr + 4s 530ms krn
  1 proc starts
Apk edu.umich.PowerTutor:
  Service edu.umich.PowerTutor.service.UMLoggerService:
    Created for: 4m 4s 750ms uptime
    Starts: 1, launches: 1
```

In principle, one might create tools that use this output — or perhaps steal a peek at the data used by the Settings application – to create something a bit more developer-friendly.

Sources of Power Drain

If you can measure power drain well yourself, that is the best way for you to determine precisely where your power consumption is going. Alas, for various reasons, you may not be able to get good power consumption data.

Which means you may have to guess.

We know the general sorts of things that consume power in a device, such as the screen and the CPU. We know that if we use these things less, we will use less power. Eventually, though, we have an app that does nothing, and while this may result in optimal power usage, we are still likely to get poor reviews, because *the app does nothing*.

What we need is some rough idea of how bad certain things are, so we can weigh our use of those system components appropriately.

This chapter will try to give you some “rule of thumb” heuristics of how to estimate power usage of various system components, plus some general recommendations of how to use less of that particular component without necessarily eliminating useful functionality from your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Also note that:

- mA = milliamps, where the ampere (or “amp”) is the SI unit of current

- mAh = milliamp-hours, which is how battery capacities are measured (e.g., 2000mAh can power a 200mA draw for 10 hours)

Screen

Screen size and battery size generally trend together. Tablets have bigger batteries and bigger screens than do phones, which in turn are bigger in both areas than are wearables.

A rough rule of thumb is to expect to consume ~10% of the device's battery for every hour you keep the screen on. Or, to look at it another way, on a phone-sized screen, expect a power draw of ~100–200mA, depending on variations in screen size and display technology (e.g., AMOLED).

Normally, the user is in control over how long your app is in the foreground and therefore is “to blame” for the screen being on. There are a couple of cases where you can make the screen be more of a problem.

The first is if you acquire() a `WakeLock` (other than a `PARTIAL_WAKE_LOCK`)... and forget to ever release() it. Since the `WakeLock` will keep the screen on, the screen will stay on, even if your app is in the background, until such time as your process is terminated or the device shuts down due to low battery.

In fact, such `WakeLock` types have been deprecated, with the last of them being flagged as deprecated in API Level 17. The recommended alternative is to use `android:keepScreenOn` or `setKeepScreenOn()` on some `View`. This will keep the screen on, so long as the activity hosting that `View` is in the foreground. That way, just moving to the background releases the underlying `WakeLock`, allowing the device to return to sleep.

However, in some cases, even that may be insufficient. Suppose that the user is in your activity, and they get distracted, putting down their device for an extended period. Unless you somehow detect the inactivity, and manually turn off the keep-screen-on mode, the screen will stay on indefinitely, until the power is drained. Hence, if you have a decent way of determining if the user is still using your activity, consider using that as a way to determine when the device is inactive (e.g., a `postDelayed()` that gets canceled and rescheduled when the user does something, so if the `postDelayed()` `Runnable` gets invoked, you know the user has done nothing for the delay period). Then, if you know the device is inactive, call `setKeepScreenOn(false)` to return the screen to its normal operating mode.

The academic paper [“How is Energy Consumed in Smartphone Display Applications?”](#) has a more extended analysis of screen power draw.

Disk I/O

Disk I/O gets more efficient with bigger operations.

You can see this in something like SQLite, where wrapping a bunch of INSERT statements into a single transaction can have substantial benefits in terms of how long the I/O takes.

Not surprisingly, this has a similar impact on power consumption:

- Writing 1GB of data 1,000 bytes at a time is about twice as expensive as is writing it 10,000,000 bytes at a time
- Writing 1GB of data 100 bytes at a time is about five times as expensive as is writing it 1,000 bytes at a time

Hence, you want to try to batch up your disk I/O, where possible, to do fewer, bigger operations, rather than lots of little ones. This includes:

- Batching database I/O in a transaction, as noted above
- Caching data that you intend to log to disk in memory and only writing when your in-memory buffer reaches a certain size or age (though beware the dangers of your process being terminated before you get a chance to write the data)
- Consider using larger buffer sizes with `BufferedInputStream` and `BufferedOutputStream`, if you can afford the heap space, though the 8KB defaults are not that bad

As a rough model, consider disk I/O to draw ~200mA. The smaller the I/O operations, the more time it takes you to accomplish the work, and hence the less efficient those operations are.

While disk I/O is relatively expensive while it is occurring, most apps are not continuously reading or writing, and therefore the total impact to the battery will not be that bad. Apps that *do* continuously use the disk — such as music or video players — will

WiFi and Mobile Data

Internet access via WiFi and mobile data networks are another area that you, the developer, tend to control. Some apps require continuous Internet access and only while in the foreground, like a streaming media player. But many more apps wind up doing Internet access periodically in the background, looking for new information on some server somewhere. Unfortunately, these are the sorts of “vampire” apps that can drain the battery without users necessarily being aware of it. Individually, these apps might not even appear all that bad, but when a device has dozens of them, the combined impact results in poor battery life.

Moreover, we also have the problem of dealing with multiple ways of getting to the Internet. Simple solutions will leave us totally oblivious to the differences in downloading via WiFi versus mobile data, at the potential cost in battery consumption. Slightly less-simple solutions optimize for mobile data, to try to minimize power drain in that model. More-elaborate solutions detect what sort of connection we have (using `ConnectivityManager`) and choose among different strategies as connectivity changes.

Here are some things you can do to try to help manage your Internet power consumption.

Use Less

The simplest, rough-cut way to consume less power for Internet access is to do less Internet access in the first place. The less time you spend downloading (or uploading) data, the less power you tend to draw while doing so. In a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

And, of course, consuming less bandwidth can have other benefits, particularly for people on metered mobile data plans.

There are chapters [elsewhere in the book](#) that cover ways to deal with bandwidth consumption for bandwidth’s sake.

Use What You Already Downloaded

For data that is likely to be unchanging, use a disk cache, so you can avoid downloading the same content again. Such a cache can be used at two levels:

1. Simply by having the file in the cache can be a signal to your app that you already have the data and can avoid any sort of request to fetch it again.
2. For HTTP, by recording some additional details (If-Modified-Since and ETag headers), you can make a request to the server to download the content again, where the server can tell you if you already have the current copy of the content (via a 304 response code).

Many of the Internet libraries discussed [earlier in this book](#) offer disk caching as part of their services.

Use In Batches

As noted earlier in this section, in a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

Unfortunately, that approximation is pretty coarse.

We as developers tend to think of Internet access as being like a faucet with two states: on and off. In reality, wireless radios tend to have three states: full power, low power, and standby mode. Opening a socket will bring the radio to full power. An idle radio (no packets transferred) will drop to low power after a while, and eventually back to standby mode. Not surprisingly, the power draw for full power is substantially more than low power, which in turn is more than standby.

However, this model introduces some problems:

- There is some latency to move from standby or low power to full power. This slows down data transfer while the radio “warms up”.
- The idle time needed to transition to a lower power state is substantial, with values in the 5–15 second range well within reason. This means that making a request has lingering power cost even *after* our request has completed.

The net is that you want to bring the radio to full power as few times as possible (to minimize the percentage of time we are slowly dropping back to standby and consuming power while we do). And, while we are at full power, we want to do all necessary — or perhaps possibly necessary — data transfers, to avoid having to go back to full power again any time soon.

In other words, you want to batch your network I/O. This is reminiscent of the recommendations to batch disk I/O from earlier in this chapter.

So, for example, if you are going to upload data to a server, use that same pulse of work to download anything that needs downloading, rather than having separate schedules for uploads and downloads. Doing more in a batch and having fewer batches will reduce the cost of the power state changes.

Use When the Server Wants You To

One common pattern for Internet access is to poll a server. This is fairly easy to code, using something like `AlarmManager` to get control every so often.

However, this approach resembles children in the back seat of a car, frequently pestering their parents with “Are we there yet?”.

Just as the parents will tell the children “We will get there when we get there, and we will tell you when we get there”, you can take a similar approach, using [Google Cloud Messaging \(GCM\)](#). Rather than poll the server periodically, have the server contact your app on the device when there is data ready to be downloaded. This works well in cases where polls are likely to result in “yes, we have no data” responses — the pushes can be far less frequent than the polls would be. This can also reduce load on your servers, for not having to respond to poll requests across all your users.

Note, though, that the battery benefits are from using GCM itself. From the standpoint of an app, GCM is “always on”, and the power consumed by GCM is attributed to Android itself, not to the app. Hence, pushes are almost “free” from the standpoint of power cost. This will *not* be the case if you “roll your own” push system (MQTT, WebSockets, etc.). In this case, you are attempting to keep a long-lived socket yourself, *in addition* to the one maintained by GCM. Clearly, there are ways to do this that minimize the power consumption of the long-lived socket connection, but that is not easy to accomplish. Hence, you need to weigh the costs of depending upon the Play Services SDK and routing your communications through Google’s servers with the costs of trying to do your own separate push mechanism in a battery-friendly fashion.

Use When Android Wants You To

If server push through GCM is impractical (e.g., you do not control the server), you can reduce your power use for Internet access by batching *across apps*, in addition to batching within your app.

What Google wants you to use for synchronizing data with a server is the `SyncManager`. This is an overly-complicated framework that, among other things,

gives you control to sync to the server at the same time that other apps needing to sync get control. That way, we can “warm up” the wireless radio once and handle several apps’ worth of data transfers at once. SyncManager will be covered in this book eventually.

Part of the reason why Android moved to make alarms with AlarmManager more “inexact” in API Level 19+ is for this same sort of batching. While AlarmManager certainly can be used for a variety of purposes, a lot of apps use it for Internet data transfer. Allowing Android to control when those alarms occur allows Android to try to coalesce them, and perhaps even time them to happen when SyncManager-led transfers occur, with the objective of minimizing the number of times we bring the wireless radio out of standby mode.

Use Additional Reading

The Android developer documentation has [a series of “training” pages](#) on minimizing power consumption for data transfers. This expands upon Reto Meier’s Google I/O presentations that touch upon this topic.

GPS

In light testing, GPS seems to draw ~35mA. Additional power will be consumed for using those results, though, and so the net effect on the battery will be somewhat higher, depending upon what your app does when it gets a GPS fix.

That figure is corroborated by the academic paper [“An Analysis of Power Consumption in a Smartphone”](#), though that paper tested rather old devices (HTC Dream and Nexus One).

Again, different devices will have different components, and some devices’ GPS modules may be more or less efficient.

Hence, GPS itself is a power drain, but not a massive one... if what you are doing with the GPS fixes itself is efficient. Keeping the GPS on for several hours will certainly take a chunk out of the battery charge, but if you are doing lots of work (e.g., navigation app) in response to those fixes, several hours may be more than the battery can handle.

If you can get by with the dependency on the Play Services SDK, using [LocationClient](#) can help here, particularly in cases where the user may not be

moving much, as Google's fused location provider uses the accelerometer to help determine how much they need to use GPS versus other possible means of determining location.

Camera

The camera will consume power while it is actively receiving input, whether that is for the preview frames or for taking full-resolution pictures or video. Of course, it will also consume additional power when recording images to disk, whether those be still photos or continuous video.

A rough guide is that a camera preview will draw ~200mA *plus* the power for screen, CPU, etc. That could easily total over 350mA, even if you are not doing much. Normally, though, the camera preview is on for short periods of time, and only under user control.

A corresponding value for recording video, including the disk I/O and camera preview, would be ~600mA (plus the screen). That is the sort of thing you only want to do in short bursts, as a couple of hours of video recording can really take a bite out of battery. However, once again, normally the user is the one controlling when video is recorded.

Additional Sources

The above sources of power drain are comparatively easy to model and provide a heuristic for determining your possible power usage.

However, there are plenty of other things that can drain the battery, for which this chapter does not provide such a heuristic. In many cases, the usage patterns of the system component will vary so widely that a simple heuristic is unrealistic. In some cases, the power drain from components from different manufacturers will be very different. In some cases, the author of this book simply lacks sufficient expertise with the technology to provide much help (e.g., Bluetooth).

The sections that follow will try to provide some help, though.

CPU/GPU

Perhaps the biggest source of power drain beyond the components listed above will be the processors: the CPU and the GPU. These draw a fair bit of power, which is why processor manufacturers go to great lengths to try to adapt to varying conditions, turning off cores or switching clock speeds, to try to minimize the power drain.

Usually, so long as we are in the foreground, any CPU/GPU usage impact on power will be considered “normal” by the user. Of course, trying to boost performance here can benefit the user, not only in terms of possibly reduced power consumption, but less lag or other forms of sluggishness. Hence, trying to optimize processor utilization is worthwhile.

However, the bigger complaints from the user will come from power drain while your app is in the background. The biggest source of those complaints will come from your use of WakeLocks, preventing the device from going into a low-power sleep state.

There are some apps available on the Play Store that reportedly can give you some idea of how long you may be holding a WakeLock, however they generally require root, particularly for Android 4.4+.

Sensors

Sensors, more so than many other device components, seem to get sourced from a wide range of manufacturers. They also seem to be tied into the devices differently from device to device. For example, some devices allow sensors to continue collecting data while the device is otherwise in a sleep mode, while many do not.

As such, it is difficult to give much guidance in terms of power drain tied to your use of sensors.

That being said, here are a few notes that may help:

1. Generally speaking, the more you use a sensor, the more likely it is that it will reflect in power drain. However, only some of that power drain will be from the sensor hardware itself. Your application code processing sensor events will bear much of the blame. Reducing the periods of time when you are registered for sensor events, using longer delays between events, and

sensor event batching are ways that you can reduce the power drain associated with the sensors and your associated code.

2. Conversely, in some environments, use of a particular sensor may be “free”, insofar as the device uses the sensor itself on a continuous basis. For example, the accelerometer and/or gyroscope is used by devices to detect orientation changes. Hence, those sensors must be powered on regularly, and therefore you cannot be “blamed” for the fact that the sensors are drawing power. Your use of the sensor data may contribute to power drain, of course.

Audio Input and Output

Playing audio through the earpiece, speaker, wired headset, or Bluetooth, will consume some amount of power. The amount will vary by how long you are playing the audio and how the audio is played (e.g., Bluetooth may require more power than on-device audio output). However, in both cases, usually the user has control over the audio, particularly if it is to be playing for a lengthy period of time (e.g., music player), and so the power drain associated with audio playback is less likely to be considered to be a problem, as users will get annoyed with *uncontrolled* power drain, more so than power drain that they can manage themselves.

Recording audio via the on-board microphone or Bluetooth should also consume some incremental power. In cases where the user is in control over when recording is happening, the power drain is unlikely to cause the user much distress.

Where both playback and recording of audio may cause perceived power problem is in places where the user has less control. For example, an alarm clock app should have some sort of timeout to stop playing the ringtone (or whatever) after some period, if the user fails to respond to the alarm. After all, it is possible that the user is not where the device is and is not in position to stop the alarm. In this case, the power drain will be from several components, audio playback being just one, but it is the uncontrolled nature of the power drain that can get you in trouble.

Addressing Application Size Issues

Sometimes, our apps are just too big, where “too big” can be defined as:

- Bigger than the 50MB limit imposed by the Play Store
- Bigger than some other limit imposed by some other distribution channel
- Big enough that we worry about bandwidth costs, particularly for users on metered data plans
- Big enough that we hit some internal Dalvik limitations

This chapter will review various techniques for trying to keep the size of your app down to a reasonable level.

Prerequisites

This chapter assumes that you have read the core chapters of the book.

Java Code, and the 64K Method Limit

In ordinary Java development, there are few limits as to how big your applications can get. You tend to run into physical limitations, such as available system RAM, before you run into any limitations of the programming language or runtime environment.

And, normally, in Android applications, you do not worry about how many classes or methods you have. However, “normally” is not “always”, and there is a specific scenario that complex apps need to worry about.

What Is It?

[Quoting Andy Fadden](#), Android platform engineer:

The issue is not with the Dalvik runtime nor the DEX file format, but with the current set of Dalvik instructions.

You can reference a very large number of methods in a DEX file, but you can only invoke the first 65536, because that's all the room you have in the method invocation instruction.

I'd like to point out that the limitation is on the number of methods referenced, not the number of methods defined. If your DEX file has only a few methods, but together they call 70,000 different externally-defined methods, you're going to exceed the limit.

[An externally-defined method is] a method defined in a separate DEX file. For most apps this would just be framework and core library / uses-library stuff.

Specifically, you will crash at compile time, with an error message akin to:

```
Unable to execute dex: method ID not in [0, 0xffff]: 65536
Conversion to Dalvik format failed: Unable to execute dex: method ID not
in [0, 0xffff]: 65536
```

64K Seems Like a Lot of Typing...

Well, it is, and it isn't.

First, it is not merely your own methods. You can reach the 64K method limit without implementing 64K methods in your application yourself. You can:

- Call lots of methods defined by the framework
- Absorb lots of methods from libraries, particularly larger libraries that offer many more features than your app uses

This still tends to mean that simpler apps are unlikely to run into this limit, while more complex apps might.

Jake Wharton has published [a shell script](#) that can provide you with a count of referenced methods.

Mitigation Tactics

If you are relatively close to the 64K method limit, you may be able to tweak your project to get back under the limit without having to significantly rework your project.

Use Granular Libraries

Some libraries, like Google Play Services, come in two forms: a “kitchen sink” and more granular libraries for individual features. If your need for the library can be met by the granular libraries, use them, and you can remove your dependency on the “kitchen sink”.

In the case of Google Play Services, try *not* to depend upon the `com.google.android.gms:play-services` artifact. Instead, try to depend upon one of the more granular artifacts, such as `com.google.android.gms:play-services-maps` for [Maps V2](#). For services, like [Google Cloud Messaging](#), that have no specific granular artifact, depend instead upon `com.google.android.gms:play-services-base` — while still large, this is far smaller than is `com.google.android.gms:play-services`.

Use Better Libraries

One common culprit of hitting the 64K method limit comes from libraries, as their methods count along with yours. Hence, choosing different libraries can perhaps reduce your method count.

One specific case of this comes from the code generated by Google’s [Protocol Buffers](#). If you are using Protocol Buffers heavily, your generated classes may each be defining hundreds of unused methods. Switching to an alternative implementation can reduce this significantly. Some such implementations include:

- [micro-protobuf](#)
- Square’s [Wire](#)

Use ProGuard

If your debug builds are failing due to the 64K method limit, try a release build. If that works, the reason is ProGuard and its ability to strip out code that is deemed to be unreachable.

In this case, you can “buy yourself some time” by arranging to build your app in debug mode with ProGuard, but without ProGuard’s normal code obfuscation work (e.g., `-dontoptimize` `-dontobfuscate` switches in the ProGuard configuration).

[Quoting Eric Lafortune](#), ProGuard’s lead developer:

If you apply ProGuard with shrinking enabled but optimization and obfuscation disabled (`-dontoptimize` `-dontobfuscate`), the code will already be more compact, and you can still use a debugger. The source files, class names, method names, line numbers, etc remain unchanged and any breakpoints in removed unreachable code are irrelevant.

However, this is not possible with standard Eclipse builds and is difficult to arrange with Ant. With Gradle-based builds, it should be possible to set this up using `minifyEnabled true` and a custom ProGuard configuration file:

```
android {  
    buildTypes {  
        debug {  
            minifyEnabled true  
            proguardFile 'proguard-no-obfuscate.txt'  
        }  
    }  
}
```

(where `proguard-no-obfuscate.txt` contains the `-dontoptimize` `-dontobfuscate` switches)

Mitigation Strategies

If the aforementioned tactics are insufficient — or if they help somewhat, but you are still near the limit with a lot of development yet to be done — you may need to pursue some more strategic ways of resolving your application size.

Don't Go Overboard

One source of method explosion comes from too much adherence to server-side Java coding styles.

For example, if you find yourself defining hundreds of interfaces and/or abstract classes, with Factory classes (and perhaps FactoryFactory classes), you are more likely to hit the 64K method limit due to all those separate definitions. Consider whether the flexibility that you believe that you obtain from this coding style is worth the risk.

Smaller Apps, Loosely Connected

It may be that you are simply creating an app that is entirely too complicated for the Android environment. Android's Intent system is designed to enable apps to inter-operate, and so you may need to consider splitting your app into pieces, such as:

- A suite of related apps
- A host app and plugin apps that enable additional functionality
- An app and an affiliated Web app, where certain functionality is handled by the Web app in a standard browser

Splitting Into Separate DEX Files

It is also possible — though rather risky — to split your app into multiple DEX files. The basic technique is outlined by Google in [an Android Developers Blog post](#).

In Google's formulation, the secondary DEX file is packaged as an application asset and is unpacked into internal storage on first run of your app. This keeps all of your code in your one APK file for distribution.

The risk comes in if you decide to *not* ship the secondary DEX file with the APK, but rather obtain it by other means, such as downloading it from your own Web site. If somebody hacks your Web site, or employs a man-in-the-middle attack when users try downloading the DEX file, your DEX could be replaced by one that contains malware or otherwise harms the user. If you elect to distribute the secondary DEX files yourself by this sort of means, *please* consider the security ramifications and take appropriate steps to ensure that the DEX you download is the unmodified DEX file.

Native Code

Native code, implemented as NDK-compiled libraries, represent another source of app bloat. This will occur regardless of whether the NDK code is yours or if you are using a third-party library that supplies those binaries (e.g., SQLCipher for Android).

Native code is not intrinsically large. However, in some cases, native code is a port from some other environment (or environments) and may contain a lot of stuff that your app does not need. Worse, ProGuard will not strip out unused native code, as its algorithms only work with Java-style bytecode. Hence, it is not out of the question for apps to devote several MB just to the Linux .so files that make up the NDK-compiled libraries.

Fortunately, there are some workarounds.

Mitigation via Per-CPU APKs

Some distribution channels, like the Play Store, support publishing multiple versions of an APK, with different versions for different CPU architectures. Hence, you could have one APK with x86 binaries and one APK with ARM binaries, as opposed to having one “fat binary” with both.

While setting this up using the classic build tools would be a major pain, [Gradle for Android](#) makes this fairly straight-forward, using product flavors for the CPU architectures:

```
productFlavors {  
    x86 {  
        ndk {  
            abiFilter "x86"  
        }  
    }  
    arm {  
        ndk {  
            abiFilter "armeabi-v7a"  
        }  
    }  
    mips {  
        ndk {  
            abiFilter "mips"  
        }  
    }  
}
```

Using product flavors this way will give you separate commands for compiling each of the CPU architectures (e.g., `gradle assembleArmRelease`).

More details about using the NDK with Gradle can be found [elsewhere in the book](#).

Mitigation via libhoudini

As is noted in [the chapter on the NDK](#), libhoudini is proprietary Intel code that allows ARM-compiled NDK binaries to run on x86 CPUs, using the same sort of opcode translation that is used by the Android emulator. Many, though not all, x86-powered Android devices have libhoudini. Those that do could run your app even if you only ship ARM NDK binaries and not x86 ones. This gives you the same sort of space savings as you would get by publishing separate ARM vs. x86 APKs (per the previous section), without having to manage multiple APKs yourself. The cost is speed, as the translation layer adds significant overhead, much as you see with the Android emulator running ARM emulator images instead of x86 ones.

Mitigation via Ignoring Non-ARM

Of course, what a lot of developers do is simply only worry about ARM.

While Google does not publish percentages of CPU architectures the way they do Android OS versions, it is safe to say that, as of early 2014, ~1% of Android devices are powered by non-ARM CPUs. That percentage may climb, particularly as Intel pushes more x86 chipsets. But the *vast* majority of Android devices are powered by ARM. So, even if some of those x86 environments lack libhoudini (e.g., the manufacturer did not license libhoudini from Intel), they are so few in number that developers are prone to ignore x86.

Ironically, what drives x86 for developers is the development environment itself, not the production environment. The x86 emulator is nicely responsive, compared to a similarly-configured ARM emulator image. Many developers eschew the ARM emulator entirely, with it being too slow. Hence, developers may be interested in having x86 binaries in the APK to allow the app to run on the x86 emulator (which lacks libhoudini). In this case, it may be worthwhile to have a dedicated release build process that strips out the x86 binaries, if the space that those binaries take up is more than you can afford.

Images

Bitmap images are notorious for taking up lots of heap space. However, they can also swell the size of your APK. While the bitmap PNG or JPEG files will be compressed on disk, if you have enough of them, they can still consume many MB of space in the APK, particularly since the APK cannot compress them further.

Mitigation via Resource Aliases

You may have multiple copies of the same image.

The example cited in the Android documentation is where you want to have locale-specific drawable images. For example, perhaps you want to show a flag, and you use language resource sets to try to map the right flag to the right language. However, some flags are going to be used in multiple languages, such as the Canadian flag being needed for `en-rCA` and `fr-rCA`. By default, you would place your flag icon in each of those resource sets, duplicating your results. This gets worse if you have a few versions of the same flag icon for different densities.

However, you can elect to use a resource aliases to handle this differently.

Suppose that your code refers to a `flag` drawable resource (e.g., `@drawable/flag` or `R.drawable.flag`). For many languages, you would have a unique flag in the appropriate resource set. For cases where the same flag is used in multiple situations:

1. Put the flag in a resource set that is not tied to locale (e.g., `res/drawable-hdpi/` instead of `res/drawable-en-rCA-hdpi/`), for as many densities as you choose, but under a different name (e.g., `flag_canada.png` instead of `flag.png`)
2. Create a small XML file, `flag.xml`, in each of the locale-specific directories (e.g., `res/drawable-en-rCA/` and `res/drawable-fr-rCA/`), pointing to your `flag_canada` drawable:

```
<?xml version="1.0" encoding="utf-8"?>
<bitmap
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/flag_canada" />
```

When you reference `R.drawable.flag` on an `en-rCA` or `fr-rCA` device, Android will read in the XML resource, then turn around and retrieve the `flag_canada` drawable,

and use that. Since the two XML files are likely to be smaller than the sum total of the duplicate copies, you save disk space.

Mitigation via pngquant

In practice, the above technique is just not that commonly used, because it addresses a fairly narrow scenario. A more general-purpose solution is to try to tweak the images to be visually nearly identical, yet take up less disk space.

There are a variety of tools for this, mostly aimed at Web development, where smaller image file sizes means faster-loading Web pages.

One such tool is [pngquant](#). Given a PNG file as input, it generates a smaller PNG file as output, one with an optimized color palette, using mathematical techniques to choose colors that will maintain as much of the original look as possible. Many of the images in this book were optimized using **pngquant**, at a substantial savings in disk size, without materially sacrificing image quality.

APK Expansion Files

The ultimate solution to disk space concerns, for distribution through the Play Store, is to get stuff out of your app entirely and distribute that stuff by other means. The Play Store offers [APK expansion files](#) with this in mind. You can publish one or two expansion files, each containing up to 2GB of files. While these will not be treated as resources or assets, you do have access to the file contents at runtime. Game developers will use these for sound effects, additional artwork, and so on. The biggest limitation is that these files may not be supported by all distribution channels.

Trail: Alternatives for App Development

The Role of Alternative Environments

You might think that Android is all about Java. The official Android Software Development Kit (SDK) is for Java development, the build tools are for Java development, the discussion groups and blog posts and, yes, most books are for Java development. Heck, most of this book is about Java.

However (and with apologies to William Goldman), it just so happens that Android is only mostly Java. There's a big difference between mostly Java and all Java. Mostly Java is slightly not Java.

So, while Android's "sweet spot" will remain Java-based applications for the near term, you can still create applications using other technologies. This part of the book will take a peek at some of those alternatives.

This chapter starts with an examination of the [pros](#) and [cons](#) of Android's Java-centric strategy. It then enumerates some [reasons](#) why you might want to use something else for your Android applications. The downsides of alternative Android application environments – [lack of support](#) and [technical challenges](#) – are also discussed.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

In the Beginning, There Was Java...

The core Android team made a fairly reasonable choice of language when they chose Java. It is a very popular language, and in the mobile community it had a clear predecessor in Java Micro Edition ([J2ME](#)). Lacking direct access to memory addresses (so-called “pointers”), a Java-based application will be less prone to developer errors leading to buffer overruns, resulting in possible hacks. And there is a fairly robust ecosystem around Java, in terms of educational materials, existing code bases, integrated development environments (IDEs), and so on.

However, while you can program Android in the Java language, an Android device does not run a Java application. Instead, your Java code is converted into something that runs on the “Dalvik virtual machine”. This is akin to the technology used for regular Java applications, but Dalvik is specifically tuned for Android’s environment. Moreover, it limits the dependency of Android on Java itself to a handful of programming tools, important as Java’s stewardship moves from Sun to Oracle to wherever.

That Dalvik virtual machine is also capable of running code from other programming languages, a feature that makes possible much of what this book covers.

... And It Was OK

No mobile development environment is perfect, and so the combination of Java and Android has its issues.

Java uses garbage collection to save people from having to keep track of all of their memory allocations. That works for the most part, and it is generally a boon to developer productivity. However, it is not a cure-all for every memory and resource allocation problem. You can still have what amounts to “memory leaks” in Java, even if the precise mechanics of those leaks differ from the classic leaks you get in C, C++, etc.

Most importantly, though, not everybody likes Java. It could be because they lack experience with it, or perhaps they have experience with it and did not enjoy that experience. Certainly, Java is slowly being considered as a language for big enterprise systems and, therefore, is not necessarily “cool”. Advocates of different languages will have their own pet peeves with Java as well (e.g., to a Ruby developer, Java is really verbose).

So, while Java was not a bad choice for Android, it was not perfect, either.

Bucking the Trend

However, just because Java is the dominant way to build apps for Android, that does not mean it is the only way, and for you, it may not even be the best way.

Perhaps Java is not in your existing skill set. You might be a Web developer, more comfortable with HTML, CSS, and JavaScript. There are frameworks to help you with that. Or, maybe you cut your teeth on server-side scripting languages like Perl or Python — there are ways to sling that code on Android as well. Or perhaps you already have a bunch of code in C/C++, such as game physics algorithms, that would be painful to rewrite in Java — you should be able to reuse that code too.

Even if you would be willing to learn Java, it may be that your inexperience with Java and the Android APIs will just slow you down. You might be able to get something built much more quickly with another framework, even if you wind up replacing it with a Java-based implementation in the future. Rapid development and prototyping is frequently important, to get early feedback with minimal investment in time.

And, of course, you might just find Java programming to be irritating. You would not be the first, nor the last, to have that sentiment. Particularly if you are getting into Android as a hobby, rather than as part of your “day job”, having fun will be important to you, and you might not find Java to be much fun.

Support, Structure

However, “friendly” and “fully supported” are two different things.

Some alternatives to Java-based development are officially supported by the core Android team, such as C/C++ development via the Native Development Kit (NDK) and Web-style development via HTML5.

Some alternatives to Java-based development are supported by companies. Adobe supports AIR, Nitobi supports PhoneGap, Rhomobile supports Rhodes, and so on. Other alternatives are supported by standards bodies, like the World Wide Web Consortium (W3C) supporting HTML5. Still others are just tiny projects with only the backing of a couple of developers.

You will need to make the decision for yourself which of these levels of support will meet your requirements. For many things, support is not much of an issue, but there will always be cases where support becomes paramount (e.g., enterprise application development).

Caveat Developer

Of course, going outside the traditional Java environment for Android development has its issues, beyond just how much support might be available.

Some may be less efficient, in terms of processor time, memory, or battery life, than will development in Java. C/C++, on the whole, is probably better than Java, but HTML5 may be worse, for example. Depending on what you are writing and how heavily it will be used will determine how critical that inefficiency will be.

Some may not be available on all devices. Right now, Flash is the best example of this — some devices offer some amount of Flash support, while other devices have no Flash at all. Similarly, HTML5 support was only added to Android in Android 2.0, so devices running older versions of Android do not have HTML5 as a built-in option.

Every layer between you and officially supported environments makes it that much more difficult for you to ensure compatibility with new versions of Android, when they arise. For example, if you create an application using PhoneGap, and a new Android version becomes available, there may be incompatibilities that only the PhoneGap team can address. While they will probably address those quickly — and they may provide some measure of insulation to you from those incompatibilities — the response time is outside of your control. In some cases, that is not a problem, but in other cases, that might be bad for your project.

Hence, just because you are developing outside of Java does not mean everything is perfect. You simply have to trade off between these problems and the ones Java-based development might cause you. Where the balance lies is up to each individual developer or firm.

Prior to the current wave of interest in mobile applications, the technology *du jour* was Web applications. A lot of attention was paid to AJAX, Ruby on Rails, and other techniques and technologies that made Web applications climb close to the experience of a desktop application, and sometimes superior.

The explosion of Web applications eventually drove the next round of enhancements to Web standards, collectively called HTML5. Android 2.0 added the first round of support for these HTML5 enhancements. Notably, Android supports offline applications and Web storage, meaning that HTML5 becomes a relevant technique for creating Android applications, without dealing with Java.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the [chapter on WebView](#) would be a good idea, as would reading the [introduction to this trail](#).

Offline Applications

The linchpin for using HTML5 for offline applications — on Android or elsewhere — is the ability for those applications to be used when there is no connectivity, either due to problems on the client side (e.g., on an airplane sans WiFi) or on the server side (e.g., Web server maintenance).

What Does It Mean?

Historically, Web applications have had this annoying tendency to require Web servers. This led to all sorts of workarounds for offline use, up to and including shipping a Web server and deploying it to the desktop.

HTML5 solves this problem by allowing Web pages to specify their own caching rules. A Web app can publish a “cache manifest”, describing which resources:

1. Can be safely cached, such that if the Web server is unavailable, the browser will just use the cached copy
2. Cannot be safely cached, such that if the Web server is unavailable, the browser should fail like it normally does
3. Have a “fallback” resource, such that if the Web server is unavailable, the cached fallback resource should be used instead

For mobile devices, this means that a fully HTML5-capable browser should be able to load all its assets up front and keep them cached. If the user loses connectivity, the application will still run. In this respect, the Web app behaves almost identically to a regular app.

How Do You Use It?

For this chapter, we will use the Checklist “mini app” created by Alex Gibson. While the most up-to-date version of this app can be found [on Mr. Gibson’s Web site](#), this chapter will review the copy found in [HTML5/Checklist](#). This copy is also hosted online on the [CommonsWare site](#), or via a shortened URL: <http://bit.ly/cw-html5>.

About the Sample App

Checklist is, as the name suggests, a simple checklist application. When you first launch it, the list will be empty:

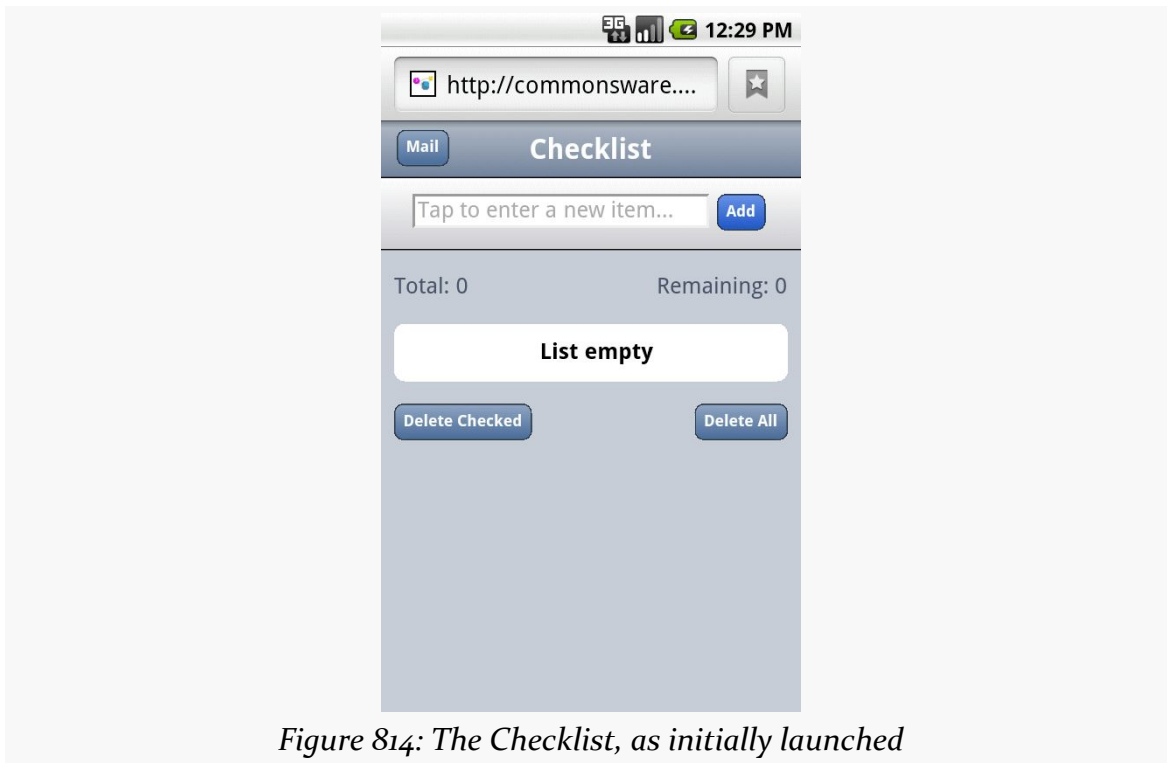

Figure 814: The Checklist, as initially launched

You can enter some text in the top field and click the Add button to add it to the list:

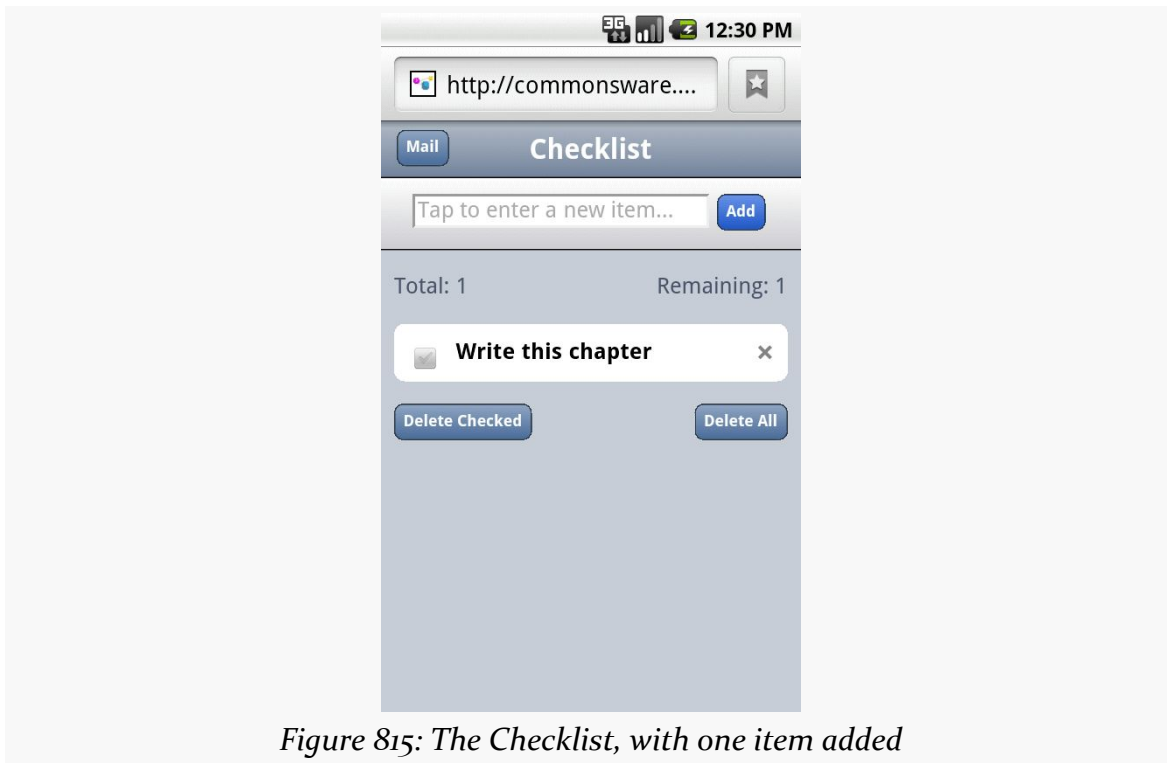

Figure 815: The Checklist, with one item added

You can “check off” individual items, which are then displayed in strike-through:

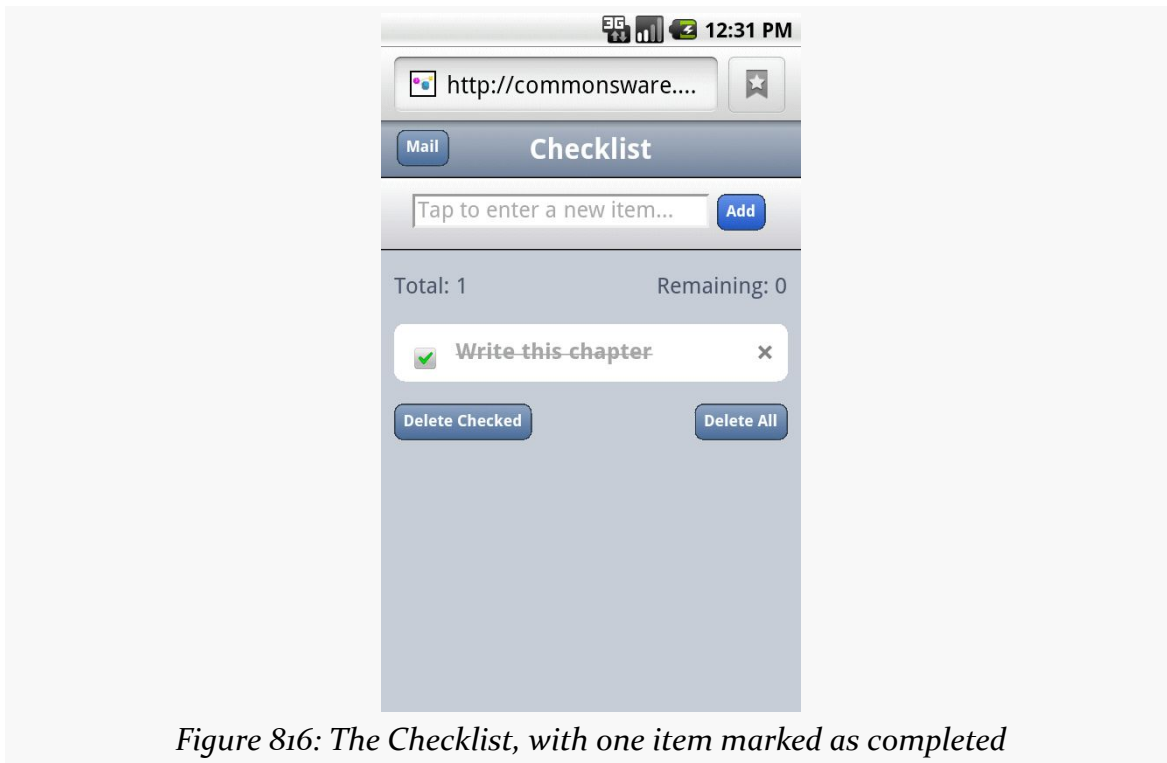

Figure 816: The Checklist, with one item marked as completed

You can also delete the checked entries (via the Delete Checked button) or all entries (via the Delete All button), which will pop up a confirmation dialog before proceeding:

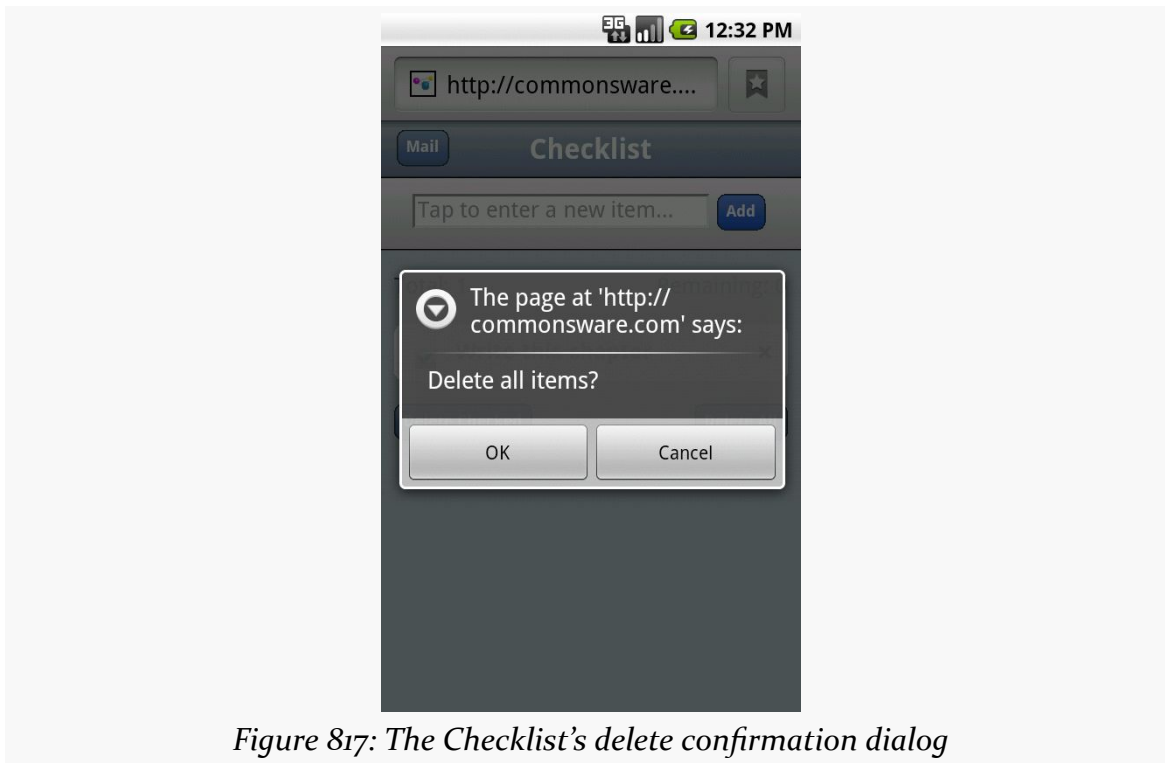

Figure 817: The Checklist's delete confirmation dialog

“Installing” Checklist on Your Phone

To access Checklist on your Android device, visit one of the URLs above for the hosted edition using the Browser application — the shortened one may be easiest to enter into the browser on the device. You can then add a bookmark for it (More > Add bookmark from the browser's options menu) to come back to it later.

You can even set up a shortcut for the bookmark on your home screen, if you so choose — just long-tap on the background, choose Bookmark, then choose the Checklist bookmark you set up before.

Examining the HTML

All of that is accomplished using just a handful of lines of HTML:

```
<!DOCTYPE html>
<html lang="en" manifest="checklist.manifest">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Checklist</title>
<meta name="viewport"
```

HTML5

```
    content="width=device-width; initial-scale=1.0; maximum-scale=1.0;
user-scalable=0;" />
<meta name="apple-mobile-web-app-capable" content="yes" />
<meta name="apple-mobile-web-app-status-bar-style" />
<link rel="apple-touch-startup-image" href="splashscreen.png" />
<link rel="stylesheet" href="styles.css" />
<link rel="apple-touch-icon-precomposed"
      href="apple-touch-icon-precomposed.png" />
</head>
<body>
<section>
  <header>
    <button type="button" id="sendmail">Mail</button>
    <h1>Checklist</h1>
  </header>
  <article>
    <form id="inputarea" onsubmit="addNewItem()">
      <input type="text" name="name" id="name" maxlength="75"
        autocorrect placeholder="Tap to enter a new item&hellip;" />
      <button type="button" id="add">Add</button>
    </form>
    <ul id="maillist">
      <li class="empty"><a href="" id="maillink">Mail remaining items</a></li>
    </ul>
    <p id="totals"><span id="tally1">Total: <span id="total">0</span></span>
      <span id="tally2">Remaining: <span id="remaining">0</span></span></p>
    <ul id="checklist">
      <li class="empty">Loading&hellip;</li>
    </ul>
  </article>
  <fieldset>
    <button type="button" id="deletechecked">Delete Checked</button>
    <button type="button" id="deleteall">Delete All</button>
  </fieldset>
</section>
<script src="main.js"></script>
</body>
</html>
```

For the purposes of offline applications, though, the key is the manifest attribute of our html element. Here, we specify the relative path to a manifest file, indicating what the rules are for caching various portions of this application offline.

Examining the Manifest

So, since the manifest is where all the fun is, here is what Checklist's manifest looks like:

```
CACHE MANIFEST
#version 54
styles.css
```

```
main.js  
splashscreen.png
```

The HTML5 manifest format is extremely simple. It starts with a `CACHE MANIFEST` line, followed by a list of files (technically, relative URLs) that should be cached. It also supports comments, which are lines beginning with `#`.

The manifest can also have a `NETWORK:` line, followed by relative URLs that should never be cached. Similarly, the manifest can have a `FALLBACK:` line, followed by pairs of relative URLs: the URL to try to fetch off the network, followed by the URL of a cached resource to use if the network is not available.

In principle, the manifest should request caching for everything that the application needs to run, though the page that requested the caching (`index.html` in this case) is also cached.

Web Storage

Caching the HTML5 application's assets for offline use is all well and good, but that will be rather limiting on its own. In an offline situation, the application would not be able to use AJAX techniques to interact with a Web service. So, if the application is going to be able to store information, it will need to do so on the browser itself.

Google Gears and related tools pioneered this concept and blazed the trail for what is now variously called "Web Storage" or "DOM Storage" for HTML5 applications. An HTML5 app can store data persistently on the client, within client-imposed limits. That, in conjunction with offline asset caching, means an HTML5 application can deliver far more value when it lacks an Internet connection, or for data that just does not make sense to store "in the cloud".

Note that, technically, Web Storage is not part of HTML5, but is a related specification. However, it tends to get "lumped in with" HTML5 in common conversation.

What Does It Mean?

On a Web Storage-enabled browser, your JavaScript code will have access to a `localStorage` object, representing your application's data. More accurately, each "origin" (i.e., domain) will have a distinct `localStorage` object on the browser.

The `localStorage` object is an “associative array”, meaning you can work with it either via numerical indexes or string-based keys at your discretion. Values typically are strings. You can:

1. Find out how many entries are in the array via `length()`
2. Get and set items by key via `getItem()` and `setItem()`
3. Get the key for a numerical index via `key()`
4. Remove individual entries via `removeItem()` or remove all items via `clear()`

This means you do not have the full richness of a SQL database, like you might have with SQLite in a native Android application. But, for many applications, this should suffice.

How Do You Use It?

Checklist stores the list items as keys in the associative array, with a value of 0 for a regular item and 1 for a deleted item. Here, we see the code for putting a new item into the checklist:

```
try {
    localStorage.setItem(strippedString, data);
}
catch (e) {
    if (e == QUOTA_EXCEEDED_ERR) {
        alert('Quota exceeded!');
    }
}
```

Here is the code where those items are pulled back out of storage and put into an array for sorting and, later, display as DOM elements on the Web page itself:

```
/*get all items from localStorage and push them one by one into an array.*/
for (i = 0; i <= listlength; i++) {
    var item = localStorage.key(i);
    myArray.push(item);
}

/*sort the array into alphabetical order.*/
myArray.sort();
```

When the user checks the checkmark next to an item, the storage is updated to toggle the checked setting persistently:

```
/*toggle the check flag.*/
if (target.previousSibling.checked) {
    data = 0;
}
else {
    data = 1;
}
/*save item in localStorage.*/
try {
    localStorage.setItem(name, data);
} catch (e) {

    if (e == QUOTA_EXCEEDED_ERR) {
        alert('Quota exceeded!');
    }
}
```

Checklist also has code to delete items from storage, either all those marked as checked:

```
/*remove every item from localStorage that has the data flag checked.*/
while (i <= localStorage.length-1) {

    var key = localStorage.key(i);
    if (localStorage.getItem(key) === '1') {
        localStorage.removeItem(key);
    }
    else { i++; }
}
```

... or all items:

```
/*deletes all items in the list.*/
deleteAll: function() {

    /*ask for user confirmation.*/
    var answer = confirm("Delete all items?");

    /*if yes.*/
    if (answer) {

        /*remove all items from localStorage.*/
        localStorage.clear();
        /*update view.*/
        checklistApp.getAllItems();
    }
    /*clear up.*/
    delete checklistApp.deleteAll;
},
```

Web SQL Database

Android's built-in browser also supports a “Web SQL Database” option, one where you can use SQLite-style databases from JavaScript. This adds a lot more power than basic Web Storage, albeit at a complexity cost. It is also not part of an active standard — the [WHATWG team](#) working on this standard has set it aside for the time being.

You might consider evaluating [Lawnchair](#), which is a JavaScript API that allows you to store arbitrary JSON-encoded objects. It will use whatever storage options are available, and therefore will help you deal with cross-platform variety. In particular, it supports the Google Gears facility found in some older versions of Android.

Going To Production

Creating a little test application requires nothing magical. Presumably, though, you are interested in others using your application – perhaps many others. Classic Java-based Android applications have to deal with testing, having the application digitally signed for production, distribution through various channels (such as the Android Market), and updates to the application by one means or another. Those issues do not all magically vanish because HTML5 is used as the application environment. However, HTML5 does change things significantly from what Java developers have to do.

Testing

Since HTML5 works in other browsers, testing your business logic could easily take advantage of any number of HTML and JavaScript testing tools, from [Selenium](#) to [QUnit](#) to [Jasmine](#).

For testing on Android proper — to ensure there are no issues related to Android's browser implementation — you can use Selenium's [Android Driver](#) or [Remote Control](#) modes.

Signing and Distribution

Unlike native Android applications, you do not need to worry about signing your HTML5 applications.

The downside of this is that there is no support for distribution of HTML5 applications through the Play Store, which today only supports native Android apps. Users will have to find your application by one means or another, visit it in the browser, bookmark the page, and possibly create a home screen shortcut to that bookmark.

Updates

Unlike native Android applications, which by default must be updated manually, HTML5 applications will be transparently updated the next time they run the app while connected to the Internet. The offline caching protocol will check the Web server for new editions of files before falling back to the cached copies. Hence, there is nothing more for you to do other than publish the latest Web app assets.

Issues You May Encounter

Unfortunately, nothing is perfect. While HTML5 may make many things easier, it is not a panacea for all Android development problems.

This section covers some potential areas of concern you will want to consider as you move forward with HTML5 applications for Android.

Android Device Versions

Not all Android devices support HTML5 — only those running Android 2.x or higher. Ideally, therefore, you do a bit of “user-agent sniffing” on your Web server and redirect older Android users to some other page explaining the limitations in their device.

Here is the user-agent string for a Nexus One device running Android 2.1:

```
Mozilla/5.0 (Linux; U; Android 2.1-update1; en-us; Nexus One  
Build/ERE27) AppleWebKit/530.17 (KHTML, like Gecko) Version/4.0 Mobile  
Safari/530.17
```

As you can see, it is formatted like a typical modern user-agent string, meaning it is quite a mess. It does indicate it is running Android 2.1-update1.

Eventually, somebody will create a database of user-agent strings for different device models, and from there we can derive appropriate regular expressions or similar algorithms to determine whether a given device can support HTML5 applications.

Screen Sizes and Densities

HTML5 applications can be run on a wide range of screen sizes, from QVGA Android devices to 1080p LCDs and beyond. Similarly, screen densities may vary quite a bit, so while a 48x48 pixel image on a smartphone may be an appropriate size, it may be too big for a 1080p television, let alone a 24" LCD desktop monitor.

Other than increasing the possible options on the low end of screen sizes, none of this is unique to Android. You will need to determine how best to design your HTML and CSS to work on a range of sizes and densities, even if Android were not part of the picture.

Limited Platform Integration

HTML5, while offering more platform integration than ever before, does not come close to covering everything an Android application might want to be able to do. For example, an ordinary HTML5 application cannot:

1. Launch another application
2. Work with the contacts database
3. Raise a notification
4. Do work truly in the background (though “Web workers” may alleviate this somewhat someday)
5. Interact with Bluetooth devices
6. Record audio or video
7. Use the standard Android preference system
8. Use speech recognition or text-to-speech
9. And so on

Many applications will not need these capabilities, of course. And, one can expect that other application environments, like [PhoneGap](#), will evolve into “HTML5 Plus” for Android. That way, you could create a stock application that works across all devices and an enhanced Android application that leverages greater platform integration, at the cost of some additional amount of programming.

Performance and Battery

There has been a nagging concern for some time that HTML-based user interfaces are inefficient compared to native Android UIs, in terms of processor time, memory,

and battery. For example, one of the stated reasons for avoiding [BONDI](#)-style Web widgets for the Android home screen is performance.

Certainly, it is possible to design HTML5 applications that will suck down the battery. For example, if you have a hunk of JavaScript code running every second indefinitely, that is going to consume a fair amount of processor time. However, outside of that, it seems unlikely that an ordinary application would be used so heavily as to materially impact battery life. Certainly, more testing will need to be done in this area.

Also, an HTML5 application may be a bit slower to start up than are other applications, if the Browser has not been used in a while, or if the network connection is there but has minimal bandwidth to your server.

Look and Feel

HTML5 applications can certainly look very slick and professional – after all, they are built with Web technologies, and Web apps can look very slick and professional.

However, HTML5 applications will not necessarily look like standard Android applications, at least not initially. Some enterprising developers will, no doubt, create some reusable CSS, JavaScript, and images that will, for example, mirror an Android native Spinner widget (a type of drop-down control). Similarly, HTML5 applications will tend to lack options menus, notifications, or other UI features that a native Android application may well use.

This is not necessarily bad. Considering the difficulty in creating a very slick-looking Android application, HTML5 applications may tend to look better than their Android counterparts. After all, there are many more people skilled in creating slick Web apps than are skilled in creating slick Android apps.

However, some users may complain about the look-and-feel disparity, just because it is different.

Distribution

HTML5 applications can be trivially added to a user's device — browse, bookmark, and add a shortcut to the home screen.

However, HTML5 applications will not show up in the Play Store, so users trained to look at the Market for available applications will not find HTML5 applications, even ones that may be better than their native counterparts.

It is conceivable that, someday, the Play Store will support HTML5 applications. It is also conceivable that, someday, Android users will tend to find their apps by means other than searching the Android Market, and will be able to get their HTML5 apps that way. However, until one of those becomes true, HTML5 applications may be less “discoverable” than their native equivalents.

HTML5: The Baseline

HTML5 is likely to become rather popular for conventional application development. It gives Web developers a route to the desktop. It may be the only option for Google’s Chrome OS. And, with ever-improving support on popular mobile devices — Android among them — developers will certainly be enticed by another round of “write once, run anywhere” promises.

It is fairly likely that, over time, HTML5 will be the #2 option for Android application development, after the conventional Java application written to the Android SDK. That will make HTML5 the baseline for comparing alternative Android development options — not only will those options be compared to using the SDK, they will be compared to using HTML5.

PhoneGap is perhaps the original alternative application framework for Android, arriving on the scene in early 2009. PhoneGap is open source, backed by Adobe, who in 2011 acquired Nitobi, the firm founded by PhoneGap's creators.

Prerequisites

Understanding this chapter requires that you have read the [chapter on WebView](#) and the [chapter on HTML5](#).

What Is PhoneGap?

As the [PhoneGap About page](#) puts it:

Mobile development is a mess. Building applications for each device — iOS, Android, Windows Phone and more — requires different frameworks and languages. One day, the big players in mobile may decide to work together and unify third-party app development processes. Until then, PhoneGap will use standards-based web technologies to bridge web applications and mobile devices. Plus, because PhoneGap apps are standards compliant, they're future-proofed to work with browsers as they evolve.

PhoneGap, today, focuses on bridging the gap between Web technologies and native mobile development, with access to more features than [HTML5 applications](#) have.

What Do You Write In?

A PhoneGap application is made up of HTML, CSS, and JavaScript, no different than a mobile Web site or HTML5 application, except that the Web assets are packaged with the application, rather than downloaded on the fly.

A pre-installed PhoneGap application, therefore, can contain comparatively large assets, such as complex JavaScript libraries, that might be too slow to download over slower EDGE connections. However, PhoneGap will still be limited by the speed of mobile devices and how quickly WebKit can load and process those assets.

Also, development for WebKit-for-mobile has its differences over development for WebKit-for-desktops, particularly with respect to touch versus mouse events. You may want to develop using mobile layers of JavaScript frameworks (e.g., [jQT](#) versus plain [jQuery](#)) where practical.

What Features Do You Get?

As with an HTML5 application, you get the basic capabilities of a Web browser, including AJAX support. Beyond that, PhoneGap adds a number of JavaScript APIs to allow you to get at the underlying features of the Android platform. At the time of this writing, that includes:

1. Accelerometer access, for detecting movement of the device
2. Audio recording
3. Camera access, for taking still pictures
4. Database access, both to databases of your creation (SQLite) or others built into Android (e.g., contacts)
5. File system access, such as to the SD card or other external storage
6. Geolocation, for determining where the device is
7. Vibration, for shaking the phone (e.g., force-feedback)

Since some of these are part of the HTML5 specification (e.g., geolocation), you have your choice of APIs. Also, this list changes over time, so you may have access to more than what is described here.

What Do Apps Look Like?

They will look like Web pages, more so than native Android apps. You can use CSS and images to mimic the Android look and feel to some extent, but only for those

sorts of widgets that are readily able to be created in both Android and HTML. For example, the Android Spinner widget — which resembles a drop-down list — may be difficult to mimic in HTML.

Here is a screenshot of a PhoneGap example application:

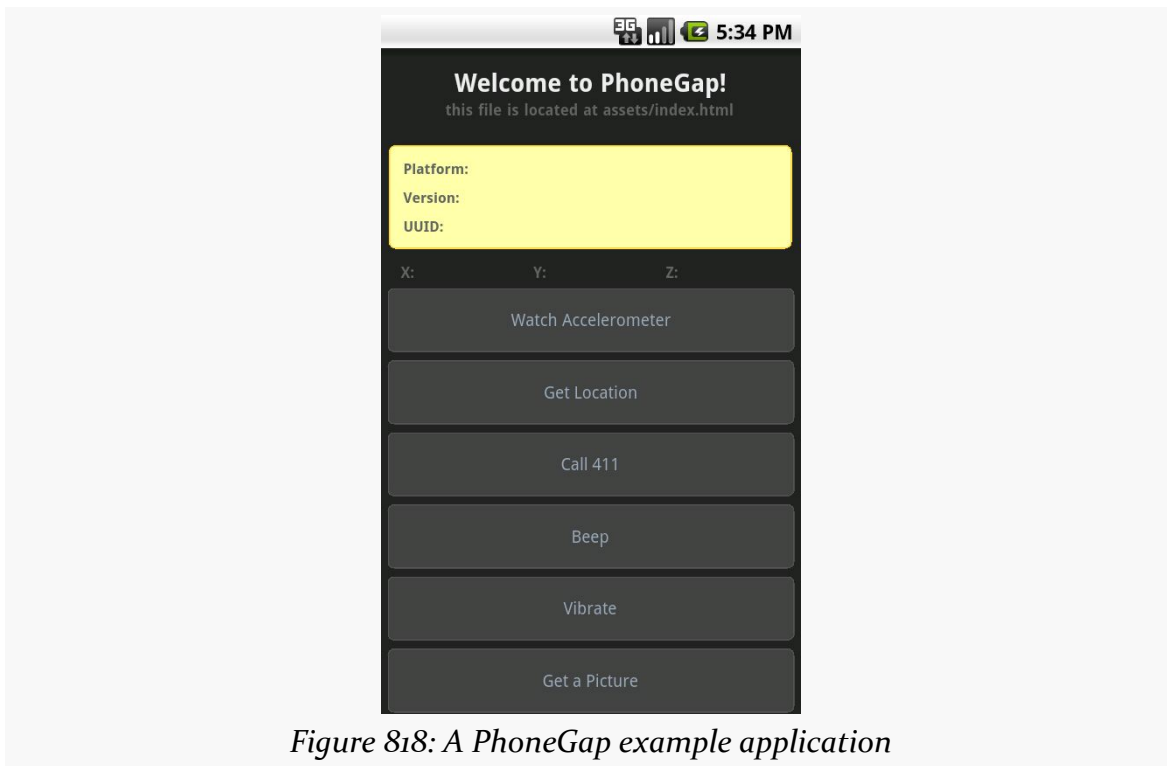

Figure 818: A PhoneGap example application

How Does Distribution Work?

Distributing a PhoneGap application is pretty much identical to distributing any other standard Android application. After testing, you will create a standard APK file with the Android build tools, from an Android project generated for you by PhoneGap. This project will contain the Java, XML, and other necessary bits to wrap around your HTML, CSS, and JavaScript to make up your application. Then, you digitally sign the application and upload it to the Play Store or any other distribution mechanism you wish to use.

What About Other Platforms?

PhoneGap is not just for Android. You can create PhoneGap applications for iOS, Blackberry, some flavors of Symbian, and more. In theory, at least, you can create

one application using HTML, CSS, JavaScript, and the PhoneGap JavaScript APIs, and have it run across many devices.

There are a couple of limitations that will hamper your progress to that goal:

- The Web browsing component used by PhoneGap across all those platforms is not identical. Even multiple platforms using WebKit will have different WebKit releases, based upon what was available when WebKit was integrated into a given device's firmware. Hence, you will want to test and ensure your CSS, in particular, works as you would expect on as many devices as possible.
- Not all PhoneGap JavaScript APIs are available on all devices as yet, due to a variety of factors (e.g., not exposed in the platform's native APIs, lack of engineering time to hoist the capability into the PhoneGap APIs). There is a [table on the PhoneGap site](#) that will keep you apprised of what works and what does not across the devices. You will want to restrict your feature use to match your desired platforms, or restrict your platforms to match your desired features.

How Is It Licensed?

PhoneGap is available under the Apache Software License 2.0. In 2011, Nitobi contributed PhoneGap to the Apache Software Foundation (ASF) for independent management, just prior to being acquired by Adobe. This has now turned into [Apache Cordova](#).

Using PhoneGap

Now, let's look at more of the mechanics for using PhoneGap.

PhoneGap's installation and usage, as of the time of this writing, normally requires an expert in Java-based Android development. You need to install a whole bunch of tools, edit configuration files by hand, and so forth. If you want to do all of that, documentation is available on the PhoneGap site.

If you are reading this chapter, there's a decent chance that you would rather skip all of that. Hence, for many, the best answer is the [PhoneGap/Build](#) service.

Installation

The PhoneGap Web site will allow you to download the latest PhoneGap tools as a ZIP archive. You can unpack those wherever it makes sense for your development machine and platform.

For Android development, that is all of the PhoneGap-specific installation you will need. However, you will need the Android SDK and related tools (e.g., Eclipse, if you wish to use Eclipse) for setting up the project.

Creating and Installing Your Project

A PhoneGap Android project is, at its core, a regular Android project, which you can create following the instructions outlined [earlier in this book](#). To convert the standard generated “Hello, World” application into a PhoneGap project, you need to do the following:

- From the `Android/` directory of wherever you unZIPped the PhoneGap ZIP file, copy the PhoneGap JAR file to the `libs/` directory of your project. If you are using Eclipse, you will also need to add it to your build path.
- Create an `assets/www/` directory in your project. Then, copy over the PhoneGap JS file from the `Android/` directory of wherever you unZIPped the PhoneGap ZIP file.
- Adjust the standard “Hello, World” activity to inherit from `DroidGap` instead of `Activity`. This will require you to import `com.phonegap.DroidGap`.
- In your activity’s `onCreate()` method, replace `setContentView()` with `super.loadUrl("file:///android_asset/www/index.html");`
- In your manifest, add all of the permissions that PhoneGap requests, listed [later in this chapter](#).
- Also in your manifest, add a suitable `<supports-screens>` element based upon what screen sizes you are willing to test and support.
- Also in your manifest, add `android:configChanges="orientation|keyboardHidden"` to your `<activity>` element, as `DroidGap` handles orientation-related configuration changes

At this point, you can create an `assets/www/index.html` file in your project and start creating your PhoneGap application using HTML, CSS, and JavaScript. You will need to have a reference to the PhoneGap JavaScript file (e.g., `<script type="text/javascript" charset="utf-8"`

`src="phonegap.0.9.4.js" />).` When you want to test the application, you can build and install it like any other Android application (e.g., `ant clean debug install` if you are using the command line build process).

For somebody experienced in Android SDK development, setting this up is not a big challenge.

PhoneGap/Build

PhoneGap/Build is a Tools-as-a-Service (TaaS) hosted approach to creating PhoneGap projects. This way, all of the Android build process is handled for you by PhoneGap-supplied servers. You just focus on creating your HTML, CSS, and JavaScript as you see fit.

When you log into PhoneGap/Build, you are first prompted to create your initial project, by supplying a name and the Web assets to go into the app:

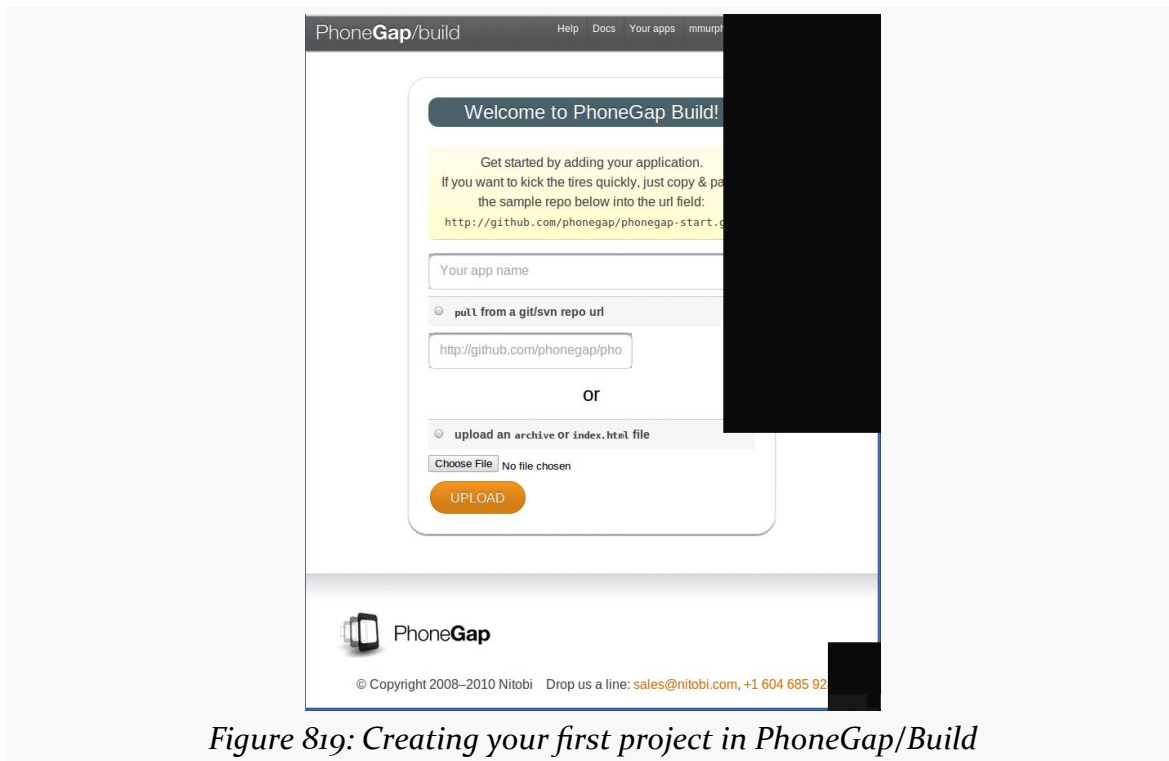

Figure 819: Creating your first project in PhoneGap/Build

You will be able to add new projects later on via a New App button, which gives you the same set of options.

PHONEGAP

Your choices for the assets are to upload a ZIP file containing all of them, or to specify the URL to a public GitHub repository that PhoneGap/Build can pull from. The latter tends to be more convenient, if you are used to using Git for version control, and if your project is open source (and therefore has a public repository).

Once you click the Upload button, the PhoneGap/Build server will immediately start building your application for Android, plus Blackberry, Symbian, and WebOS:

Figure 820: Building your first project in PhoneGap/Build

Each of the targets has its own file extension (e.g., apk for Android). Clicking that link will let you download that file. Or, click on the name of the project, and you get QR codes to enable downloads straight to your test device:

Figure 821: Your project's QR codes in PhoneGap/Build

This page also gives you a link to update the app from its GitHub repo (if you chose that option). Or, click Edit to specify more options, such as the version of your application or its launcher icon:

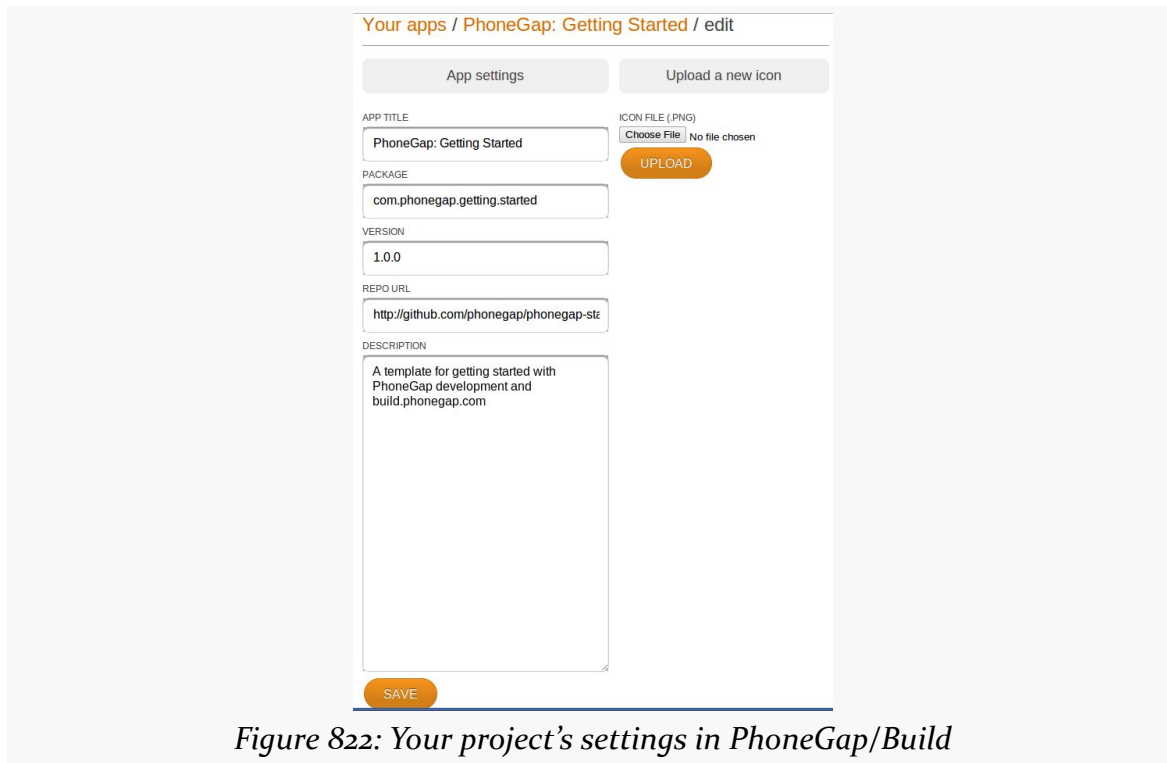

Figure 822: Your project's settings in PhoneGap/Build

All in all, if you do not otherwise need the Android SDK and related tools on your development machine, PhoneGap/Build certainly simplifies the PhoneGap building process.

PhoneGap/Build is free for open source (public) projects, but there are fees associated with private use beyond a single app.

PhoneGap and the Checklist Sample

The beauty of PhoneGap is that it wraps around HTML, CSS, and JavaScript. In other words, you do not have to do much of anything PhoneGap-specific to be able to take advantage of PhoneGap delivering to you an APK suitable for installation on an Android device. That being said, PhoneGap does expose more stuff to you than you can get from the standards, if you need them and are willing to use proprietary PhoneGap APIs for them.

Sticking to the Standards

Given an existing HTML5 application, all you need to do to make it be an installable APK is wrap it in PhoneGap.

For example, to convert the HTML5 version of Checklist into an APK file, you need to:

- Follow the steps to create an empty PhoneGap project outlined [earlier in this chapter](#)
- Copy the HTML, CSS, JavaScript, and images from the HTML5 project into the `assets/www/` directory of the PhoneGap project (note that you do not need things unique to HTML5, such as the cache manifest)
- Make sure that your HTML entry point filename matches the path you used with the `loadUrl()` call in your activity (e.g., `index.html`)
- Add a reference to the PhoneGap JavaScript file from your HTML
- Build and install the project

Here is the DroidGap activity for our app, from the PhoneGap/Checklist project:

```
package com.commonware.pg.checklist;

import android.app.Activity;
import android.os.Bundle;
import com.phonegap.DroidGap;

public class Checklist extends DroidGap {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        super.loadUrl("file:///android_asset/www/index.html");
    }
}
```

Here is the manifest, with all of the PhoneGap-requested settings added:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
    android:versionName="1.0"
    package="com.commonware.pg.checklist"
    xmlns:android="http://schemas.android.com/apk/res/android">

    <application android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity android:configChanges="orientation|keyboardHidden"
            android:label="@string/app_name"
            android:name="Checklist">
```

```
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
</activity>
</application>
<supports-screens android:anyDensity="true"
  android:largeScreens="true"
  android:normalScreens="true"
  android:resizeable="true"
  android:smallScreens="true" />
<uses-permission android:name="android.permission.CAMERA" />
<uses-permission android:name="android.permission.VIBRATE" />
<uses-permission android:name="android.permission.ACCESS_COARSE_LOCATION" />
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION" />
<uses-permission
android:name="android.permission.ACCESS_LOCATION_EXTRA_COMMANDS" />
<uses-permission android:name="android.permission.READ_PHONE_STATE" />
<uses-permission android:name="android.permission.INTERNET" />
<uses-permission android:name="android.permission.RECEIVE_SMS" />
<uses-permission android:name="android.permission.RECORD_AUDIO" />
<uses-permission android:name="android.permission.MODIFY_AUDIO_SETTINGS" />
<uses-permission android:name="android.permission.READ_CONTACTS" />
<uses-permission android:name="android.permission.WRITE_CONTACTS" />
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE" />
</manifest>
```

And here is the HTML — almost identical to the HTML5 original, removing some HTML5 offline stuff (e.g., iOS icons) and adding in the reference to PhoneGap's JavaScript file:

```
<!DOCTYPE html>
<html lang="en" manifest="checklist.manifest">
<head>
  <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
  <title>Checklist</title>
  <meta name="viewport"
    content="width=device-width; initial-scale=1.0; maximum-scale=1.0;
user-scalable=0;" />
  <link rel="stylesheet" href="styles.css" />
  <script type="text/javascript" charset="utf-8"
src="phonegap.0.9.4.js"></script>
</head>
<body>
  <section>
    <header>
      <button type="button" id="sendmail">Mail</button>
      <h1>Checklist</h1>
    </header>
    <article>
      <form id="inputarea" onsubmit="addNewItem()">
        <input type="text" name="name" id="name" maxlength="75"
```

```
        autocorrect placeholder="Tap to enter a new item&hellip;"
    />
        <button type="button" id="add">Add</button>
    </form>
    <ul id="maillist">
        <li class="empty"><a href="" id="maillink">Mail remaining
items</a></li>
    </ul>
    <p id="totals"><span id="tally1">Total: <span
id="total">0</span></span>
    <span id="tally2">Remaining: <span
id="remaining">0</span></span></p>
    <ul id="checklist">
        <li class="empty">Loading&hellip;</li>
    </ul>
</article>
<fieldset>
    <button type="button" id="deletechecked">Delete Checked</button>
    <button type="button" id="deleteall">Delete All</button>
</fieldset>
</section>
<script src="main.js"></script>
</body>
</html>
```

For many applications, this is all you will need — you are simply looking at PhoneGap to give you something you can distribute on the Play Store, on the iOS App Store, and so on.

Adding PhoneGap APIs

If you want to take advantage of more device capabilities, you can augment your HTML5 application to use PhoneGap-specific APIs. These run the gamut from telling you the device's model to letting you get compass readings. Hence, their complexity will vary. For the purposes of this chapter, we will look at some of the simpler ones.

Set up Device-Ready Event Handler

For various reasons, PhoneGap will not be ready to respond to all of its APIs right away when your page is loaded. Instead, there is a `deviceready` event that you will need to watch for in order to know when it is safe to use PhoneGap-specific JavaScript globals. The typical recipe is:

- Add an `onload` attribute to your `<body>` tag, referencing a global JavaScript function (e.g., `onLoad()`)

- In `onLoad()`, use `addEventListener()` to register another global JavaScript function (e.g., `onDeviceReady()`) for the `deviceready` event
- In `onDeviceReady()`, start using the PhoneGap APIs

Use What PhoneGap Gives You

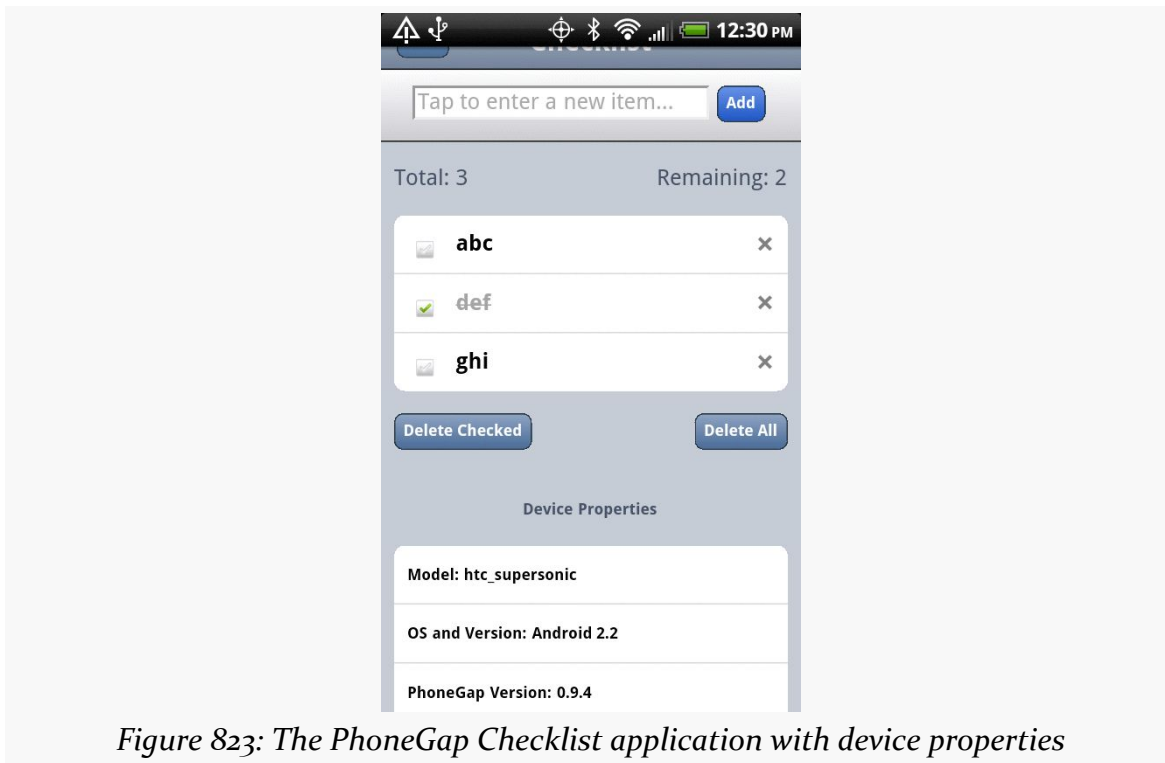

PhoneGap makes a number of methods available to you through a series of virtual JavaScript objects. Here, “virtual” means that you cannot check to see if the objects exist, but you can call methods and read properties on them. So, for example, there is a device object that has a handful of useful properties, such as `phonegap` to return the PhoneGap version and `version` to return the OS version. These virtual objects are ready for use in or after the `deviceready` event.

For example, here is a JavaScript file (`props.js` from the PhoneGap/ChecklistEx project) that implements an `onLoad()` function (to register for `deviceready`) and an `onDeviceReady()` function (to use the device object’s properties):

```
// PhoneGap's APIs are not immediately ready, so set up an  
// event handler to find out when they are ready  
  
function onLoad() {  
    document.addEventListener("deviceready", onDeviceReady, false);  
}  
  
// Now PhoneGap's APIs are ready  
  
function onDeviceReady() {  
    var element=document.getElementById('props');  
  
    element.innerHTML='<li>Model: '+device.name+'</li>' +  
                    '<li>OS and Version: '+device.platform +  
'+device.version+'</li>' +  
                    '<li>PhoneGap Version: '+device.phonegap+'</li>';  
}
```

The `onDeviceReady()` function needs a list element with an id of `props`.

The resulting app looks like:

Obviously, reading a handful of properties is far simpler than, say, taking a picture with the device's camera. However, the difference in complexity is mostly in what PhoneGap's virtual JavaScript objects give you and how you can use them, more so than anything peculiar to Android.

Issues You May Encounter

PhoneGap is a fine choice for creating cross-platform applications. However, it is not without its issues. Some of these issues may be resolved in time; some may be endemic to the nature of PhoneGap.

Security

Android applications use a permission system to request access to certain system features, such as making Internet requests or reading the user's contacts. Applications must request these permissions at install time, so the user can elect to abandon the installation if the requested permissions seem suspect.

A general rule of thumb is that you should request as few permissions as possible, and make sure that you can justify why you are requesting the remaining permissions.

PhoneGap, for a new project, requests quite a few permissions:

1. CAMERA
2. VIBRATE
3. ACCESS_COARSE_LOCATION
4. ACCESS_FINE_LOCATION
5. ACCESS_LOCATION_EXTRA_COMMANDS
6. READ_PHONE_STATE
7. INTERNET
8. RECEIVE_SMS
9. RECORD_AUDIO
10. MODIFY_AUDIO_SETTINGS
11. READ_CONTACTS
12. WRITE_CONTACTS
13. WRITE_EXTERNAL_STORAGE
14. ACCESS_NETWORK_STATE

Leaving this roster intact will give you an application that can use every API PhoneGap makes available to your JavaScript... and an application that will scare away many users. After all, it is unlikely that your application will be able to use, let alone justify, all of these permissions.

It is certainly possible for you to trim down this list, by modifying the `AndroidManifest.xml` file in the root of your PhoneGap project. However, you will then need to thoroughly test your application to make sure you did not get rid of a permission that you actually need. Also, it may be unclear to you which permissions you can safely remove.

Eventually, the PhoneGap project may have tools to help guide you in the choice of permissions, perhaps by statically analyzing your JavaScript code to see which PhoneGap APIs you are using. In the meantime, though, getting the proper set of permissions will involve a lot of trial and error.

Screen Sizes and Densities

Normal Web applications primarily focus on screen resolution and window sizes as their primary variables. However, mobile Web applications will not have to worry

about window sizes, as browsers and apps typically run full-screen. Mobile Web applications will need to deal with physical size and density, though — issues that are “off the radar” for traditional Web development.

Netbooks can have screens that are 10” or smaller. Desktops can have screens that are 24” or larger. On the surface, therefore, physical screen size would seem to be something Web developers would need to address. However, generally, screen resolution (in pixels) tracks well with physical size in the netbook/notebook/desktop realm. That is because screen density is fairly consistent across their LCDs, and that density is fairly low.

Smartphones, on the other hand, have several different densities, causing the connection between resolution and size to be broken. Some low-end phones, particularly with small (e.g., 3”) LCDs, have densities on par with nice monitors. Mid-range phones have twice the density (240dpi versus 120dpi). Apple’s iPhone 4 has even higher density, and there are some Android devices with similar densities. Hence, an 800x480 resolution could be on a screen ranging anywhere from 4” to 7”, for example. Tablets add even more possible sizes to the mix.

This is compounded by the problems caused by touchscreens. A mouse can get pixel-level precision in its clicks. Fingers are much less precise. Hence, you tend to need to make your buttons and such that much bigger on a touchscreen, so it can be “finger-friendly”.

This causes some problems with scaling of assets, particularly images. What might be “finger-friendly” on a low-density 3” device might be entirely too small for a high-density 4” device.

Native Android applications have built-in logic for dealing with this issue, in the form of multiple sets of “resources” (e.g., images) that can be swapped in based upon device characteristics. Eventually, PhoneGap and similar tools will need to provide relevant advice for their users for how to create applications that can similarly adapt to circumstances.

Look and Feel

A Web app never quite looks like a native one. This is not necessarily a bad thing. However, some users may find it disconcerting, particularly since they will not understand why their newly-installed app (made with PhoneGap, for example) would necessarily look substantially different than any other similar app they may already have.

As HTML5 applications become more prominent on Android, this issue should decline in importance. However, it is something to keep in mind for the next year or two.

For More Information

At the moment, the best information on PhoneGap can be found on [the PhoneGap site](#), including their API documentation.

Other Alternative Environments

The alternative application environments described in the preceding chapters are but the tip of the iceberg. Here, we will take a look at a few other alternative application environments, from the growing flood of such technologies.

Note that this area changes rapidly, and so the material in this chapter may be somewhat out of date relative to the progress each of these technologies has made.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the [introduction to this trail](#) might not be a bad idea.

Rhodes

Spiritually, Rhodes is similar to [PhoneGap](#), in that you develop an Android application whose user interface is defined via HTML, CSS, and JavaScript. The difference is that Rhodes bakes in a full Ruby environment, with a Rails-esque framework. Your Ruby code generates HTML and such to be “served” to an activity via a WebView widget, much like a server-side Ruby Web app would generate HTML to be served to a standalone Web browser.

Similar to PhoneGap, you can either build the project on your development machine or use their hosted build process. The latter is recommended, partly because the requirements for local builds are higher than those for PhoneGap — notably, Rhodes requires the Native Development Kit (NDK) for building and linking the Ruby interpreter to your application.

Rhodes winds up creating larger applications than does PhoneGap, due to the overhead of the Ruby interpreter (~1.5MB). However, if you are used to server-side Web development, Rhodes may be easier for you to pick up than would PhoneGap.

Flash, Flex, and AIR

Adobe has been hard at work extending their Flash, Flex, and AIR technologies to the mobile space. You can use Flex (the “Hero” edition) and Flash Builder (the “Burrito” edition... raising the question of whether the “hero” is hungry) to create Android APK files that can be distributed on the Play Store and deployed to Android devices. Those devices will need to have the AIR runtime installed — this is free, but a large download, and it only works on Android 2.2+ devices. The same projects can be repackaged for iOS and Blackberry OS 10 devices, and possibly future devices down the road.

AIR does not have quite as tight of integration to the platform as does PhoneGap (e.g., no access to the device’s contacts), though one imagines that this is an area on which Adobe will devote more resources over time. And, Adobe is a large firm, with a large ecosystem behind it and many existing Flash, Flex, and AIR developer resources to tap into.

Note, though, that Adobe is officially discontinuing the Flash plug-in for Android after the Android 4.0 (Ice Cream Sandwich) release, which casts some doubt as to their long-term plans in the Flash/AIR space on mobile.

JRuby and Ruboto

One of the most popular languages designed to run on the JVM — besides Java itself — is JRuby. JRuby was quickly ported to run on Android, but with some optimizations disabled, since JRuby is really running on the Dalvik virtual machine that underlies the Android environment, not a classic Java VM.

However, JRuby alone cannot create Android applications. As a scripting language, there is no way for it to define an activity or other component — those need to be registered in the application’s manifest as regular Java class files.

This is where Ruboto comes in.

Ruboto is a framework for a generic JRuby/Android application. It provides skeletal activities via a code generator and allows JRuby scripts to define handlers for all of

the lifecycle methods (e.g., `onCreate()`), plus define user interfaces using JRuby code, etc. The result can be packaged up as an APK file using supplied Rake script. The results can be uploaded to the Play Store or distributed however else you desire.

App Inventor

App Inventor is an Android application development tool originally made available by Google, but outside of the normal Android developer site. App Inventor was originally developed for use in education, but they have been inviting others into their closed beta.

App Inventor is theoretically a Web-based development tool. Here, “theoretically” means that, in practice, users have to do a fair amount of work outside of the browser to get everything set up:

1. Have Java installed and functioning in the browser, capable of running Java Web Start (.jnlp) applications
2. Download and install a large (~55MB) client-side set of tools
3. Have a phone and have it configured to work with App Inventor and the Android SDK

Once set up, App Inventor gives you a drag-and-drop GUI editor:

OTHER ALTERNATIVE ENVIRONMENTS

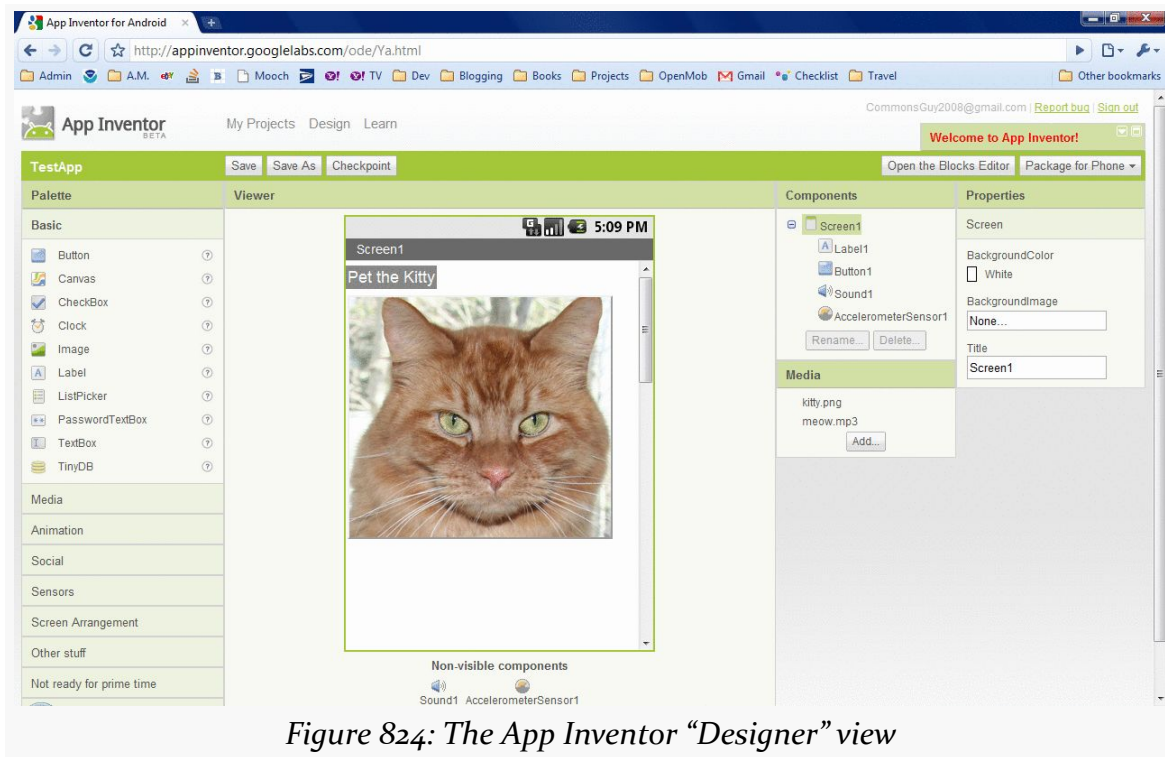

Figure 824: The App Inventor “Designer” view

... and a “blocks” editor, where you attach behaviors to events (e.g., button clicks) by snapping together various “blocks” representing events, methods, and properties:

OTHER ALTERNATIVE ENVIRONMENTS

Figure 825: The App Inventor “Blocks” view

While working in the GUI editor, you see what you are building live on an attached phone and can be tested in real time. Later, when you are ready, you can package the application into a standard APK file.

However, App Inventor is not really set up for production application use today:

1. You cannot distribute App Inventor apps on the Play Store
2. It has more components aimed at “sizzle” (e.g., Twitter integration) and fewer delivering capabilities that a typical modern app might need (e.g., relational databases, lists)
3. Only one developer at a time can work on a project

In 2011, Google discontinued direct support for App Inventor, electing to transfer the project to MIT’s Media Lab for ongoing development.

Titanium Mobile

Titanium Mobile’s claim to fame is using JavaScript to completely define the user interface, eschewing HTML entirely. Rather, their JavaScript library — in addition to

providing access to databases and platform capabilities — also lets you declare user interface widgets. Its layout capabilities, for positioning said widgets, leaves a bit to be desired.

As of the time of this writing, Appcelerator — the creators of Titanium Mobile — does not offer a cloud-based set of tools. Their Titanium tool has a very slick-looking UI, but it still requires the Java SDK and Android SDK in order to be able to build Android applications, making the setup a bit daunting for some.

As of the time of this writing, Titanium Mobile supports development for Android and iOS, with Blackberry support in a private beta.

Other JVM Compiled Languages

If your issue is less with regular Android development, but you just do not like Java, any language that can generate compatible JVM bytecode should work with Android. You would have to modify the build chain for that other language to do the rest of the Android build process (e.g., generate R.java from the resources, create the APK file in the end).

Scala and Clojure are two such languages, for which their respective communities have put together instructions for using their languages for Android development.

Trail: Miscellaneous Topics

Anti-Patterns

Much of this book has been focused on what you should do. In contrast, this chapter is focused on what you should *not* do.

All platforms have their anti-patterns: things that are technically possible but are not in the best interests of the users of that platform. Android is no exception. Some anti-patterns are simply annoying to users, while other anti-patterns can significantly infringe upon a user's use of their Android device, or even the user's freedom.

Much as the Hippocratic Oath directs doctors to “first, do no harm”, Android application developers owe it to the users of their apps to avoid these anti-patterns to the greatest extent possible.

Prerequisites

This chapter assumes that you have read much of the book, particularly the core chapters.

Leak Threads... Or Things Attached to Threads

Leaking a thread means that you start a thread and never cause it to stop. For example, you might start a thread that runs in an infinite loop, doing some work and then sleeping for a while. The problem with infinite loops is that “infinite” is an awfully long time.

All threads should clean up, in a timely fashion, when the component (e.g., activity, service) that started the thread is destroyed — or, in the case of an activity, perhaps just moved into the background.

How you ensure that the thread gets cleaned up is up to you. For threads doing transactional work, such as literally running a database transaction, it may be fine to just let them run to completion and shut down of their own accord. For “infinite” loops, there should be some way to tell the thread that it is no longer needed, such as via an `AtomicBoolean` flag, or using something more structured than a plain timing loop, such as a `ScheduledExecutorService`.

Also, bear in mind that you are responsible for threads that are created, on your behalf, by other things that you do. The most common leak scenario here comes with listeners associated with system services, like `LocationManager` and `SensorManager`. If you register a `LocationListener` via `requestLocationUpdates()` and fail to unregister that listener, you will not only be leaking the listener, but the component associated with that listener, and every system resource tied to that listener, such as any background threads.

The Costs

Threads are intrinsically static in scope. Hence, any object they can reach, directly or indirectly, cannot be garbage-collected while the thread is still running. Hence, if an activity forks a thread, it might do so using an anonymous inner class:

```
new Thread() {  
    public void run() {  
        // do something  
    }  
}.start();
```

Instances of an inner class — anonymous or otherwise — have an implicit reference back to the object that created them. Hence, the `Thread` would hold onto the `Activity` that created the thread, which in turn would hold onto all of its widgets and so forth. None of that can be garbage-collected until after the thread terminates, even if the activity is destroyed.

The Counter-Arguments

I want the thread to keep running even after the activity is destroyed

In this case, the thread should be created and managed by a service, not simply leaked. Not only does this give you an opportunity to clean up the thread when needed, but it also alerts Android that you are still trying to do some work, so Android will not necessarily terminate your process very quickly.

However, be careful about assuming that you can have a thread — even one managed by a service — run forever, as you will see in the next couple of sections.

I do not know when the thread is no longer needed

Then you have a serious design problem.

A common variation on this theme is:

The thread is needed so long as I have an activity in the foreground

This is a bit tricky, as Android does not really expose the concept of *applications* being in the foreground, just activities.

The safest course of action is to have the thread be managed by a service, then keep track of whether or not you have an activity in the foreground. For example, in `onPause()` of each activity, use `postDelayed()` to return control to you after a short delay, and in `onResume()`, update a timestamp of your last return to the foreground (held in a static data member). When the `Runnable` for `postDelayed()` executes, check that timestamp — if it is too old, you know that none of your activities are in the foreground, and you can stop the service, having it stop your thread.

Use Large Heap Unnecessarily

Encountering an `OutOfMemoryError` certainly sucks. These are caused either by a memory leak or by trying to use more memory than is practical given the device. For example, loading up lots of bitmaps can easily chew up your available heap space.

To some, therefore, `android:largeHeap` seems to be the perfect solution.

Added in API Level 11, `android:largeHeap` tells Android to give you a much larger heap size than is normally given to a process. So, instead of having 32MB or 48MB or so of heap, you might have 256MB of heap.

The right solution, in most cases, is to fix the underlying memory problem, not to mask it by requesting an over-sized heap.

The Costs

To you, having hundreds of megabytes of extra heap may be a blessing. To the user, it may be a curse. That memory has to come from somewhere, and the “somewhere” is from other processes. Your app will force other apps’ processes to be terminated far more quickly than normal, which may slow the user down when she tries to switch between your app and others. Your app may even materially harm the functionality of other apps, who have their processes terminated before they can finish their work, just to satisfy your memory craving.

Bear in mind that Android does not employ swap space (the Linux equivalent of a Windows pagefile). Hence, whereas Windows can allocate lots of memory and slows down as it goes, Android is far more limited, in accordance with its mobile roots.

Furthermore, in many cases, adding more heap space does not eliminate the problem, any more than spraying air freshener gets rid of the dead cat in your living room that is causing the odor. With a memory leak, for example, all the larger heap does is increase the time before you eventually run out of memory.

The Counter-Arguments

I really need to be able to manipulate large chunks of memory

There are certainly apps for which `android:largeHeap` is justified, such as complex data editors, such as image editors, video editors, etc.

Hence, in practice, the real anti-pattern is not using `android:largeHeap`, but rather in doing so for apps where the user would not feel that the resulting effects are justified. For example, neither a Twitter client, nor a banking app, should need a large heap, even if the developer is running into memory management issues.

Android makes it too hard to manage memory, so I need a large heap

There is no question that developing mobile applications is challenging, particularly when it comes to memory management. That is not unique to Android — embedded systems developers are used to writing apps where the heap size is better measured in KB instead of MB, for example.

Outside of bitmaps and massive data sets, though, it is a bit difficult to actually run out of memory. While a `TextView` may take up 1KB of heap space, it takes a *lot* of `TextView` widgets to chew through a 48MB heap.

The reason why bitmaps tend to trip up developers is that Android makes using them *too easy*. For example, it is simple to set a bitmap as a background of some container like a `LinearLayout`, where developers then blindly ignore the fact that if the bitmap is not *precisely* the size of the container, Android will need to scale the image, consuming more heap space.

Misuse the MENU Button

The MENU button on Android devices is designed to display either the options menu (on Android 1.x/2.x devices that are not using an action bar backport like [ActionBarSherlock](#)) or the action bar overflow menu.

The MENU button is *not* designed for any other purpose. Some developers have taken to using it for arbitrary aims, and that is a mistake.

The Costs

The MENU button does not exist on many Android devices. In particular, devices designed for Android 3.0 and higher do not *need* a MENU button. Some will have them, but most will not. Hence, anything that requires the MENU button will simply be unavailable on those devices.

And, as of Android 4.4, Google is putting increasing pressure on device manufacturers to dump the MENU button, making it less likely to appear in the future.

The Counter-Arguments

Well, if I keep `targetSdkVersion` below 11, I can have a soft MENU button

This is true, insofar as a menu affordance will be added to the system bar or navigation bar on devices that lack a dedicated MENU button.

Whether the *user* is expecting to use this button is another thing entirely.

As more and more users run Android 3.0+ devices, they will use more and more apps that have `android:targetSdkVersion` set to 11 or higher. The remaining handful of apps that do not will be “weird”. In particular, they may not notice the menu affordance, as they are not looking for one, or they may not know what it does, as they are not used to needing it.

Moreover, eventually, other things will drive you to want an `android:targetSdkVersion` higher than 10, as the menu affordance is not the only feature driven by this value. The sooner you can remove your dependence on a menu affordance, the sooner you can upgrade your `android:targetSdkVersion` to solve other problems that you are encountering.

I think the action bar is ugly, a waste of space, or otherwise bad

That's nice. It does not mean that you need a menu affordance and a tie to a MENU button.

For example, well-written games will have a menu integrated into the game UI itself. This was often done even before Android 3.0, since the options menu UI would not look much like the game's UI, and the developer wanted a consistent look-and-feel.

So long as the user recognizes how to reach the menu (e.g., a three-dots or three-bars icon), the menu does not have to be driven by Android, but instead could be handled by your app directly. You can see this in the Google Navigation app, which avoids an action bar but still displays its own menu from its own on-screen menu affordance.

Interfere with Navigation

Some developers try to take over the device. They attempt to block the use of anything not related to their app: the HOME key, the recent tasks list, the notification drawer, etc.

Android treats such behavior as malware. Android is designed to keep control of the device in the hands of the user and tries very hard to prevent apps from stealing that control.

The Costs

While there are certain cases where blocking navigation outside the app may seem justified (see the counter-arguments, below), there is simply too much opportunity for malfeasance. Users tend to want to use their devices on their terms, not necessarily the terms of some random developer. Malware authors, in particular, love to learn about script-kiddie hacks that allow them to control a device, and by extension, control the users.

The Counter-Arguments

I am writing a lock screen

No, you are not. You are writing something that you *think* is a lock screen. Really what you are writing is something that weakens device security... if the app in question is designed to be downloaded and run on arbitrary devices.

Android devices can be rebooted into “safe mode”. Much like the Windows boot option that bears the same name, “safe mode” only runs apps that are part of the system firmware, not any third-party apps.

So, let’s assume that the user installs your “lock screen”. Inevitably, part of the setup of a third-party “lock screen” is to disable any sort of security that is part of the native lock screen, so the user does not have to unlock things twice. Even though your lock screen may implement all sorts of security, all somebody else has to do is reboot the device in safe mode, and they now have complete access to the device, including the ability to uninstall your lock screen. By contrast, the native lock screen is in force even if the device reboots in safe mode.

I am writing a parental control app

Rebooting in safe mode is within the motor-control skills of your average three-year-old child. Hence, the primary limitation is whether or not the child knows *how* to reboot the device in safe mode, which they can learn from the Internet, friends, etc. And, if the device is really an adult’s device, where the “lock screen” allows access to a subset of child-friendly apps, the real risk is not from the child rebooting the device in safe mode, but from the crook who steals the device rebooting in safe mode.

I am writing a lock screen designed to run on whole-disk-encrypted devices

While whole disk encryption — available on Android 4.0+ — does solve the issue of rebooting in safe mode, bear in mind that users then cannot disable the required password security on the native lock screen, as that is tied into the whole disk encryption process.

I am writing a kiosk app

Here, the term “kiosk app” refers to an app that represents the functionality of a single-purpose device. For example, a restaurant might want to distribute menus to customers in the form of a tablet app; the menu app would be the “kiosk app”.

In this case, the owner of the device is the one trying to lock it down to be single-purpose. That is completely reasonable... except that it runs counter to the behavior of standard consumer builds of Android.

The right solution, in this case, is to create custom firmware for the single-purpose devices. This firmware can set up the kiosk app to be the home screen (thereby blunting the effectiveness of HOME, BACK, etc.), and modifications to the firmware can apply access controls to other aspects of the device (e.g., notifications). Unfortunately, there are few (if any) businesses set up to help create such single-purpose firmware for single-purpose devices.

Use `android:sharedUserId`

If you are creating more than one application, where those applications should be sharing data, you may be tempted to use `android:sharedUserId`. This attribute, applied to the root `<manifest>` element in your manifest, allows two or more apps to share a Linux user account. That will allow these apps full access to the other apps' files. The limitations are that you must use the same value for `sharedUserId` and that all such apps must be signed with the same signing key.

However, this is a fairly crude and somewhat risky approach to sharing information between apps. In most cases, you will be better served using any of the structured IPC options within Android, such as remote services and content providers.

The Costs

First, you must make the decision to use `android:sharedUserId` before you ever ship your app in production. Should you change the `sharedUserId` value — or switch from no value to a new value — when your change is installed, the new version of your app will have no rights to access the old version of your app's files. This is unlikely to turn out well.

Second, it will be up to you to maintain data integrity of these files in the face of simultaneous access from multiple apps. SQLite should handle this for you for your databases, as it is set up to use process-level locking — this is why SQLite can be used as the out-of-the-box database solution for Web frameworks like Rails.

However, any other sort of file, including `SharedPreferences`, will lack that coordination, unless you somehow arrange to do it yourself. And even the SQLite-level coordination has its limits, as one app has no way to know about another app's changes to the data, except by re-querying the database.

Third, using `android:sharedUserId` limits your flexibility. You cannot use it with third-party apps. You cannot readily sell one of your apps in your suite, as then it becomes a third-party app and can no longer be signed by the same signing key as are the rest of your apps. Basically, `sharedUserId` causes multiple separate APKs to behave, in some respects, as one larger APK.

The Counter-Arguments

I need to ensure only my apps can share the data, not others

Use a signature-level permission. This gives you the same level of security as does `android:sharedUserId` without most of the risks.

Writing IPC code is tedious

So is writing cross-process data integrity code.

Implement a “Quit” Button

Perhaps the most contentious question and answer on Stack Overflow's `android` tag is [“Quitting an application - is that frowned upon?”](#). This exchange is nearly three years old (as of the time of this writing), yet the answer receives both upvotes (and a few downvotes) with some regularity.

Other Android experts, such as Reto Meier, have weighed in on the issue and have [offered similar recommendations](#) – that is, do not have a “quit” or “exit” button in your app.

(here, “button” is shorthand for any command-style interface, and includes menu options, action bar items, and the like by extension)

The reason is simple: whatever your “quit” or “exit” button does *should be happening in other conditions as well*, and handling those other conditions should eliminate the need for the button.

If the app moves into the background *for any reason*, you need to treat the user and her device with respect. This means stopping background threads that are not needed, releasing system resources like the GPS radio (immediately or after a modest delay), and the like. The user should not need to “quit” your app to accomplish this, because your app will move to the background for other reasons, such as incoming phone calls, or the user pressing the HOME button.

The Costs

You might think “well, what’s the harm in having the ‘quit’ button that, say, just calls `finish()`?”

First, rarely is it that simple. Calling `finish()` will return the user to the previous activity, and so for any multi-activity app, there will be scenarios where `finish()` is not really “quit”. The only simple thing you can universally do is have “quit” bring up the home screen, in which case all you have done is waste screen real estate duplicating the HOME button functionality. Worse, the developer might say “oh, well, I will just terminate my process when they press ‘quit’”, and *that* anti-pattern [is coming up next in this chapter](#).

Second, the user will start to think that they *need* to press “quit”, or else bad things might happen. They will see an explicit “quit” option and start to wonder “well, gee, when am I supposed to press that, and what happens if I do not?” This, in turn, will lead to the user going out of their way to make sure to press your “quit” button, even if doing so does not actually change anything about the behavior of your app, courtesy of [the placebo effect](#).

The Counter-Arguments

I need to let the user log out of the app, so I need a “quit” button

No, you need a “logout” button that clears your cached authentication credentials (e.g., sets a static data member to `null`), then brings up the login activity using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your process. And, probably, you need to have some sort of inactivity-based “timeout” that also logs out the user (e.g., sets that static data member to `null`).

I am running stuff in the background, so I need a “quit” button

No, you need a “stop that background stuff” button, preferably with a shorter, more specific label. And, you need that to also be available from the Notification that you are using with your foreground service, where applicable.

Terminate Your Process

Closely related to the above anti-pattern is to forcibly stop your process, such as via `System.exit()`, `Runtime.exit()`, `Process#killProcess()`, and so forth. These are often used in concert with [an in-app “quit” button](#), or sometimes for other reasons (e.g., could not figure out how to handle an exception gracefully).

The Costs

Simply put, Google has warned, repeatedly, that there may be side effects from terminating your own process, rather than having Android do proper cleanup first.

- “You should really think about not exiting the application. This is not how Android apps usually work.” ([Romain Guy](#))
- “To be clear: using `System.exit()` is strongly recommended against, and can cause some poor interactions with the system. Please don’t design your app to need it.” ([Dianne Hackborn](#))
- “There is no reason or need to call `[exit()]`” ([Dianne Hackborn](#))
- “Nobody has said anything about `Process.kill()` not doing anything. You want to kill your *own* process and cause the user to experience your *own* application having weird behavior at times due to it? Have at it. I just want to be clear that this is not what we recommend doing... and you are likely to cause bad behavior in your app at least at times due to it... There is no API to quit an application, because there is no such concept on Android, and trying to implement such a thing is going to result in fighting against how Android works.” ([Dianne Hackborn](#))

The Counter-Arguments

I am using a C library that is buggy, so I need to terminate my process

Fix the bugs in the library. For example, C libraries that rely too heavily on global variables may need to be adjusted to use session handles that get passed around.

Well, it is not my C library, but one from a third party, so I need to terminate my process

Find a library that is Android-compatible, then. It is likely that you will encounter other problems with this library, if it is not designed to work on Android (e.g., not set up to work properly on ARM CPUs).

There is a bug in Android for which I have found no workaround short of terminating my process

This is one of the few legitimate reasons for terminating a process, but it is so rare that it is difficult to find a citation of a place where such a bug (and workaround) exists.

I need to do *something* from my top-level exception handler!

Set relevant static data members to null, then start up your launcher activity, using FLAG_ACTIVITY_SINGLE_TOP and FLAG_ACTIVITY_CLEAR_TOP to wipe out all other activities in your task. This should reset you to your original state, as if the user had launched the app.

Try to Hide from the User

Some developers view the user as the enemy. These developers try to insulate their app from the user, to make data inaccessible to the user, to make the app “unkillable” by the user, etc. In many cases, this is at the behest of some enterprise, wanting to exert control over the user’s use of the app or even the device.

Android is a consumer operating system. It is designed to put power in the hands of whoever is holding the device and can authenticate themselves to the device (e.g., via a password on the lock screen). Enterprises and malware authors have much the same interests: they wish to take control away from the user and give the control to somebody else. Android defends against malware; enterprises get caught in the crossfire.

Inevitably, the right solution here will be an enterprise remix of Android, designed to be loaded on enterprise-supplied devices, that put the control in the hands of the enterprise.

The Costs

Simply put, you are wasting your time, which could be better spent on other pursuits.

With respect to data, if your app can access that data, by definition, a sufficiently talented user can get at the data:

- If you put it on internal storage, the user can root the device
- If you further encrypt the data, the user can find the encryption algorithm and key in your app, then decrypt the data
- If you try obfuscation or other techniques to mask the encryption algorithm and key, the user will use cracking tools to find this information anyway, or will transfer your app to a ROM mod that contains a modified version of the Android framework that can collect this information when you go to decrypt the data
- And so on

With respect to the process, the user can force-stop anything installed app via the Settings app. And, even if you use script-kiddie tricks to try to prevent access to Settings, the user can nuke your app from orbit via the command line, using the full Android SDK or third-party tools.

The Counter-Arguments

I am creating an app for an enterprise, and we need to control the app

Then you further need to control the device, which leads to the “enterprise flavor of Android” solution mentioned earlier in this section.

I am creating a lock screen/parental control app/kiosk app

Please see the counter-arguments for “Interfering with Navigation” from [earlier in this chapter](#).

Use Multiple Processes

Some Android professionals recommend the use of `android:process` to have components run in separate processes from the main one for an application. For example, you might have all of your activities in the main process but isolate a service in a separate process. Or, you might have some memory-intensive activity (e.g., an image editor) run in a separate process.

As with most of these anti-patterns, while the `android:process` feature is valid, it is rarely necessary. To some extent, developers get caught up in process isolation from

its use on servers and forget that mobile devices typically have fewer resources — RAM and CPU — than do their server counterparts. Few of Google’s apps use `android:process`; even complex apps like Gmail or the original Browser avoid it.

The Costs

Each process gets its own heap space, cutting into the heap available for other applications. As with the large-heap anti-pattern [discussed above](#), this will tend to force other apps to be ejected from memory sooner than normal, with commensurate impacts on user experience.

Inter-process communication (IPC) is not cheap, compared with normal method invocation within a process. Hence, tightly-coupled processes will chew through more CPU than their single-process counterparts. While it is unlikely that you will see major performance implications (unless you are doing a preposterous amount of IPC), this will consume more battery than is otherwise warranted.

The Counter-Arguments

I am using a C library that is buggy, and you told me not to terminate my process

As noted earlier, fix the bugs in the library.

Hello? It is not my C library, but one from a third party!

Find a library that is Android-compatible, then.

I need more heap space

On Android 3.0 and higher, `android:largeHeap` is available, though its misuse is [another anti-pattern, discussed above](#). However, prior to Android 3.0, `android:largeHeap` was not an option. One workaround used by some apps is to fork several processes, thereby getting several “small” heap allocations (e.g., 32MB) instead of just one.

In cases where `android:largeHeap` is indeed justified, using multiple processes as a workaround on older Android versions is justified as well. However, bear in mind that IPC overhead is non-trivial, so have a plan to dump the multiple processes and use `android:largeHeap` once you drop support for Android 1.x/2.x.

I want my UI not to freeze when doing background work

Use threads, not processes, for this.

Hog System Resources

Some of these anti-patterns, like the multiple-process one just now, are really concrete sub-types of a more general anti-pattern: assuming yours is the only app running on the device. While your app may be the only one running in the foreground (assuming that you actually *are* in the foreground), there are other apps in the background, and ones that soon will come to the foreground. You need to “play nice” and ensure that these other apps will have their fair share of system resources.

One example is open files on external storage. For some devices — but not all — there is a limit of 1,024 simultaneously open files. In principle, that should be plenty. However, if some app — maybe yours? — opens a whole bunch of files, it is possible that other apps trying to access external storage at that point will crash because the limit was hit.

The Counter-Arguments

Um, well, I’m just more important than those other developers

::facepalm::

Trail: Widget Catalog

Widget Catalog: AdapterViewFlipper

A [regular ViewFlipper](#) shows only one child widget or container at a time. So does an AdapterViewFlipper. The difference is where the children come from. With a regular ViewFlipper, you add children much like you would any other standard container class, such as defining the children in your layout XML resource. With AdapterViewFlipper, the children come from an Adapter.

While AdapterViewFlipper does not inherit from ViewFlipper (or vice versa, for that matter), their public API is largely the same:

- You can control which child is visible, either by index or via `showNext()/showPrevious()` methods to rotate between them.
- You can set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.
- You can set up AdapterViewFlipper to automatically flip between children on a specified period.

There are two key advantages for AdapterViewFlipper:

1. Since it uses an Adapter model, it can be more memory efficient for lots of children, through child view recycling
2. It is available for use in an [app widget](#)

However, AdapterViewFlipper is new to API Level 11 and is unavailable on older versions of Android. It is not included in the Android Support package backport.

Key Usage Tips

All of the usage tips from [ViewFlipper](#) are relevant for AdapterViewFlipper.

A Sample Usage

The sample project can be found in [WidgetCatalog/AdapterViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<AdapterViewFlipper xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

Activity:

```
package com.commonware.android.avflip;

import android.app.Activity;
import android.os.Bundle;
import android.widget.AdapterViewFlipper;
import android.widget.ArrayAdapter;

public class FlipperDemo2 extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
    AdapterViewFlipper flipper;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        flipper=(AdapterViewFlipper)findViewById(R.id.details);
        flipper.setAdapter(new ArrayAdapter<String>(this, R.layout.big_button,
items));
        flipper.setFlipInterval(2000);
        flipper.startFlipping();
    }
}
```

Visual Representation

There is no visual representation of an AdapterViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Widget Catalog: CalendarView

CalendarView, as you might have guessed, displays a calendar to the user, designed to allow the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Note that this is a small calendar – it is not designed to show details *within* a date, such as appointments and times.

This view is available standalone and also as an optional adjunct to [the DatePicker widget](#).

This view was added in API Level 11 and therefore will not be available on older versions of Android, though [a backport is available](#) that works on Android 2.2 onwards.

Key Usage Tips

If you do nothing, the CalendarView will start with today's date, though you can call a `setDate()` method to pass in a `Calendar` object to use to change the initially-selected date. You can also call `setOnDateChangeListener()` to supply an `OnDateChangeListener` to learn when the user changes the date in the CalendarView.

CalendarView works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the CalendarView (as supplied to the `onSelectedDayChange()` method of your `OnDateChangeListener`) and converting it into something you can use in your code.

A Sample Usage

The sample project can be found in [WidgetCatalog/CalendarView](#).

Layout:

```
<CalendarView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/calendar"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

Activity:

```
package com.commonware.android.wc.calendar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CalendarView;
import android.widget.CalendarView.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class CalendarDemoActivity extends Activity implements
    OnDateChangeListener {
    CalendarView calendar=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        calendar=(CalendarView)findViewById(R.id.calendar);
        calendar.setOnDateChangeListener(this);
    }

    @Override
    public void onSelectedDayChange(CalendarView view, int year,
        int monthOfYear, int dayOfMonth) {
        Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

        Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
            .show();
    }
}
```

Visual Representation

This is what a CalendarView looks like in a few different Android versions and configurations, based upon the sample app shown above.

WIDGET CATALOG: CALENDARVIEW

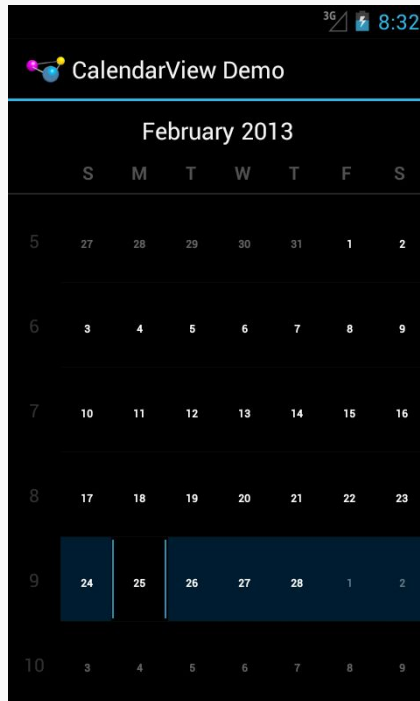

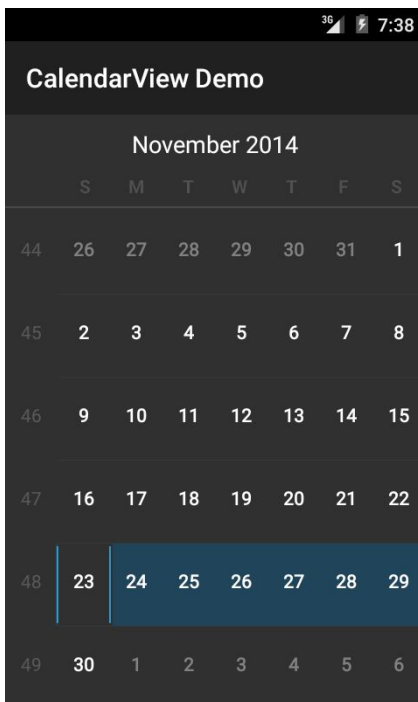

Figure 827: Android 4.1

Widget Catalog: DatePicker

DatePicker, as the name might suggest, allows the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Key Usage Tips

If you do nothing, the DatePicker will start with today's date. However, if you want to set up an `OnDateSetListener` to find out when the date changes, you will need to call `init()` to do so, in which you also need to set the date.

DatePicker works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the DatePicker and converting it into something you can use in your code.

API Level 11 introduced an optional `CalendarView` adjunct to the DatePicker, determined via `setCalendarViewShown()` or `android:calendarViewShown`. This works well on -normal screens in landscape and on -large/-xlarge screens. On -normal screens in portrait, the year portion of the picker may be chopped off to save room. Using the `CalendarView` option on -small screens is probably not a good idea.

However, on Android 5.0, the `CalendarView` is *always* shown and cannot be removed, as the “picker” itself does not allow the user to pick a date. The user uses the `CalendarView` to pick a date, or taps on the year in the “picker” to choose a year. This means that DatePicker is not a particularly good widget to use, especially on smaller screens.

A Sample Usage

The sample project can be found in [WidgetCatalog/DatePicker](#).

Layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_horizontal">

    <DatePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="1"
        android:calendarViewShown="true"/>

    <CheckBox
        android:id="@+id/showCalendar"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="@string/calendar"/>

</LinearLayout>
```

Activity:

```
package com.commonware.android.wc.datepick;

import android.app.Activity;
import android.os.Build;
import android.os.Bundle;
import android.view.View;
import android.widget.CheckBox;
import android.widget.CompoundButton;
import android.widget.CompoundButton.OnCheckedChangeListener;
import android.widget.DatePicker;
import android.widget.DatePicker.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class DatePickerDemoActivity extends Activity implements
    OnCheckedChangeListener, OnDateChangeListener {
    DatePicker picker=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);
setContentView(R.layout.main);

CheckBox cb=(CheckBox)findViewById(R.id.showCalendar);

if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
    cb.setOnCheckedChangeListener(this);
}
else {
    cb.setVisibility(View.GONE);
}

GregorianCalendar now=new GregorianCalendar();

picker=(DatePicker)findViewById(R.id.picker);
picker.init(now.get(Calendar.YEAR), now.get(Calendar.MONTH),
           now.get(Calendar.DAY_OF_MONTH), this);
}

@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
        picker.setCalendarViewShown(isChecked);
    }
}

@Override
public void onChanged(DatePicker view, int year, int monthOfYear,
                     int dayOfMonth) {
    Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

    Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
        .show();
}
}
```

The CheckBox is tied to the visibility of the CalendarView. Since this is only available on API Level 11 and higher, we simply remove the CheckBox on earlier versions of Android, so we do not have to worry about whether or not the CheckBox gets unchecked by the user.

Visual Representation

This is what a DatePicker looks like in a few different Android versions and configurations, based upon the sample app shown above.

Widget Catalog: ExpandableListView

Android does not have a “tree” widget, allowing users to navigate an arbitrary hierarchy of stuff. In large part, that is because such trees are difficult to navigate on small touchscreens with comparatively large fingers.

Android *does* have `ExpandableListView`, a subclass of `ListView` that supports a two-layer hierarchy: groups and children. Groups can be expanded to show their children or collapsed to hide them, and you can get control on various events for the groups or the children.

Key Usage Tips

Android offers an `ExpandableListActivity` as a counterpart to its `ListActivity`. However, it does not offer an `ExpandableListFragment`. This is not a major issue, as you can work with an `ExpandableListView` inside a regular `Fragment` yourself, just as you would for most other widgets not named `ListView`.

Rather than use a `ListAdapter` with `ExpandableListView`, you will use an `ExpandableListAdapter`, where you can control separate details for groups and children. These include:

- `SimpleExpandableListAdapter`, roughly analogous to `ArrayAdapter`, where your data resides in a `List` of `Map` objects for groups, and a `List` of a `List` of `Map` objects for the children
- `CursorTreeAdapter` and `SimpleCursorTreeAdapter`, roughly analogous to `CursorAdapter` and `SimpleCursorAdapter`, for mapping data in a `Cursor` to rows and columns

In many cases, though, the complexity of managing groups and children will steer you down the path of extending `BaseExpandableListAdapter` and handling all of the view construction yourself. There are many methods that you will need to implement:

- `getGroupCount()`, to return the number of groups
- `getGroup()` and `getGroupId()`, to return an `Object` and unique `int` ID for a group given its position
- `getGroupView()`, to return the `View` that should be used to render the group, perhaps using the built-in `android.R.layout.simple_expandable_list_item_1` that is set up for such groups and handles rendering the expanded and collapsed states
- `getChildrenCount()`, to return the number of children for a given group
- `getChild()` and `getChildId()`, to return an `Object` and unique `int` ID for a child given its position (and its group's position)
- `getChildView()`, to return the `View` that should be used to render the child, given its position and its group's position
- `isChildSelectable()`, to indicate if the user can select a given child, given its position and its group's position
- `hasStableIds()`, to indicate if the ID values you returned from `getGroupId()` and `getChildId()` will remain constant for the life of this adapter

There are four major events that you will be able to respond to with respect to the user's interaction with an `ExpandableListView`:

- Clicks on a child (`setOnChildClickListener()`)
- Clicks on a group (`setOnGroupClickListener()`)
- When groups expand (`setOnGroupExpandListener()`) or collapse (`setOnGroupCollapseListener()`)

If you use `setOnGroupClickListener()` to be notified about clicks on a group, be sure to return `false` from your implementation of the `onGroupClick()` method required by the `OnGroupClickListener` interface. If you return `true`, you consume the click event, which prevents `ExpandableListView` from using that event to expand or collapse the group.

A Sample Usage

The sample project can be found in [WidgetCatalog/ExpandableListView](#).

WIDGET CATALOG: EXPANDABLELISTVIEW

Layout:

```
<ExpandableListView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/elv"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

</ExpandableListView>
```

JSON data:

```
{
  "Group A": ["Child A1", "Child A2", "Child A3"],
  "Group B": ["Child B1", "Child B2"],
  "Group C": ["Child C1"],
  "Group D": [],
  "Group E": ["Child E1", "Child E2", "Child E3"]
}
```

Activity:

```
package com.commonware.android.wc.elv;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.ExpandableListAdapter;
import android.widget.ExpandableListView;
import android.widget.ExpandableListView.OnChildClickListener;
import android.widget.ExpandableListView.OnGroupClickListener;
import android.widget.ExpandableListView.OnGroupCollapseListener;
import android.widget.ExpandableListView.OnGroupExpandListener;
import android.widget.Toast;
import java.io.BufferedReader;
import java.io.InputStream;
import java.io.InputStreamReader;
import org.json.JSONObject;

public class MainActivity extends Activity implements
    OnChildClickListener, OnGroupClickListener, OnGroupExpandListener,
    OnGroupCollapseListener {
    private ExpandableListAdapter adapter=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        InputStream raw=getResources().openRawResource(R.raw.sample);
        BufferedReader in=new BufferedReader(new InputStreamReader(raw));
        String str;
```

```
StringBuffer buf=new StringBuffer();

try {
    while ((str=in.readLine()) != null) {
        buf.append(str);
        buf.append('\n');
    }

    in.close();

    JSONObject model=new JSONObject(buf.toString());

    ExpandableListView elv=(ExpandableListView)findViewById(R.id.elv);

    adapter=new JSONExpandableListAdapter(getLayoutInflater(), model);
    elv.setAdapter(adapter);

    elv.setOnChildClickListener(this);
    elv.setOnGroupClickListener(this);
    elv.setOnGroupExpandListener(this);
    elv.setOnGroupCollapseListener(this);
}
catch (Exception e) {
    Log.e(getClass().getName(), "Exception reading JSON", e);
}
}

@Override
public boolean onChildClick(ExpandableListView parent, View v,
                           int groupPosition, int childPosition,
                           long id) {
    Toast.makeText(this,
                  adapter.getChild(groupPosition, childPosition)
                      .toString(), Toast.LENGTH_SHORT).show();

    return(false);
}

@Override
public boolean onGroupClick(ExpandableListView parent, View v,
                           int groupPosition, long id) {
    Toast.makeText(this, adapter.getGroup(groupPosition).toString(),
                  Toast.LENGTH_SHORT).show();

    return(false);
}

                  "Expanding: "
                      + adapter.getGroup(groupPosition).toString(),
                  Toast.LENGTH_SHORT).show();
}
```

```
@Override
public void onGroupCollapse(int groupPosition) {
    Toast.makeText(this,
        "Collapsing: "
        + adapter.getGroup(groupPosition).toString(),
        Toast.LENGTH_SHORT).show();
}
}
```

This activity loads up a JSON file from a raw resource on the main application thread in `onCreate()`, which is not a good idea. It would be better to do that work in a background thread, perhaps an `AsyncTask` managed by a retained fragment. The implementation shown here is designed to keep the sample small, not to demonstrate the best way to load data from a raw resource.

Adapter:

```
package com.commonware.android.wc.elv;

import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.BaseExpandableListAdapter;
import android.widget.TextView;
import java.util.Iterator;
import org.json.JSONArray;
import org.json.JSONException;
import org.json.JSONObject;

public class JSONExpandableListAdapter extends
    BaseExpandableListAdapter {
    LayoutInflater inflater=null;
    JSONObject model=null;

    JSONExpandableListAdapter(LayoutInflater inflater, JSONObject model) {
        this.inflater=inflater;
        this.model=model;
    }

    @Override
    public int getGroupCount() {
        return(model.length());
    }

    @Override
    public Object getGroup(int groupPosition) {
        @SuppressWarnings("rawtypes")
        Iterator i=model.keys();
    }
```

```
while (groupPosition > 0) {
    i.next();
    groupPosition--;
}

return(i.next());
}

@Override
public long getGroupId(int groupPosition) {
    return(groupPosition);
}

@Override
public View getView(int groupPosition, boolean isExpanded,
                    View convertView, ViewGroup parent) {
    if (convertView == null) {
        convertView=
            inflater.inflate(android.R.layout.simple_expandable_list_item_1,
                            parent, false);
    }

    TextView tv=
        ((TextView)convertView.findViewById(android.R.id.text1));
    tv.setText(getGroup(groupPosition).toString());

    return(convertView);
}

@Override
public int getChildrenCount(int groupPosition) {
    try {
        JSONArray children=getChildren(groupPosition);

        return(children.length());
    }
    catch (JSONException e) {
        // JSONArray is really annoying
        Log.e(getClass().getSimpleName(), "Exception getting children", e);
    }

    return(0);
}

@Override
public Object getChild(int groupPosition, int childPosition) {
    try {
        JSONArray children=getChildren(groupPosition);

        return(children.get(childPosition));
    }
    catch (JSONException e) {
        // JSONArray is really annoying
        Log.e(getClass().getSimpleName(),
```

```
        "Exception getting item from JSON array", e);
    }

    return(null);
}

@Override
public long getChildId(int groupPosition, int childPosition) {
    return(groupPosition * 1024 + childPosition);
}

@Override
public View getChildView(int groupPosition, int childPosition,
                        boolean isLastChild, View convertView,
                        ViewGroup parent) {
    if (convertView == null) {
        convertView=
            inflater.inflate(android.R.layout.simple_list_item_1, parent,
                            false);
    }

    TextView tv=(TextView)convertView;
    tv.setText(getChild(groupPosition, childPosition).toString());

    return(convertView);
}

@Override
public boolean isChildSelectable(int groupPosition, int childPosition) {
    return(true);
}

@Override
public boolean hasStableIds() {
    return(true);
}

private JSONArray getChildren(int groupPosition) throws JSONException {
    String key=getGroup(groupPosition).toString();

    return(model.getJSONArray(key));
}
}
```

This adapter wraps a `JSONObject` and assumes that the JSON structure is an object, keyed by strings, whose values are arrays of strings. The object returned by `getGroup()` is the key for that group's position; the object returned by `getChild()` is the string at that child's array index for it's group's array. Since the data structure is treated as immutable, and since there are no other better IDs in the data structure itself, the group ID is simply the group's position, and the child's ID is simply a mash-up of the group and child positions.

Visual Representation

This is what an `ExpandableListView` looks like in a few different Android versions and configurations, based upon the sample app shown above.

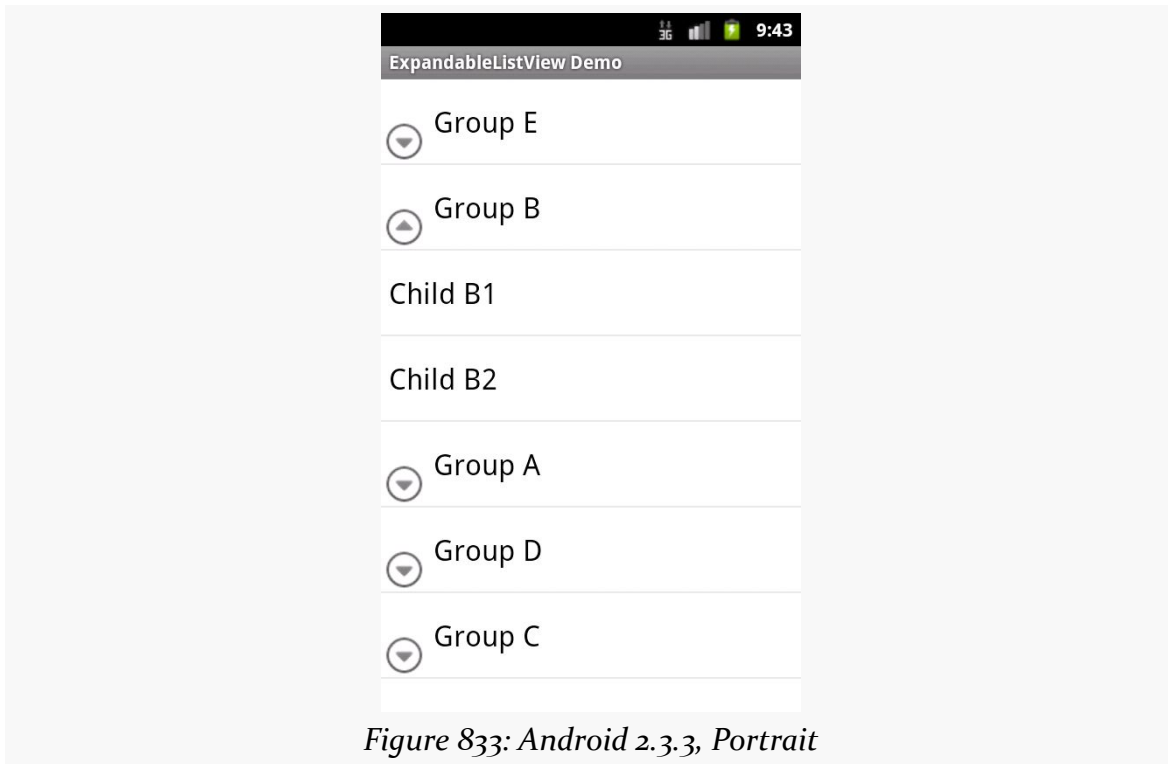

Figure 833: Android 2.3.3, Portrait

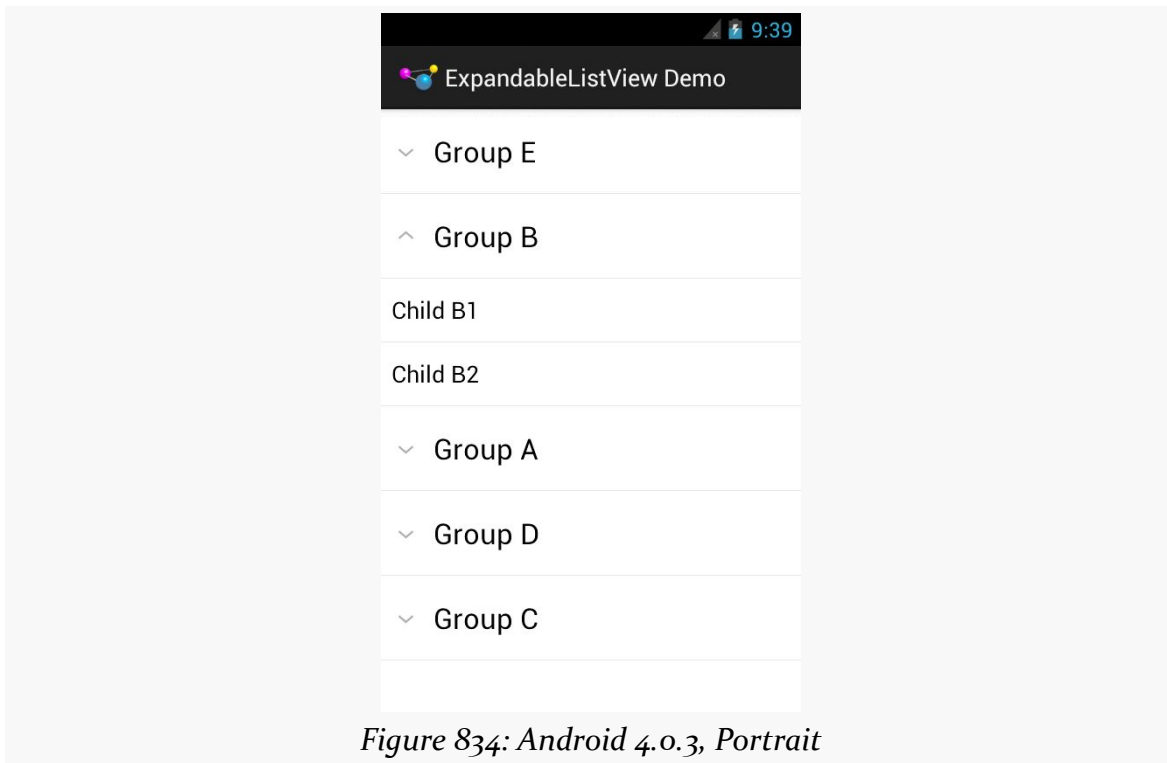

Figure 834: Android 4.0.3, Portrait

Note that while the data in the JSON file has the groups sorted alphabetically, because `JSONObject` effectively loads its data into a `HashMap`, the sorting gets lost in the data model, which is why the groups appear out of order.

Also note that the visual representation of the “collapsed” and “expanded” states is controlled by the `ExpandableListAdapter` and the view used for the groups. In this sample, we use `android.R.layout.simple_expandable_list_item_1` for the groups, which gives us the caret designation for expanded versus collapsed states in 4.0.3 and the lower-left arrowhead-in-circle icon for 2.3.3. You can create your own rows with your own indicators as you see fit.

Widget Catalog: SeekBar

SeekBar allows the user to choose a value along a continuous range by sliding a “thumb” along a horizontal line. In effect — and in practice, as it turns out — SeekBar is a user-modifiable ProgressBar.

Key Usage Tips

The value range of a SeekBar runs from 0 to a developer-set maximum value. As with ProgressBar, the default maximum is 100, but that can be changed via an `android:max` attribute or the `setMax()` method. The minimum value is always 0, so if you want a range starting elsewhere, just add your starting value to the actual value (obtained via `getProgress()`) to slide the range as desired.

You can find out about changes in the SeekBar value by attaching an `OnSeekBarChangeListener` implementation. The primary method on that interface is `onProgressChanged()`, where you are notified about changes in the progress value (second parameter) and whether that change was initiated directly by the user interacting with the widget (third parameter). The interface also has `onStartTrackingTouch()` and `onStopTrackingTouch()`, to indicate when the user is attempting to change the position of the thumb via the touchscreen, though these methods are less-commonly used.

A Sample Usage

The sample project can be found in [WidgetCatalog/SeekBar](#).

Layout:

WIDGET CATALOG: SEEKBAR

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="center_vertical"
    tools:context=".MainActivity">

    <TextView
        android:id="@+id/value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="0"
        android:ems="2"
        android:gravity="right|center_vertical"
        android:layout_marginRight="10dp"
        android:textAppearance="@android:style/TextAppearance.Large"/>

    <SeekBar
        android:id="@+id/seek_bar"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:layout_marginRight="10dp"
        android:max="50"/>

</LinearLayout>
```

Activity:

```
package com.commonware.android.wc.seekbar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.SeekBar;
import android.widget.SeekBar.OnSeekBarChangeListener;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnSeekBarChangeListener {
    TextView value=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        value=(TextView)findViewById(R.id.value);

        SeekBar seekBar=(SeekBar)findViewById(R.id.seek_bar);

        seekBar.setOnSeekBarChangeListener(this);
    }
}
```

WIDGET CATALOG: SEEKBAR

```
@Override
public void onProgressChanged(SeekBar seekBar, int progress,
                             boolean fromUser) {
    value.setText(String.valueOf(progress));
}

@Override
public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
}

@Override
public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
}
}
```

Widget Catalog: SlidingDrawer

Having some form of means of allowing the user to swipe to show more things is an important visual pattern. We saw this earlier in the book with [the ViewPager container](#). And there are other modern techniques for doing this that you will see in apps like Google+.

SlidingDrawer, while implementing a variation on this pattern, is a bit out of date at present. Mostly, that's a question of its UI: tapping a drawer “handle” to open it is not what you tend to see nowadays. That being said, it works perfectly well, wrapping around a container to make it appear or disappear based on user input, complete with a sliding animation effect.

Note that SlidingDrawer was deprecated in API Level 17 (a.k.a., Android 4.2). This means that Google is steering you in other directions, including forking [the AOSP code for SlidingDrawer](#) and maintaining it yourself. The [animator framework](#) offers other ways of implementing sliding widgets that may be better suited for your UI, anyway.

Also note that SlidingDrawer is broken on Android 5.0, and so you *definitely* should be considering alternative widgets at this time.

Key Usage Tips

The SlidingDrawer itself is transparent, except for the button to trigger the slide and its accompanying horizontal bar. Hence, if you want the drawer contents to completely obscure what is outside of the drawer, you will need to use an appropriate background. Otherwise, the drawer contents and what lies outside the drawer will be alpha-blended based on their own translucency, as is seen in [the screenshots later in this chapter](#).

The `SlidingDrawer` can be horizontal or vertical; it is vertical by default. However, it only slides one way (bottom-to-top for vertical, right-to-left for horizontal). There is no way to reverse the direction of the sliding effect.

You must supply `android:content` and `android:handle` attributes in `SlidingDrawer`, containing references to the widget that forms the content of the drawer and the drawer's handle, respectively. Typically, the drawer's handle is an `ImageView`. Note that you *must* supply a handle — you cannot skip either of these attributes.

A Sample Usage

The sample project can be found in [WidgetCatalog/SlidingDrawer](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:text="@string/drawer_closed"/>

    <SlidingDrawer
        android:id="@+id/drawer"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:content="@+id/content"
        android:handle="@+id/handle">

        <ImageView
            android:id="@+id/handle"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:src="@drawable/tray_handle_normal"/>

        <Button
            android:id="@+id/content"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:text="@string/drawer_msg"/>
    </SlidingDrawer>
</RelativeLayout>
```

Activity:

```
package com.commonware.android.drawer;

import android.app.Activity;
import android.os.Bundle;

public class DrawerDemo extends Activity
{
    /** Called when the activity is first created. */
    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

Visual Representation

This is what a SlidingDrawer looks like in a few different Android versions and configurations, based upon the sample app shown above.

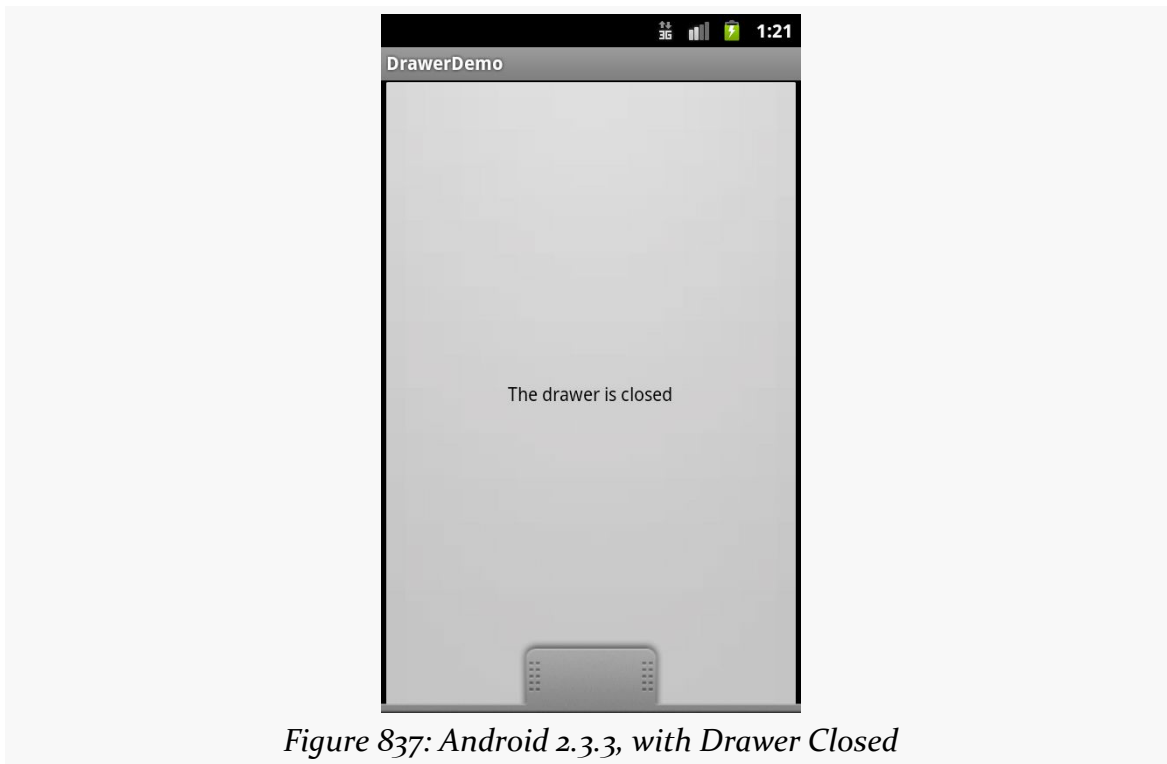

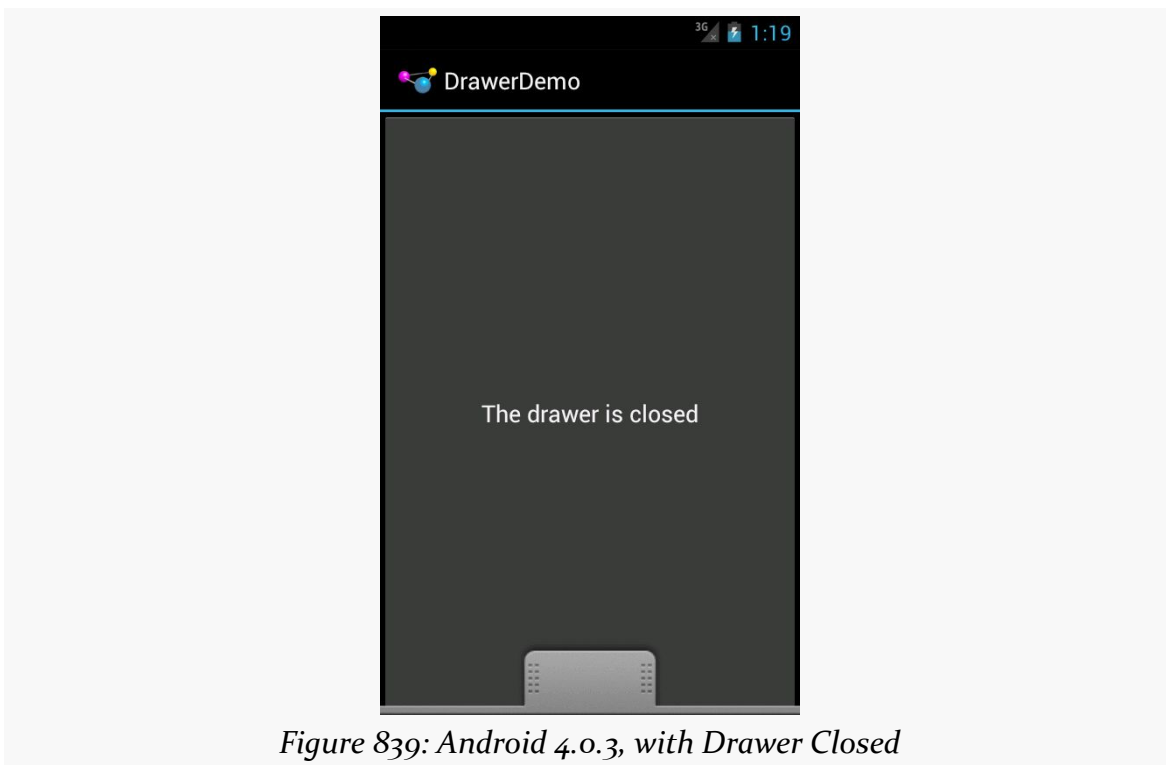

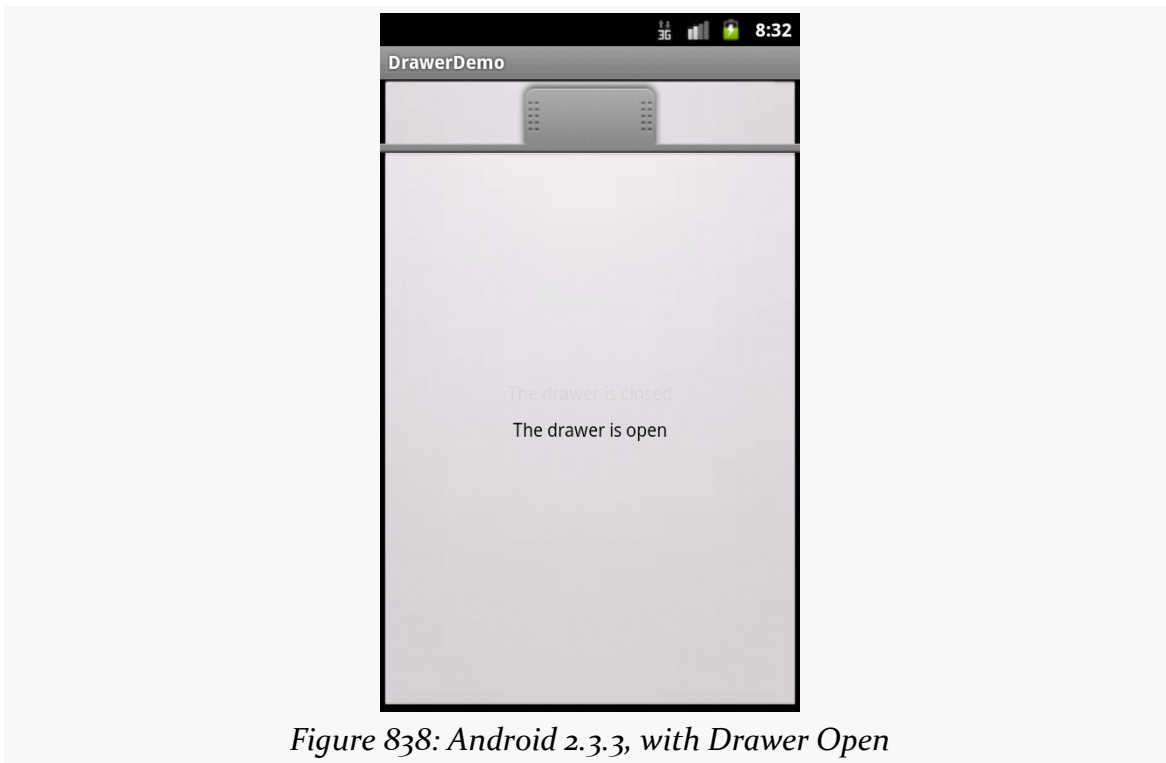

Figure 837: Android 2.3.3, with Drawer Closed

Widget Catalog: StackView

StackView is an AdapterView. Whereas ListView uses a horizontal scrolling list as its UI metaphor, StackView uses a stack of cards as its metaphor. Just as ListView shows a handful of rows, StackView shows a handful of cards. These cards can be swiped away via a swipe towards the southwest corner of the screen. The top card is fully visible; the edges of a few other cards can be seen but are otherwise obscured by cards “higher in the stack”.

While certainly usable in activities and fragments, StackView was introduced in support of app widgets. App widgets like bookmarks, Google Books covers, and the like use StackView to show an item and allow users to navigate to the rest of the items by flipping these virtual cards.

Key Usage Tips

Generally speaking, working with StackView is not significantly different than is working with any other AdapterView. You create an Adapter defining the contents (in this case, defining the cards), you attach the Adapter to the StackView, and put the StackView somewhere on the screen.

As the cards overlap, however, transparency becomes an issue. If the top card is not completely opaque, you will see the card beneath it “peeking through” as its contents are blended in via the alpha channel. In some cases, this is a perfectly desirable outcome. However, if that is not what you want, make sure that the backgrounds of your overall container for the card’s contents (e.g., a RelativeLayout) has an opaque background, such as a color with FF for the alpha value.

Also, since the objective is to have the children be visually stacked, the children cannot be the size of the StackView itself (e.g., the children cannot use `match_parent` for a dimension). StackView seems to work best with children that have explicit sizes (e.g., values in dp).

A Sample Usage

The sample project can be found in [WidgetCatalog/StackView](#).

Activity Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<StackView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

Item Layout:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="200dp"
    android:layout_height="200dp"
    android:background="#FFFF0000"
    android:gravity="center"
    android:textAppearance="?android:attr/textAppearanceLarge"/>
```

Activity:

```
package com.commonware.android.wc.stack;

import android.app.Activity;
import android.content.Context;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.StackView;

public class MainActivity extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
    StackView stack;

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(icicle);
setContentView(R.layout.main);

stack=(StackView)findViewById(R.id.details);
stack.setAdapter(new ItemAdapter(this, R.layout.item, items));
}

private static class ItemAdapter extends ArrayAdapter<String> {
    public ItemAdapter(Context context, int textViewResourceId,
        String[] objects) {
        super(context, textViewResourceId, objects);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        result.setBackgroundColor(0xFF330000 + (position * 0x0A0A));

        return(result);
    }
}
```

Visual Representation

This is what a StackView looks like in Android 4.0.3, based upon the sample app shown above:

Widget Catalog: TabHost and TabWidget

Before we had the action bar and ViewPager, we had TabHost and TabWidget as our means of displaying tabs. Nowadays, in most cases, using [tabs in the action bar](#) would be preferable, or perhaps using [“swipecy tabs” with ViewPager](#). However, there may be cases where the classic tabs are a better solution, or you may have inherited legacy code that still uses TabHost.

Deprecation Notes

Just as ListActivity helps one use a ListView, TabActivity helps one use a TabHost. However, TabActivity is marked as deprecated. That is largely because its parent class, ActivityGroup, is deprecated. While you can still use TabActivity, it is no longer recommended. It also is not necessary, as there are ways to use TabHost and TabWidget without using TabActivity, as will be demonstrated later in this chapter.

Key Usage Tips

There are a few widgets and containers you need to use in order to set up a tabbed portion of a view:

- TabHost is the overarching container for the tab buttons and tab contents
- TabWidget implements the row of tab buttons, which contain text labels and optionally contain icons
- FrameLayout is the container for the tab contents; each tab content is a child of the FrameLayout

You load contents into that `FrameLayout` in one of two ways:

1. You can define the contents simply as child widgets (or containers) of the `FrameLayout` in a layout XML file you are using for the whole tab setup
2. You can define the contents at runtime

Curiously, you do not define what goes in the tabs themselves, or how they tie to the content, in the layout XML file. Instead, you must do that in Java, by creating a series of `TabSpec` objects (obtained via `newTabSpec()` on `TabHost`), configuring them, then adding them in sequence to the `TabHost` via `addTab()`.

The two key methods on `TabSpec` are:

- `setContent()`, where you indicate what goes in the tab content for this tab, typically the `android:id` of the view you want shown when this tab is selected
- `setIndicator()`, where you provide the caption for the tab button and, in some flavors of this method, supply a `Drawable` to represent the icon for the tab

Note that tab “indicators” can actually be views in their own right, if you need more control than a simple label and optional icon.

Also note that you must call `setup()` on the `TabHost` before configuring any of these `TabSpec` objects. The call to `setup()` is not needed if you are using the `TabActivity` base class for your activity.

A Sample Usage

The sample project can be found in [WidgetCatalog/Tab](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<TabHost xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/tabhost"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <LinearLayout
        android:orientation="vertical"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
        <TabWidget android:id="@android:id/tabs"
```

```
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    />
    <FrameLayout android:id="@android:id/tabcontent"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
        <AnalogClock android:id="@+id/tab1"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
        />
        <Button android:id="@+id/tab2"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:text="A semi-random button"
        />
    </FrameLayout>
</LinearLayout>
</TabHost>
```

Activity:

```
package com.commonware.android.tabhost;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TabHost;

public class TabDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        TabHost tabs=(TabHost)findViewById(R.id.tabhost);

        tabs.setup();

        TabHost.TabSpec spec=tabs.newTabSpec("tag1");

        spec.setContent(R.id.tab1);
        spec.setIndicator("Clock");
        tabs.addTab(spec);

        spec=tabs.newTabSpec("tag2");
        spec.setContent(R.id.tab2);
        spec.setIndicator("Button");
        tabs.addTab(spec);
    }
}
```

Note that ordinarily you would use icons with your tabs, and so the second parameter to `setIndicator()` would be a reference to a drawable resource. This particular sample skips the icons.

Visual Representation

This is what a `TabHost` and `TabWidget` look like in a few different Android versions and configurations, based upon the sample app shown above.

Figure 841: Android 2.3.3

Figure 842: Android 4.0.3

Widget Catalog: TimePicker

Just as [DatePicker](#) allows the user to pick a date, TimePicker allows the user to pick a time. This widget is a bit simpler to use, insofar as you do not have the option of the integrated `CalendarView` as you do with `DatePicker`. In other respects, TimePicker follows the patterns established by `DatePicker`.

Note that TimePicker only supports hours and minutes, not seconds or finer granularity.

Key Usage Tips

With `DatePicker`, the act of supplying an `OnDateSetListener` also required you to supply the year/month/day to use as a starting point. TimePicker is more intelligently designed: setting the `OnTimeSetListener` is independent from adjusting the hour or minute.

As with `DatePicker`, TimePicker works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the hour/minute/second from the TimePicker and converting it into something you can use in your code.

There is [a bug in Android 4.0/4.0.3](#) in which your `OnTimeSetListener` is not invoked when the user changes between AM and PM when viewing the TimePicker in 12-hour display mode.

A Sample Usage

The sample project can be found in [WidgetCatalog/TimePicker](#).

WIDGET CATALOG: TIMEPICKER

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_vertical">

    <TimePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```

Activity:

```

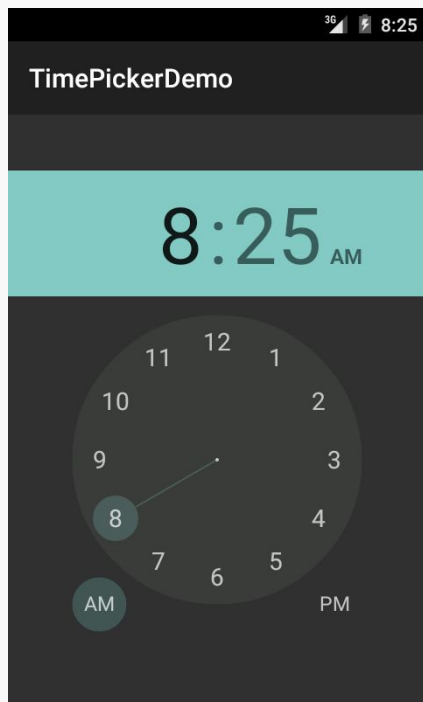

Figure 845: Android 5.0

Widget Catalog: ViewFlipper

A ViewFlipper behaves a bit like a FrameLayout that is set up such that only one child can be visible at a time. You can control which of those children is visible, either by index or via `showNext()`/`showPrevious()` methods to rotate between them.

You can also set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.

And, you can set up ViewFlipper to automatically flip between children on a specified period, without further developer involvement. This, coupled with the animation, can be used for news tickers, ad banner rotations, or the like where light animations (e.g., fade out and fade in) can be used positively.

Key Usage Tips

ViewFlipper can have as many children as needed (within memory constraints), though you will want at least two for it to be meaningful.

By default, the transition between children is an immediate “smash cut” — the old one vanishes and the new one appears instantaneously. You can call `setInAnimation()` and/or `setOutAnimation()` to supply [an Animation object or resource](#) to use for the transitions instead.

By default, the ViewFlipper will show its first child and stay there. You can manually flip children via `showNext()`, `showPrevious()`, and `setDisplayChild()`, the latter of which taking a position index of which child to display. You can also have automatic flipping, by one of two means:

1. In your layout, `android:flipInterval` will set up the amount of time to display each child before moving to the next, and `android:autoStart` will indicate if the automated flipping should begin immediately or not
2. In Java, `setFlipInterval()` serves the same role as `android:flipInterval`, and you can control when flipping is enabled via `startFlipping()` and `stopFlipping()`

A Sample Usage

The sample project can be found in [WidgetCatalog/ViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <ViewFlipper android:id="@+id/details"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        >
    </ViewFlipper>
</LinearLayout>
```

Activity:

```
package com.commonware.android.flipper2;

import android.app.Activity;
import android.os.Bundle;
import android.view.ViewGroup;
import android.widget.Button;
import android.widget.ViewFlipper;

public class FlipperDemo2 extends Activity {
    static String[] items={"lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit",
        "morbi", "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque",
        "augue", "purus"};

    ViewFlipper flipper;

    @Override
    public void onCreate(Bundle icle) {
```

```
super.onCreate(icle);
setContentView(R.layout.main);

flipper=(ViewFlipper)findViewById(R.id.details);

for (String item : items) {
    Button btn=new Button(this);

    btn.setText(item);

    flipper.addView(btn,
        new ViewGroup.LayoutParams(
            ViewGroup.LayoutParams.FILL_PARENT,
            ViewGroup.LayoutParams.FILL_PARENT));
}

flipper.setFlipInterval(2000);
flipper.startFlipping();
}
```

Visual Representation

There is no visual representation of a ViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Trail: Device Catalog

Device Catalog: Kindle Fire

The most aggressive firm in creating a Google-free Android ecosystem is Amazon. The most visible aspect of that work is Amazon's Kindle Fire series of devices. From 2011 through 2013, each year has brought forth a new generation of Kindle Fire models, each with newer versions of Android and more powerful hardware. However, none support the Play Store or other Google proprietary apps and technologies. As a result, Amazon has also been building their own replacements, which developers can elect to use if they need the capabilities but are targeting the Fire.

This chapter will outline what you should expect as you start working on apps for the Kindle Fire series of devices.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Introducing the Kindle Fire series

Once upon a time, there was the Kindle Fire. It was a 7" tablet, made by Amazon.

Nowadays, there is a series of devices in the Kindle Fire family:

- The original first-generation Kindle Fire
- The second-generation Kindle Fire, with an updated OS and slightly faster CPU
- The Kindle Fire HD 7", with a 720p display

- The Kindle Fire HD 8.9” with a 1080p display (available as a WiFi-only device or with mobile data capability)
- The Kindle Fire HDX 7”, with a 1920x1200 display and optional mobile data
- The Kindle Fire HDX 8.9”, with a 2560x1600 display and optional mobile data

This chapter will attempt to point out which of these devices certain statements pertain to. The phrase “the original Kindle Fire” refers to the first-generation Kindle Fire.

What Features and Configurations Does It Use?

Any time you are looking at a device that is known to be a significant departure from conventional Android devices, you need to consider what capabilities the device has and how that relates to your code and graphic assets. Android’s flexibility means that, in many cases, you can work within the limits of the SDK to craft something that will look well on unusual devices. However, you will need to understand what is and is not possible for the device in question, in this case the Kindle Fire.

However, there are now several devices in the Kindle Fire family, which makes this more complicated.

OS Version

Amazon has branded their variation of Android “FireOS”.

The first-generation Kindle Fire runs an Amazon-customized version of Android 2.3.3. The HD models run an Amazon-customized version of Android 4.0.3, while the HDX models run a FireOS based on Android 4.2.2.

Note that these devices will not show up in Google’s “Device Dashboard” pie chart, as Google can only count those devices that use the Play Store, which the Kindle Fire series lacks.

Screen Size and Density

The original Kindle Fire (first and second generation) uses -large, -mdpi resources. On the surface, this would not be terribly surprising, as the 7” display works out to around 169dpi, and 7” displays are definitely in the -large resource bucket.

However, bear in mind that Android 2.3 did not fully support tablets. The only Google-endorsed tablet that shipped with Android 2.x was the original Samsung Galaxy Tab, and that technically was a really large phone that, er, could not place phone calls.

As such, Android 2.3 did not consider a 1024x600 display to be -large. It considered such a display to be -xlarge. This was corrected in Android 3.1, in preparation for a new line of ~7" Honeycomb tablets.

In general, this should not pose an issue when testing your app on hardware. In practice, it will pose a problem for your emulator, as will be explained [later in this chapter](#).

The Kindle Fire HD 7" and 8.9" are -large, though they are -hdpi in terms of screen density.

The Kindle Fire HDX 7" is -large, while the Kindle Fire HDX 8.9" is -xlarge. Both are xhdpi in terms of screen density.

Hardware Features

All of the Kindle Fire devices support:

1. An accelerometer, both for direct use and for detecting screen orientation changes
2. Multitouch, but only for two fingers (e.g., pinch-to-zoom)
3. WiFi
4. The USB accessory interface
5. A light/proximity sensor

The Kindle Fire HD devices add:

1. Front-facing camera
2. Network-based location (the Kindle Fire HD 8.9", with the mobile data option, also has GPS)
3. Bluetooth
4. Microphone

The Kindle Fire HDX devices add:

1. GPS

2. Compass

The Kindle Fire HDX 8.9” offers a rear-facing camera in addition to the front-facing camera.

None of the Kindle Fire series support telephony (voice or SMS).

If your application truly needs any of those missing capabilities, you are out of luck.

If your application could use some of those capabilities but can get by without them, be sure to add the appropriate `<uses-feature>` elements to your manifest with `android:required="false"` (e.g., `<uses-feature android:name="android.hardware.camera" android:required="false" />`). Otherwise, your app will not be available for the original Kindle Fire if Android thinks that you really do need the capability (e.g., you have requested the CAMERA permission).

What Is Really Different?

All of the devices profiled in this part of the book are clearly different than what you are used to from an Android development standpoint. Some things, like availability of Bluetooth, will fit within the Android SDK’s framework for optional capabilities. Other things will represent where a device manufacturer has meandered farther from the Android device norm, in ways that may not be completely obvious to you, let alone your code.

The Menu Bar

As was noted previously in this chapter, the original version of the Kindle Fire runs Android 2.3, a version of Android not designed for tablets. Moreover, Android 2.3 was designed for devices that had dedicated off-screen options for HOME, BACK, and MENU buttons. However, Amazon apparently wanted to avoid such buttons, yet they lacked source code access to Honeycomb, where support for the system bar was added.

So, they faked it.

The Kindle Fire supports what Amazon refers to as the “menu bar”. This is akin to the system bar found on tablets running Android 3.0+, insofar as:

1. It appears at the bottom of the screen
2. It contains the HOME, BACK, and MENU buttons, along with a search button

However, unlike the system bar:

1. The menu bar disappears when not in use, in some cases
2. There is still a status bar at the top containing signal strength, battery level, time, etc.

Here, for example, is an application running on the original Kindle Fire:

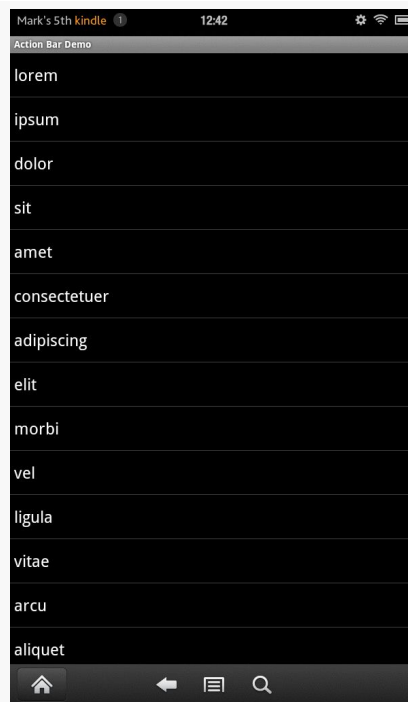

Figure 846: The original Kindle Fire, running a sample application, showing the menu bar

In this case, this is a normal activity, and the menu bar is always visible.

However, here is the same activity with `android:theme="@android:style/Theme.NoTitleBar.Fullscreen"` in the manifest:

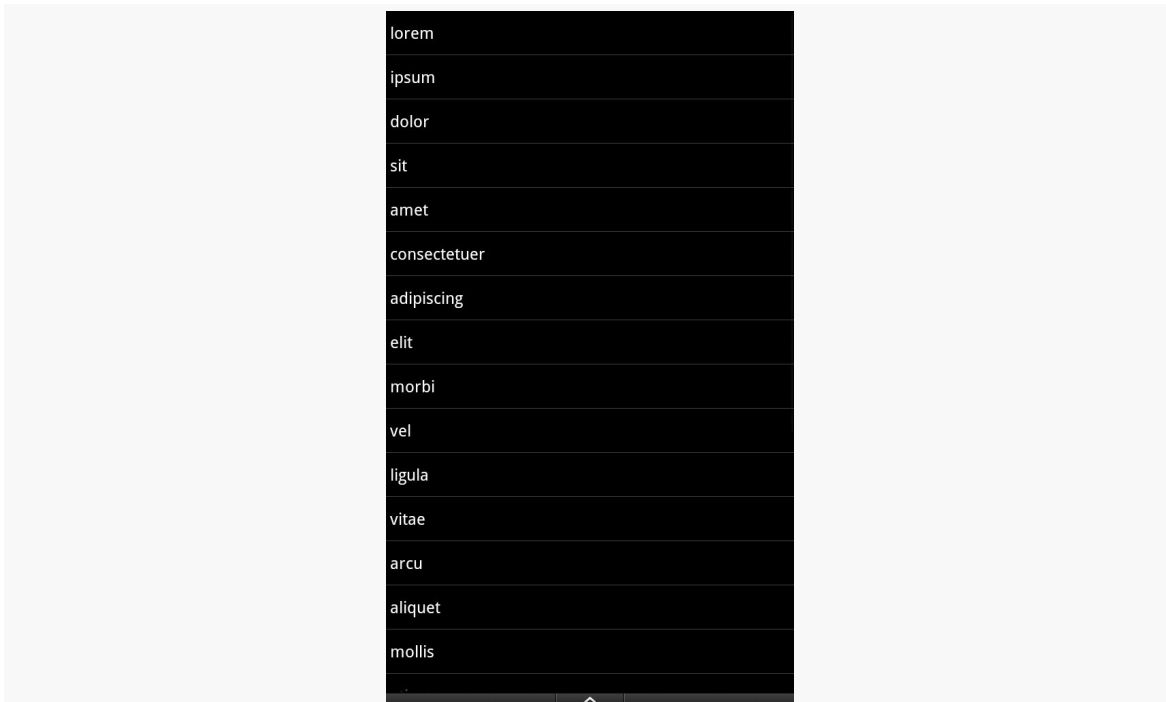

Figure 847: The original Kindle Fire, running a sample application, with the menu bar collapsed

Hence, if you set your activity to be full-screen, the status bar at the top goes away, and the menu bar shrinks to a smaller bar. Tapping on that bar brings back the menu bar, but this time overlaying the bottom portion of your activity.

Nothing Googly

The Kindle Fire lacks Google Maps, both the app and the library used for things like MapView.

The Kindle Fire lacks the Play Store and anything that depends upon it, such as [GCM](#).

The Kindle Fire lacks Gmail.

The Kindle Fire lacks anything from Google that is not part of the Android Open Source Project.

If your application depends on one or more of these, your app will not work well on a Kindle Fire without adjustments, though [some have alternatives from Amazon that can be used](#).

Sideloaded Limitations

If you enable the standard Android setting, you can install apps on the Kindle Fire from alternative sources, such as sideloading via USB. This is how the development tools deploy apps to a device when you are working on your app, and anyone can use this technique so long as they have the Android SDK (or at least enough to provide adb access).

However, there is one notable limitation of sideloading: icon quality.

When you submit your app for distribution through the Amazon AppStore, you will upload what they refer to as the “thumbnail” image. This is a 512x512 pixel rendition of your icon and is independent from any icons you may have put as resources in the APK file itself. When your app is installed from the Amazon AppStore, your thumbnail is downloaded as well and is used for the home screen carousel, among other things:

Figure 848: The original Kindle Fire home screen, with a high-resolution version of the QuickOffice icon

However, when you sideload an app, or install it off the Web, there is no “thumbnail”. The Kindle Fire will use your in-APK icon, no different than any other home screen. However, when it blows up your, say, 72x72 pixel icon to the large shelf in the carousel, it does not look very pretty:

Figure 849: The original Kindle Fire home screen, with a not-so-high-resolution version of the stock Android launcher icon

Things are somewhat better on the HD series:

Figure 850: Kindle Fire HD, with CommonsWare App Icon

Getting Your Development Environment Established

Developing for the Kindle Fire series is best accomplished using an actual Kindle Fire device. For example, there is no good way to simulate the behavior of the Kindle Fire menu bar using the standard Android emulator. That being said, having an emulator that at least resembles the Kindle Fire will be useful for debugging purposes, since you can do more with an emulator (e.g., run Hierarchy View) than you can with production devices.

Emulator Configuration

Amazon does not distribute an emulator image for the Fire, meaning that developers have to fake it as best they could using a stock emulator. This is fairly limiting, as the Fire does not look much like a standard Android emulator.

Briefly, Amazon was distributing an SDK add-on with emulator images, but that SDK add-on no longer seems to offer such images.

Note that the emulators in portrait mode get a bit tall, in terms of pixels, so be sure to use the scaling option in the AVD Manager to scale down the emulator so that it will fit your development machine's monitor.

Figure 851: Kindle Fire Emulator

The official original Kindle Fire emulator image also overcomes a limitation in the standard Android emulator image.

As mentioned earlier in this chapter, Gingerbread did not support tablets. More importantly, it had a snippet of code that assumes that devices running with the Kindle Fire's resolution must be `-xlarge`. In reality, the Kindle Fire (and other 7" tablets) should use a `-large` configuration. However, the standard Android emulator will use `-xlarge`. However, the official Kindle Fire emulator will correctly report the emulator as `-large`, matching the device.

Developing on Hardware

The Kindle Fire is ready for use with your development tools, once you teach your development machine how to have `adb` connect to the fire.

Linux and OS X users simply need to run `android update adb`, after having installed the Kindle Fire SDK components, to have the ADB USB entries added to the `adb_usb.ini` file.

On Windows, you will need to do that too, after doing some other things to unpack a local copy of the device drivers. Details for this process can be found in [the Kindle Fire developer documentation](#).

Note that the original Kindle Fire automatically switches into USB Mass Storage mode when you plug it into a PC using the USB cable. This means that apps on the Kindle Fire do not have access to external storage. You will need to unmount the Kindle from your development machine's OS and click the Disconnect button on the Kindle Fire's "You can now transfer files from your computer to Kindle" screen to be both connected via USB *and* allow apps access to external storage.

How Does Distribution Work?

Unlike the vast majority of Android devices, the Kindle Fire series lacks the Play Store. It is quite likely the most popular device ever shipped that does not include the Play Store, though it is far from the first. Hence, if you want your app to be available to Kindle Fire users, you will need to explore other ways of promoting and delivering the app.

Amazon AppStore

The primary way to reach Kindle Fire users is through the Amazon AppStore. This is Amazon's equivalent to the Play Store. And, unlike the Play Store, which is only available pre-installed on devices, any Android device can download an app client for the Amazon AppStore. That, coupled with Amazon's promotions like the "free app of the day", means that your app on the Amazon AppStore has reach beyond just the Kindle Fire series and future Amazon Android devices.

At a high level, publishing on the Amazon AppStore is not significantly different than publishing on the Play Store: you supply the APK and descriptive material to Amazon, and it gets listed. However, the devil, as they say, is in the details:

1. Your app will be reviewed by Amazon before publishing, and it may be rejected for the same sorts of reasons why apps are rejected from the iOS App Store, for anything from content concerns to poor programming practices

2. If you are trying to sell a paid app, Amazon holds final pricing decisions, and your prices on the Amazon AppStore cannot be higher than on other venues
3. Your app will be wrapped in Amazon-supplied code and re-signed by Amazon, so that if a non-Kindle Fire user uninstalls the Amazon AppStore client, your app will no longer run
4. And so on

This is not to say that distributing through the Amazon AppStore is intrinsically a bad idea. Because of some of these hurdles, plus the AppStore's much smaller user base, many developers are skipping it. This results in less competition and greater visibility for your app. However, you need to review all the Amazon AppStore developer rules and make decisions for yourself as to whether it makes sense for you and what you are trying to accomplish with the app.

In April 2013, Amazon also launched Coins, which is their replacement for Google's in-app purchasing model for the Play Store.

Alternatives

Because Amazon did not license the Play Store or other commercial components from Google, you cannot reach Kindle Fire users through the Market (except for those who install pirated versions of the Play Store client on their devices).

However, all other distribution vectors should work as they would on any other device. In addition to sideloading via USB, users can install apps off of the Web by visiting a URL in the device's browser (by default, Amazon Silk) and tapping on the link to the APK. This will trigger a download of the app — users can then tap on the Notification for the download to trigger an install. Similarly, one would imagine that other apps whose job is to download and install apps (e.g., enterprise app “markets”) should work normally as well.

Note, though, that all off-AppStore installs will have rough icons, so you will want to supply your icons in all densities, in hopes that the Kindle Fire will choose a higher-quality rendition of the icon.

Amazon Equivalents of Google Services

Since Amazon does not license the Google proprietary apps, the Kindle Fire series lacks common things like Google Maps.

However, Amazon has their own equivalents for some of these:

- The [Amazon Maps API](#) allows you to embed maps on Kindle Fire devices like you would embed Google Maps on more traditional Android devices
- The [Amazon Device Messaging API](#) is roughly analogous to GCM for pushing messages to a Kindle Fire device
- The [Amazon In-App Purchasing API](#) allows your apps to tie into Amazon Payments and the like for collecting fees from users inside your app

Getting Help with the Kindle Fire

Amazon maintains a set of documentation related to [Kindle Fire](#) and [Kindle Fire HDX](#) development, along with [a set of forums](#) for asking Amazon-specific development questions regarding the Kindle Fire or their various SDKs.

Amazon is also reported to monitor [the kindle-fire tag on Stack Overflow](#).

Device Catalog: BlackBerry

BlackBerry — formerly Research In Motion (BlackBerry) — is known around the world for their phones and messaging services. In 2011, they leapt into the tablet arena with the BlackBerry Playbook, and the 2.0 version of the Playbook OS supported running carefully repackaged Android applications.

While the Playbook itself had modest success, the ability to distribute Android applications to BlackBerry devices continues with their BlackBerry 10 platform. Many developers have enjoyed success distributing their app through BlackBerry World (the distribution channel for apps to BlackBerry products).

This chapter will describe a bit about what is involved in getting your Android app to BlackBerry devices.

I Thought BlackBerry Had Their Own OS?

They do.

However, current versions of that OS — this chapter was written when version 10.2 was the latest shipping version — contain an Android runtime environment. BlackBerry OS can run Android apps alongside apps written natively for BlackBerry OS or running on other runtimes (e.g., Adobe AIR). This gives developers a wide range of ways to get their app onto modern BlackBerry devices. However, it does mean that our apps may have somewhat less direct access to hardware, as there is another layer between us and that hardware.

What Else Is Different?

At its core, BlackBerry is a device manufacturer, no different than any other manufacturer that you may have dealt with previously. The biggest difference is BlackBerry's ability to run Android applications that you prepare for their devices.

That being said, the world of BlackBerry is a *bit* different than what you may be used to.

Hardware

BlackBerry makes phones with a variety of capabilities, much as do other manufacturers. You should be writing your apps to support a range of device characteristics, such as screen size and density. That will help you with BlackBerry support, just as it helps you with support for other manufacturers' devices.

Note, though, that BlackBerry has some history which will affect their device designs, and your apps by extension. Notably, BlackBerry has been renowned for their hardware keyboards. While not all BlackBerry devices today have such keyboards, it is likely that BlackBerry will ship keyboard-equipped devices for some time to come.

This has three impacts upon you as a developer:

1. Do not assume that the user is using a soft keyboard. Usually, this is not a problem from a programming standpoint, though you may wish to take it into account in documentation.
2. Do not assume that the user always uses the touchscreen to navigate. Some BlackBerry users may use the hardware keyboard for navigation. This is particularly true for users who gravitate towards hardware keyboards for accessibility reasons. Your app should support [proper focus](#) to allow it to be navigated without accessing the touchscreen, to the greatest extent possible.
3. BlackBerry keyboards often have not been "slider" keyboards (i.e., ones that might slide under the display when not in use). Rather, they are always available, below the screen. This will often result in somewhat smaller screen sizes, and odd aspect ratios, compared to what you are used to. There simply is not enough room for a large touchscreen *and* an always-available physical keyboard without having an excessively large device. The BlackBerry Q10, for example, has a 720x720 resolution screen, and most Android developers do not encounter square screen resolutions. You will need to take this into

account, but only in cases where such an aspect ratio might cause you problems (e.g., full-screen image backgrounds).

BlackBerry OS 10.2

Beyond the hardware, the BlackBerry OS — and the Android runtime environment that executes our Android apps — puts some limits on what we can do in our apps. Of note:

- BlackBerry OS 10.2's Android environment uses Android 4.2 (API Level 17), so apps that have an `android:minSdkVersion` higher than that will not be eligible to run on 10.2 devices.
- Some classes will be non-functional, particularly those related to telephony capabilities. You cannot use `SmsManager`, for example.
- Some types of apps will not work well, because the Android runtime runs alongside other non-Android apps on the hardware. Replacement home screen implementations, for example, are unlikely to work. Similarly, background apps that display a UI (e.g., Facebook “chatheads”-style popups) using `SYSTEM_ALERT_WINDOW` are unlikely to work.
- App widgets are not supported. So long as the app widget is a non-essential feature of your app, this should not be a problem — after all, the user does not *have* to use your app widget on any Android device. However, if the *sole purpose* of your app is to provide an app widget, such an app will not be useful on BlackBerry.
- Accounts via `AccountManager` are apparently not supported.
- Not all connectivity is surfaced in the Android runtime from the underlying hardware. Bluetooth Low Energy (BLE), Wi-Fi Direct, NFC, and direct USB access are all unavailable.

Note that at the time of this writing (mid-2014), a BlackBerry OS 10.3 version is being beta-tested. This is slated to lift some of these restrictions and limitations, including:

- The Android runtime will be based on Android 4.3, giving you access to API Level 18 classes and methods
- `AccountManager`, Bluetooth LE, and NFC support should be added

Navigation

Like most Android tablets, BlackBerry devices offer little in the way of physical or off-screen navigation buttons. For example, there is no BACK button. However, a navigation bar will contain a BACK soft button for users. If your app takes over the full screen, this bar will not be there all the time, but a swipe down from the top of the screen should expose it.

Similarly, your menu will not be accessed via a MENU key, but rather via a downward swipe to expose the menu. This also means that any special MENU-button logic of yours may not work, if you are using the MENU button for things other than displaying the action bar overflow or other form of options menu.

Nothing Googly

As with other devices cited in this book, the BlackBerry series of devices lack support for Google's proprietary apps. For app developers, this means that you lack access to Google Play Services and the various APIs exposed by it, such as [Maps V2](#) and [Google Cloud Messaging](#).

BlackBerry does offer its replacement for GCM, in the form of the [BlackBerry Push Service](#). However, for maps, they steer you towards using [geo: Intent structures and startActivity\(\)](#). BlackBerry OS 10.2.1 also supports apps using the old Maps V1 APIs, for which BlackBerry has created their own implementation, backed by OpenStreetMap.

If you are dependent upon other APIs offered by Google Play Services (e.g., [LocationClient](#)), you will need to reconsider your use of those APIs if you wish to ship on devices that are outside the Google ecosystem.

Package Name Length

The BlackBerry Android runtime only supports package names of 29 characters or less. The build tools will fail if your package name is longer than 29 characters.

Note that this should only pertain to the “application ID” role of a package name, not the “hey, where does R.java get generated?” role of the package name. Hence, it should be possible to replace the application ID of your app via a [Gradle for Android product flavor](#), to give yourself a shorter identifier while not breaking your source code references to resources.

What Are We Making?

This might seem like an odd question. After all, the point of this chapter is to make an Android application that can run on BlackBerry devices.

Up until early 2014, that meant you had one option: write a BAR.

A BAR (BlackBerry ARchive, presumably) is a repackaged version of an Android APK, designed to be distributed by BlackBerry and installed on BlackBerry devices. Most of [the tooling supplied by BlackBerry](#) surrounds this process of validating that an APK should abide by BlackBerry's requirements and converting that APK into a BAR.

With the release of BlackBerry OS 10.2.1, though, BlackBerry device users can download and install an APK directly. That APK still needs to work within the confines of the BlackBerry Android runtime and must avoid things that will not work there (e.g., replacement home screens). But the user is no longer reliant upon the developer going ahead and creating a BAR file.

At the present time (mid-2014), it appears that the BAR format is still required for distribution by BlackBerry itself through [BlackBerry World](#). Hence, the APK installation option is mostly there for user benefit, for users who install various Android “market” apps and wish to try some of those apps on their BlackBerry devices.

Getting Your Development Environment Established

By and large, developing an app to run on the BlackBerry OS Android runtime is the same as is developing an app to run on any other Android environment. You have your standard choices of IDEs and other development tools, the ability to use third-party libraries, and so forth.

Where things start to differ is in testing, where BlackBerry OS ships a [Simulator](#) that fills a role similar to that of the Android emulator. To use the Simulator, you will need to package your app into a BAR file, and BlackBerry provides tools to assist you in that process as well.

Checking and Repackaging Your App

There are two basic technical steps for preparing your app for distribution through [the BlackBerry World market](#).

The first is to validate that your app does indeed stick to APIs that are supported by the BlackBerry Android runtime. This helps prevent apps from appearing on BlackBerry World that are guaranteed to fail.

The second is to convert the APK into a BAR file. BAR files are used for all of the BlackBerry OS runtimes, including ones like Adobe AIR. Your BAR will contain the same stuff that is in your APK, plus some additional metadata, in a format shared by all of the other runtimes, for interpretation and use by the BlackBerry OS.

At the time of this writing (mid-2014), there is a beta edition of an Android Studio plugin available for you to try. In terms of release versions of tools, though, your choices are an Eclipse plugin or command-line tools.

All of these tools are available from [the BlackBerry Android developer site](#).

Eclipse Plugin

BlackBerry publishes an Eclipse plugin that will handle most of the chores for you: test your app for compatibility, convert it into a BAR, apply signing keys, etc. This plugin is certified for use on Windows, OS X, and Linux. This plugin also supports the creation of run configurations to deploy your app to a device or simulator, including supporting IP-based debugging.

Command-Line Tools

The only option available for Linux are the command-line tools (though these also support Windows and OS X).

The main tool is `apk2bar`, which creates a BAR file out of the APK file. It, in turn, will run `apk2barVerifier`, which performs a validation check to see if you obviously use or do something that makes your app incompatible.

To test the BAR, `batchbar-deploy` will upload one or more BAR files to a device or running copy of [the Simulator](#). This works with unsigned and signed BARs.

To distribute the BAR, you will need to sign it, much like you need to sign an APK to be distributed through major channels. The signing process for BlackBerry OS is a bit complex when compared to the APK signing process.

BlackBerry 10 Simulator

BlackBerry distributes VMWare images that embody a BlackBerry 10 Simulator. You can use these with VMWare Player (Windows and Linux) or VMWare Fusion (OS X), versions 3.1 or higher.

The Simulator fills a role similar to that of the standard Android emulator, allowing you to test your apps for BlackBerry OS without necessarily having a Blackberry OS 10.2+ device, or for testing scenarios that are difficult to test with actual hardware.

In particular, the Simulator offers a wide range of simulated input and output, including:

- Simulated sensor input for the accelerometer and ambient light sensor
- Using a development machine's Bluetooth adapter for testing Bluetooth
- Simulated NFC tags

In addition, the Simulator supports some of the same types of simulated input that you see with the Android emulator, such as simulated GPS fixes and simulated incoming phone calls.

The VMWare image will have its own IP address, which you can obtain from the Simulator running in the image. You can then deploy your BAR to it using the Eclipse plugin or the command-line `blackberry-deploy` tool.

Developing on Hardware

A BlackBerry OS 10.2+ device can run either signed or unsigned BAR files. Unsigned BAR files, though, require a one-time upload of a “debug token”, the creation of which requires the same credentials as you would use to sign the BAR in the first place.

How Does Distribution Work?

As with any environment where the Play Store is not available, developers have to determine how best to get their apps to the users of BlackBerry devices.

As with most non-Play Store ecosystems, there is the official solution... and then there are the other solutions.

BlackBerry World

BlackBerry's own "market" is BlackBerry World. This supports native BlackBerry apps, plus those for runtimes like the Android runtime. So long as your app is packaged as a BAR, it should be able to be released through BlackBerry World, much like how you distribute an APK through the Play Store.

BlackBerry World is a curated marketplace, meaning that BlackBerry staff will review your app submissions and may reject them if they violate requirements or other terms.

Beyond that, BlackBerry World has most of the standard capabilities that you would expect from an app market, such as paid apps, in-app purchases, multiple billing options (PayPal and carrier billing), control for distribution to various countries and mobile carriers, etc.

Alternatives

Starting with BlackBerry OS 10.2.1, you can distribute APK files through your Web site or similar means, and BlackBerry users can download and install them. However, nothing is done to validate that the apps you download will work on BlackBerry OS's Android runtime, as they may use APIs that are not available. [IOW](#), [YMMV](#).

(though, since BlackBerry is a Canadian firm, perhaps that should be [YKMOV](#))

Also note that the BlackBerry OS settings have an equivalent to the Android "allow apps from other sources" setting that must be enabled for such installation to occur.

As an example, you can install the [F-Droid "market" app](#) to download free and open source Android apps to a BlackBerry OS device. How many of the apps distributed through F-Droid will work on BlackBerry OS, besides F-Droid itself, is unknown.

Device Catalog: Wrist Wearables

A new growth area in mobile technology is the rise of the “wearable”: a device designed to be worn on the body in one way or another.

Figure 852: NOTE: Clocks Are Not Normally Considered “Wearables” (image courtesy of Wikimedia Commons)

While large timepieces are not in the domain of what we think of as “wearables”, the humble wristwatch has been converted into a new location for computing power. Major manufacturers, such as Samsung and SONY, have launched forays into wrist wearables, and Google has pushed forward with its Android Wear initiative.

In this chapter, we will cover some of the players in the wrist wearable space and what things you may need to think of as you look to start developing apps for such items.

Note that this chapter is focused on general design/implementation issues. Specific coverage of Android Wear, with respect to notifications, can be found in [the chapter on advanced notifications](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book.

Divvying Up the Wearables Space

For the purposes of this chapter, we will consider wearables along two axes:

- What OS does the wearable run?
- What OS can we use for developing apps for the wearable?

Devices vs. Accessories

For this chapter, a “device” is a wearable that runs a recognized mobile operating system. Mostly, right now, that is Android, for devices like the Android Wear watch series, the Omate TrueSmart, and the I’m Watch. In principle, in the future, other operating systems used on phones or tablets could make the jump to run directly on the wearable.

In contrast, an “accessory” is a wearable that runs... something else. Usually, this is some proprietary OS, one we do not work with directly. So, the Pebble smartwatch is an accessory, as the Pebble runs its own OS, not something like Android that is popularly used on phones and tablets.

App OS

In the case of devices, usually we will write apps for the OS of the device. Writing an app for the Omate TrueSmart is reminiscent of writing an app for a small-screen Android phone, for example. Writing apps for Android Wear are a bit different, in

that Google has a specific way to package those as part of an app for a mobile device, but otherwise it is relatively similar.

In the case of accessories, the accessory maker may have provided SDKs to allow for apps to be created that run on a phone or tablet that the accessory is tethered to. Basically, the phone or tablet provides the “brains”, while the accessory is simply a very tiny input/output terminal. Since this book is on Android application development, either an accessory supports apps that run on Android, or it does not (e.g., it only supports iOS at the moment).

NOTA (None Of The Above)

Some devices do not fit these buckets, for the simple reason that they do not support app development of any kind at present. For example, the first-generation Galaxy Gear from Samsung, and the Qualcomm Toq, are closed environments. In the case of the Toq, it is unclear if anyone has an SDK for it. In the case of the Galaxy Gear, Samsung appears to have a private SDK that they have made available to select partners, eschewing the broader Android development ecosystem for the time being.

Example Wrist Wearables

The following sections outline several wrist wearable devices. This is not meant to be an exhaustive list. Instead, it is here to give you a sense of what is available, both in terms of brands and opportunities for app developers.

Android Wear

Google announced the Android Wear initiative at Google I/O 2014, and the first devices soon followed. Some are square (e.g., Samsung Galaxy Gear), while others are round (e.g., Moto 360). All are wearable devices, as they run Android 4.4W, which is standard Android minus a few things, like WebView.

Fitbit

Fitbit is a wrist wearable, one with only a few LEDs for output, designed almost exclusively for collecting sensor input (e.g., pedometer). While the Fitbit site offers an API, it is not an API to the Fitbit wearable, but rather to a Fitbit Web service, for retrieving Fitbit results. As such, the Fitbit does not qualify as either a device or an accessory in terms of this chapter’s model.

I'm Watch

The [I'm Watch](#) was one of the first wrist wearable devices, running Android. The I'm Watch runs Android 1.6, which works well in limited hardware, and with only 128MB of RAM and a ~400MHz CPU, the I'm Watch hardware is limited. From the standpoint of Android developers, Android 1.6 is “rather long in the tooth”, as most developers have abandoned Android 1.x development, and many have even stopped worrying about Android 2.x.

The I'm Watch offers a 1.5", 240x240 pixel screen, 4GB of on-board storage, and a couple of sensors (accelerometer and magnetic field). Distribution of apps for the I'm Watch is handled through the manufacturer's own storefront, though developers can deploy apps through adb.

MetaWatch

[MetaWatch](#) was born out of [a Kickstarter project](#). It is an accessory, running some tiny OS of its own, designed for “widgets” (MetaWatch apps) to be powered by a tethered device. Alas, [momentum seems to have stalled on their app SDKs](#), and so there does not appear to be a well-supported way to create apps to run on Android devices that push content to the MetaWatch.

Omate TrueSmart

[Another Kickstarter](#) was for [the Omate TrueSmart](#). This is a wearable device, powered by Android 4.2. Writing apps for the Omate TrueSmart closely resembles developing apps for a tiny Android phone.

The hardware specs are more in line with modern devices, when compared with the I'm Watch:

- Dual-core ARM 1.3GHz CPU
- 512MB or 1GB of system RAM
- 4–8GB of internal storage, plus microSD expansion
- 1.5" 240x240 touchscreen
- WiFi, mobile data, and Bluetooth

As of February 2014, the Omate TrueSmart has shipped to most of its Kickstarter backers and should be available for sale to others shortly.

Pebble

Of course, the Kickstarter that, um, kick-started the whole “Kickstart-a-wearable” phenomenon was [the Pebble smartwatch](#). The [Pebble](#) is an accessory, where the on-board OS runs apps written in C that can optionally communicate with Android or iOS apps running on tethered devices.

Qualcomm Toq

Qualcomm, in late 2013, decided to get into the wearables game directly, via their [Toq smartwatch](#). This is an accessory, designed to work in conjunction with an Android device. In February 2014, Qualcomm released [an SDK](#) to allow Android developers to create apps that can work with the Toq.

However, the license terms for this SDK contain clauses that should be discussed with qualified legal counsel, including:

- granting Qualcomm the right to modify and demonstrate your application to whoever it wants to;
- precluding the development of apps (or libraries) that employ a number of popular open source licenses;
- prohibiting distribution of an app without Qualcomm’s prior written permission; and
- giving Qualcomm the right to tell you to uninstall your app, from any device, at any time, for any reason

Samsung Gear Series

One of the bigger brands to get into wrist wearables has been Samsung, with their Galaxy Gear device. The Galaxy Gear is a device, running Android. However, as of February 2014, there is no publicly-available SDK for writing apps for this device, nor any officially-supported means of installing third-party apps on the device. You can load apps on it via `adb`, though this is not supported and has substantial limitations (e.g., no Internet access).

In February 2014, Samsung announced the Gear 2 and Gear 2 Neo. These are devices, but running Tizen, not Android. Samsung released an SDK for these devices](<http://developer.samsung.com/samsung-gear>) in March 2014.

In February 2014, Samsung also announced the Gear Fit. This *does* have an SDK (as part of Samsung's overall mobile SDK package), and qualifies as an accessory.

SONY SmartWatch and SmartWatch 2

SONY is another major brand to get into wrist wearables. In fact, they were the first major brand to do so, debuting their [SONY SmartWatch](#) back in 2012. SONY then released the SmartWatch 2 in 2013. Both are accessories, where the apps for the SmartWatch actually run on a tethered Android device, with the SmartWatch serving as a display surface and input mechanism (via simple taps and gestures on the touchscreen).

That Theorized Apple Watch

Of course, the brand that everyone is waiting for to get into the wearables space is Apple. There have been rumors of an “iWatch” for quite some time, though with no actual device having been released as of February 2014.

WIMM One (RIP)

There used to be a firm called WIMM Labs, which made a wrist wearable device called the WIMM One. The device was much along the lines of the I'm Watch and Omate TrueSmart, falling roughly in between them in terms of Android OS version and hardware capability. Their approach was to be more of an OEM, though, looking to supply branded versions of the WIMM One to firms who might want a wearable but were not in that technology space, such as clothiers like Nike.

Google acquired WIMM Labs, at which time the WIMM One was pulled from the market. Some of the WIMM Labs capabilities perhaps moved into the Google Glass project, though it is certainly possible that Google could offer a “Nexus Watch” sometime in the future.

Strategic Considerations

Before leaping into extending your app to support wearables of any sort — ones worn on the wrist or otherwise — you really need to spend some time thinking about whether or not this is the best thing for you and your users.

Do We Bother?

While wearables are touted as “the next big thing”, there have been plenty of such “things” that have never gotten to be that big. This is not to suggest that wearables will go the way of [tree-style Web site directories](#), but they may not become quite as popular as the phones and tablets they are meant to accompany.

While developing for wearables has a “cool factor”, the time you spend on wearables is time taken away from other things. For developers, you lose time that you might have spent on other features of your app. For independent developers, the time might come out of your time budgets for marketing or product research.

While a pure hobbyist might pursue wearables just because it is an interesting area to get into, many other developers need to weigh whether adding wearable support will be worth the time investment.

Which Types?

Developing apps for Android wearable devices, like the Omate TrueSmart and the I’m Watch, is comparatively straight-forward. Device limitations may cause you to spend some more development time, such as crafting a UI that works well on ~1.5" displays. And, depending on the device, you may have to use alternative APIs for some basic operations — the WIMM One, for example, did not have its own WiFi or mobile data, and so you had to wait until the WIMM One told you it was safe to try Internet operations, when the device was tethered to a phone that had its own connectivity. But, at the end of the day, it is still the same Android development that you have come to love (or at least tolerate, occasionally through gritted teeth).

Accessories, or devices running other mobile operating systems, require custom development. And, since there are no standards in this area yet, it usually requires per-device custom development. This may be a graceful extension of logic you already have, such as repurposing your app widget code to use for a watch. But the APIs for delivering content to, say, a SONY SmartWatch do not closely resemble app widget APIs, which will require some restructuring of your code, in addition to the SONY-specific work. How little or how much work this is will vary by app and, secondarily, by wearable.

Which Devices?

Once again, developing for Android wearable devices may be a small enough leap that you could consider them as a matter of course. This is especially true of “pure” enough devices that your business logic will just work, with only a watch-sized UI being needed. It may be that one pulse of work can get your app working on multiple Android wearables that share common capabilities (similar screen sizes, standard connectivity, etc.).

However, beyond that, you are going to need to consider whether developing for a specific wearable is worth the specific work. For example, many of these wearables use their own “market” or “store” for app distribution. Will listing your app in their market get you enough results to make the work worthwhile? Will the wearable maker offer any sorts of co-marketing opportunities, to help promote your app? Does their market offer things that you are used to from more traditional markets, like in-app purchases, that your app uses? Is your app so tightly tied to the Play Services Framework (e.g., Maps V2, GCM, LocationClient) that it simply cannot be distributed by any other means?

So, for example, the I’m Watch has their own store, and you will be limited by the capabilities of that store. SONY, on the other hand, expects apps for their SmartWatch line to be distributed however you want, particularly through the Play Store, which gives you more options.

Tactical Considerations

Given that, for strategic reasons or “just because”, you have decided to go ahead and work on extending your app to wearables, there are a variety of things you are going to need to think about as you start in on that work. A lot of the details will vary by the specific wearable device or accessory you are trying to support, but some common themes will emerge. Some of those themes are discussed in this section.

The Postage Stamp User Interface

When writing apps to display to televisions — whether for a dedicated box like an OUYA game console or for [an external display](#) attached to a traditional touchscreen device — you think of the “10-foot user interface”. Here, “10-foot” is not referring to the size of the television (usually), but the distance between the viewer’s eyes and the television. Even though you may have a nice 1080p television, you sit so much farther back from it than you do a 1080p phone or tablet, that the UI needs to take

this into account. Also, input options for a television tend to be different than on a phone or tablet, as televisions rarely are touchscreens.

Writing apps for wearables has a similar UI distinction, though in a much smaller dimension. Trying to determine how best to package your content to be accessible on a ~1.5" screen is tricky.

One approach is to consider your app widget, if you have one. An app widget on a phone or tablet often times takes up a watch-sized chunk of space on the home screen. Also, app widgets have constrained forms of user input (simple taps, scrolling or swiping only on select widgets like `ListView`), matching the constraints imposed by some wearable APIs and by the reality of large fingers and small touchscreens.

Your UI design for your app widget may be a fine starting point for your UI design for your wrist wearable. In some cases, the same UI will work, while in other cases, some tweaks may be required:

- You designed your app widget to be rectangular, rather than square, so a slight redesign will be needed to take best advantage of a (roughly) square smartwatch display
- You designed your app widget with `ListView` at its core, but the particular wearable you are targeting does not support `ListView`, so you have to revert to other UI structures
- You designed your app widget around a rich color screen, but the wearable that you are supporting offers a more limited color palette, due to its use of particular types of display technology (e.g., “e-ink”)
- And so on

Connectivity (Or Lack Thereof)

Some wearables have their own WiFi radios. Some have their own mobile data options, if they are outfitted with a suitable SIM card. If these are devices, writing an app for the device’s operating system should allow you to connect to the Internet more or less as you do with an app for a phone or tablet.

Some wearables have apps that run on the device, but the device lacks any native Internet connectivity. In that case, you may have access to some APIs that allow you to work with an app on a tethered phone or tablet, and be able to access the Internet that way.

Wearables where the app itself runs on the phone or tablet return you to regular connectivity options, as the wearable does not need independent Internet access.

In sum, how well you can get to the Internet is partly determined by the nature of the wearable, and partly determined by normal mobile development practices (e.g., are we connected to WiFi?).

Power (Or Lack Thereof)

The Omate TrueSmart is one of the larger wrist wearable devices. It has a 600mAH battery, a fraction of the size of batteries in most Android phones, let alone tablets.

On the one hand, a wearable will tend to draw less power, simply because the wearable manufacturer will have taken steps to minimize power drain. One example is turning off the LCD more aggressively than you might expect to see on a corresponding phone or tablet.

That being said, power drain is an issue on phones and tablets already; it will be that much worse in the world of wearables. In some cases, you have *two* batteries' worth of power to consider: the wearable's own battery, plus the battery of some phone or tablet (particularly in the case of an accessory, where the app runs on that phone or tablet).

Security (Or... Well, You Get the Picture)

Few, if any, wearable devices offer much in the way of on-board security, such as full-disk encryption, or even a PIN or password for access. That is because a wearable is designed for rapid access, and such security usually impedes such access. The assumption is that if the wearable falls into the wrong hands, that anything on the wearable is subject to inspection.

As such, you need to be a bit careful about what you use the wearable for. Most apps involving a wearable may have limited security requirements, but not all. Wearable devices, in particular, have the risk that they offer some amount of on-board storage that your on-device app can use, making it somewhat more likely that you might try actually storing something there... something that the user might want to keep secret.

Similarly, the communications between a wearable and a tethered phone or tablet may be insufficiently secure. For example, Bluetooth communications may be secure, [or they may not](#), depending on hardware and circumstances.

This does not prohibit the creation of secure wearable apps, but it make it more difficult.

What About Android Wear?

[Android Wear](#) is an initiative by Google for wearable devices, with a particular emphasis on wrist wearables. This book will cover Android Wear in a future edition.

Device Catalog: Android TV

Google not only offers the Chromecast, but also offers Android TV as a way to get content “into the living room”. Android TV devices — whether they be set-top boxes or are integrated into televisions directly — run Android apps directly, unlike Chromecast. Android TV, therefore, is a competitor to devices like [Amazon’s Fire TV](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on [“ten-foot” user experiences](#) is also a good idea.

Hey, Wait a Minute... I Thought the Name Was “Google TV”?

You can be forgiven for any confusion over the names.

Google TV was Google’s initial attempt to get content onto televisions. Debuting in 2011, Google TV has some of the same characteristics as does Android TV:

- It ran Android apps directly (at the time, on Android 3.1)
- It could be a dedicated set-top box, integrated into other sorts of media players (e.g., Blu-Ray), or integrated into televisions

However, Google TV did not prove all that popular.

In 2014, Google announced that they were no longer supporting app development for Google TV, much to the consternation of the ~17 people still using Google TV devices.

That being said, designing an app for Android TV resembles designing an app for Google TV or for any other [“ten-foot” user experience](#). Hence, design guidance that you may run across for Google TV may have some tips that are still relevant for Android TV and other TV-centric Android environments.

Some Android TV Hardware

Android TV debuted in 2014. However, as of the end of 2014, there were a total of two Android TV device models... both available from Google. While other manufacturers had announced plans regarding Android TV, none were available at the time of this writing.

ADT-1

When Google TV was announced, there was a similar lack of hardware. To help ensure that there were TV-capable apps at the time of a wider Google TV rollout, Google offered free developer devices to various firms and solo developers.

Google did the same thing with Android TV, where they offered a free ADT-1 device to qualified registrants. While deliveries of the ADT-1 were spread out over a few months, they generally arrived significantly in advance of production Android TV hardware.

Figure 853: ADT-1 Developer Android TV Device

Nexus Player

The first production-grade Android TV device is Google's own Nexus Player. As with the ADT-1, the Nexus Player has an HDMI port for connecting to a TV (or projector, monitor, etc.). It also has its own remote control and power adapter.

Figure 854: Nexus Player Android TV Device

Both the ADT-1 and the Nexus Player are presently running Android 5.0.

What Features and Configurations Does It Use?

Android has built into the SDK a fair bit of device flexibility. Most of this comes in the form of configurations (things that affect resources) and features (other stuff). If your application can handle a range of configurations and features, or can advertise that they need certain configurations or features, they can handle Android TV or arrange to not be available for Android TV on the Play Store.

Screen Size and Density

Android TV devices are always categorized as xlarge screen size.

Densities, however, are a bit more complicated.

Android TV is for use with HDTV, whether Android TV is integrated into the television or it comes as an external set-top box. There are two predominant HDTV resolutions, known as 720p (1280x720) and 1080p (1920x1080). A 1080p television

will be categorized as an xhdpi density device. A 720p television will be categorized as a tvdpi device. tvdpi is for devices around 213dpi, in between mdpi and hdpi. In practice, you might elect to skip tvdpi for your drawable resources, allowing Android to resample your mdpi, hdpi, or xhdpi drawables as needed.

Input Devices

Android TV will not normally be navigated using a touchscreen. Instead, the normal form of input will be a D-pad remote. Developers will need to ensure that their apps are navigable this way.

Other Hardware

Android TV has no sensors, no camera, no microphone, and no telephony features. As such, any application requiring such features will not run on Android TV and will not even show up in the Play Store for such devices.

Bear in mind that some of these will be driven by permissions. If you ask for the SEND_SMS permission, Android will assume you need android.hardware.telephony unless you specifically state otherwise, via a <uses-feature> element for android.hardware.telephony with android:required="false".

What Is Really Different?

Beyond the features and configurations, there are other things about Android TV that will depart from what you might expect for an Android environment, due to the nature of the TV set-top box platform and the Android implementation upon it.

Overscan

Since Android TV typically uses a television for its primary output, overscan can be an issue. Addressing overscan is covered as part of [the chapter on the “10 foot UI”](#).

Ethernet

While Android TV devices will generally be connected to the Internet, it may not be via WiFi. Since Android TV devices generally are not portable, some will have Ethernet jacks, and hence some users will elect to wire in their Android TV as opposed to using WiFi.

The upshot is that you should not assume that `WifiManager` will necessarily give you useful results. Also, `ConnectivityManager` should report wired Ethernet as `TYPE_ETHERNET`, added in API Level 13, when you call methods like `getActiveNetworkInfo()`.

Location

Generally speaking, Android TV devices will tend not to move, earthquakes and large dogs notwithstanding.

As such, Android TV devices do not have GPS receivers. Rather, location is determined in an approximate fashion via address-based lookups, using a postal code. Hence, asking Android for a GPS fix on a Android TV device will be ineffective.

However, since users of Android TV devices tend not to be moving much at the time, it is a bit more likely than normal that they will want information about some location other than where they are. If your app is exclusively tied to providing information about their current location, you may wish to consider how you could extend your app to help users get information about other places that they may be interested in.

Media Keys

Android TV devices are usually manipulated by remote controls. Some of these remotes will have lots of buttons, such as media-specific buttons for play, pause, etc.

The `KeyEvent` class has had support for some media buttons since API Level 3, mostly for use with wired headsets. API Level 11 added a bunch more media buttons. Your Android TV application may wish to respond to these, via `onKeyDown()` in a `View` or `Activity`.

In particular, an Android TV application should not be using on-screen controls for play, pause, etc., as they take up screen space that probably could be put to better use. Rather, use layouts that offer such controls for touchscreen devices (e.g., phones and tablets) but rely on the media buttons for non-touchscreen devices.

Getting Your Development Environment Established

Android TV emulator images are available in the SDK Manager for Android 5.0 and above:

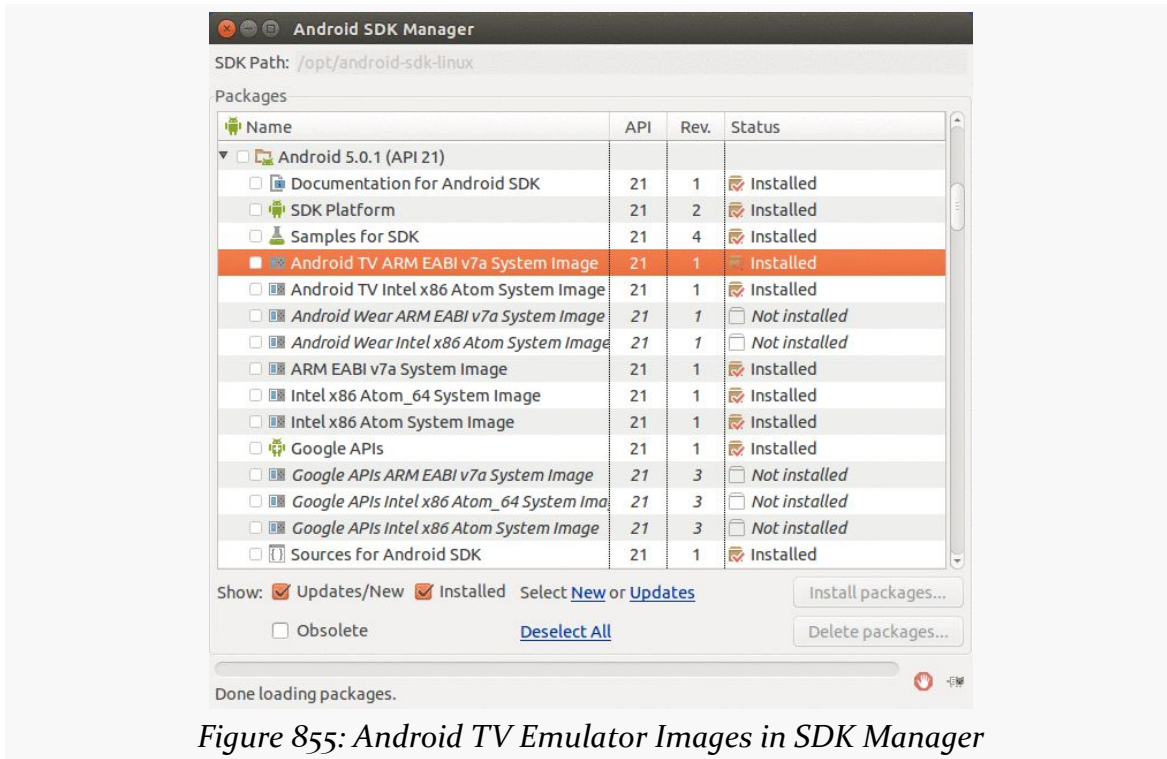

Figure 855: Android TV Emulator Images in SDK Manager

Your AVD Manager can then help you set up TV emulator images, for rather large theoretical screen sizes:

DEVICE CATALOG: ANDROID TV

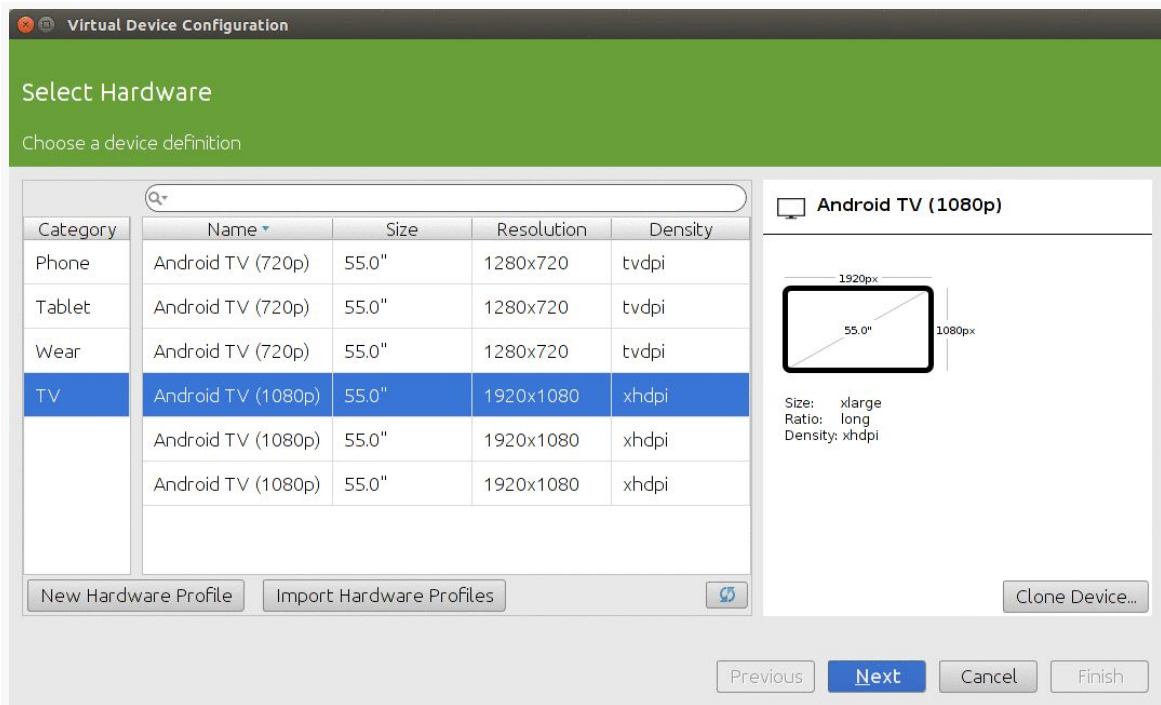

Figure 856: Android TV Hardware Profiles in AVD Manager

The rest of the emulator setup is the same as you would have for phone or tablet emulators.

The emulator even has “leanback” UI characteristics, rather than a standard Android emulator home screen:

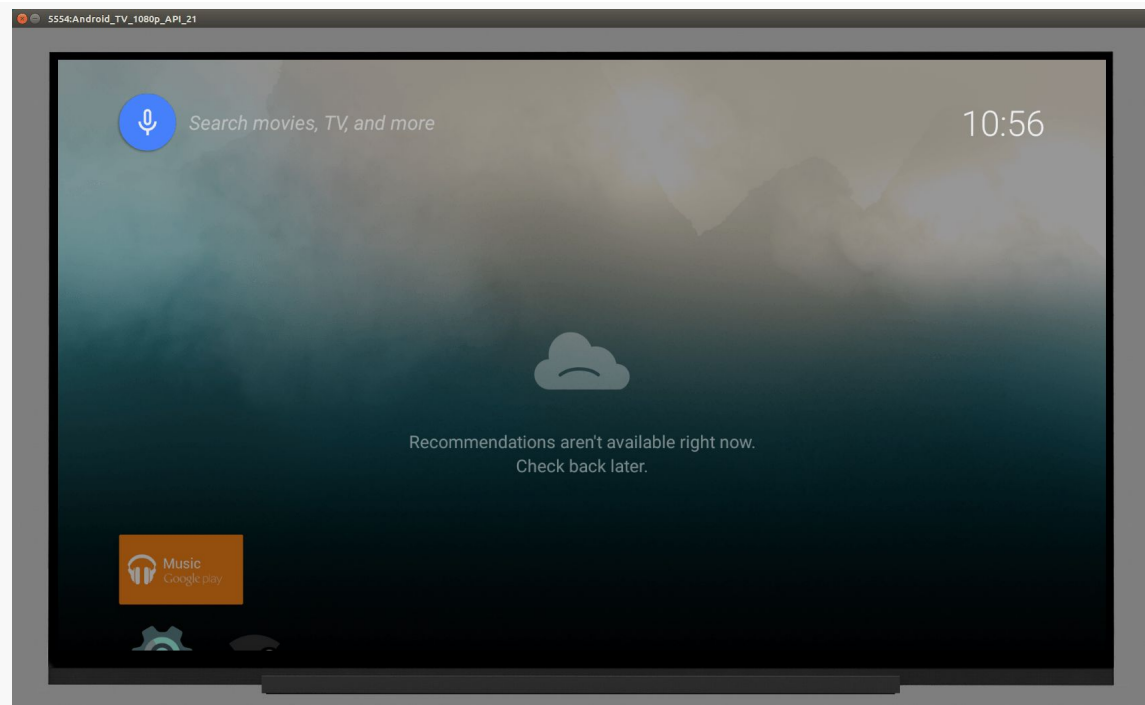

Figure 857: Android TV 1080p Emulator, As Initially Launched

Connecting to Physical Devices

The ADT-1 and Nexus Player have micro-USB ports for debugging purposes. This, though, requires that your player and your development machine be with USB cable reach of one another. The author of this book uses [a pico projector](#) to be able to work with TV-native devices (Android TV, Fire TV, etc.) or external displays (HDMI, MHL, etc.).

To enable an Android TV for debugging, you will need to enable developer options, much like you do for a mobile device (click on the build number 7 times in the Setting's About screen). Then, in the "Developer Options" screen, you can go into Debugging and elect to enable "USB debugging".

How Does Distribution Work?

Your app probably falls in one of three buckets: you want it on Android TV (along with other devices), it *only* supports Android TV, or it will not work on Android TV. Whichever of those buckets best fits your device will determine the manifest

settings you will want to ensure that the Play Store (and perhaps other third-party markets in the future) will honor your request.

Getting Your App on Android TV

The first criterion for getting your app visible to Android TV devices on the Play Store is to add a `<uses-feature>` element to your manifest, indicating that you do not require the `android.hardware.touchscreen` feature:

```
<uses-feature android:name="android.hardware.touchscreen"
android:required="false"/>
```

By default, Android assumes that you need a touchscreen, and so without this clarification in your manifest, you will not appear in the Play Store.

Also, add similar `<uses-feature>` elements for any hardware that you might like to use where available but do not absolutely need, particularly hardware that Android TV may lack. The [documentation](#) outlines the features that Android TV devices will likely lack.

You need to have an activity that has an `<intent-filter>` for `ACTION_MAIN` and `CATEGORY_LEANBACK_LAUNCHER`. This will be your launcher activity on Android TV devices, instead of your `ACTION_MAIN/CATEGORY_HOME` activity. Of course, you are welcome to have one activity serving as the launcher for both types of devices, if you can come up with one with a solid presentation for both mobile devices and TVs.

In addition, do not have any activities with `android:screenOrientation` set to `portrait`, as Android TV devices always display in landscape

Supporting Only Android TV

If your app only supports Android TV, in addition to the above requirements, you should also add one more `<uses-feature>` element to your manifest:

```
<uses-feature android:name="android.hardware.type.television"
android:required="true"/>
```

This will filter you out of the Market for all non-TV environments.

Avoiding Android TV

If your app specifically is untested on Android TV, you need to have something in the manifest that will keep you *off* Android TV devices' views of the Play Store. The easiest is to say that you need a touchscreen:

```
<uses-feature android:name="android.hardware.touchscreen"  
android:required="true"/>
```

Note that `true` is the default setting for this particular feature, though putting it in your manifest to remind you that you do require a touchscreen is a good idea.

Device Catalog: Amazon Fire TV and Fire TV Stick

Amazon has joined the TV set-top box fray with the Fire TV and, more recently, the Fire TV Stick. These devices are powered by FireOS, Amazon's variation of Android. And, as with other Amazon FireOS devices, like the Kindle Fire tablet series, you can write apps that run on Fire TV and the Fire TV Stick.

This chapter will review these devices from a developer's standpoint, to help you create apps for this platform. Note that the Fire TV line of devices have some elements in common with Amazon's Kindle Fire series of tablets, covered [elsewhere in this book](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapter on [the Kindle Fire tablets](#). Reading [the chapter on the ten-foot user interface](#) is also recommended, either before or after this chapter.

Also, some sections will make reference to [Android TV](#) as a point of reference.

Introducing the Fire TV Devices

As of January 2015, there were two major flavors of Fire TV device: the original Fire TV, and the Fire TV Stick.

Fire TV

As with most Android-powered set-top boxes, the original Fire TV is small and is designed to connect with your television (or monitor, or projector, or whatever) via HDMI:

Figure 858: Fire TV

It comes with a small wireless remote designed for basic controls, akin to what you might find on other streaming boxes or similar entertainment devices:

Figure 859: Fire TV Remote

Optionally, you can get a gaming controller that works with the Fire TV. While the regular controller is fine for navigating the Fire TV UI, the gaming controller will be more suitable for more serious game play:

Figure 86o: Fire TV Gaming Controller

While the Fire TV is powered by Android, the on-device UI is definitely targeting a set-top box environment. The home screen is dominated by media, coming from whatever supported streaming content providers you have set up with the Fire TV (e.g., Amazon Prime):

DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

Figure 861: Fire TV Home Screen

The “Apps” section shows a mix of what is installed and what is available for you to download, with “cloud” icons indicating apps that are available but are not presently installed:

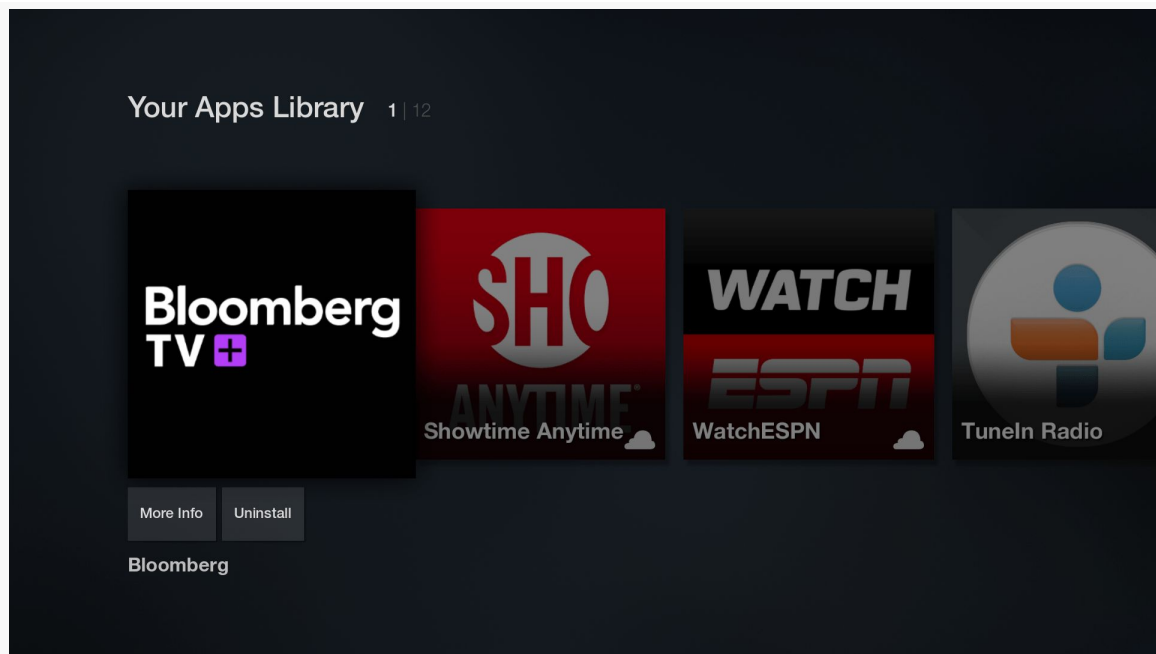

Figure 862: Fire TV “Your Apps Library”

Fire TV Stick

The Fire TV Stick is physically substantially smaller than is the Fire TV, designed to more closely resemble the Chromecast:

Figure 863: Fire TV Stick, with Remote, AC Adapter, and HDMI Extension Cable

The user experience of a Fire TV Stick, though, is largely the same as with a regular Fire TV. Both run the same FireOS environment, with the same sort of browsing metaphor.

The biggest difference is that the Fire TV Stick is less powerful (less RAM, weaker CPU and GPU). For conventional apps, this is unlikely to be a problem, as the Fire TV Stick is as powerful as many standard Android phones and tablets. Games, however, are more likely to stress the hardware.

From the user's standpoint, the Fire TV Stick's big selling point is its low price, about a third of what the Fire TV costs.

What Features and Configurations Do They Use?

The Fire TV device family behaves a bit like a “mashup” of other TV-centric devices (Android TV, OUYA, etc.) and the Kindle Fire series.

OS Version

At the present time, Fire TV devices are powered by a version of FireOS that corresponds to Android 4.2.2 (API Level 17). It is possible that Fire TV devices could be upgraded to a newer version of FireOS in the future, one based on a newer version of Android, but there are no guarantees.

Screen Size, Density, and Orientation

One area where the Fire TV series differs from pretty much anything that came before it comes with the behavior of the screen. As with other TV-centric devices like Android TV and the OUYA, the assumption is that the screen is locked to landscape. However, beyond that, Amazon has struck out on its own in terms of screen characteristics.

With Android TV, the screen size and density are based on the type of display that the Android TV box is plugged into.

With the Fire TV devices, your code deals with a rendering surface of 1920x1080 pixels, regardless of whether the device is plugged into a 1080p screen or something else (720p, 4K, etc.). The density is always treated as `-xhdpi`, giving you a resolution of 960dp by 540dp, and a `-large` screen size. The hardware will handle scaling the output down (or, in theory, up for 4K) as needed.

On the plus side, this simplifies app development, as you do not need to deal with different screen capabilities yourself. However, it remains to be seen how well the Fire TV will scale the output.

Also, note that Fire TV devices do not address [overscan](#) when they apply this scaling. Hence, you will want to keep your content away from the edges of the available space, only showing your background there, in case those edges are not visible on some televisions.

As with any TV-centric device, since the screen is locked to landscape, activities that are locked to portrait (e.g., `android:screenOrientation="portrait"` in the manifest for the activity) will behave oddly. If you are targeting devices like the Fire TV series, be sure to allow your activities to work in portrait or landscape, not just portrait.

Input Devices

As noted earlier, Fire TV devices ship with a simple remote control, designed for media management (play, pause, etc.) and basic D-pad navigation. Some users may also elect to pick up a Fire TV game controller or use other Bluetooth game controllers. Technical details for working with these input devices can be found [later in this chapter](#).

Conversely, Fire TV devices do not have touchscreens. You cannot assume that the user can tap on random portions of the screen. Instead, you need to make sure that your app is completely reachable via a D-pad. This is described in greater detail in [the chapter on the “ten-foot UI”](#).

Hardware Features

As a set-top box, Fire TV devices lack a lot of hardware that you normally associate with phones and tablets, such as:

- GPS
- camera
- microphone
- sensors
- telephony

The microphone is actually a bit complicated. The Fire TV remote has a microphone and a button to activate it. The Fire TV Stick remote does not have a microphone. There is a Fire TV Remote app available on [the Play Store](#) and Amazon Appstore for Android that offers microphone input as well. However, all these microphones are just for Fire TV voice search. There is no means for developers to use these for arbitrary audio input, the way that a microphone on a phone or a tablet can.

What Is Really Different?

Some things are “really different” simply because the output screen is TV-sized, not phone-sized or tablet-sized. See [the chapter on the “ten-foot UI”](#) for more about this.

Some things are “really different” in the same way that they are “really different” for the Kindle Fire series, such as having [nothing “Googly”](#), like Google Maps or Google

Cloud Messaging. Note that the Amazon Maps API does not work on the Fire TV series, as those devices have no location services.

The biggest additional “really different” item is the limitation on where apps can come from, which is discussed [later in this chapter](#) as part of the overall app distribution options for Fire TV devices.

Note that Fire TV devices have their own way of representing notifications. A standard Android Notification will not appear anywhere on a Fire TV device. Instead, you will need to support the Fire TV series’ own [notifications API](#). While their API is modeled after Android’s Notification and NotificationManager, they do have their own classes, and the results are more reminiscent of Toasts and Dialogs.

Also note that Fire TV devices do not display an Android action bar, representing those items in a pop-up menu triggered by the MENU button of the Fire TV remote control.

Casting and Fire TV

The success of Chromecast means that TV-connected Android devices will tend to be compared to Chromecast, particularly in terms of how apps on phones and tablets can work with the TV-connected device.

At the time of this writing, Amazon has not shipped anything for Fire TV that would enable apps [using MediaRouteActionProvider and RemotePlaybackClient](#) to work with Fire TV. In principle, Amazon or somebody else could implement a MediaRouteProvider and distribute that as an app that goes on ordinary Android phones and tablets, where that MediaRouteProvider enables media routes pointing to a connected Fire TV. The MediaRouteProvider would forward requests from the phone or tablet to the Fire TV, which would be displayed by some app on the Fire TV.

Amazon more formally supports [the “Discovery and Launch” \(DIAL\) protocol](#) with Fire TV. DIAL allows an app on a phone or tablet to launch apps on Fire TV. Unfortunately, documentation for this is lacking at the present time.

Amazon claims that the Fire TV series supports serving as a Miracast endpoint, so phones and tablets could connect to Fire TV devices and use them as an external

display. Reports from users suggests that this rarely works, and Android developers would be wise to not rely heavily upon it at this time.

Getting Your Development Environment Established

Developing for the Fire TV series, as with developing for the Kindle Fire series, is best accomplished using an actual Fire TV or Fire TV Stick device. That being said, having an emulator that at least resembles a Fire TV device may be useful for debugging purposes.

Emulator Configuration

Amazon is distributing an SDK add-on that supplies an emulator image you can use, in theory, to emulate a Fire TV device.

To install it:

- Start the SDK Manager, such as via the toolbar button in Android Studio or Eclipse
- Choose Tools > Manage Add-on Sites from the SDK Manager main menu
- Click on the User Defined Sites tab, and click the New... button
- Fill in `https://s3.amazonaws.com/android-sdk-manager/redirect/addon.xml` as the URL in the field in the “Add Add-on Site URL” dialog, then click OK (to close up that dialog), then click Close (to close up the Manage Add-on Sites dialog)
- Wait for the progress bar at the bottom of the SDK Manager to finish
- Install the Fire TV entry in API Level 17

This will give you an “Amazon Fire TV SDK” option as an API level target when setting up an emulator image. However, you will also need to set up a device definition that emulates a suitable screen resolution (e.g., 1080p). And, the resulting emulator does not even vaguely resemble a Fire TV device in terms of the firmware and such.

In truth, at present, you will need to use Fire TV hardware to develop for Fire TV.

Developing on Hardware

The primary thing notably different about testing your app on a Fire TV device is that it does not use a micro USB cable for the adb connection, the way that you may be used to from testing with most Android hardware. It does not even use some sort of proprietary cable. Instead, adb runs over the network.

To set this up, you must first enable USB debugging, much like you do with other Android devices. On a Fire TV device, this is in Settings > System > Developer Options:

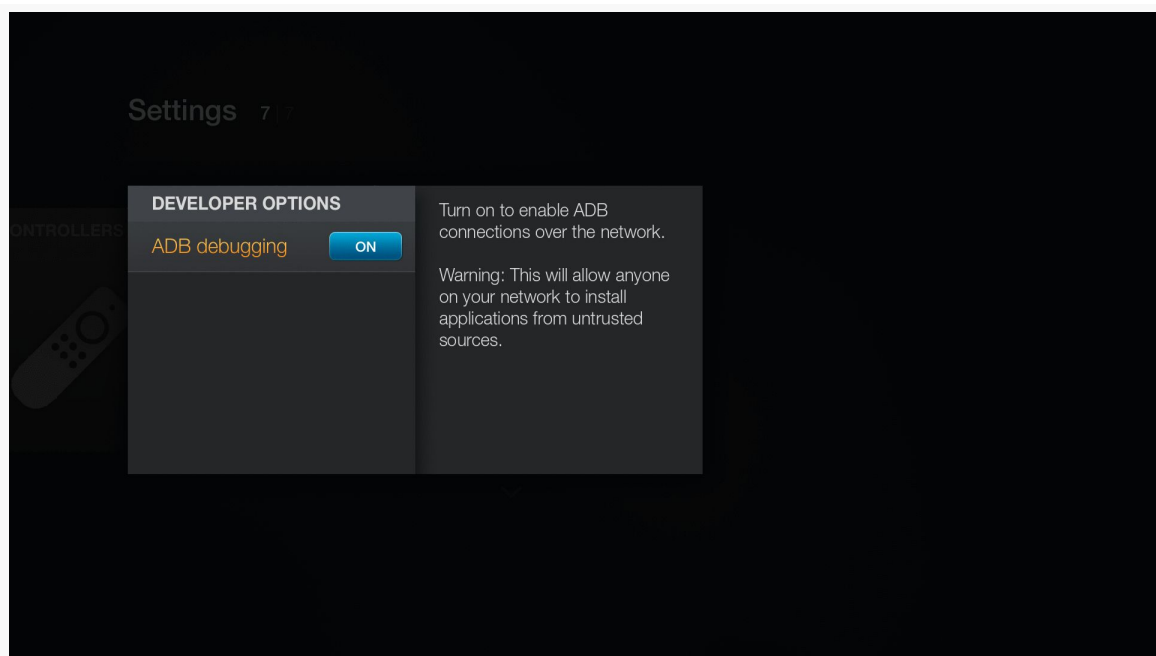

Figure 864: Fire TV Developer Settings

You will then need the IP address of your Fire TV device. Most likely the easiest way for you to find that is via the Settings > System > About > Network screen:

Figure 865: Fire TV Network Settings

You can then run `adb connect` (followed by the IP address) at a command prompt to make the connection. You may need to stop and restart `adb` before doing this, via `adb kill-server` and `adb start-server`.

At this point, if all is set up properly, `adb devices` will list the Fire TV device's IP address, and the Fire TV device will be accessible from your IDEs and other development tools.

Note that this `adb` setup will persist until `adb` is next restarted, even if the Fire TV device is powered down. You can use `adb disconnect` (followed by the IP address) to break the connection if you no longer need it.

Working with the Remote and Controller

Your Fire TV users will be interacting with their Fire TV using the supplied remote, the Fire TV gaming controller, or other controllers.

Wireless Remote

Mostly, the wireless remote offers buttons that you should be handling already, assuming you are [implementing a ten-foot UI](#) or are otherwise correctly handling [focus management and accessibility](#). BACK and the D-pad buttons will work on the Fire TV much as you would expect.

The Fire TV device remote has a MENU button, which will bring up an old-style Android options menu. Your simple action bar items, particularly those in the overflow, will appear in this menu without issue. Most likely you will want to skip the action bar on your Fire TV apps, though, which means that action views, action providers, and the like will need to be replaced with alternatives.

The remote also offers play/pause, rewind, and fast-forward buttons that map to their corresponding Android KeyEvent types (e.g., KEYCODE_MEDIA_PLAY_PAUSE). You can watch for these events in `onKeyDown()` of your activity to be able to respond to them.

Note that you do not have the ability to intercept home or voice search button presses on the wireless remote. And, the Fire TV Stick's remote does not offer the voice search button.

Gaming Controller

The wireless remote's input options are purely buttons. The Fire TV series gaming controller, like most such controllers, are designed for more “analog” input, where the force you apply to a stick might trigger slightly different behavior in a game.

As such, the gaming controller support in Android and FireOS takes a two-tier approach, with primary and secondary ways of handling events. If your code consumes the primary event, the secondary event is not triggered. The idea is that fairly “vanilla” apps might pay attention to the secondary events, as they tend to be more in common with the events you might get from the wireless remote or non-Fire TV devices. But apps that are more game-centric might pay attention to the primary events instead.

For analog inputs — the left and right sticks and the D-pad — the primary event input is supplied as `MotionEvent` objects, which you can pick up in methods like `onGenericMotionEvent()` in a `View`. Secondary event input comes in the form of standard D-pad events. So, an ordinary app will automatically support the sticks and D-pad, simply by accepting D-pad input.

Some buttons also take the two-tier approach. The A button (bottom one in the button cluster on the upper-right side of the controller) can be picked up either as a `KEYCODE_BUTTON_A` KeyEvent (primary) or a `KEYCODE_DPAD_CENTER` KeyEvent (secondary). The B button (right one) maps to `KEYCODE_BUTTON_B` (primary) and `KEYCODE_BACK` (secondary).

Other buttons just fire simple KeyEvents (e.g., left shoulder is `KEYCODE_BUTTON_L1`), while the two triggers just use MotionEvents (`AXIS_BRAKE` on the left, `AXIS_GAS` on the right).

Amazon's Fire TV site has [full details of the options and how to use them](#), plus a dedicated [game controller API](#) to help you manage multiple controllers and the like.

How Does Distribution Work?

Like the Kindle Fire, Fire TV devices lack the Play Store. If you want your app to be available to Fire TV device users, you will need to explore other ways of promoting and delivering the app.

The principal — and nearly exclusive — way to get apps onto a Fire TV device is by listing them in the Amazon AppStore for Android, [much as you would do for Kindle Fire devices](#).

However, for ordinary users, that is the *only* option. Most Android devices — including the Kindle Fire series — allow the user to download apps from Web sites, if they have the appropriate option checked in Settings. The Fire TV lacks this setting, and therefore ordinary users cannot download an app to the Fire TV from third-party app stores.

“Sideloading” an app using `adb` works, though this is usually only viable for developers or serious power users. Such apps will not appear in the home screen launcher and must be launched instead via Settings > Applications.

Getting Help

Trail: Appendices

CWAC Libraries

CommonsWare — the publisher of this book — has also published a series of open source libraries, collectively named the CommonsWare Android Components (CWAC). If you have read through the book, you will have seen many of these libraries.

This appendix lists all of the CWAC libraries. If the library is covered elsewhere in the book, the appendix links you to that coverage. Those that are not covered elsewhere will be described in this appendix, to accompany the online documentation found at the library's GitHub repository.

cwac-adapter

[The cwac-adapter repository](#) contains a small AdapterWrapper class that wraps a ListAdapter. The default implementation of all AdapterWrapper methods is to forward the request along to the wrapped ListAdapter. However, you can subclass AdapterWrapper to override that behavior.

cwac-camera

[The cwac-camera repository](#) holds the CommonsWare library to assist with the use of the hardware cameras on Android devices. This library is covered extensively in [the chapter on using the camera](#).

cwac-colormixer

The [cwac-colormixer repository](#) holds a custom ColorMixer View, along with wrappers for using that View as a dialog, activity, or preference for use with PreferenceScreen.

ColorMixerDialog and ColorPreference are covered in [the chapter on custom dialogs](#). The ColorMixer widget is similar to the implementation found in [the chapter on custom views](#).

This library also contains a ColorMixerActivity, which you can use via startActivityForResult() to obtain a color, rather than by integrating the widget, dialog, or preference.

cwac-layouts

The [cwac-layouts repository](#) contains a series of custom containers and related views.

The current contents of this library — AspectLockedFrameLayout, MirroringFrameLayout, and kin — are covered in [the chapter on custom views](#).

cwac-mediarouter

The [cwac-mediarouter repository](#) contains a cross-port of the mediarouter-v7 portion of the Android Support package, to eliminate its dependency on appcompat-v7 and support the native action bar.

cwac-merge

The [cwac-merge repository](#) contains MergeAdapter. It simply stitches together lots of smaller ListAdapters into one larger ListAdapter to put inside of a ListView or similar AdapterView. It also allows you to blend individual “row” Views with other ListAdapters.

One use of this is for section headers, using row Views for the headers and ListAdapters for the sections.

Another use is where you have multiple disparate data sources (e.g., queries across a few databases or ContentProviders), each with distinct row formatting, but you want to present them as one contiguous list.

cwac-pager

[The cwac-pager repository](#) includes code written in support of the ViewPager widget.

ArrayPagerAdapter is covered in [the chapter on advanced uses of ViewPager](#).

cwac-presentation

[The cwac-presentation repository](#) contains code in support of the Presentation system, for sending alternative content to an external display, independent of the device's primary screen.

All of the classes in this repository are covered in [the chapter on the Presentation system](#).

cwac-provider

[The cwac-provider repository](#) contains StreamProvider, a riff on Google's FileProvider, offering a “canned” implementation of a ContentProvider that can serve files from a variety of sources, such as assets and raw resources from your project.

This is discussed briefly in [the chapter on ContentProvider implementations](#).

cwac-richedit

[The cwac-richedit repository](#) contains the RichEditText widget, a drop-in replacement for EditText that supports “rich text” (a.k.a., formatted text) editing, such as bold and italics. The use of this widget is covered in [the chapter on Android's rich text handling](#).

cwac-sacklist

[The cwac-sacklist repository](#) contains SackOfViewsAdapter, which implements the ListAdapter interface for a collection of individual Views that serve as rows. This is used in support of [the MergeAdapter](#), for example.

cwac-security

[The cwac-security repository](#) contains code to help app developers help their users defend against attacks. At the moment, this contains the PermissionUtils class, used to help determine if a custom permission was defined by another app before yours was installed. This is discussed in [the chapter on advanced permission techniques](#).

cwac-strictmodeex

[The cwac-strictmodeex repository](#) contains classes that serve a similar role to Android's StrictMode, yelling at you for problematic code.

Specifically, this repository contains StrictAdapter, which measures the timing of methods like getView(), logging information about slow adapters that may result in sluggish ListView scrolling.

cwac-wakeful

[The cwac-wakeful repository](#) contains the WakefulIntentService and related support classes, for doing work and keeping the device awake while that work is going on. This is covered in [the chapter on AlarmManager](#).
