Table of Contents

Headings formatted in ***bold-italic*** have changed since the last version.

• Preface	
◦ Welcome to the Book!	xxxv
◦ The Book's Structure	xxxv
◦ <i>The Trails</i>	<i>xxxvi</i>
◦ About the Updates	xli
◦ Warescription	xli
◦ Book Bug Bounty	xlii
◦ Source Code and Its License	xliii
◦ <i>Creative Commons and the Four-to-Free (42F) Guarantee</i>	<i>xliv</i>
◦ Acknowledgments	xliv
• Key Android Concepts	
◦ Android Applications	1
◦ Android Devices	7
◦ Don't Be Scared	10
• Choosing Your Development Toolchain	
◦ Android Studio	11
◦ Eclipse	11
◦ IntelliJ IDEA	12
◦ Command-Line Builds via Gradle for Android	12
◦ Yet Other Alternatives	13
◦ IDEs... And This Book	13
◦ What We Are Not Covering	13
• Tutorial #1 - Installing the Tools	
◦ Step #1 - Checking Your Hardware Requirements	15
◦ <i>Step #2 - Setting Up Java and 32-Bit Linux Support</i>	<i>16</i>
◦ Step #3 - Install the Developer Tools	16
◦ <i>Step #4 - Install the SDKs and Add-Ons</i>	<i>20</i>
◦ In Our Next Episode... ..	28
• Android and Projects	
◦ <i>Common Concepts</i>	<i>29</i>
◦ Projects and Android Studio	30
◦ Projects and Eclipse	37
◦ Starter Project Generators	43
• Tutorial #2 - Creating a Stub Project	
◦ About Our Tutorial Project	45

◦ About the Rest of the Tutorials	46
◦ About Our Tools	46
◦ Step #1: Creating the Project	47
◦ Step #2 - Set Up the Emulator	53
◦ Step #3 - Set Up the Device	65
◦ Step #4: Running the Project	68
◦ In Our Next Episode...	71
• Getting Around Android Studio	
◦ Navigating The Project Explorer	73
◦ Running Projects	76
◦ Viewing Output	77
◦ Accessing Android Tools	78
◦ Android Studio and Release Channels	82
• Contents of Android Projects	
◦ What You Get, In General	85
◦ The Contents of an Android Studio Project	87
◦ The Contents of an Eclipse Project	89
◦ What You Get Out Of It	90
• Introducing Gradle and the Manifest	
◦ Gradle: The Big Questions	91
◦ Obtaining Gradle	94
◦ Versions of Gradle and Gradle for Android	96
◦ Gradle Environment Variables	97
◦ Examining the Gradle Files	97
◦ Introducing the Manifest	99
◦ Things In Common Between the Manifest and Gradle	100
◦ Other Gradle Items of Note	103
◦ The Rest of the Manifest	105
◦ Learning More About Gradle	107
◦ Visit the Trails!	107
• Tutorial #3 - Changing Our Manifest (and Gradle File)	
◦ Some Notes About Relative Paths	109
◦ Step #1: Supporting Screens	110
◦ Step #2: Adding our Minimum and Target SDK Versions	113
◦ In Our Next Episode...	115
• Some Words About Resources	
◦ String Theory	118
◦ Got the Picture?	122
◦ Dimensions	126
◦ The Resource That Shall Not Be Named... Yet	128
• Tutorial #4 - Adjusting Our Resources	

◦ Step #1: Changing the Name	129
◦ Step #2: Changing the Icon	131
◦ Step #3: Running the Result	140
◦ In Our Next Episode...	142
• The Theory of Widgets	
◦ What Are Widgets?	143
◦ Size, Margins, and Padding	145
◦ What Are Containers?	145
◦ The Absolute Positioning Anti-Pattern	146
◦ The Theme of This Section: Themes	147
• The Android User Interface	
◦ The Activity	151
◦ Dissecting the Activity	152
◦ Using XML-Based Layouts	153
• Basic Widgets	
◦ Common Concepts	159
◦ Assigning Labels	162
◦ A Commanding Button	172
◦ Fleeting Images	177
◦ Fields of Green. Or Other Colors.	184
◦ More Common Concepts	190
◦ Visit the Trails!	192
• Debugging Your App	
◦ Get Thee To a Stack Trace	194
◦ The Case of the Confounding Class Cast	198
◦ Point Break	199
• LinearLayout and the Box Model	
◦ Concepts and Properties	201
◦ Android Studio Graphical Layout Editor	205
◦ Eclipse Graphical Layout Editor	206
• Other Common Widgets and Containers	
◦ Just a Box to Check	209
◦ Don't Like Checkboxes? How About Toggles or Switches?	214
◦ Turn the Radio Up	219
◦ All Things Are Relative	223
◦ Tabula Rasa	230
◦ Scrollwork	237
◦ Making Progress with ProgressBars	240
◦ Visit the Trails!	241
• Tutorial #5 - Making Progress	
◦ Step #1: Removing The "Hello, World"	243

◦ Step #2: Adding a ProgressBar	245
◦ Step #3: Seeing the Results	248
◦ In Our Next Episode...	248
• GUI Building, Continued	
◦ Making Your Selection	249
◦ Including Includes	250
◦ Wrap It Up (In a Container)	252
◦ Morphing Widgets	253
◦ Preview of Coming Attractions	254
• AdapterViews and Adapters	
◦ Adapting to the Circumstances	255
◦ Lists of Naughty and Nice	257
◦ Clicks versus Selections	259
◦ Spin Control	263
◦ Grid Your Lions (Or Something Like That...)	266
◦ Fields: Now With 35% Less Typing!	269
◦ Customizing the Adapter	273
◦ Visit the Trails!	281
• The WebView Widget	
◦ Role of WebView	283
◦ WebView and WebKit	284
◦ Adding the Widget	284
◦ Loading Content Via a URL	285
◦ Supporting JavaScript	286
◦ Alternatives for Loading Content	287
◦ <i>Listening for Events</i>	288
◦ WebView and Android 4.4	291
◦ Visit the Trails!	292
• Defining and Using Styles	
◦ Styles: DIY DRY	293
◦ Elements of Style	295
◦ Themes: Would a Style By Any Other Name...	298
◦ What Happens If You Have No Theme	298
• JARs and Library Projects	
◦ The Dalvik VM, and a Bit of ART	302
◦ Getting the Library	302
◦ The Outer Limits	304
◦ JAR Dependency Management	305
◦ OK, So What is a Library Project?	305
◦ Using a Library Project	306
◦ Library Projects: What You Get	307

◦ The Android Support Package	308
• Tutorial #6 - Adding a Library	
◦ Step #1: Attaching the Android Support Package	313
◦ Step #2: Downloading the Third-Party JARs	314
◦ In Our Next Episode...	316
• The Action Bar	
◦ Bar Hopping	317
◦ Yet Another History Lesson	323
◦ Your Action Bar Options	324
◦ Setting the Target	325
◦ Defining the Resource	327
◦ Applying the Resource	329
◦ Responding to Events	330
◦ The Rest of the Sample Activity	331
◦ MENU Key, We Hardly Knew Ye	337
◦ Action Bars, Live in Living Color!	338
◦ Visit the Trails!	348
• Tutorial #7 - Setting Up the Action Bar	
◦ Step #1: Acquiring Some Icons	349
◦ Step #2: Defining Some Options	350
◦ Step #3: Loading and Responding to Our Options	353
◦ In Our Next Episode...	357
• Android's Process Model	
◦ When Processes Are Created	359
◦ BACK, HOME, and Your Process	360
◦ Termination	361
◦ Foreground Means "I Love You"	362
◦ You and Your Heap	362
• Activities and Their Lifecycles	
◦ Creating Your Second (and Third and...) Activity	364
◦ Warning! Contains Explicit Intents!	370
◦ Using Implicit Intents	372
◦ Extra! Extra!	377
◦ Pondering Parcelable	379
◦ Asynchronicity and Results	380
◦ Schroedinger's Activity	380
◦ Life, Death, and Your Activity	381
◦ When Activities Die	383
◦ Walking Through the Lifecycle	384
◦ Recycling Activities	387
◦ Application: Transcending the Activity	388

• Tutorial #8 - Setting Up An Activity	
◦ Step #1: Creating the Stub Activity Class and Manifest Entry	391
◦ Step #2: Launching Our Activity	394
◦ In Our Next Episode...	395
• The Tactics of Fragments	
◦ The Six Questions	397
◦ Where You Get Your Fragments From	400
◦ Your First Fragment	400
◦ The Fragment Lifecycle Methods	403
◦ Your First Dynamic Fragment	404
◦ Fragments and the Action Bar	407
◦ Fragments Within Fragments: Just Say “Maybe”	409
◦ Fragments and Multiple Activities	409
• Tutorial #9 - Starting Our Fragments	
◦ Step #1: Create a SimpleContentFragment	411
◦ Step #2: Examining SimpleContentFragment	414
◦ In Our Next Episode...	414
• Swiping with ViewPager	
◦ Swiping Design Patterns	415
◦ Pieces of a Pager	416
◦ Paging Fragments	416
◦ Paging Other Stuff	421
◦ Indicators	422
• Tutorial #10 - Rigging Up a ViewPager	
◦ Step #1: Add a ViewPager to the Layout	427
◦ Step #2: Obtaining Our ViewPager	428
◦ Step #3: Creating a ContentsAdapter	429
◦ Step #4: Setting Up the ViewPager	430
◦ In Our Next Episode...	431
• Resource Sets and Configurations	
◦ What’s a Configuration? And How Do They Change?	433
◦ Configurations and Resource Sets	434
◦ Screen Size and Orientation	435
◦ Coping with Complexity	438
◦ Choosing The Right Resource	439
◦ API-Versioned Resources	443
◦ Default Change Behavior	445
◦ State Saving Scenarios	446
◦ Your Options for Configuration Changes	447
◦ Blocking Rotations	459
◦ And Now, a Word From the Android Project View	459

• Material Design Basics	
◦ Your App, in Technicolor!	463
• Dealing with Threads	
◦ The Main Application Thread	471
◦ Getting to the Background	473
◦ Asyncing Feeling	473
◦ Alternatives to AsyncTask	483
◦ And Now, The Caveats	484
◦ Event Buses	485
◦ Visit the Trails!	492
• Requesting Permissions	
◦ Mother, May I?	494
◦ New Permissions in Old Applications	496
◦ Permissions: Up Front Or Not At All	496
◦ Signature Permissions	497
◦ Requiring Permissions	498
• Assets, Files, and Data Parsing	
◦ Packaging Files with Your App	499
◦ Files and Android	501
◦ Working with Internal Storage	502
◦ Working with External Storage	505
◦ Multiple User Accounts	509
◦ Linux Filesystems: You Sync, You Win	510
◦ StrictMode: Avoiding Janky Code	511
◦ XML Parsing Options	514
◦ JSON Parsing Options	515
◦ Visit the Trails!	515
• Tutorial #11 - Adding Simple Content	
◦ Step #1: Adding Some Content	517
◦ Step #2: Using SimpleContentFragment	518
◦ Step #3: Launching Our Activities, For Real This Time	519
◦ In Our Next Episode...	521
• Tutorial #12 - Displaying the Book	
◦ Step #1: Adding a Book	523
◦ Step #2: Creating a ModelFragment	524
◦ Step #3: Defining Our Model	525
◦ Step #4: Examining Our Model	527
◦ Step #5: Defining Our Event	527
◦ Step #6: Loading Our Model	529
◦ Step #7: Registering for Events	531
◦ Step #8: Adapting the Content	532

◦ Step #9: Showing the Content When Loaded	533
◦ Step #10: Attaching our ModelFragment	533
◦ Step #11: Showing the Content After a Configuration Change	535
◦ Step #12: Going Home, Again	535
◦ Step #13: Setting Up StrictMode	536
◦ In Our Next Episode...	537
• Using Preferences	
◦ Getting What You Want	539
◦ Stating Your Preference	540
◦ Introducing PreferenceActivity	541
◦ Types of Preferences	551
◦ Intents for Headers or Preferences	554
◦ Conditional Headers	555
• Tutorial #13 - Using Some Preferences	
◦ Step #1: Defining the Preference XML Files	561
◦ Step #2: Creating Our PreferenceActivity	564
◦ Step #3: Adding To Our Action Bar	566
◦ Step #4: Launching the PreferenceActivity	567
◦ Step #5: Loading the Preferences	571
◦ Step #6: Saving the Last-Read Position	574
◦ Step #7: Restoring the Last-Read Position	576
◦ Step #9: Keeping the Screen On	576
◦ In Our Next Episode...	578
• SQLite Databases	
◦ Introducing SQLite	579
◦ Thinking About Schemas	580
◦ Start with a Helper	580
◦ Getting Data Out	585
◦ The Rest of the CRUD	591
◦ Hey, What About Hibernate?	597
◦ Visit the Trails!	597
• Tutorial #14 - Saving Notes	
◦ Step #1: Adding a DatabaseHelper	599
◦ Step #2: Examining DatabaseHelper	601
◦ Step #3: Creating a NoteFragment	601
◦ Step #4: Examining NoteFragment	606
◦ Step #5: Creating the NoteActivity	606
◦ Step #6: Examining NoteActivity	608
◦ Step #7: Add Notes to the Action Bar	608
◦ Step #8: Defining a NoteLoadedEvent	610
◦ Step #9: Loading a Note from the Database	611

◦ Step #10: Loading the Note Into the Fragment	612
◦ Step #11: Updating the Database	613
◦ Step #12: Saving the Note	614
◦ Step #13: Adding a Delete Action Bar Item	616
◦ Step #14: Closing the NoteFragment When Deleted	618
◦ In Our Next Episode...	623
• Internet Access	
◦ DIY HTTP	625
◦ HTTP via DownloadManager	635
◦ Using Third-Party JARs	636
◦ SSL	637
◦ Using HTTP Client Libraries	637
◦ Visit the Trails	651
• Intents, Intent Filters	
◦ What's Your Intent?	653
◦ Stating Your Intent(ions)	655
◦ Responding to Implicit Intents	655
◦ Requesting Implicit Intents	658
◦ ShareActionProvider	662
• Broadcasts and Broadcast Receivers	
◦ The Stopped State	667
◦ Example System Broadcasts	668
◦ The Order of Things	676
◦ Keeping It Local	677
◦ Visit the Trails!	678
• Tutorial #15 - Sharing Your Notes	
◦ Step #1: Adding a ShareActionProvider	679
◦ Step #2: Sharing the Note	680
◦ Step #3: Testing the Result	682
◦ In Our Next Episode...	683
• Services and the Command Pattern	
◦ Why Services?	685
◦ Setting Up a Service	686
◦ Communicating To Services	688
◦ Scenario: The Music Player	690
◦ Communicating From Services	693
◦ Scenario: The Downloader	695
• Tutorial #16 - Updating the Book	
◦ Step #1: Adding a Stub DownloadCheckService	701
◦ Step #2: Tying the Service Into the Action Bar	703
◦ Step #3: Defining Our Event	704

◦ Step #4: Defining Our JSON	705
◦ Step #5: Defining Our Retrofit Interface	706
◦ Step #6: Retrieving Our JSON Via Retrofit	707
◦ Step #7: Downloading the Update	708
◦ Step #8: Unpacking the Update	710
◦ Step #9: Using the Update	714
◦ In Our Next Episode...	719
• AlarmManager and the Scheduled Service Pattern	
◦ Scenarios	721
◦ Options	722
◦ A Simple Example	724
◦ The Five set...() Varieties	726
◦ The Four Types of Alarms	727
◦ When to Schedule Alarms	728
◦ Archetype: Scheduled Service Polling	730
◦ Staying Awake at Work	733
◦ Warning: Not All Android Devices Play Nice	737
◦ Debugging Alarms	738
◦ WakefulBroadcastReceiver	741
• Tutorial #17 - Periodic Book Updates	
◦ Step #1: Adding a Stub UpdateReceiver	745
◦ Step #2: Scheduling the Alarms	747
◦ Step #3: Adding the WakefulIntentService	748
◦ Step #4: Using WakefulIntentService	750
◦ Step #5: Completing the UpdateReceiver	750
◦ In Our Next Episode...	751
• Notifications	
◦ What's a Notification?	753
◦ Showing a Simple Notification	756
◦ The Activity-Or-Notification Scenario	761
◦ Big (and Rich) Notifications	761
◦ Foreground Services	768
◦ Disabled Notifications	771
• Tutorial #18 - Notifying the User	
◦ Step #1: Raising the Notification	775
◦ In Our Next Episode...	777
• Large-Screen Strategies and Tactics	
◦ Objective: Maximum Gain, Minimum Pain	779
◦ The Fragment Strategy	779
◦ Fragment Example: The List-and-Detail Pattern	788
◦ Other Master-Detail Strategies	800

◦ Showing More Pages	812
◦ Fragment FAQs	818
◦ Screen Size and Density Tactics	819
◦ Other Considerations	822
• Tutorial #19 - Supporting Large Screens	
◦ Step #1: Creating Our Layouts	827
◦ Step #2: Loading Our Sidebar Widgets	833
◦ Step #3: Opening the Sidebar	834
◦ Step #4: Loading Content Into the Sidebar	835
◦ Step #5: Removing Content From the Sidebar	837
• Backwards Compatibility Strategies and Tactics	
◦ Think Forwards, Not Backwards	845
◦ Aim Where You Are Going	847
◦ A Target-Rich Environment	847
◦ Lint: It's Not Just For Belly Buttons	848
◦ A Little Help From Your Friends	849
◦ Avoid the New on the Old	849
◦ Testing	853
◦ Keeping Track of Changes	853
• Getting Help	
◦ Questions. Sometimes, With Answers.	855
◦ Heading to the Source	856
◦ Getting Your News Fix	857
• Working with Library Projects	
◦ Prerequisites	859
◦ Creating a Library Project	859
◦ Using a Library Project, Part II	863
◦ Library Projects and the Manifest	863
◦ Limitations of Library Projects	864
• Gradle and Eclipse Projects	
◦ Prerequisites and Warnings	865
◦ "Legacy"?	865
◦ Creating Your Gradle Build File	866
◦ Examining the Gradle File	871
• Gradle and Tasks	
◦ Key Build-Related Tasks	873
◦ Results	875
• Gradle and the New Project Structure	
◦ Prerequisites and Warnings	877
◦ Objectives of the New Project Structure	878
◦ Terminology	878

◦ <i>Creating a Project in the New Structure</i>	882
◦ What the New Project Structure Looks Like	882
◦ <i>Configuring the Stock Build Types</i>	885
◦ Adding Build Types	890
◦ Adding Product Flavors and Getting Build Variants	892
◦ Doing the Splits	896
◦ Revisiting the Legacy Gradle File	898
◦ Working with the New Project Structure in Android Studio	900
• Gradle and Dependencies	
◦ Prerequisites and Warnings	903
◦ “Dependencies”?	904
◦ <i>A Tale of Two Dependencies Closures</i>	904
◦ <i>Depending Upon a JAR</i>	904
◦ Depending Upon NDK Binaries	906
◦ <i>Depending Upon an Android Library Project</i>	906
◦ Depending Upon Sub-Projects	908
◦ <i>Depending Upon Artifacts</i>	909
◦ Creating Android JARs from Gradle	917
◦ A Property of Transitive (Dependencies)	918
◦ Dependencies By Build Type	918
◦ Dependencies By Flavor	919
◦ <i>Examining Some CWAC Builds</i>	920
• Manifest Merger Rules	
◦ Prerequisites	927
◦ Manifest Scenarios	928
◦ Pieces of Manifest Generation	929
◦ Examining the Merger Results	931
◦ Merging Elements and Attributes	932
◦ Employing Placeholders	938
• Signing Your App	
◦ Prerequisites	943
◦ Role of Code Signing	943
◦ What Happens In Debug Mode	944
◦ <i>Production Signing Keys</i>	945
• Distribution	
◦ Prerequisites	961
◦ <i>Get Ready To Go To Market</i>	961
• Advanced Gradle for Android Tips	
◦ Prerequisites	967
◦ <i>Gradle, DRY</i>	967
◦ <i>Automating APK Version Information</i>	973

◦ Adding to BuildConfig	975
◦ Down and Dirty with the DSL	977
• JUnit and Android	
◦ Prerequisites	981
◦ JUnit Basics	981
◦ Pondering Gradle for Android	982
◦ Where Your Test Code Lives	983
◦ Where Your Test Code Runs	987
◦ Writing Your Test Cases	988
◦ Your Test Suite	993
◦ Running Your Tests	994
◦ Testing Android Library Projects	1000
◦ Test Dependencies	1001
◦ Testing Legacy Project Structures with Gradle for Android	1002
• Testing with JUnit4	
◦ Prerequisites	1005
◦ The AndroidJUnitRunner	1005
◦ JUnit4	1008
• MonkeyRunner and the Test Monkey	
◦ Prerequisites	1017
◦ MonkeyRunner	1017
◦ Monkeying Around	1019
• Testing with UIAutomator	
◦ Prerequisites	1021
◦ What Is UIAutomator?	1021
◦ Why Choose UIAutomator Over Alternatives?	1022
◦ Creating Some Tests	1022
◦ Running Your Tests	1031
◦ Finding Your Widgets	1032
• Introducing GridLayout	
◦ Prerequisites	1035
◦ Issues with the Classic Containers	1035
◦ The New Contender: GridLayout	1037
◦ GridLayout and the Android Support Package	1037
◦ Eclipse and GridLayout	1039
◦ Trying to Have Some Rhythm	1039
◦ Our Test App	1040
◦ Replacing the Classics	1042
◦ Implicit Rows and Columns	1048
◦ Row and Column Spans	1050
• Dialogs and DialogFragments	

◦ Prerequisites	1055
◦ DatePickerDialog and TimePickerDialog	1055
◦ AlertDialog	1061
◦ DialogFragments	1062
◦ DialogFragment: The Other Flavor	1066
◦ Dialogs: Modal, Not Blocking	1067
• Advanced ListViews	
◦ Prerequisites	1069
◦ Multiple Row Types, and Self Inflation	1069
◦ Choice Modes and the Activated Style	1075
◦ Custom Mutable Row Contents	1076
◦ From Head To Toe	1082
• Action Bar Navigation	
◦ Prerequisites	1087
◦ List Navigation	1087
◦ Tabs (And Sometimes List) Navigation	1092
◦ Custom Navigation	1098
• Action Modes and Context Menus	
◦ Prerequisites	1100
◦ Another Wee Spot O' History	1100
◦ Manual Action Modes	1101
◦ Multiple-Choice-Modal Action Modes	1105
◦ Long-Click To Initiate an Action Mode	1109
◦ Split Action Modes	1114
• Other Advanced Action Bar Techniques	
◦ Prerequisites	1119
◦ Splitting the Bar	1119
◦ Floating Action Bars	1123
◦ Action Layouts, Action Views, and Action Providers	1125
◦ Searching with SearchView	1126
• AppCompat: The Official Action Bar Backport	
◦ Prerequisites	1133
◦ Ummmm... Why?	1133
◦ The Basics of Using AppCompat	1135
◦ Other AppCompat Effects	1142
◦ And Then, There Are the Bugs	1148
◦ To Material, or Not to Material	1149
• ActionBarSherlock	
◦ Prerequisites	1153
◦ Installation	1154
◦ Code Changes	1154

• Implementing a Navigation Drawer	
◦ Prerequisites	1157
◦ What is a Navigation Drawer?	1157
◦ A Simple Navigation Drawer	1159
◦ Alternative Row Layouts	1165
◦ Additional Considerations	1167
◦ What Should Not Be in the Drawer	1176
◦ Independent Implementations	1176
• Advanced Uses of WebView	
◦ Prerequisites	1179
◦ Friends with Benefits	1179
◦ Turnabout is Fair Play	1185
◦ Navigating the Waters	1189
◦ Settings, Preferences, and Options (Oh, My!)	1190
◦ Security and Your WebView	1190
• The Input Method Framework	
◦ Prerequisites	1195
◦ Keyboards, Hard and Soft	1195
◦ Tailored To Your Needs	1196
◦ Tell Android Where It Can Go	1201
◦ Fitting In	1203
◦ Jane, Stop This Crazy Thing!	1205
• Fonts	
◦ Prerequisites	1207
◦ Love The One You're With	1207
◦ Yeah, But Do We Really Have To Do This in Java?	1211
◦ Here a Glyph, There a Glyph	1212
• Rich Text	
◦ Prerequisites	1215
◦ The Span Concept	1215
◦ Loading Rich Text	1217
◦ Editing Rich Text	1219
◦ Saving Rich Text	1224
◦ Manipulating Rich Text	1225
• Animators	
◦ Prerequisites	1227
◦ ViewPropertyAnimator	1227
◦ The Foundation: Value and Object Animators	1232
◦ Animating Custom Types	1235
◦ Hardware Acceleration	1236
◦ The Three-Fragment Problem	1237

• Legacy Animations	
◦ Prerequisites	1249
◦ It's Not Just For Toons Anymore	1249
◦ A Quirky Translation	1250
◦ Fading To Black. Or Some Other Color.	1254
◦ When It's All Said And Done	1256
◦ Loose Fill	1257
◦ Hit The Accelerator	1257
◦ Animate. Set. Match.	1258
◦ Active Animations	1259
• Custom Drawables	
◦ Prerequisites	1261
◦ ColorDrawable	1262
◦ AnimationDrawable	1262
◦ StateListDrawable	1265
◦ ColorStateList	1267
◦ LayerDrawable	1268
◦ TransitionDrawable	1270
◦ LevelListDrawable	1270
◦ ScaleDrawable and ClipDrawable	1272
◦ InsetDrawable	1281
◦ ShapeDrawable	1282
◦ BitmapDrawable	1292
◦ Composite Drawables	1299
◦ A Stitch In Time Saves Nine	1303
• Mapping with Maps V2	
◦ Prerequisites	1313
◦ A Brief History of Mapping on Android	1314
◦ Where You Can Use Maps V2	1315
◦ Licensing Terms for Maps V2	1315
◦ What You Need to Start	1316
◦ The Book Samples... And You!	1320
◦ Setting Up a Basic Map	1320
◦ Playing with the Map	1325
◦ Map Tiles	1328
◦ Placing Simple Markers	1328
◦ Seeing All the Markers	1331
◦ Flattening and Rotating Markers	1333
◦ Sprucing Up Your "Info Windows"	1337
◦ Images and Your Info Window	1342
◦ Setting the Marker Icon	1348

◦ Responding to Taps	1349
◦ Dragging Markers	1351
◦ The “Final” Limitations	1353
◦ A Bit More About IPC	1356
◦ Finding the User	1357
◦ Drawing Lines and Areas	1361
◦ Gestures and Controls	1364
◦ Tracking Camera Changes	1365
◦ Maps in Fragments and Pagers	1367
◦ Animating Marker Movement	1372
◦ Maps, of the Indoor Variety	1381
◦ Taking a Snapshot of a Map	1381
◦ MapFragment vs. MapView	1382
◦ About That AbstractMapActivity Class... ..	1383
◦ Helper Libraries for Maps V2	1387
◦ Problems with Maps V2 at Runtime	1391
◦ Problems with Maps V2 Deployment	1391

• The ContactsContract Provider	
◦ Prerequisites	1713
◦ Introducing You to Your Contacts	1714
◦ Pick a Peck of Pickled People	1715
◦ Spin Through Your Contacts	1718
◦ Makin' Contacts	1727
• The CalendarContract Provider	
◦ Prerequisites	1734
◦ You Can't Be a Faker	1734
◦ Do You Have Room on Your Calendar?	1734
◦ Penciling In an Event	1739
• The MediaStore Provider	
◦ Prerequisites	1741
◦ What Is the MediaStore?	1742
◦ MediaStore and "Other" External Storage	1743
◦ How Does My Content Get Indexed?	1744
◦ <i>How Do I Retrieve Video from the MediaStore?</i>	1744
• Consuming Documents	
◦ Prerequisites	1753
◦ The Storage Access... What?	1753
◦ The Storage Access Framework Participants	1755
◦ Picking How to Pick (a Peck of Pickled Pepper Photos)	1755
◦ Opening a Document	1756
◦ The Rest of the CRUD	1759
◦ Pondering Persistent Permissions	1760
• Providing Documents	
◦ Prerequisites	1763
◦ Have Your Content, and Provide it Too	1763
◦ Key Provider Concepts	1765
◦ Pieces of a Provider	1766
◦ Optional Provider Capabilities	1780
• Encrypted Storage	
◦ Prerequisites	1788
◦ Scenarios for Encryption	1788
◦ Obtaining SQLCipher	1789
◦ Attaching SQLCipher To Your Project	1789
◦ Using SQLCipher	1790
◦ SQLCipher Limitations	1793
◦ Passwords and Sessions	1794
◦ About Those Passphrases...	1794
◦ Encrypted Preferences	1802

◦ IOCipher	1804
• Packaging and Distributing Data	
◦ Prerequisites	1805
◦ <i>Packing a Database To Go</i>	1805
• Advanced Database Techniques	
◦ Prerequisites	1809
◦ Full-Text Indexing	1809
• Miscellaneous Network Capabilities	
◦ Prerequisites	1825
◦ Downloading Files	1825
• Audio Playback	
◦ Prerequisites	1839
◦ Get Your Media On	1839
◦ MediaPlayer for Audio	1840
◦ Other Ways to Make Noise	1846
• Audio Recording	
◦ Prerequisites	1849
◦ Recording by Intent	1849
◦ Recording to Files	1852
◦ Recording to Streams	1855
◦ Raw Audio Input	1858
◦ <i>Requesting the Microphone</i>	1858
• Video Playback	
◦ Prerequisites	1861
◦ Moving Pictures	1861
• Using the Camera via 3rd-Party Apps	
◦ Prerequisites	1867
◦ Being Specific About Features	1867
◦ Still Photos: Letting the Camera App Do It	1868
◦ Scanning with ZXing	1870
◦ Videos: Letting the Camera App Do It	1871
◦ Directly Working with the Camera	1873
• Working Directly with the Camera	
◦ Prerequisites	1876
◦ Basic CameraFragment Usage	1876
◦ Simple Configuration and Usage	1877
◦ Core Camera Concepts	1884
◦ Advanced CWAC-Camera Features	1907
• Media Routes	
◦ Prerequisites	1915
◦ Terminology	1915

◦ <i>A Tale of Three MediaRouters</i>	1916
◦ Attaching to MediaRouter	1917
◦ <i>User Route Selection with MediaRouteActionProvider</i>	1919
◦ Using Live Audio Routes	1936
◦ Using Live Video Routes	1936
◦ <i>Using Remote Playback Routes</i>	1936
• Supporting External Displays	
◦ Prerequisites	1955
◦ <i>A History of External Displays</i>	1955
◦ What is a Presentation?	1956
◦ Playing with External Displays	1957
◦ Detecting Displays	1963
◦ A Simple Presentation	1964
◦ A Simpler Presentation	1969
◦ Presentations and Configuration Changes	1974
◦ Presentations as Fragments	1975
◦ Another Sample Project: Slides	1985
◦ Device Support for Presentation	1992
◦ Presentations from a Service	1993
◦ Hey, What About Chromecast?	1996
• Google Cast and Chromecast	
◦ Prerequisites	1997
◦ Here a Cast, There a Cast	1997
◦ Common Chromecast Development Notes	1999
◦ Your API Choices	1999
◦ Senders and Receivers	2000
◦ Supported Media Types	2001
◦ Cast SDK Dependencies	2002
◦ Developing Google Cast Apps	2004
• The “Ten-Foot UI”	
◦ <i>Prerequisites</i>	2005
◦ What is the “Ten-Foot UI”?	2006
◦ <i>Overscan</i>	2006
◦ <i>Navigation</i>	2007
◦ <i>Stylistic Considerations</i>	2008
◦ <i>The Leanback UI</i>	2010
◦ <i>Testing Your Theories</i>	2024
• Putting the TVs All Together: Decktastic	
◦ <i>Prerequisites</i>	2028
◦ <i>Introducing Decktastic</i>	2028
◦ <i>Trying Decktastic Yourself</i>	2032

◦ <i>Implementing Decktastic</i>	2032
• Creating a MediaRouteProvider	
◦ Prerequisites	2065
◦ Terminology	2065
◦ DIY Chromecast	2066
◦ Creating the MediaRouteProvider	2068
◦ Consuming the MediaRouteProvider	2078
◦ Implementing This “For Realz”	2081
• SSL	
◦ Prerequisites	2085
◦ Basic SSL Operation	2085
◦ Common SSL Problems	2086
◦ TrustManagers	2087
◦ TrustManagerBuilder	2090
◦ About That Man in the Middle	2093
◦ Self-Signed Certificates, Revisited	2095
◦ Certificate Memorizing	2096
◦ Pinning	2100
◦ NetCipher	2101
• Advanced Permissions	
◦ Prerequisites	2103
◦ Securing Yourself	2103
◦ Signature Permissions	2106
◦ The Custom Permission Vulnerability	2108
• Restricted Profiles and UserManager	
◦ Prerequisites	2119
◦ Android Tablets and Multiple User Accounts	2119
◦ Determining What the User Can Do	2125
◦ Impacts of Device-Level Restrictions	2128
◦ Enabling Custom Restrictions	2128
◦ Implicit Intents May Go “Boom”	2139
◦ The Future: App Ops?	2139
• Tapjacking	
◦ Prerequisites	2141
◦ What is Tapjacking?	2141
◦ Detecting Potential Tapjackers	2146
◦ <i>Defending Against Tapjackers</i>	2148
◦ Why Is This Being Discussed?	2151
◦ What Changed in 4.0.3?	2152
• Miscellaneous Security Techniques	
◦ Prerequisites	2153

◦ Public Key Validation	2153
◦ Choosing Your Signing Keysize	2169
◦ Avoiding Accidental APIs	2170
◦ Other Ways to Expose Data	2175
• Accessing Location-Based Services	
◦ Prerequisites	2179
◦ Location Providers: They Know Where You're Hiding	2180
◦ Finding Yourself	2180
◦ On the Move	2182
◦ Are We There Yet? Are We There Yet? Are We There Yet?	2183
◦ Testing... Testing...	2184
◦ Alternative Flavors of Updates	2185
◦ The Fused Option	2186
• The Fused Location Provider	
◦ Prerequisites	2187
◦ Why Use the Fused Location Provider?	2187
◦ Why Not Use the Fused Location Provider?	2188
◦ Finding Our Location, Once	2188
◦ Requesting Location Updates	2197
◦ Gaps in the Fused Location Provider	2199
• Working with the Clipboard	
◦ Prerequisites	2201
◦ Using the Clipboard on Android 1.x/2.x	2201
◦ Advanced Clipboard on Android 3.x and Higher	2204
◦ Monitoring the Clipboard	2209
◦ The Android 4.3 Clipboard Bug	2211
• Telephony	
◦ Prerequisites	2213
◦ Report To The Manager	2214
◦ You Make the Call!	2214
◦ No, Really, You Make the Call!	2217
• Working With SMS	
◦ Prerequisites	2219
◦ <i>Sending Out an SOS, Give or Take a Letter</i>	2220
◦ Monitoring and Receiving SMS	2227
◦ The SMS Inbox	2233
◦ Asking to Change the Default	2234
◦ SMS and the Emulator	2235
• NFC	
◦ Prerequisites	2237
◦ What Is NFC?	2237

◦ To NDEF, Or Not to NDEF	2239
◦ NDEF Modalities	2239
◦ NDEF Structure and Android's Translation	2240
◦ The Reality of NDEF	2241
◦ Sources of Tags	2243
◦ Writing to a Tag	2243

◦ Mobile Devices are Mobile	2253
◦ Enabled and Disabled	2253
◦ Android Beam	2254
◦ Beaming Files	2260
◦ Another Sample: SecretAgentMan	2262
◦ Additional Resources	2271
• Device Administration	
◦ Prerequisites	2273
◦ Objectives and Scope	2273
◦ Defining and Registering an Admin Component	2274
◦ Going Into Lockdown	2280
◦ Passwords and Device Administration	2287
◦ Getting Along with Others	2291
• PowerManager and WakeLocks	
◦ Prerequisites	2293
◦ Keeping the Screen On, UI-Style	2293
◦ The Role of the WakeLock	2294
◦ What WakefulIntentService Does	2295
• JobScheduler	
◦ Prerequisites	2297
◦ The Limitations of AlarmManager	2297
◦ Enter the JobScheduler	2298
◦ Employing JobScheduler	2298
◦ Pondering Backoff Criteria	2311
◦ Other JobScheduler Features	2312
• Push Notifications with GCM	
◦ Prerequisites	2315
◦ The Precursor: C2DM	2316
◦ The Replacement: GCM	2316
◦ The Re-Replacement: GCM 2013	2316
◦ The Pieces of Push	2317
◦ A Simple Push	2323
◦ Message Options and Advanced Features	2337

◦ Re-Registration	2339
◦ <i>Additional Features</i>	2339
◦ Considering Encryption	2342
◦ Issues with GCM	2342
◦ Amazon Simple Notification Service and GCM	2344
• Basic Use of Sensors	
◦ Prerequisites	2345
◦ The Sensor Abstraction Model	2345
◦ Considering Rates	2346
◦ Reading Sensors	2347
◦ Batching Sensor Readings	2357
• Printing and Document Generation	
◦ Prerequisites	2360
◦ The Android Print System	2360
◦ About the Sample App	2361
◦ Printing a Bitmap	2362
◦ Printing an HTML Document	2364
◦ Printing a PDF File	2368
◦ Printing Using a Canvas	2376
◦ Print Jobs	2378
◦ Printing, Threads, and Services	2379
◦ Printing Prior to Android 4.4	2381
◦ HTML Generation	2382
◦ PDF Generation Options	2386
• Other System Settings and Services	
◦ Prerequisites	2387
◦ Setting Expectations	2387
◦ Can You Hear Me Now? OK, How About Now?	2392
◦ The Rest of the Gang	2395
• Dealing with Different Hardware	
◦ Prerequisites	2397
◦ <i>Filtering Out Devices</i>	2397
◦ Runtime Capability Detection	2400
◦ Dealing with Device Bugs	2401
• Responding to URLs	
◦ Prerequisites	2403
◦ Manifest Modifications	2403
◦ Creating a Custom URL	2405
◦ Reacting to the Link	2406
• Plugin Patterns	
◦ Prerequisites	2409

◦ Definitions, Scenarios, and Scope	2409
◦ The Keys to Any Plugin System	2410
◦ Case Study: DashClock	2418
◦ Other Plugin Examples	2421
• PackageManager Tricks	
◦ Prerequisites	2439
◦ Asking Around	2439
◦ Preferred Activities	2443
◦ Middle Management	2448
• Searching with SearchManager	
◦ Prerequisites	2451
◦ Hunting Season	2451
◦ Search Yourself	2453
◦ Searching for Meaning In Randomness	2460
◦ May I Make a Suggestion?	2461
◦ Putting Yourself (Almost) On Par with Google	2465
• Remote Services and the Binding Pattern	
◦ Prerequisites	2471
◦ The Binding Pattern	2472
◦ When IPC Attacks!	2478
◦ Service From Afar	2480
◦ Servicing the Service	2486
◦ Thinking About Security	2491
◦ The “Everlasting Service” Anti-Pattern	2491
• Advanced Manifest Tips	
◦ Prerequisites	2493
◦ Just Looking For Some Elbow Room	2493
◦ Using an Alias	2500
◦ Getting Meta (Data)	2502
• Miscellaneous Integration Tips	
◦ Prerequisites	2507
◦ Take the Shortcut	2507
◦ Homing Beacons for Intents	2514
• Reusable Components	
◦ Prerequisites	2515
◦ Where Do I Find Them?	2515
◦ How Are They Packaged?	2516
◦ How Do I Create Them?	2517
◦ Other Considerations for Publishing Reusable Code	2520
• The Role of Scripting Languages	
◦ Prerequisites	2525

◦ All Grown Up	2525
◦ Following the Script	2526
◦ Going Off-Script	2527
• The Scripting Layer for Android	
◦ Prerequisites	2531
◦ The Role of SL4A	2531
◦ Getting Started with SL4A	2532
◦ Writing SL4A Scripts	2540
◦ Running SL4A Scripts	2545
◦ Potential Issues	2548
• JVM Scripting Languages	
◦ Prerequisites	2551
◦ Languages on Languages	2551
◦ A Brief History of JVM Scripting	2552
◦ Limitations	2553
◦ SL4A and JVM Languages	2554
◦ Embedding JVM Languages	2554
◦ Other JVM Scripting Languages	2568
• Advanced Emulator Capabilities	
◦ Prerequisites	2571
◦ x86 Images	2571
◦ Hardware Graphics Acceleration	2574
◦ Defining New Devices	2577
◦ Keyboard Behavior	2580
◦ Headless Operation	2580
• Using Lint	
◦ Prerequisites	2581
◦ What It Is	2581
◦ When It Runs	2582
◦ What to Fix	2585
◦ What to Configure	2585
• Using Hierarchy View	
◦ Prerequisites	2591
◦ Launching Hierarchy View	2591
◦ Viewing the View Hierarchy	2592
◦ ViewServer	2595
• Using DDMS	
◦ Prerequisites	2597
◦ Starting DDMS	2597
◦ File Push and Pull	2598
◦ Screenshots	2599

◦ Location Updates	2599
◦ Placing Calls and Messages	2600
• Issues with Speed	
◦ Prerequisites	2603
◦ Getting Things Done	2603
◦ Your UI Seems... Janky	2604
◦ Not Far Enough in the Background	2604
◦ Playing with Speed	2605
• Finding CPU Bottlenecks	
◦ Prerequisites	2607
◦ Traceview	2608
◦ Other General CPU Measurement Techniques	2617
◦ UI “Jank” Measurement	2619
• Focus On: NDK	
◦ Prerequisites	2635
◦ The Role of the NDK	2636
◦ NDK Installation and Project Setup	2639
◦ Writing Your Makefile(s)	2643
◦ Building Your Library	2644
◦ Using Your Library Via JNI	2645
◦ Building and Deploying Your Project	2650
◦ Gradle and the NDK	2652
• Improving CPU Performance in Java	
◦ Prerequisites	2659
◦ Reduce CPU Utilization	2659
◦ Reduce Time on the Main Application Thread	2664
◦ Improve Throughput and Responsiveness	2672
• Finding and Eliminating Jank	
◦ Prerequisites	2675
◦ The Case: ThreePaneDemoBC	2675
◦ Are We Janky?	2676
◦ Finding the Source of the Jank	2676
◦ Where Things Went Wrong	2686
◦ Removing the Jank	2687
• Issues with Bandwidth	
◦ Prerequisites	2689
◦ You’re Using Too Much of the Slow Stuff	2690
◦ You’re Using Too Much of the Expensive Stuff	2690
◦ You’re Using Too Much of Somebody Else’s Stuff	2691
◦ You’re Using Too Much... And There Is None	2692
• Focus On: TrafficStats	

◦ Prerequisites	2693
◦ TrafficStats Basics	2693
◦ Example: TrafficMonitor	2695
◦ Other Ways to Employ TrafficStats	2703
• Measuring Bandwidth Consumption	
◦ Prerequisites	2705
◦ On-Device Measurement	2705
◦ Off-Device Measurement	2707
◦ Tactical Measurement in DDMS	2709
• Being Smarter About Bandwidth	
◦ Prerequisites	2713
◦ Bandwidth Savings	2713
◦ Bandwidth Shaping	2719
◦ Avoiding Metered Connections	2722
• Issues with Application Heap	
◦ Prerequisites	2725
◦ You Are in a Heap of Trouble	2726
◦ Determining Your Heap Size At Runtime	2726
◦ Fragments of Memory	2727
◦ Getting a Trim	2728
◦ Warning: Contains Graphic Images	2729
◦ Releasing SQLite Memory	2740
◦ In Too Deep (on the Stack)	2740
• Finding Memory Leaks with MAT	
◦ Prerequisites	2743
◦ Setting Up MAT	2743
◦ Getting Heap Dumps	2744
◦ Basic MAT Operation	2750
◦ Some Leaks and Their MAT Analysis	2757
• Issues with System RAM	
◦ Prerequisites	2765
◦ Can't We All Just Get Along?	2765
◦ Contributors to System RAM Consumption	2766
◦ Measuring System RAM Consumption: Tools	2767
◦ Measuring System RAM Consumption: Runtime	2782
◦ Learn To Let Go (Of Your Heap)	2783
• Issues with Battery Life	
◦ Prerequisites	2785
◦ You're Getting Blamed	2786
◦ Not All Batteries Are Created Equal	2787
◦ Stretching Out the Last mWh	2787

• Power Measurement Options	
◦ Prerequisites	2789
◦ batterystats and the Battery Historian	2790
◦ The Qualcomm Tool (That Must Not Be Named)	2800
◦ PowerTutor	2801
◦ Battery Screen in Settings Application	2805
◦ BatteryInfo Dump	2807
• Sources of Power Drain	
◦ Prerequisites	2811
◦ Screen	2812
◦ Disk I/O	2813
◦ WiFi and Mobile Data	2814
◦ GPS	2817
◦ Camera	2818
◦ Additional Sources	2818
• Addressing Application Size Issues	
◦ Prerequisites	2821
◦ Java Code, and the 64K Method Limit	2821
◦ Native Code	2826
◦ Images	2828
◦ APK Expansion Files	2829
• The Role of Alternative Environments	
◦ Prerequisites	2831
◦ In the Beginning, There Was Java...	2832
◦ ... And It Was OK	2832
◦ Bucking the Trend	2833
◦ Support, Structure	2833
◦ Caveat Developer	2834
• HTML5	
◦ Prerequisites	2835
◦ Offline Applications	2835
◦ Web Storage	2842
◦ Going To Production	2845
◦ Issues You May Encounter	2846
◦ HTML5: The Baseline	2849
• PhoneGap	
◦ Prerequisites	2851
◦ What Is PhoneGap?	2851
◦ Using PhoneGap	2854
◦ PhoneGap and the Checklist Sample	2859
◦ Issues You May Encounter	2864

◦ For More Information	2867
• Other Alternative Environments	
◦ Prerequisites	2869
◦ Rhodes	2869
◦ Flash, Flex, and AIR	2870
◦ JRuby and Ruboto	2870
◦ App Inventor	2871
◦ Titanium Mobile	2873
◦ Other JVM Compiled Languages	2874
• Anti-Patterns	
◦ Prerequisites	2877
◦ Leak Threads... Or Things Attached to Threads	2877
◦ Use Large Heap Unnecessarily	2879
◦ Misuse the MENU Button	2881
◦ Interfere with Navigation	2882
◦ Use android:sharedUserId	2884
◦ Implement a “Quit” Button	2885
◦ Terminate Your Process	2887
◦ Try to Hide from the User	2888
◦ Use Multiple Processes	2889
◦ Hog System Resources	2891
• Widget Catalog: AdapterViewFlipper

Preface

Welcome to the Book!

Thanks!

Thanks for your interest in developing applications for Android! Android has grown from nothing to arguably the world's most popular smartphone OS in a few short years. Whether you are developing applications for the public, for your business or organization, or are just experimenting on your own, I think you will find Android to be an exciting and challenging area for exploration.

And, most of all, thanks for your interest in this book! I sincerely hope you find it useful and at least occasionally entertaining.

The Book's Structure

As you may have noticed, this is a rather large book.

To make the equivalent of 2,800+ pages of material manageable, the chapters are divided into the *core* chapters and a series of *trails*.

The core chapters represent many key concepts that Android developers need to understand in order to build an app. While an occasional “nice to have” topic will drift into the core — to help illustrate a point, for example — the core chapters generally are fairly essential.

The core chapters are designed to be read in sequence and will interleave both traditional technical book prose with tutorial chapters, to give you hands-on experience with the concepts being discussed. Most of the tutorials can be skipped,

though the first two — covering setting up your SDK environment and creating a project – everybody should read.

The bulk of the chapters are divided into trails, covering some particular general topic, from data storage to advanced UI effects to performance measurement and tuning. Each trail will have several chapters. However, those chapters, and the trails themselves, are not necessarily designed to be read in any order. Each chapter in the trails will point out prerequisite chapters or concepts that you will want to have covered in advance. Hence, these chapters are mostly reference material, for when you specifically want to learn something about a specific topic.

The core chapters will link to chapters in the trails, to show you where you can find material related to the chapter you just read. So between the book's table of contents, this preface, the search tool in your digital book reader, and the cross-chapter links, you should have plenty of ways of finding the material you want to read.

You are welcome to read the entire book front-to-back if you wish. The trails will appear after the core chapters. Those trails will be in a reasonably logical order, though you may have to hop around a bit to cover all of the prerequisites.

The Trails

Here is a list of all of the trails and the chapters that pertain to those trails, in order of appearance (except for those appearing in the list multiple times, where they span major categories):

Code Organization and Gradle

- [Working with Library Projects](#)
- [Gradle and Legacy Projects](#)
- [Gradle and Tasks](#)
- [Gradle and the New Project Structure](#)
- [Gradle and Dependencies](#)
- [Manifest Merger Rules](#)
- [Signing Your App](#)
- [Distribution](#)
- [Advanced Gradle for Android Tips](#)

Testing

- [JUnit and Android](#)
- [Testing with JUnit4](#)
- [MonkeyRunner and the Test Monkey](#)
- [Testing with UIAutomator](#)

Advanced UI

- [Introducing GridLayout](#)
- [Dialogs and DialogFragments](#)
- [Advanced ListViews](#)
- [Action Bar Navigation](#)
- [Action Modes and Context Menus](#)
- [Other Advanced Action Bar Techniques](#)
- [AppCompat: The Official Action Bar Backport](#)
- [ActionBarSherlock](#)
- [Implementing a Navigation Drawer](#)
- [Advanced Uses of WebView](#)
- [The Input Method Framework](#)
- [Fonts](#)
- [Rich Text](#)
- [Animators](#)
- [Legacy Animations](#)
- [Custom Drawables](#)
- [Mapping with Maps V2](#)
- [Crafting Your Own Views](#)
- [Custom Dialogs and Preferences](#)
- [Progress Indicators](#)
- [Advanced Notifications](#)
- [More Fun with Pagers](#)
- [Focus Management and Accessibility](#)
- [Miscellaneous UI Tricks](#)
- [Event Bus Alternatives](#)

Home Screen Effects

- [Home Screen App Widgets](#)
- [Adapter-Based App Widgets](#)

Data Storage and Retrieval

- [Content Provider Theory](#)
- [Content Provider Implementation Patterns](#)
- [The Loader Framework](#)
- [The ContactsContract Provider](#)
- [The CalendarContract Provider](#)
- [The MediaStore Provider](#)
- [Consuming Documents](#)
- [Providing Documents](#)
- [Encrypted Storage](#)
- [Packaging and Distributing Data](#)
- [Advanced Database Techniques](#)
- [Miscellaneous Network Capabilities](#)

Media

- [Audio Playback](#)
- [Audio Recording](#)
- [Video Playback](#)
- [Using the Camera via 3rd-Party Apps](#)
- [Working Directly with the Camera](#)
- [The MediaStore Provider](#)
- [Media Routes](#)
- [Supporting External Displays](#)
- [Google Cast and ChromeCast](#)
- [The “10 Foot UI”](#)
- [Putting the TVs All Together: Decktastic](#)
- [Creating a MediaRouteProvider](#)

Security

- [SSL](#)
- [Encrypted Storage](#)
- [Advanced Permissions](#)
- [Restricted Profiles and UserManager](#)
- [Tapjacking](#)
- [Miscellaneous Security Techniques](#)

Hardware and System Services

- [Accessing Location-Based Services](#)
- [The Fused Location Provider](#)
- [Working with the Clipboard](#)
- [Telephony](#)
- [Working With SMS](#)
- [NFC](#)
- [Device Administration](#)
- [PowerManager and WakeLocks](#)
- [JobScheduler](#)
- [Push Notifications with GCM](#)
- [Basic Use of Sensors](#)
- [Printing and Document Generation](#)
- [Other System Settings and Services](#)
- [Dealing with Different Hardware](#)

Integration and Introspection

- [Responding to URLs](#)
- [Plugin Patterns](#)
- [PackageManager Tricks](#)
- [Searching with SearchManager](#)
- [Remote Services and the Binding Pattern](#)
- [Advanced Manifest Tips](#)
- [Miscellaneous Integration Tips](#)
- [Reusable Components](#)

Scripting Languages

- [The Role of Scripting Languages](#)
- [The Scripting Layer for Android](#)
- [JVM Scripting Languages](#)

Other Tools

- [Advanced Emulator Capabilities](#)
- [Using Lint](#)
- [Using Hierarchy View](#)
- [Using DDMS](#)

- [Finding CPU Bottlenecks](#)
- [Finding Memory Leaks with MAT](#)

Tuning Android Applications

- [Issues with Speed](#)
- [Finding CPU Bottlenecks](#)
- [NDK](#)
- [Improving CPU Performance in Java](#)
- [Finding and Eliminating Jank](#)
- [Issues with Bandwidth](#)
- [Focus On: TrafficStats](#)
- [Measuring Bandwidth Consumption](#)
- [Being Smarter About Bandwidth](#)
- [Issues with Application Heap](#)
- [Finding Memory Leaks with MAT](#)
- [Issues with System RAM](#)
- [Issues with Battery Life](#)
- [Other Power Measurement Options](#)
- [Sources of Power Drain](#)
- [Addressing Application Size Issues](#)

Alternatives for App Development

- [The Role of Alternative Environments](#)
- [HTML5](#)
- [PhoneGap](#)
- [Other Alternative Environments](#)

Miscellaneous Topics

- [Anti-Patterns](#)

Widget Catalog

- [AdapterViewFlipper](#)
- [CalendarView](#)
- [DatePicker](#)
- [ExpandableListView](#)
- [SeekBar](#)

- [SlidingDrawer](#)
- [StackView](#)
- [TabHost](#)
- [TimePicker](#)
- [ViewFlipper](#)

Device Catalog

- [Kindle Fire](#)
- [BlackBerry](#)
- [Wrist Wearables](#)
- [Google TV](#)
- [Amazon Fire TV](#)

Appendices

- [Appendix A: CWAC Libraries](#)

About the Updates

This book is updated frequently, typically every 6–8 weeks.

Each release has notations to show what is new or changed compared with the immediately preceding release:

- The Table of Contents shows sections with changes in bold-italic font
- Those sections have changebars on the right to denote specific paragraphs that are new or modified

Warescription

You (hopefully) are reading this digital book by means of a Warescription.

The Warescription entitles you, for the duration of your subscription, to digital editions of this book and its updates, in PDF, EPUB, and Kindle (MOBI/KF8) formats. You also have access to a version of the book as its own Android APK file, complete with high-speed full-text searching. You also have access to other titles that CommonsWare may publish during that subscription period.

PREFACE

Each subscriber gets personalized editions of all editions of each title. That way, your books are never out of date for long, and you can take advantage of new material as it is made available. For example, when new releases of the Android SDK are made available, this book will be quickly updated to be accurate with changes in the APIs.

However, you can only download the books if either you have an active Warescription, or until the book is updated after your Warescription expires. Hence, **please download your updates as they come out**. You can find out when new releases of this book are available via:

1. The [commonsguy](#) Twitter feed
2. The [CommonsBlog](#)
3. The Warescription newsletter, which you can subscribe to off of your [Warescription](#) page
4. Just check back on the [Warescription](#) site every month or two

Subscribers also have access to other benefits, including:

- “Office hours” — online chats to help you get answers to your Android application development questions. You will find a calendar for these on your Warescription page.
- A Stack Overflow “bump” service, to get additional attention for a question that you have posted there that does not have an adequate answer.
- 80% off of live webinars hosted by Mark Murphy, the author of this book, on Android application development topics.

Book Bug Bounty

Find a problem in one of our books? Let us know!

Be the first to report a unique concrete problem in the current digital edition, and we will extend your Warescription by six months as a bounty for helping us deliver a better product.

By “concrete” problem, we mean things like:

1. Typographical errors
2. Sample applications that do not work as advertised, in the environment described in the book

3. Factual errors that cannot be open to interpretation

By “unique”, we mean ones not yet reported. Be sure to check [the book’s errata page](#), though, to see if your issue has already been reported. One coupon is given per email containing valid bug reports.

We appreciate hearing about “softer” issues as well, such as:

1. Places where you think we are in error, but where we feel our interpretation is reasonable
2. Places where you think we could add sample applications, or expand upon the existing material
3. Samples that do not work due to “shifting sands” of the underlying environment (e.g., changed APIs with new releases of an SDK)

However, those “softer” issues do not qualify for the formal bounty program.

Questions about the bug bounty, or problems you wish to report for bounty consideration, should be sent to bounty@commonsware.com.

Source Code and Its License

The source code samples shown in this book are available for download from the [book’s GitHub repository](#). All of the Android projects are licensed under the [Apache 2.0 License](#), in case you have the desire to reuse any of it.

If you wish to use the source code from the GitHub repository, please follow the instructions on that repository’s home page for details of how to use the projects in various development environments, notably Eclipse and Android Studio.

If you are using Eclipse, please do **NOT** import all of the projects from the repo into your main workspace. There are *hundreds* of these projects, and they may cause your Eclipse environment to become very slow, particularly when starting it up. Instead, import only those specific projects that you want to work with “live” as opposed to simply reading about them in the book.

Copying source code directly from the book, in the PDF editions, works best with Adobe Reader, though it may also work with other PDF viewers. Some PDF viewers, for reasons that remain unclear, foul up copying the source code to the clipboard when it is selected.

Creative Commons and the Four-to-Free (42F) Guarantee

Each CommonsWare book edition will be available for use under the [Creative Commons Attribution-Noncommercial-ShareAlike 3.0](#) license as of the fourth anniversary of its publication date, or when 4,000 copies of the edition have been sold, whichever comes first. That means that, once four years have elapsed (perhaps sooner!), you can use this prose for non-commercial purposes. That is our Four-to-Free Guarantee to our readers and the broader community. For the purposes of this guarantee, new Warescriptions and renewals will be counted as sales of this edition, starting from the time the edition is published.

This edition of this book will be available under the aforementioned Creative Commons license on *1 January 2019*. Of course, watch the CommonsWare Web site, as this edition might be relicensed sooner based on sales.

For more details on the Creative Commons Attribution-Noncommercial-ShareAlike 3.0 license, visit [the Creative Commons Web site](#)

Note that future editions of this book will become free on later dates, each four years from the publication of that edition or based on sales of that specific edition. Releasing one edition under the Creative Commons license does not automatically release *all* editions under that license.

Acknowledgments

I would like to thank the Android team, not only for putting out a good product, but for invaluable assistance on the Android Google Groups and Stack Overflow.

I would also like to thank the thousands of readers of past editions of this book, for their feedback, bug reports, and overall support.

Of course, thanks are also out to the overall Android ecosystem, particularly those developers contributing their skills to publish libraries, write blog posts, answer support questions, and otherwise contribute to the strength of Android.

Portions of this book are reproduced from work created and shared by the Android Open Source Project and used according to terms described in the Creative Commons 2.5 Attribution License.

Core Chapters

Key Android Concepts

No doubt, you are in a hurry to get started with Android application development. After all, you are reading this book, aimed at busy coders.

However, before we dive into getting tools set up and starting in on actual programming, it is important that we “get on the same page” with respect to several high-level Android concepts. This will simplify further discussions later in the book.

Android Applications

This book is focused on writing Android applications. An application is something that a user might install from the Play Store or otherwise download to their device. That application should have some user interface, and it might have other code designed to work in the background (multi-tasking).

This book is not focused on modifications to the Android firmware, such as writing device drivers. For that, you will need to seek [other resources](#).

This book assumes that you have some hands-on experience with Android devices, and therefore you are familiar with buttons like HOME and BACK, the built-in Settings application, the concept of a home screen and launcher, and so forth. If you have never used an Android device, you are strongly encouraged to get one (e.g., a used one on eBay, Craigslist, etc.) and spend some time with it before starting in on learning Android application development.

Programming Language

The vast majority of Android applications are written exclusively in Java. Hence, that is what this book will spend most of its time on and will demonstrate with a seemingly infinite number of examples.

However, there are other options:

- You can write parts of the app in C/C++, for performance gains, porting over existing code bases, etc.
- You can write an entire app in C/C++, mostly for games using OpenGL for 3D animations
- You can write the guts of an app in HTML, CSS, and JavaScript, using tools to package that material into an Android application that can be distributed through the Play Store and similar venues
- And so on

Coverage of these non-Java alternatives will be found in the trails of this book, as the bulk of this book is focused on Java.

The author assumes that you know Java at this point. If you do not, you will need to learn Java before you go much further. You do not need to know *everything* about Java, as Java is vast. Rather, focus on:

- [Language fundamentals](#) (flow control, etc.)
- [Classes and objects](#)
- [Methods](#) and [data members](#)
- [Public, private, and protected](#)
- [Static and instance scope](#)
- [Exceptions](#)
- [Threads](#)
- [Collections](#)
- [Generics](#)
- [File I/O](#)
- [Reflection](#)
- [Interfaces](#)

The links are to Wikibooks material on those topics, though there are countless other Java resources for you to consider.

Components

When you first learned Java — whether that was yesterday or back when dinosaurs roamed the Earth — you probably started off with something like this:

```
class SillyApp {  
    public static void main(String[] args) {  
        System.out.println("Hello World!");  
    }  
}
```

In other words, the entry point into your application was a public static void method named `main()` that took a String array of arguments. From there, you were responsible for doing whatever was necessary.

However, there are other patterns used elsewhere in Java. For example, you do not usually write a `main()` method when writing a Java servlet. Instead, you extend a particular class supplied by a framework (e.g., `HttpServlet`) to create a component, then write some metadata that enumerates your components and tell the framework when and how to use them (e.g., `WEB.XML`).

Android apps are closer in spirit to the servlet approach. You will not write a public static void `main()` method. Instead, you will create subclasses of some Android-supplied base classes that define various application components. In addition, you will create some metadata that tells Android about those subclasses.

There are four types of components, all of which will be covered extensively in this book:

Activities

The building block of the user interface is the *activity*. You can think of an activity as being the Android analogue for the window or dialog in a desktop application, or the page in a classic Web app. It represents a chunk of your user interface and, in some cases, a discrete entry point into your app (i.e., a way for other apps to link to your app).

Normally, an activity will take up most of the screen, leaving space for some “chrome” bits like the clock, signal strength indicators, and so forth.

KEY ANDROID CONCEPTS

Figure 1: Activity on the screen

Services

Activities are short-lived and can be shut down at any time, such as when the user presses the BACK button. *Services*, on the other hand, are designed to keep running, if needed, independent of any activity, for a moderate period of time. You might use a service for checking for updates to an RSS feed, or to play back music even if the controlling activity is no longer operating. You will also use services for scheduled tasks (akin to Linux or OS X “cron jobs”) and for exposing custom APIs to other applications on the device, though the latter is a relatively advanced capability.

Content Providers

Content providers provide a level of abstraction for any data stored on the device that is accessible by multiple applications. The Android development model encourages you to make your own data available to other applications, as well as your own — building a content provider lets you do that, while maintaining a degree of control over how your data gets accessed.

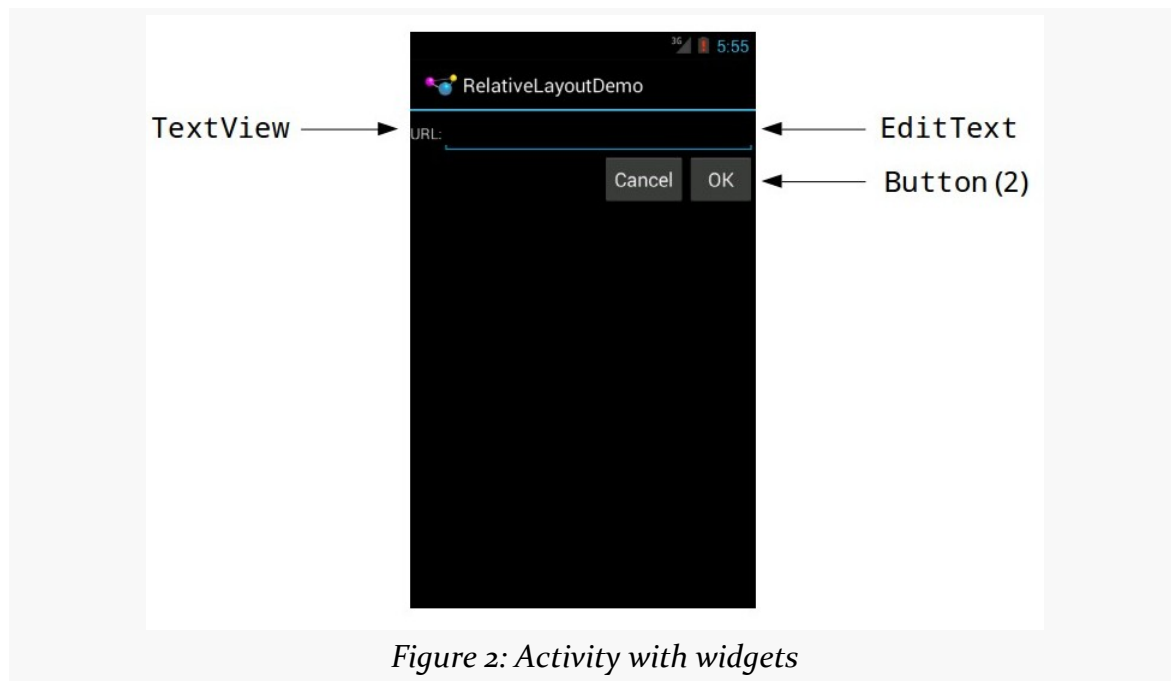

Broadcast Receivers

The system, or applications, will send out *broadcasts* from time to time, for everything from the battery getting low, to when the screen turns off, to when connectivity changes from WiFi to mobile data. A broadcast receiver can arrange to listen for these broadcasts and respond accordingly.

Widgets, Containers, Resources, and Fragments

Most of the focus on Android application development is on the UI layer and activities. Most Android activities use what is known as “the widget framework” for rendering their user interface, though you are welcome to use the 2D (Canvas) and 3D (OpenGL) APIs as well for more specialized GUIs.

In Android terms, a *widget* is the “micro” unit of user interface. Fields, buttons, labels, lists, and so on are all widgets. Your activity’s UI, therefore, is made up of one or more of these widgets. For example, here we see label (TextView), field (EditText), and push-button (Button) widgets:

If you have more than one widget — which is fairly typical — you will need to tell Android how those widgets are organized on the screen. To do that, you will use

KEY ANDROID CONCEPTS

various container classes referred to as *layout managers*. These will let you put things in rows, columns, or more complex arrangements as needed.

To describe how the containers and widgets are connected, you will typically create a *layout resource file*. *Resources* in Android refer to things like images, strings, and other material that your application uses but is not in the form of some programming language source code. UI layouts are another type of resource. You will create these layouts either using a structured tool, such as an IDE's drag-and-drop GUI builder, or by hand in XML form.

Sometimes, your UI will work across all sorts of devices: phones, tablets, televisions, etc. Sometimes, your UI will need to be tailored for different environments. You will be able to put resources into *resource sets* that indicate under what circumstances those resources can be used (e.g., use these for normal-sized screens, but use those for larger screens).

Sometimes, supporting larger screens means you will want to “snap together” parts of your smaller-screen UI. For example, Gmail on a tablet will show your list of labels, the list of conversations in a selected label, and the list of messages in a selected conversation, all in one activity. However, Gmail on a phone cannot do that, as there is not enough screen space, so it shows each of those (labels, conversations, messages) in separate activities. Android supplies a construct called the *fragment* to help make it easier for you to implement these sorts of effects.

We will be examining all of these concepts, in much greater detail, as we get deeper into the book.

Apps and Packages

Given a bucket of source code and a basket of resources, the Android build tools will give you an application as a result. The application comes in the form of an *APK file*. It is that APK file that you will upload to the Play Store or distribute by other means.

Each Android application has a package name. A package name must fulfill three requirements:

1. It must be a valid Java package name, as some Java source code will be generated by the Android build tools in this package
2. No two applications can exist on a device at the same time with the same package

3. No two applications can be uploaded to the Play Store having the same package

Note that sometimes you will see reference to an “application ID” — this is the role of the package name from the second and third items in the list.

When you create your Android project — the repository of that source code and those resources — you will declare what package name is to be used for your app. Typically, you will pick a package name following the Java package name “reverse domain name” convention (e.g., `com.commonsware.android.foo`). That way, the domain name system ensures that your package name prefix (`com.commonsware`) is unique, and it is up to you to ensure that the rest of the package name distinguishes one of your apps from any other.

Android Devices

There are well in excess of one billion Android devices in use today, representing thousands of different models from dozens of different manufacturers. Android itself has evolved since Android 1.0 in 2008. Between different device types and different Android versions, many a media pundit has lobbed the term “fragmentation” at Android, suggesting that creating apps that run on all these different environments is impossible.

In reality, it is not that bad. Some apps will have substantial trouble, but most apps will work just fine if you follow the guidance presented in this book and in other resources.

Types

Android devices come in all shapes, sizes, and colors. However, there are four dominant “form factors”:

- the phone
- the tablet
- the television (TV)
- the wearable (smart watches, Google Glass, etc.)

You will often hear developers and pundits refer to these form factors, and this book will do so from time to time as well. However, it is important that you understand that Android has no built-in concept of a device being a “phone” or a “tablet” or a

“TV”. Rather, Android distinguishes devices based on capabilities and features. So, you will not see an `isPhone()` method anywhere, though you can ask Android:

- what is the screen size?
- does the device have telephony capability?
- etc.

Similarly, as you build your applications, rather than thinking of those four form factors, focus on what capabilities and features you need. Not only will this help you line up better with how Android wants you to build your apps, but it will make it easier for you to adapt to other form factors that will come about such as:

- airplane seat-back entertainment centers
- in-car navigation and entertainment devices
- and so on

The Emulator

While there are over a billion Android devices representing thousands of models, probably you do not have one of each model. You may only have a single piece of Android hardware. And if you do not even have that, you most certainly will want to acquire one before trying to publish an Android app.

To help fill in the gaps between the devices you have and the devices that are possible, the Android developer tools ship an *emulator*. The emulator behaves like a piece of Android hardware, but it is a program you run on your development machine. You can use this emulator to emulate many different devices, with different screen sizes and Android OS versions, by creating one or more Android virtual devices, or *AVDs*.

In [an upcoming chapter](#), we will discuss how you install the Android developer tools and how you will be able to [create these AVDs and run the emulator](#).

OS Versions and API Levels

Android has come a long way since the early beta releases from late 2007. Each new Android OS version adds more capabilities to the platform and more things that developers can do to exploit those capabilities.

Moreover, the core Android development team tries very hard to ensure forwards and backwards compatibility. An app you write today should work unchanged on

KEY ANDROID CONCEPTS

future versions of Android (forwards compatibility), albeit perhaps missing some features or working in some sort of “compatibility mode”. And there are well-trodden paths for how to create apps that will work both on the latest and on previous versions of Android (backwards compatibility).

To help us keep track of all the different OS versions that matter to us as developers, Android has *API levels*. A new API level is defined when an Android version ships that contains changes that affect developers. When you create an emulator AVD to test your app, you will indicate what API level that emulator should emulate. When you distribute your app, you will indicate the oldest API level your app supports, so the app is not installed on older devices.

At the time of this writing, the API levels of significance to most Android developers are:

- API Level 10 (Android 2.3.3)
- API Level 15 (Android 4.0.3)
- API Level 16 (Android 4.1)
- API Level 17 (Android 4.2)
- API Level 18 (Android 4.3)
- API Level 19 (Android 4.4)

Here, “of significance” refers to API levels that have a reasonable number of Android devices — 5% or more, as reported by [the “Platform Versions” dashboard chart](#).

The latest API level for most form factors is 21, representing Android 5.0. There is an API Level 20, which is the version of Android running on the first-generation Android Wear devices. Unless you are specifically developing apps for Wear, you will not be worrying much about API Level 20.

Dalvik

In terms of Android, Dalvik is a virtual machine (VM). Virtual machines are used by many programming languages, such as Java, Perl, and Smalltalk. The Dalvik VM is designed to work much like a Java VM, but optimized for embedded Linux environments.

So, what really goes on when somebody writes an Android application is:

1. Developers write Java-syntax source code, leveraging class libraries published by the Android project and third parties.

2. Developers compile the source code into Java VM bytecode, using the `javac` compiler that comes with the Java SDK.
3. Developers translate the Java VM bytecode into Dalvik VM bytecode, which is packaged with other files into a ZIP archive with the `.apk` extension (the APK file).
4. An Android device or emulator runs the APK file, causing the bytecode to be executed by an instance of a Dalvik VM.

From your standpoint, most of this is hidden by the build tools. You pour Java source code into the top, and the APK file comes out the bottom.

However, there will be places from time to time where the differences between the Dalvik VM and the traditional Java VM will affect application developers, and this book will point out some of them where relevant.

Note that Android is moving to a new runtime environment, called ART. However, the “Dalvik” term will still be used for the bytecode that is generated as part of building an APK.

Processes and Threads

When your application runs, it will do so in its own process. This is not significantly different than any other traditional operating system. Part of Dalvik’s magic is making it possible for many processes to be running many Android applications at one time without consuming ridiculous amounts of RAM.

Android will also set up a batch of threads for running your app. The thread that your code will be executed upon, most of the time, is variously called the “main application thread” or the “UI thread”. You do not have to set it up, but, as we will see later in the book, you will need to pay attention to what you do and do not do on that thread. You are welcome to fork your own threads to do work, and that is fairly common, though in some places Android handles that for you behind the scenes.

Don’t Be Scared

Yes, this chapter threw a lot of terms at you. We will be going into greater detail on all of them in this book. However, Android is like a jigsaw puzzle with lots of interlocking pieces. To be able to describe one concept in detail, we will need to at least reference some of the others. Hence, this chapter was meant to expose you to terms, in hopes that they will sound vaguely familiar as we dive into the details.

Choosing Your Development Toolchain

Before you go much further in your Android endeavors (or, possibly, endeavours, depending upon your preferred spelling), you will need to determine what toolchain you will use to build your Android applications.

Android Studio

The next-generation Google-backed Android IDE is Android Studio. Based off of [IntelliJ IDEA](#), Android Studio is the new foundation of Google's efforts to give Android developers top-notch development tools. While it only reached a version 1.0 status in December 2014, Android Studio had been in use for ~18 months prior to that in various early-access and beta stages. While it still has bugs, it is certainly stable enough for app development.

The [next chapter contains a section with instructions](#) on how to set up Android Studio.

Eclipse

Eclipse is also a popular IDE, particularly for Java development. Eclipse was Google's original IDE for Android development, by means of the Android Developer Tools (ADT) add-in, which gives the core of Eclipse awareness of Android. The ADT add-in, in essence, takes regular Eclipse operations and extends them to work with Android projects.

Note, though, that Google has discontinued maintenance of ADT. The Eclipse Foundation is setting up the “Andmore” project to try to continue work on allowing Eclipse to build Android apps. This book does not cover the Andmore project at this time, and developers are **strongly** encouraged to not use the ADT-enabled Eclipse from Google.

For historical reasons, the [next chapter contains a section with instructions](#) on how to set up Eclipse for Android development, as part of getting an overall Android development environment established. Similarly, there will be Eclipse instructions in the tutorials and notes about using Eclipse elsewhere in the book. These will be removed from a future edition of the book, or perhaps migrated over to Andmore.

IntelliJ IDEA

While Android Studio is based off of IntelliJ IDEA, you can still use the original IntelliJ IDEA for Android app development. A large subset of the Android Studio capabilities are available in the Android plugin for IDEA. Plus, the commercial IDEA Ultimate Edition will go beyond Android Studio in many areas outside of Android development.

Command-Line Builds via Gradle for Android

And, of course, you do not need to use an IDE at all. While this may sound sacrilegious to some, IDEs are not the only way to build applications. Much of what is accomplished via the ADT can be accomplished through command-line equivalents, meaning a shell and an editor is all you truly need. For example, the author of this book did not use an IDE for Android development until 2011.

The recommended way to build Android apps outside of an IDE is by means of Gradle. Google has published a Gradle plugin that teaches Gradle how to build Android apps. Android Studio itself uses Gradle for its builds, so a single build configuration (e.g., `build.gradle` files) can be used both from an IDE and from a build automation tool like a continuous integration server.

An [upcoming chapter](#) gets into more about what Gradle (and the Gradle for Android plugin) are all about.

Yet Other Alternatives

Other IDEs have their equivalents of the ADT, albeit with minimal assistance from Google. For example, NetBeans has support via the NBAndroid add-on, and reportedly this has advanced substantially in the past few years.

You will also hear reference to using Apache Ant for doing command-line builds of Android apps. This has largely been supplanted by Gradle for Android at this time, and support for Apache Ant will end soon. Newcomers to Android are encouraged to not invest time in new work with Apache Ant for Android development projects.

IDEs... And This Book

You are welcome to use Android Studio or Eclipse as you work through this book. You are welcome to use another IDE if you wish. You are even welcome to skip the IDE outright and just use an editor.

This book is focused primarily on demonstrating Android capabilities and the APIs for exploiting those capabilities. Hence, the sample code will work with any IDE. However, this book will cover some Android Studio- and Eclipse-specific instructions, since they are the predominant answers today.

The tutorials will have instructions for both Android Studio and Eclipse.

What We Are Not Covering

In the beginning (a.k.a., 2007), we were lucky to have any means of creating an Android app.

Nowadays, there seems to be no end to the means by which we can create an Android app.

There are a few of these “means”, though, that are specifically out of scope for this book.

App Inventor

You may also have heard of a tool named App Inventor and wonder where it fits in with all of this.

App Inventor was originally created by an education group within Google, as a means of teaching students how to think about programming constructs (branches, loops, etc.) and create interesting output (Android apps) without classic programming in Java or other syntax-based languages. App Inventor is purely drag-and-drop, both of widgets *and application logic*, the latter by means of “blocks” that snap together to form logic chains.

App Inventor was donated by Google to MIT, which has recently re-opened it [to the public](#).

However, App Inventor is a closed system — at the present time, it does not somehow generate Java code that you can later augment. That limits you to whatever App Inventor is natively capable of doing, which, while impressive in its own right, offers a small portion of the total Android SDK capabilities.

App Generators

There are a seemingly infinite number of “app generators” available as online services. These are designed mostly for creating apps for specific vertical markets, such as apps for restaurants or apps for grocers. The resulting apps are mostly “brochure-ware”, with few capabilities beyond a mobile Web site, yet still requiring the user to find, download, and install the app. Few of these generators provide the source code to the generated app, to allow the apps to be customized beyond what the generator generates.

Tutorial #1 - Installing the Tools

Now, let us get you set up with the pieces and parts necessary to build an Android app.

NOTE: The instructions presented here are accurate as of the time of this writing. However, the tools change rapidly, and so these instructions may be out of date by the time you read this. Please refer to the [Android Developers Web site](#) for current instructions, using this as a base guideline of what to expect.

Step #1 - Checking Your Hardware Requirements

Compiling and building an Android application, on its own, is not especially hardware-intensive, except for very large projects. However, there are two commonly-used tools that demand more from your development machine: your IDE and the Android emulator. Of the two, the emulator poses the bigger problem.

The more RAM you have, the better. 8GB or higher is a very good idea if you intend to use an IDE and the emulator together.

A faster CPU is also a good idea. However, the Android emulator only utilizes a single core from your development machine. Hence, it is the single-core speed that matters. The best CPU to use is one that can leverage multiple cores to give what amounts to a faster single core, such as Intel's Core i7 with Turbo Boost. For an emulator simulating a larger-screened device (e.g., tablet, television), a Core i7 that can "boost" up to 3.4GHz makes development much more pleasant. Conversely, a CPU like a Core 2 Duo with a 2.5GHz clock speed results in a tablet emulator that is nearly unusable.

Step #2 - Setting Up Java and 32-Bit Linux Support

When you write Android applications, you typically write them in Java source code. That Java source code is then turned into the stuff that Android actually runs (Dalvik bytecode in an APK file).

You need to obtain and install the official Sun/Oracle Java SE SDK (JDK). You can obtain this from the [Oracle Java Web site](#) for Windows, OS X, and Linux. The plain JDK (sans any “bundles”) should suffice. Follow the instructions supplied by Oracle or Apple for installing it on your machine. At the time of this writing, Android supports Java 6 and Java 7, though Java 7 is required for certain scenarios and therefore is recommended. Java 8 works, though you may have to do additional work to configure your IDE to have Java 8 emit Java 7-compatible bytecode.

Android also supports the OpenJDK, particularly on Linux environments.

What Android does *not* support are any other Java compilers, including the GNU Compiler for Java (GCJ).

If your development OS is Linux, make sure that you can run 32-bit Linux binaries. This may or may not already be enabled in your Linux distro. For example, on Ubuntu 14.10, you may need to run the following to get the 32-bit binary support installed that is needed by the Android build tools:

```
sudo apt-get install lib32z1 lib32ncurses5 lib32bz2-1.0 lib32stdc++6
```

Step #3 - Install the Developer Tools

As noted in the previous chapter, there are a few developer tools that you can choose from.

There are three major options that this book covers:

1. Use [Android Studio](#)
2. Use Eclipse, as a fresh install via the [ADT Bundle](#)
3. Use Eclipse, [adding in the ADT plugin to an existing Eclipse installation](#)

A fourth option would be to skip either IDE and just use the Android SDK and Gradle for Android directly. This would only be appropriate for fairly expert developers, and so the tutorials do not walk you through this path. This book has

[several chapters on Gradle](#), but those chapters are presently designed for developers already experienced in working with Android apps. For the purposes of learning Android, you are better served working with one of the supported IDEs initially. Later on, if you wish to drop the IDE and use Gradle for Android directly, you are welcome to do so.

Options #2 and #3 are close to being mutually exclusive. And, as noted earlier in the book, Eclipse support has been officially dropped by Google and, therefore, you **really** should consider using Android Studio over Eclipse today. Otherwise, you are welcome to choose one or more of these options. The installation instructions for each are described in the sections that follow.

Option #1 - Android Studio

Visit [the Android Studio download page](#), download the ZIP file for your platform, and unZIP it to some likely spot on your hard drive. Windows users who choose to download the self-installing EXE can just run that file.

Android Studio can then be run from the `studio` batch file or shell script from your Android Studio installation's `bin/` directory.

Option #2 - Android ADT Bundle

The Android ADT Bundle contains:

- The Android SDK, which gives you all the tools you need to create and test Android applications. It comes in two parts: the base tools, plus version-specific SDKs and related add-ons.
- A copy of Eclipse, with the Android Developer Tools (ADT) plug-in pre-installed.

From [the Android Developer site's SDK area](#), choose the ADT Bundle ZIP file that is appropriate for your development machine and unZIP it in some likely location.

Option #3 - Install the ADT for Eclipse

To use Eclipse, you will need to install the base Android SDK, then configure Eclipse.

Install the Android SDK

The Android developer tools can be found on the [Android Developers Web site](#).

You will want to click on “Using an Existing IDE” (even if you have not yet installed Eclipse) and download the ZIP or TGZ file presented to you, unpacking it in some likely spot — there is no specific path that is required. Windows users also have the option of running a self-installing EXE file.

Configure Eclipse

If you have not yet installed Eclipse, you will need to do that first. Eclipse can be downloaded from the [Eclipse Web site](#). The “Eclipse IDE for Java Developers” package will work fine. Note that the Android tools require Eclipse 3.7 (Indigo) or newer at the time of this writing.

If you already had Eclipse installed, it is a good idea for you to go in and check your compiler compliance level (Preferences > Java > Compiler). That should be set to 1.6. Notably, this allows the use of `@Override` annotations to indicate methods that are implementing a Java interface, rather than truly overriding a superclass method. This annotation is very common in Java code in Android projects (including many of the samples in this book).

Next, you need to install the Android Developer Tools (ADT) plug-in. To do this, go to Help | Install New Software... in the Eclipse main menu. Then, click the Add button to add a new source of plug-ins. Give it some name (e.g., Android) and supply the following URL: `https://dl-ssl.google.com/android/eclipse/`. That should trigger Eclipse to download the roster of plug-ins available from that site:

TUTORIAL #1 - INSTALLING THE TOOLS

Figure 3: Eclipse ADT plug-in installation

Check the checkbox to the left of “Developer Tools” and click the Next button. Follow the rest of the wizard to review the tools to be downloaded and their respective license agreements. When the Finish button is enabled, click it, and Eclipse will download and install the plug-ins. When done, Eclipse will ask to restart — please let it.

Then, you need to teach ADT where your Android SDK installation is from [the preceding section](#). This should occur on your next restart of Eclipse, via a “welcome wizard”. Otherwise, to do this, choose Window | Preferences from the Eclipse main menu (or the equivalent Preferences option for OS X). Click on the Android entry in the list on the left:

TUTORIAL #1 - INSTALLING THE TOOLS

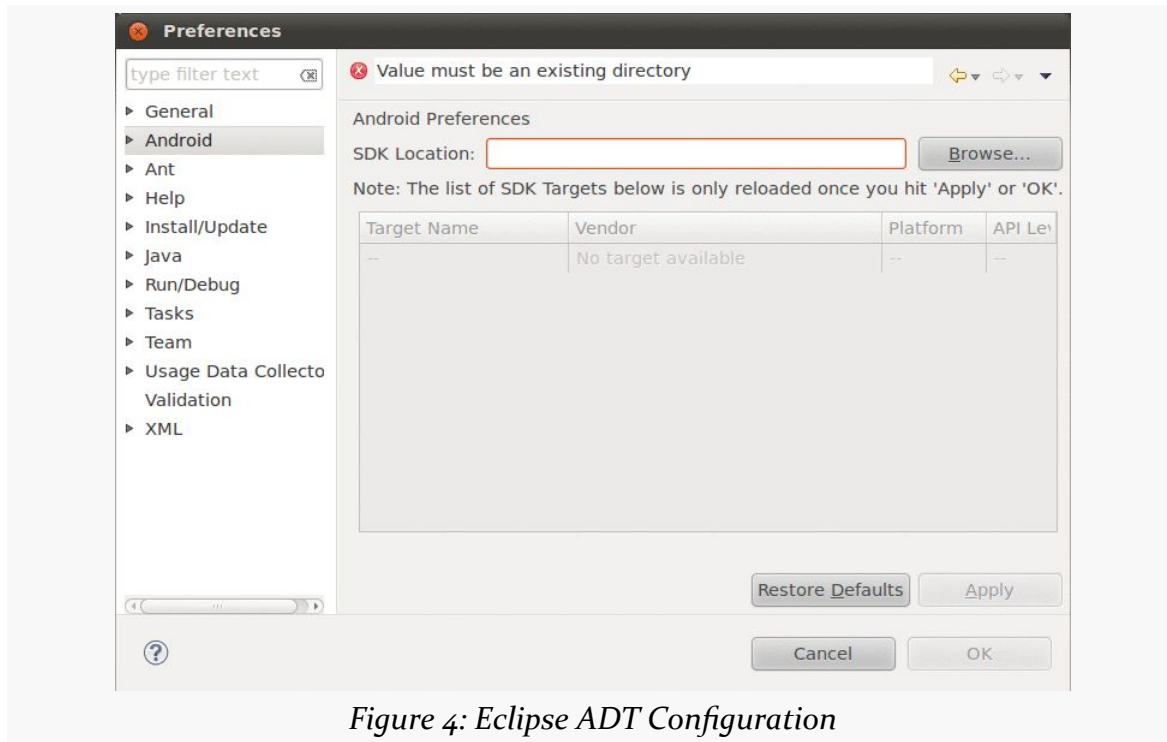

Figure 4: Eclipse ADT Configuration

Then, click the Browse... button to find the directory where you installed the SDK. After choosing it, click Apply on the Preferences window, and you should see the Android SDK versions you installed previously. Then, click OK, and the ADT will be ready for use.

Step #4 - Install the SDKs and Add-Ons

Next, we need to review what pieces of the Android SDK we have already and perhaps install some new items. To do that, you need to access the SDK Manager.

Android Studio First Run and SDK Manager Launch

When you first run Android Studio, you may be asked if you want to import settings from some other prior installation of Android Studio:

TUTORIAL #1 - INSTALLING THE TOOLS

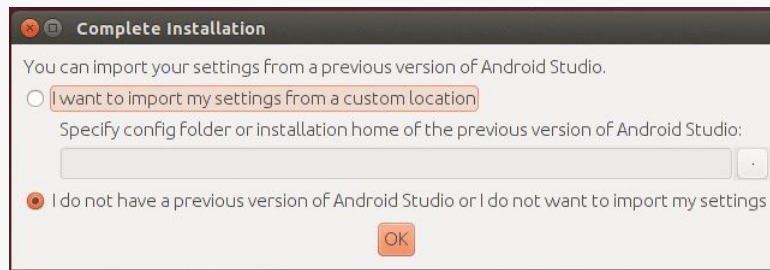

Figure 5: Android Studio First-Run Settings Migration Dialog

For most users, particularly those using Android Studio for the first time, the “I do not have...” option is the correct choice to make.

Then, after a short splash screen, you will be taken to the Android Studio Setup Wizard:

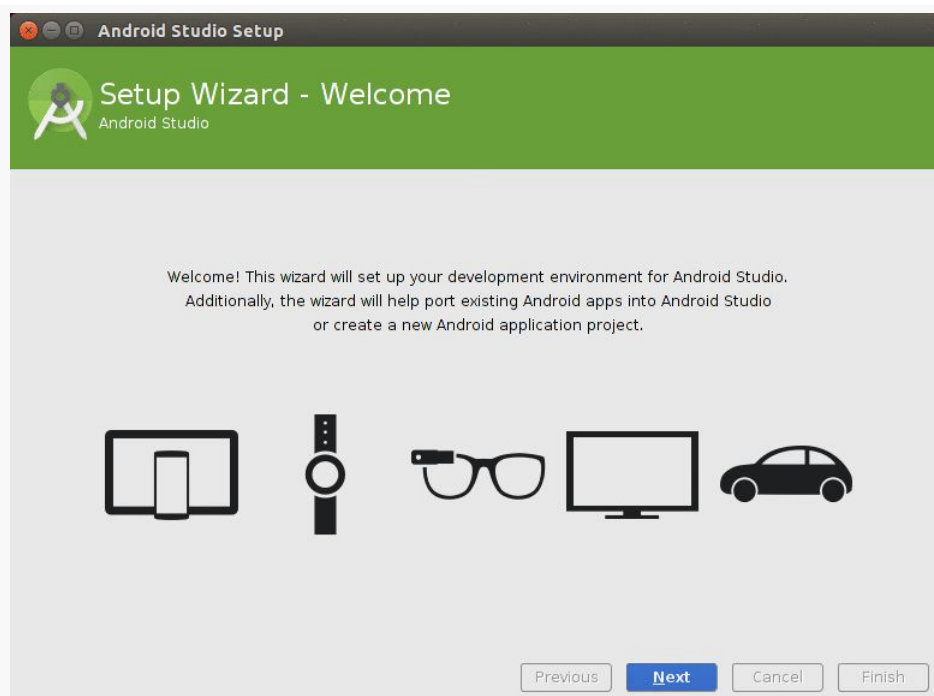

Figure 6: Android Studio Setup Wizard, First Page

Just click “Next” to advance to the second page of the wizard:

TUTORIAL #1 - INSTALLING THE TOOLS

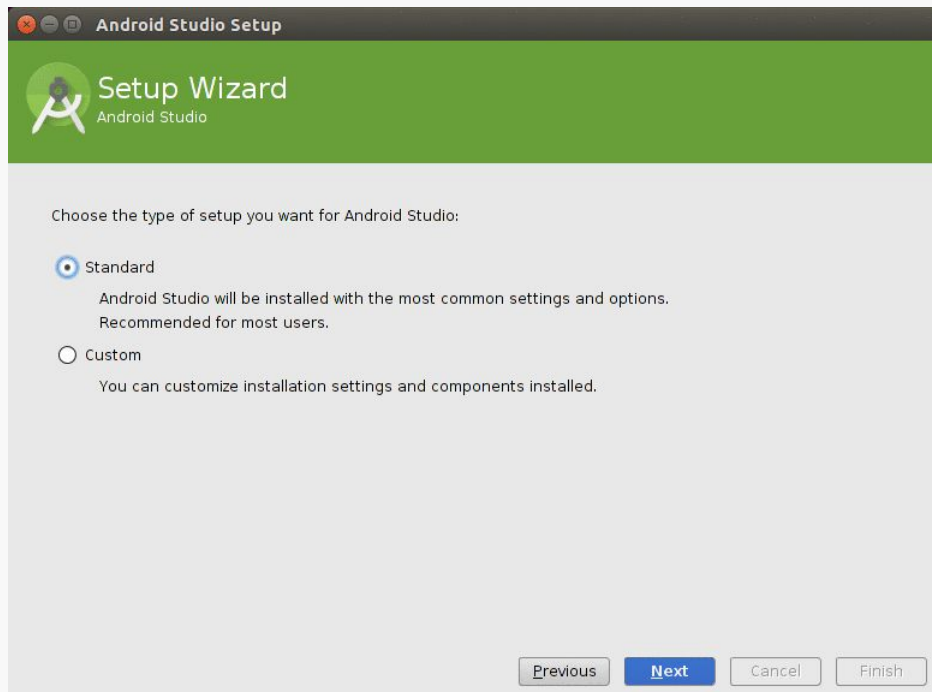

Figure 7: Android Studio Setup Wizard, Second Page

Here, you have a choice between “Standard” and “Custom” setup modes. “Custom” simply allows you to indicate what should be set up:

TUTORIAL #1 - INSTALLING THE TOOLS

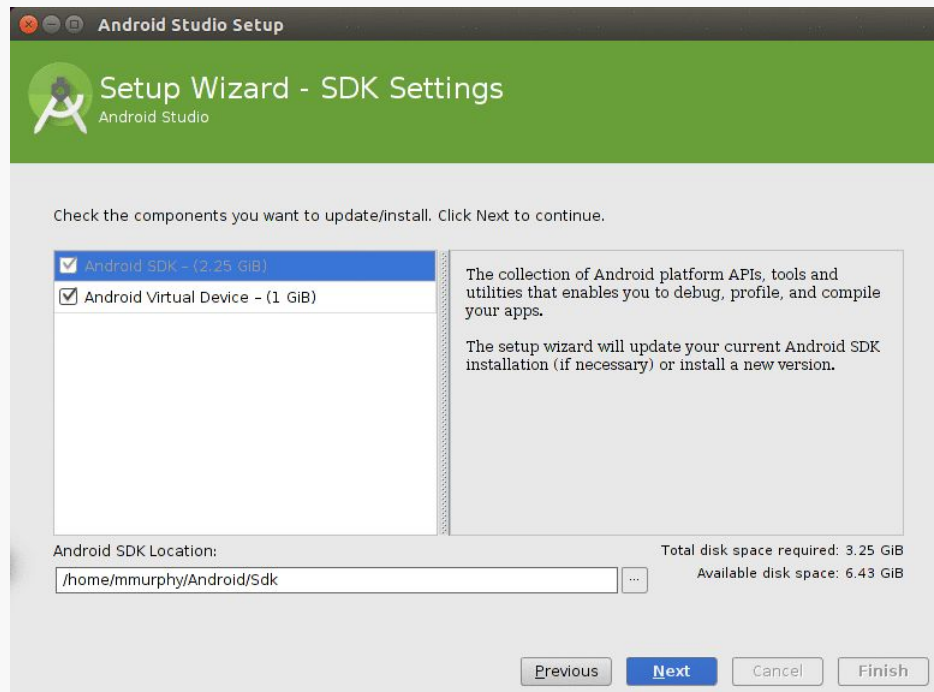

Figure 8: Android Studio Setup Wizard, Custom Page

Most likely, right now, you need all of that anyway, so the “Standard” route would be fine.

If you go the “Standard” route and click “Next”, you may be taken to a wizard page explaining some information about the Android emulator:

TUTORIAL #1 - INSTALLING THE TOOLS

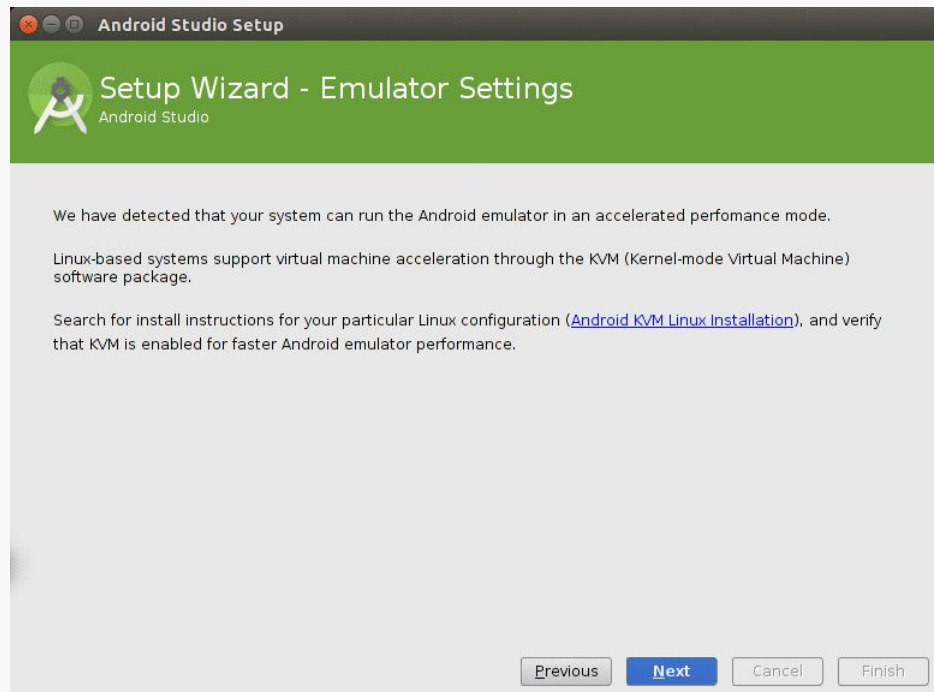

Figure 9: Android Studio Setup Wizard, Emulator Info Page

What is explained on this page may not make much sense to you. That is perfectly normal, and we will get into what this page is trying to say later in the book. Just click “Next” to advance to the next page where you will need to review the various licenses and click “Accept” if you wish to continue. At this point, clicking “Finish” will begin the setup process. This will include downloading a copy of the Android SDK and installing it into a directory adjacent to where Android Studio itself is installed.

When that is done, you will be taken to the Android Studio Welcome dialog:

TUTORIAL #1 - INSTALLING THE TOOLS

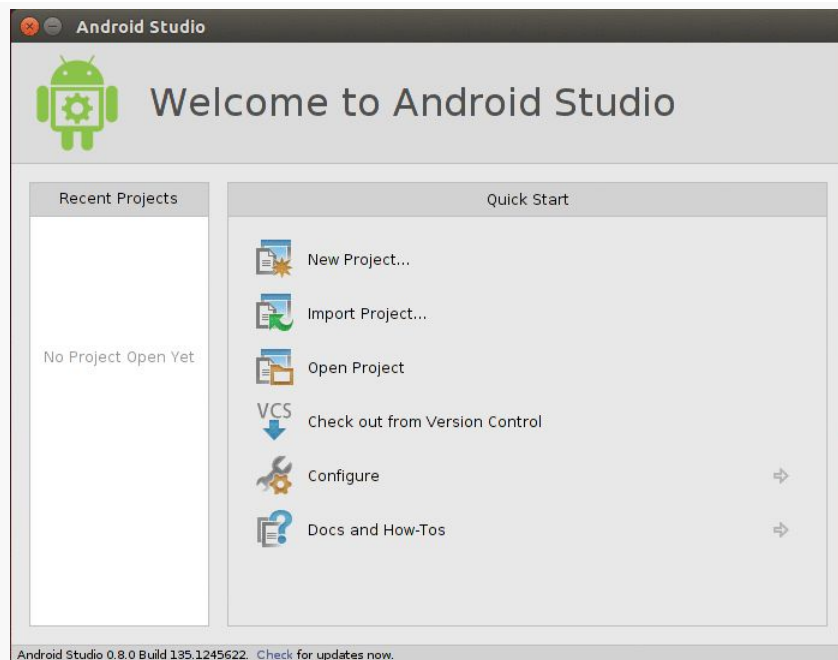

Figure 10: Android Studio Welcome Dialog

In very tiny print at the bottom of that dialog is a “Check for updates now” link. Click that, and if there are updates available, install them. This will automatically restart Android Studio. Android Studio *should* have downloaded the latest updates as part of the initial setup, so most likely this will indicate that nothing more is needed.

Then, in the welcome dialog, click Configure, to bring up a configuration sub-menu:

TUTORIAL #1 - INSTALLING THE TOOLS

Figure 11: Android Studio Welcome Dialog, Configure Sub-Menu

There, tap on SDK Manager to bring up the SDK Manager.

Eclipse SDK Manager Launch

Eclipse may take a few extra moments on its first launch to get going, but it does not do anything especially unusual.

Then, choose Windows > Android SDK Manager from the main menu, or tap on the toolbar icon that looks like the Android “bugdroid” mascot peeking out of the top of a box with a downward-pointing white arrow.

Using SDK Manager and Updating Your Environment

You should now have the SDK Manager window open:

TUTORIAL #1 - INSTALLING THE TOOLS

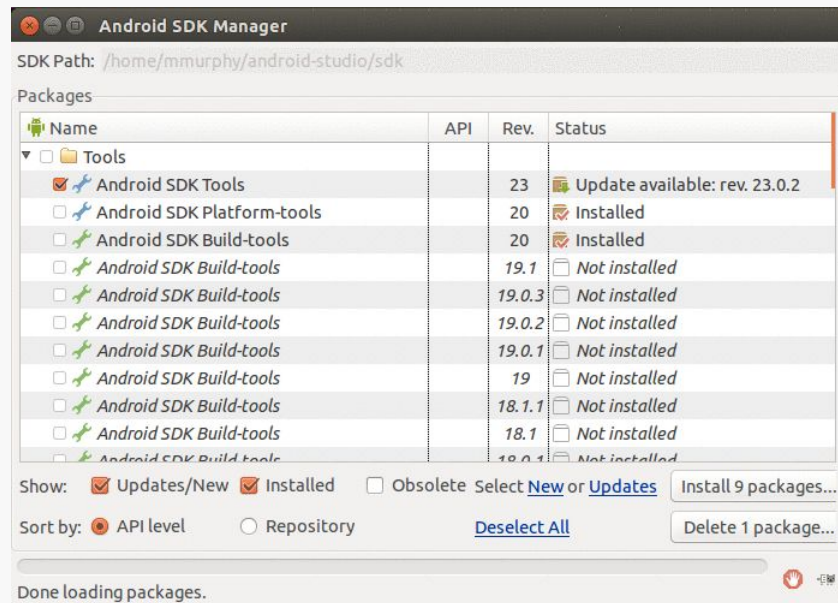

Figure 12: Android SDK Manager

At this point, while you have some of the build tools, you may lack the Java files necessary to compile an Android application. You also lack a few additional build tools, plus the files necessary to run an Android emulator. The checkboxes indicate which packages you want to install — by default, it pre-checks a number of them. If you chose the “ADT Bundle”, some things will already be pre-installed for you.

You will want to install the following items, if they have not already been installed:

1. Android SDK Tools, Platform-tools, and the latest Build-tools.
2. “SDK Platform” for all Android SDK releases you want to code against — for this version of this book API 19 (Android 4.4) is recommended, along with any others with which you wish to experiment.
3. “ARM EABI v7a System Image”, if there is an option for that for the API level you chose. You can also download the “Intel x86 Atom System Image”, if one is available to you, as it is much faster, though setting that up is [a bit of an advanced topic](#). You are also welcome to download similar images for any other Android API level that you are interested in testing against. However, for the purposes of this book, **DO NOT** choose the Android 4.4 or 4.4W emulator images, as the Android 4.4 emulator has a bug and the Android 4.4W emulator is only for Android Wear devices.
4. “Documentation for Android SDK” for the latest Android SDK release.

TUTORIAL #1 - INSTALLING THE TOOLS

5. “Samples for SDK” for the Android SDK release you chose in item #2 above, and perhaps for older releases if you wish.
6. Android Support Library and the Android Support Repository (in the Extras group at the bottom of the tree).

If you are running Windows, also choose the Google USB Driver (in the Extras group at the bottom of the tree).

Also, if anything that you presently have installed has updates available, they should already be pre-checked and will be updated when you install the items that you are adding.

Then, click the Install button beneath the tree on the right, which brings up a license confirmation dialog:

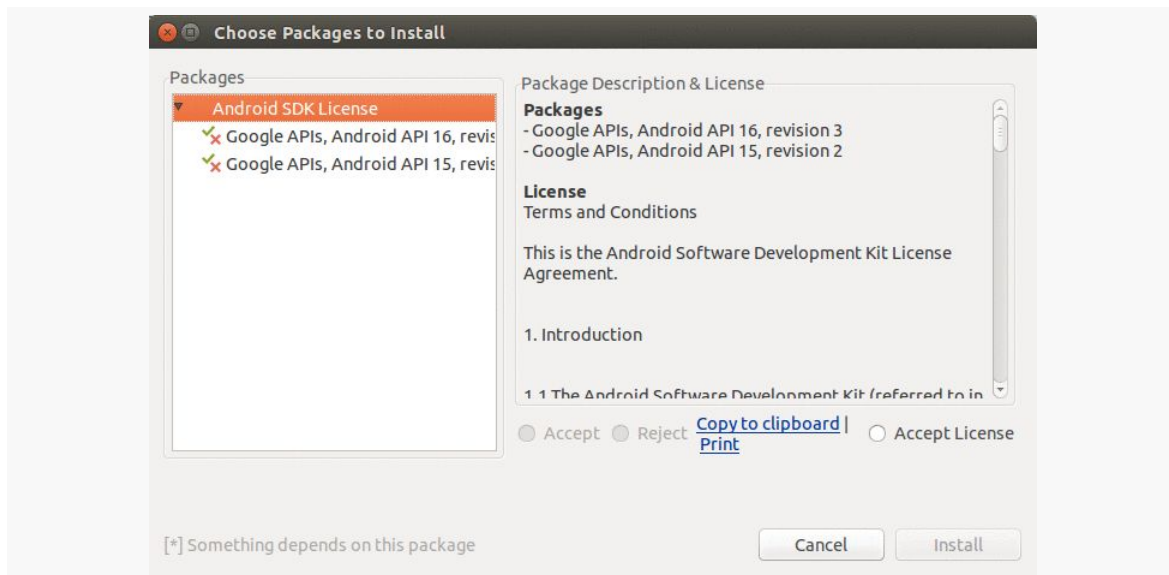

Figure 13: Android SDK Manager Installing Packages

Review and accept the licenses, then click the Install button.

When the download is complete, you can close up the SDK Manager.

In Our Next Episode...

... we will [create an Android project](#) that will serve as the basis for all our future tutorials, plus set up our emulator and device.

Android and Projects

When you work on creating an app for Android, you will do so by working in a “project”. The project is a directory containing your source code and other files, like images and UI definitions. Your IDE or other build tools will take what is in your project and generate an Android app (APK) as output.

The details of how you get started with a project vary based upon what IDE you are using, so this chapter goes through the various possibilities.

Common Concepts

The various ways we set up Android projects have some common elements.

The “Application Name” is the initial name of your project as seen by the user, in places like your home screen launcher icon and the list of installed applications.

The “Project Name” is the name of the project as it is represented inside of the IDE. As you type in an application name, the project name will automatically be filled in to match the application name, with whitespace and other invalid characters removed. Of course, you can change this as you see fit. In the case of Android Studio, the project name also forms the name of the directory that will hold the project.

The “Package Name” refers to a Java package name (e.g., `com.commonware.empublite`). This package name will be used for generating some Java source code, and it also is used as a unique identifier of this package, as was mentioned [earlier in this book](#).

The “Minimum Required SDK” refers to how far back in Android’s version history you are willing to support. The lower the value you specify here, the more Android devices can run your app, but the more work you will have to do to test whether your app really does support those devices. Nowadays, for new development, a minimum required SDK of 15 is reasonable, and you can change your chosen value later on if needed.

The “Target SDK”, roughly speaking, is the version of Android you were thinking of when you were writing the code for this app. Usually, you will set this to be the latest shipping Android API level, then change it over time as new versions of Android are released and you decide that you are ready for some of those changes. We will be exploring the ramifications of target SDK versions throughout the book.

The “Compile With” (a.k.a., “build SDK” or `compileSdkVersion`) is the version of Android whose classes and methods you want to compile against. This can be newer than the minimum required SDK, and it often is newer. On newer devices running newer versions of Android, you might want to take advantage of some new features, and you will “route around” that code on older devices to maintain backwards compatibility. Hence, typically, your build SDK is set to a fairly new version of Android, certainly one new enough to support all of the classes and methods from the Android SDK that you want to use. Note that to set this to API Level 21 or higher, you will need to be using Java 7 or higher for your Java compiler.

The “Theme” is a general statement of the look and feel of your app, particularly in terms of color scheme. The current default (“Holo Light with Dark Action Bar”) means that the body of your UI will be dark text on a light background, except for the “action bar” across the top, which will be light text on a dark background. You will be able to create your own custom themes, overriding various characteristics from one of these stock themes, to set up your own color scheme and the like. We will explore that process [later in the book](#).

Projects and Android Studio

You may have chosen to use [Android Studio](#) as your IDE.

With Android Studio, to work on a project, you can either create a new project from scratch, you can copy an existing Android Studio project to a new one, or you can import an existing Android project into Android Studio. The following sections will review the steps needed for each of these.

Creating a New Project

You can create a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the “Create Project...” menu item
- If you are inside the Android Studio IDE itself, choose File > Create Project... from the main menu

This brings up the new-project wizard:

Figure 14: Android Studio Create-Project Wizard, First Page

The first page of the wizard is where you can specify:

- The application name
- The package name
- The directory where you want the project files to go

By default, the package name will be made up of two pieces:

ANDROID AND PROJECTS

1. The domain name that you specify in the “Company Domain” field
2. The application name, converted into all lowercase with no spaces or other punctuation

If this is not what you want, click the tiny “Edit” link on the far right side of the proposed package name, which will now allow you to edit the package name directly:

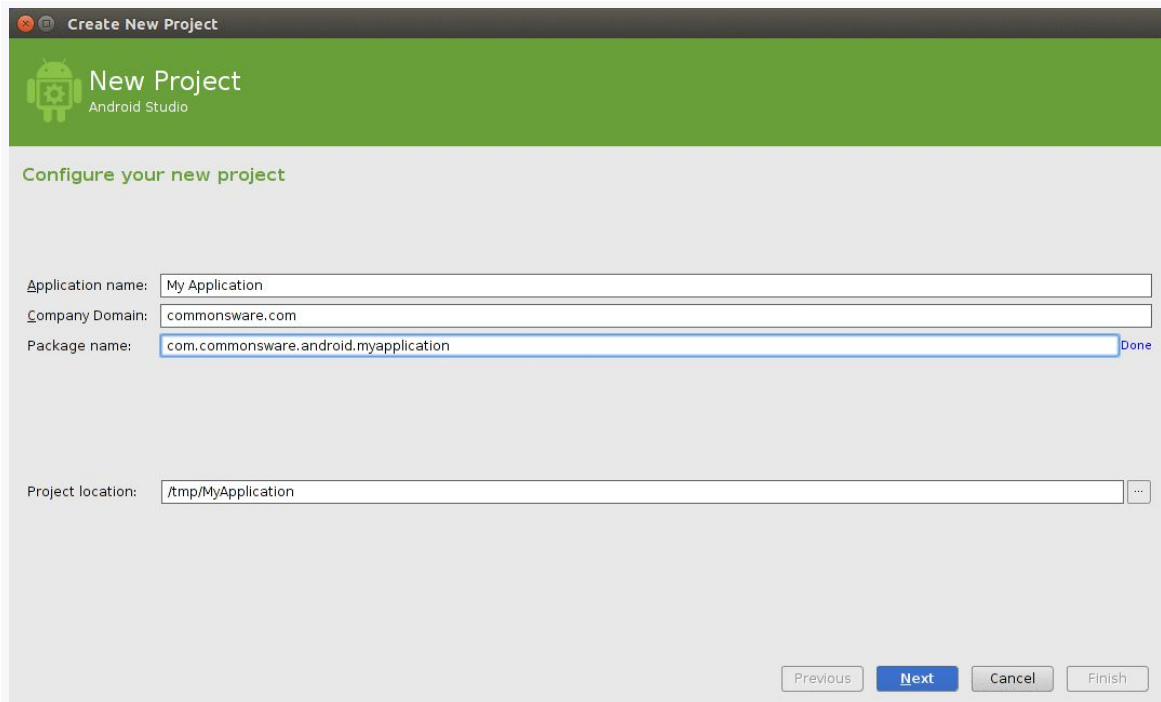

Figure 15: Android Studio Create-Project Wizard, First Page, with Editable Package Name

Clicking “Next” will advance you to a wizard page where you indicate what sort of project you are creating, in terms of intended device type (phones/tablets, TVs, etc.) and minimum required SDK level:

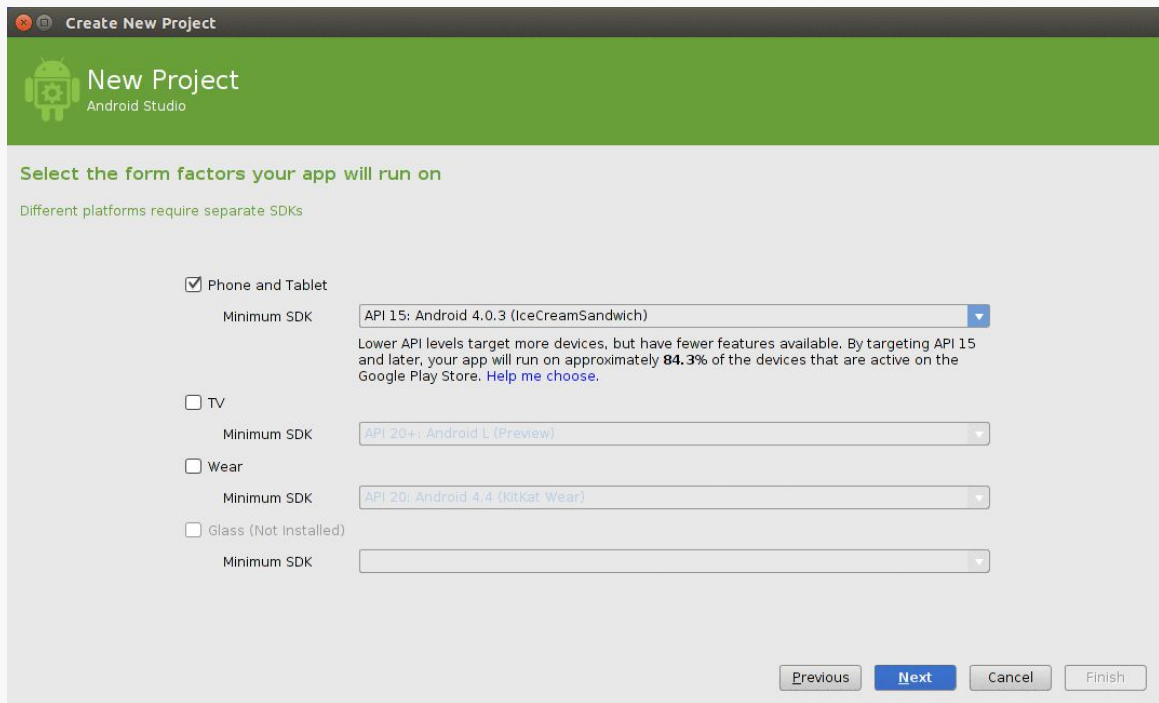

Figure 16: Android Studio Create-Project Wizard, Second Page

Developers just starting out on Android should only check “Phone and Tablet” as the device type.

Clicking “Next” advances you to the third page of the wizard, where you can choose if Android Studio should create an initial activity for you, and if so, based on what template:

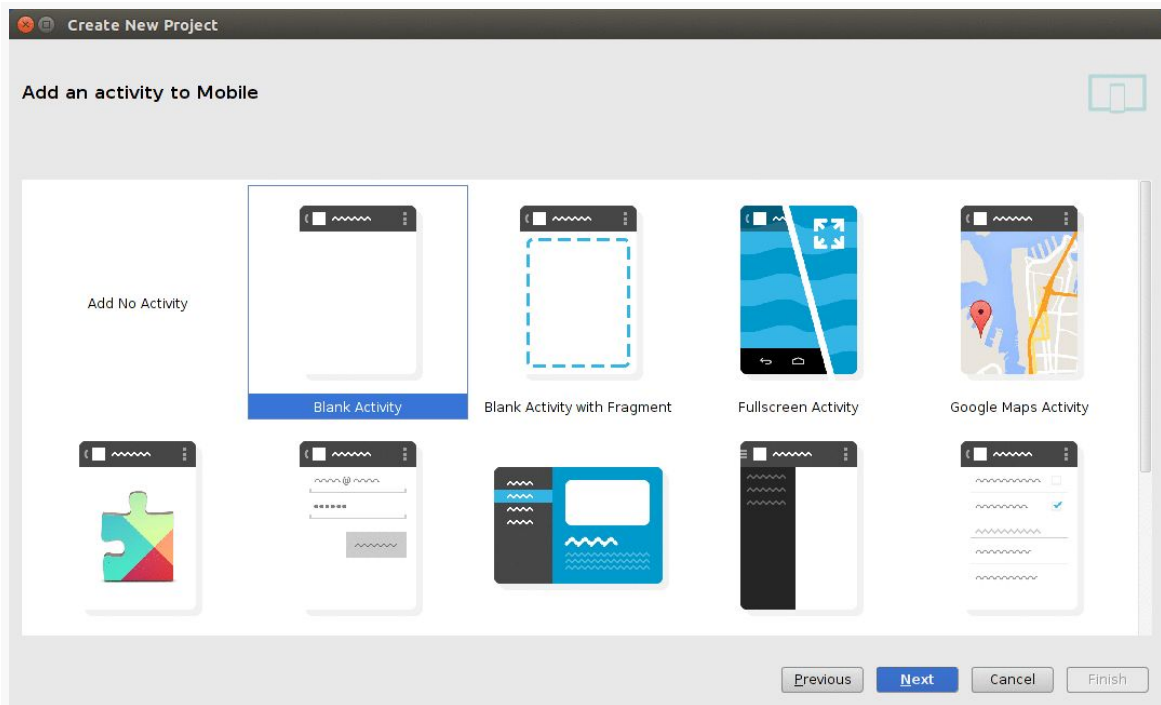

Figure 17: Android Studio Create-Project Wizard, Third Page

“Blank Activity” is a good choice for first-time Android developers.

If you choose any option other than “Add No Activity”, clicking “Next” will advance you to a page in the wizard where you can provide additional details about the activity to be created:

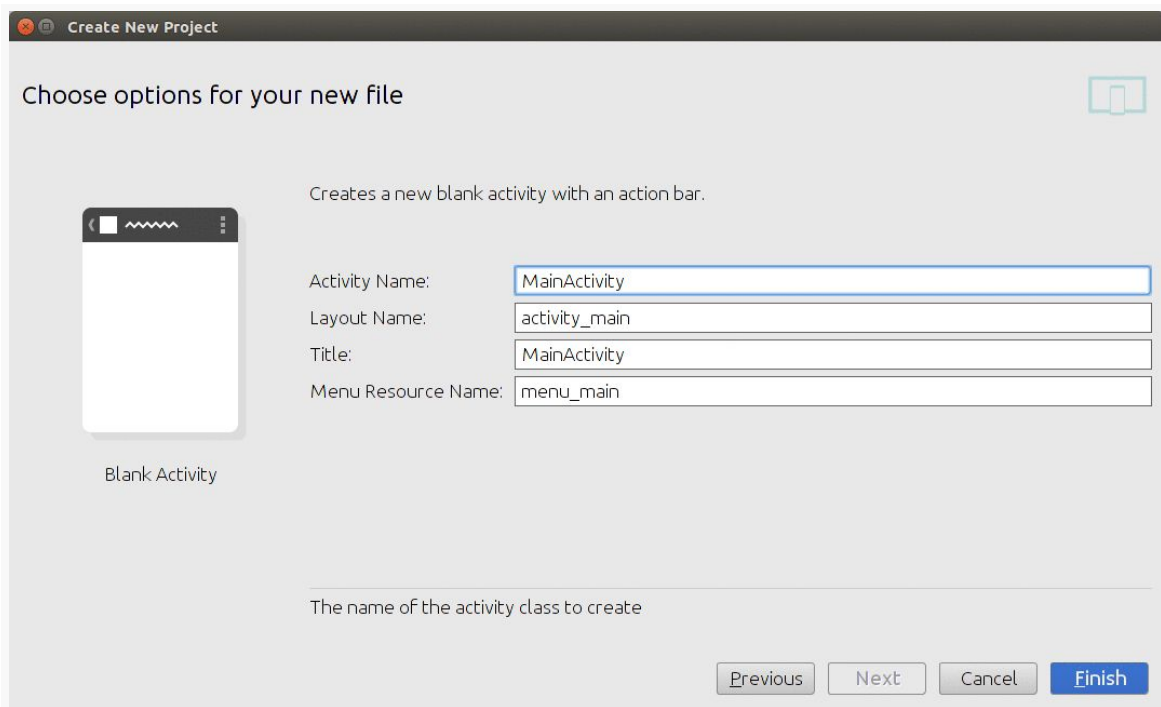

Figure 18: Android Studio Create-Project Wizard, Fourth Page

What options appear here will vary based upon the template you chose in the previous page. Common options include “Activity Name” (the name of the Java class for your activity), “Layout Name” (the base name of an XML file that will contain a UI definition of your activity), and “Title” (the caption that should appear at the top of your activity).

Clicking “Finish” will generate your project files.

Copying a Project

Android Studio projects are simply directories of files, with no special metadata held elsewhere (as is the case with Eclipse). Hence, to copy a project, just copy its directory.

Importing a Project

You can import a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the “Import Project...” menu item

- If you are inside the Android Studio IDE itself, choose File > Import Project... from the main menu

Then, choose the directory containing the project to be imported.

What happens now depends upon the nature of the project. If the project was already set up for use with Android Studio, or at least with Gradle for Android, the Android Studio-specific files will be created (or updated) in the project directory.

However, if the project was not set up for Android Studio or Gradle for Android, but does have Eclipse project files (or at least a `project.properties` file), you will be led through an Eclipse import wizard.

The first page of that wizard is where you specify where Android Studio should make a copy of the project, so it does not modify anything with the original directory:

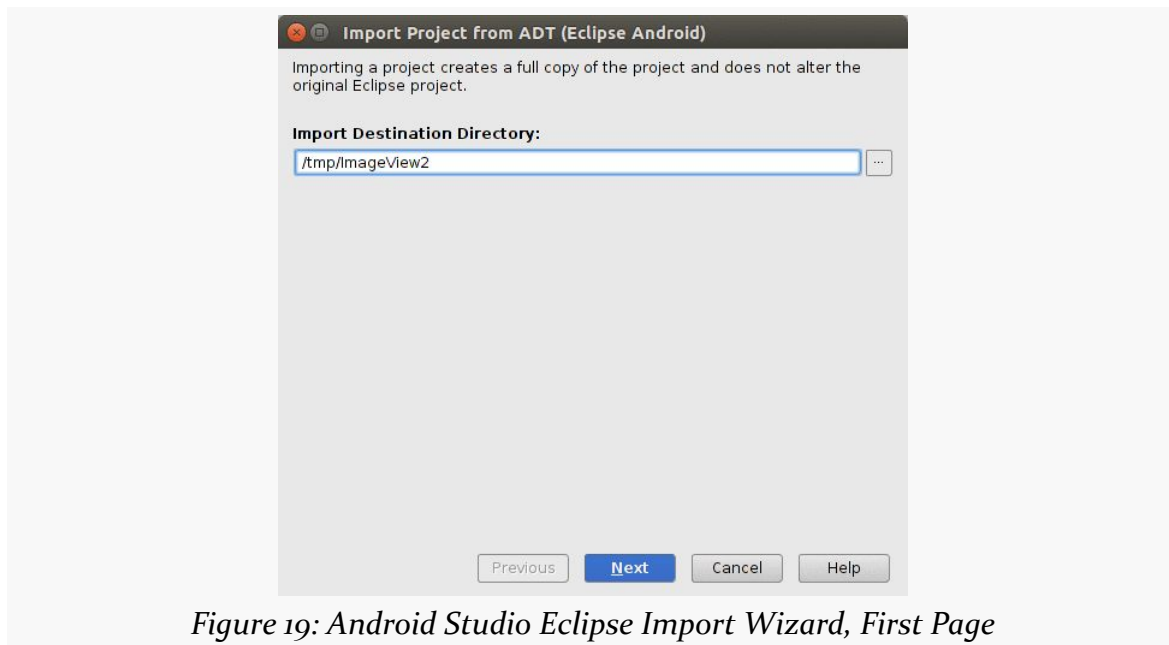

Figure 19: Android Studio Eclipse Import Wizard, First Page

Clicking “Next” will bring up a page where you can configure some automatic fixes that the import wizard will apply to the imported project code. The details of what is going on here are well past what we have covered so far in the book. Normally, the defaults are fine.

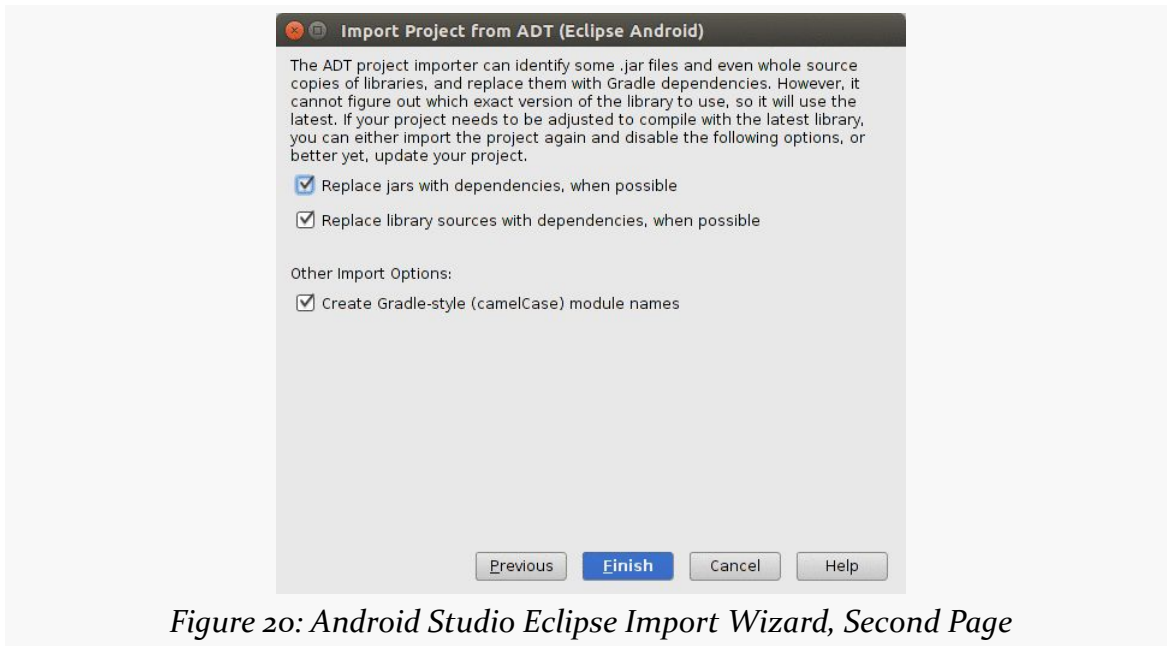

Figure 20: Android Studio Eclipse Import Wizard, Second Page

Clicking “Finish” will perform the project conversion. Android Studio will open up an `import-summary.txt` file outlining some details of how the conversion was accomplished. At this point, the copied-and-modified project is ready for use.

Projects and Eclipse

You may have chosen to use [Eclipse with the ADT plugin](#) as your IDE, whether based on the downloadable ADT Bundle or by adding the ADT plugin and Android SDK to an existing copy of Eclipse.

As with Android Studio, to work on a project in Eclipse, you can either create a new project from scratch, you can copy an existing Eclipse project to a new one, or you can import an existing Android project into Eclipse. The following sections will review the steps needed for each of these.

Creating a New Project

From the Eclipse main menu, choose `File > New > Project...` to bring up the first page of the “New Project” wizard:

ANDROID AND PROJECTS

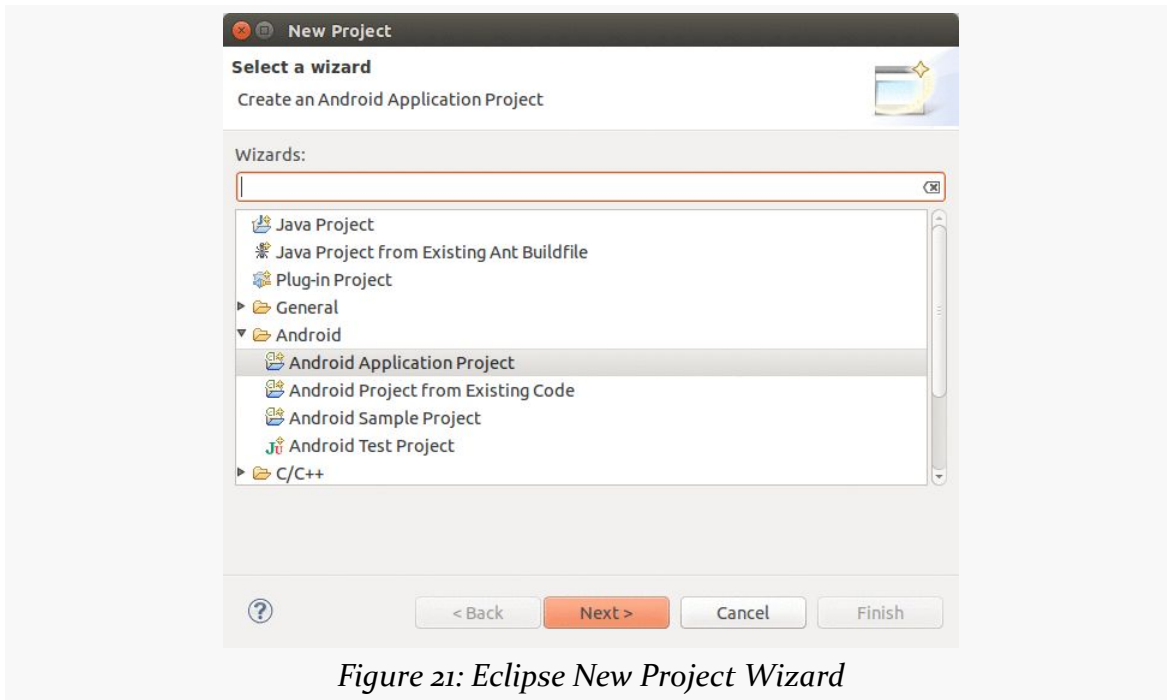

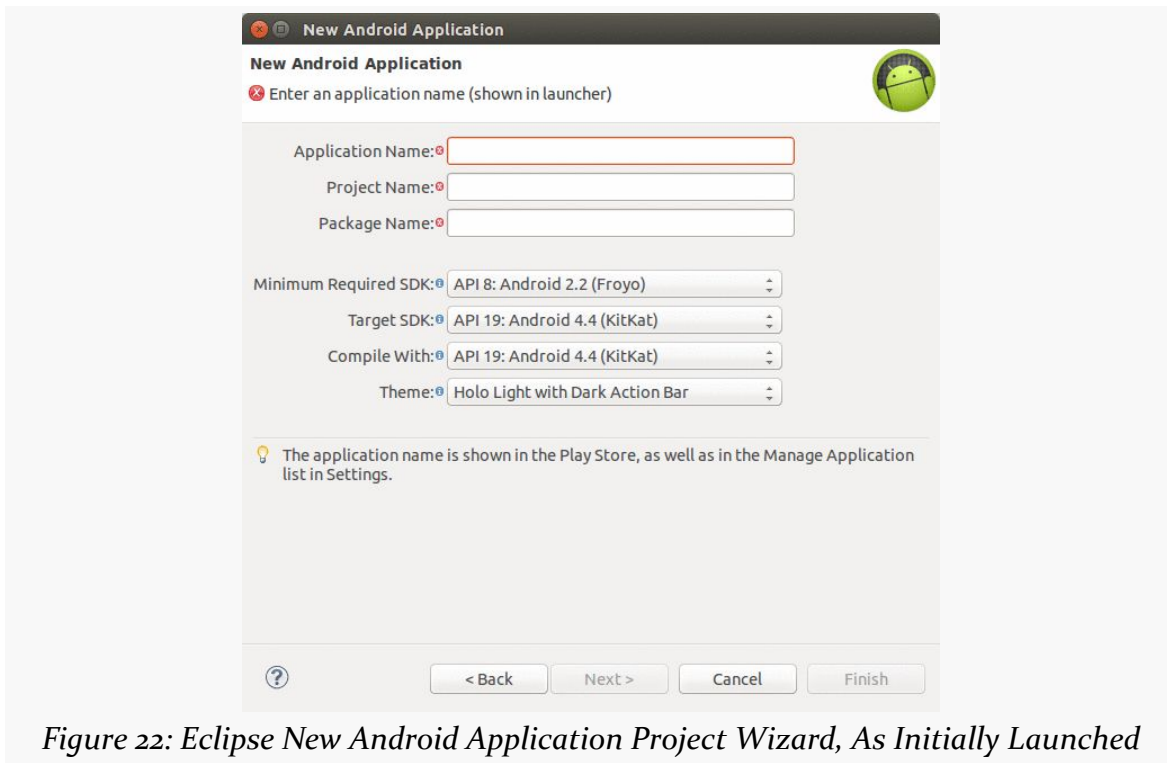

Figure 21: Eclipse New Project Wizard

Choose “Android Application Project” from the types of projects and click “Next >” to proceed to the next page of the wizard:

ANDROID AND PROJECTS

The elements on this wizard page are described in [the “Common Elements” section that opened this chapter](#).

Once those are filled in, you can click “Next >” to move to the next page of the wizard:

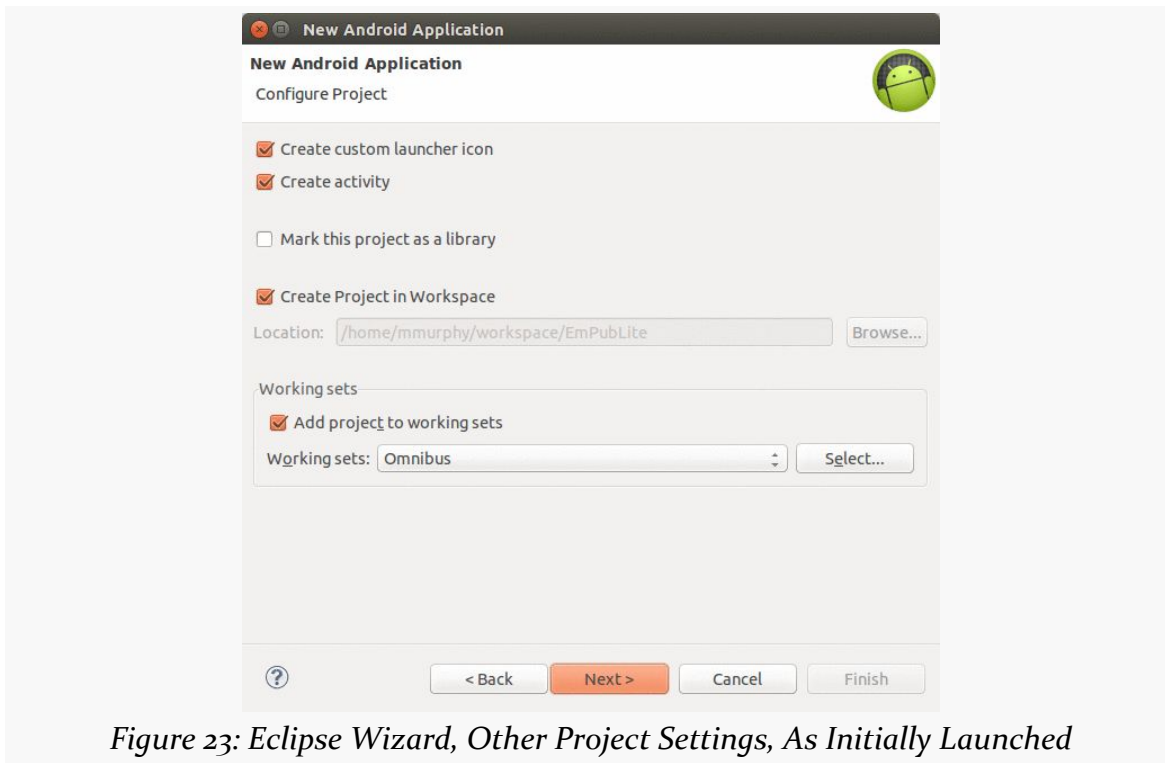

Figure 23: Eclipse Wizard, Other Project Settings, As Initially Launched

The “Create custom launcher icon” checkbox is asking you if you want to customize your app’s icon right now or not. You can always do this later, so for your first few projects, it is simplest if you uncheck this option. We will explore how to customize your app’s icon [later in this book](#). If you leave this unchecked, the new-project wizard will give you a stock icon at the outset.

The “Create activity” checkbox indicates if you want the new-project wizard to also create your first “activity” for you — in other words, creating the first screen of your UI. You do not have to have the new-project wizard create this for you, as you can add activities later on yourself, whether through a separate new-activity wizard or by just creating the appropriate files yourself. Hence, whether you leave this checked or not is up to you.

The “Mark this project as a library” checkbox indicates whether you are building an app or a library to be used by other apps. Most times, you will be creating an app, and so you will leave this checkbox unchecked. We will see what Android library projects are and what they mean [later in the book](#).

The remaining options on this wizard page are for Eclipse:

ANDROID AND PROJECTS

- Choose where you want the project files to be placed, either by leaving “Create Project in Workspace” checked, or unchecking it and choosing a directory on your development machine in which to place the files
- If you are using Eclipse’s working sets, choose your working set (if you do not know what working sets are in Eclipse, you are not using them, and so you can safely ignore this option)

Once you have filled in this page of the wizard, there are three possible next steps:

1. If you left the “Create custom launcher icon” item checked, clicking “Next >” will take you to a wizard page, from the new-icon-set wizard, for creating your launcher icon. We will explore that wizard [later in this book](#).
2. If you unchecked both the “Create custom launcher icon” and the “Create activity” checkboxes, the “Finish” button will be enabled, and clicking it will create your project.
3. If you left the “Create activity” checkbox checked, the “Next >” button will take you to a wizard page, from the new-activity wizard, for creating your first activity:

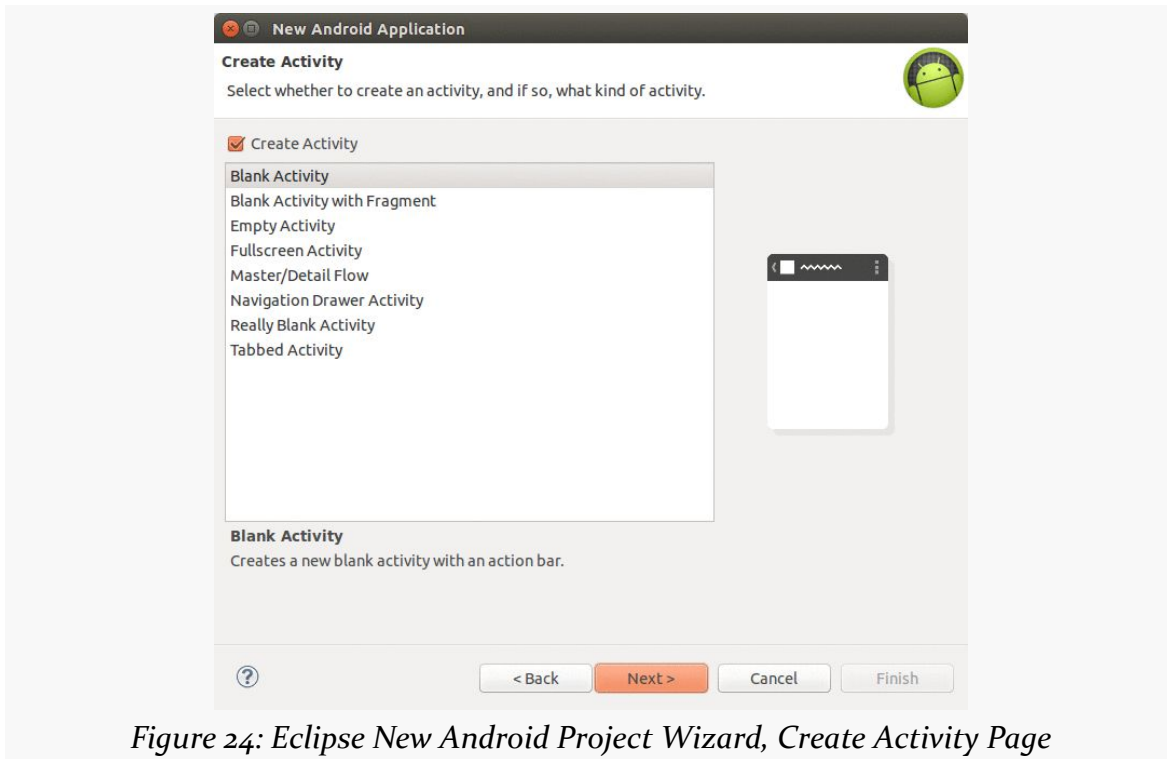

Figure 24: Eclipse New Android Project Wizard, Create Activity Page

ANDROID AND PROJECTS

Here, you choose which template activity you want to use as a starting point. The exact roster of templates will vary based upon what is shipping with Android and what third-party templates you may have installed. “Empty Activity” generates the least code for you; everything else adds more stuff that you can use (if you want) or rip out (if you did not want it).

Clicking “Next >” will bring up a wizard page where you can fill in details to be used by your chosen activity template:

Figure 25: Eclipse New Android Project Wizard, New Empty Activity Page

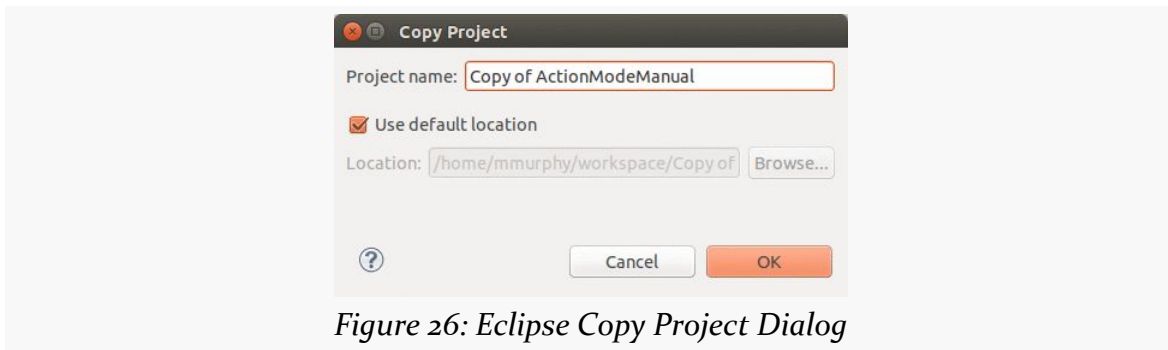

At minimum, the wizard page should ask you for an “Activity Name” (the name of the Java class for your activity) and the “Layout Name” (the base name of an XML file that will contain a UI definition of your activity). Other fields, drop-down lists, and so forth may be available depending upon the particular template that you chose.

Once you click the “Finish” button on the wizard, the wizard will generate your project for you and take you to it in Eclipse’s Package Explorer.

Copying a Project

If you already have a project in Eclipse that you just want to copy and use as a starting point for a new project, just right-click over the project in the Eclipse Package Explorer and choose “Copy” from the context menu. Or, use your platform’s standard hot-key for the copy operation (e.g., <Ctrl>-<C> on Windows and Linux).

Then, you can paste in the project to the Package Explorer, either through Edit > Paste in the Eclipse main menu or through a hot-key (e.g., <Ctrl>-<V> on Windows and Linux). This will bring up a “Copy Project” Eclipse dialog:

Here, you can choose the name of the project copy and where to copy its files to on your development machine. After clicking OK, Eclipse will copy the project.

Importing a Project

It may be that you have some source code to an Android project, such as from a public open source project, that you want to load into Eclipse. Eclipse has a means of importing such projects, and we will see how to do that in [the next tutorial](#).

Starter Project Generators

In addition to creating projects through an IDE’s new-project wizard, there are various Web sites that offer online project generators:

- [Android Bootstrap](#)
- [Android Kickstart](#)

On those sites, you provide basic configuration data, such as your application’s package name, and they generate a complete starter project for you. These projects

tend to be significantly more advanced than what you get from the IDE wizards. On the plus side, you get a more elaborate “scaffold” on which you can “hang” your own business logic. However, understanding what those generators create and how to change the generated code requires a fair bit of Android development experience.

Tutorial #2 - Creating a Stub Project

Creating an Android application first involves creating an Android “project”. As with many other development environments, the project is where your source code and other assets (e.g., icons) reside. And, the project contains the instructions for your tools for how to convert that source code and other assets into an Android APK file for use with an emulator or device, where the APK is Android’s executable file format.

Hence, in this tutorial, we kick off development of a sample Android application, to give you the opportunity to put some of what you are learning in this book in practice.

About Our Tutorial Project

The application we will be building in these tutorials is called EmPubLite. EmPubLite will be a digital book reader, allowing users to read a digital book like the one that you are reading right now.

EmPubLite will be a partial implementation of [the EmPub reader](#) used for the APK version of this book. EmPub itself is a fairly extensive application, so EmPubLite will have only a subset of its features. The main EmPub app, however, will be used elsewhere in this book to illustrate more advanced Android capabilities.

The “Em” of EmPub and EmPubLite stands for “embedded”. These readers are not designed to read an arbitrary EPUB or MOBI formatted book that you might download from somewhere. Rather, the contents of the book (largely an unpacked EPUB file) will be “baked into” the reader APK itself, so by distributing the APK, you are distributing the book.

About the Rest of the Tutorials

Of course, you may have little interest in writing a digital book reader app.

The tutorials presented in this book are certainly optional. There is no expectation that you have to write any code in order to get value from the book. These tutorials are here simply as a way to help those of you who “learn by doing” have an opportunity to do just that.

Hence, there are any number of ways that you can use these tutorials:

- You can ignore them entirely. That is not the best answer, but you are welcome to do it.
- You can read the tutorials but not actually do any of the work. This is the best low-effort answer, as it is likely that you will learn things from the tutorials that you might have missed by simply reading the non-tutorial chapters.
- You can follow along the steps and actually build the EmPubLite app.
- You can download the answers from [the book's GitHub repository](#). There, you will find one directory per tutorial, showing the results of having done the steps in that tutorial. For example, you will find a T2-Project/ directory containing a copy of the EmPubLite sample app after having completed the steps found in this tutorial. There are separate directories for Android Studio (EmPubLite-AndroidStudio/) and Eclipse (EmPubLite/) editions of the projects. You can import these projects into your IDE, examine what they contain, cross-reference them back to the tutorials themselves, and run them.

Any of these are valid options — you will need to choose for yourself what you wish to do.

About Our Tools

The instructions in the remaining tutorials should be accurate for:

- Android Studio 1.0
- Version 23.0.x of the Eclipse ADT plugin

The instructions *may* work for other versions of these IDEs, but there may also be some differences.

Step #1: Creating the Project

We need to create the Android project for EmPubLite.

First, visit [the book's GitHub repository's "releases" area](#) and download the ZIP file that corresponds with this version of the book and the tools that you wish to use:

- For Android Studio, download `EmPubLiteStarter-AndroidStudio.zip`
- For Eclipse, download `EmPubLiteStarter-Eclipse.zip`

Then, unZIP that ZIP archive into some directory on your development machine outside of where your IDE resides. The ZIP archive will expand into a set of files and subdirectories. Most likely, you will want to place those into an empty existing directory. Eclipse users should **NOT** unZIP the archive directly into the Eclipse workspace, as Eclipse gets confused easily.

Many steps in the tutorials have the same basic instructions regardless of IDE or toolchain that you wish to use. Some steps, though, have tool-specific instructions.

This step has two sets of instructions:

1. [Importing the starter project into Android Studio](#)
2. [Importing the starter project into Eclipse](#)

Just click on the link to jump to the set of instructions that you wish to follow.

Android Studio Project Import

You can import a project from one of two places:

- If you are at the initial “welcome” dialog that you first encountered when you opened Android Studio, choose the “Import Non-Android Studio Project...” menu item
- If you are inside the Android Studio IDE itself, choose File > Import Project... from the main menu

Then, just choose the `EmPubLite/` directory inside where you unzipped `EmPubLiteStarter-AndroidStudio.zip`.

Since this project is already set up for use with Android Studio, you should be taken right into the main IDE.

TUTORIAL #2 - CREATING A STUB PROJECT

Android Studio has two ways of viewing the contents of Android projects. The default one, that you are presented with when importing the project, is known as the “Android project view”:

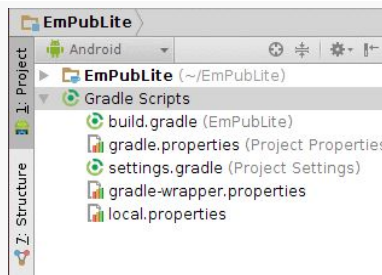

Figure 27: Android Studio “Android Project View”

While you are welcome to navigate your project using it, the tutorial chapters in this book, where they have screenshots of Android Studio, will show the classic project view:

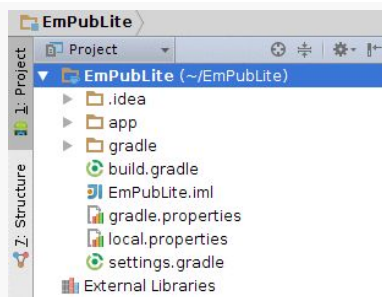

Figure 28: Android Studio “Classic Project View”

To switch to this classic view — and therefore match what the tutorials will show you — click on the drop-down list that currently shows “Android” as selected and choose “Project” instead.

Eclipse Project Import

In Eclipse, choose File > Import from the main menu, to bring up the import wizard:

TUTORIAL #2 - CREATING A STUB PROJECT

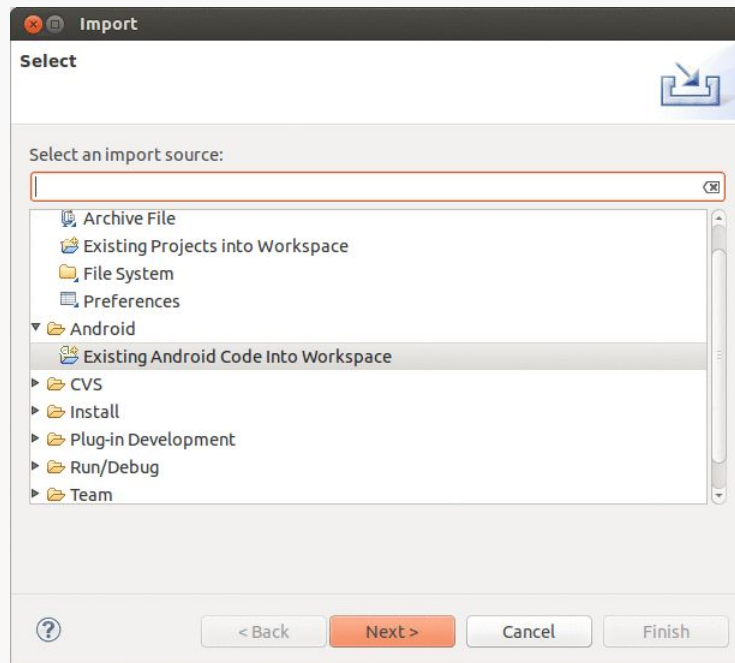

Figure 29: Eclipse Import Wizard, First Page

Choose “Existing Android Code Into Workspace” and click the Next button to bring up the next page of the wizard:

TUTORIAL #2 - CREATING A STUB PROJECT

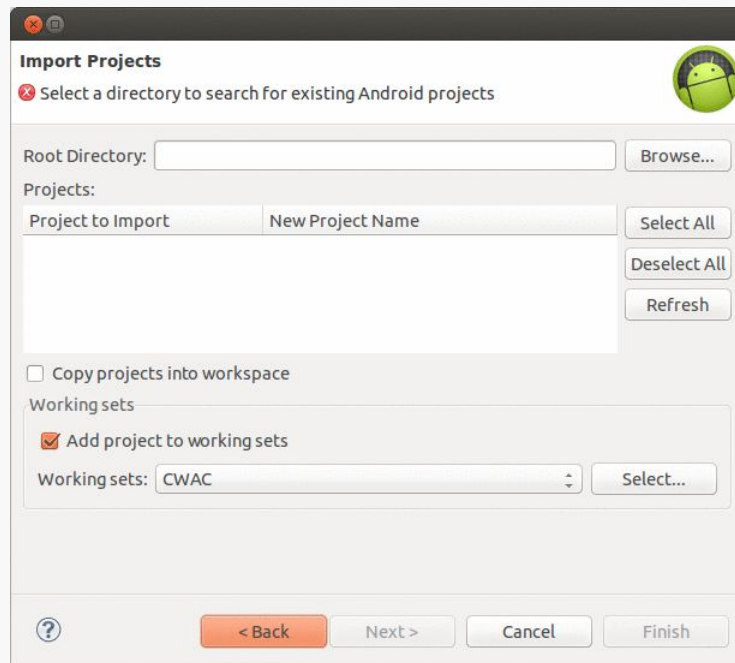

Figure 30: Eclipse Import Wizard, Second Page

Click the “Browse...” button towards the upper-right of the wizard, and from there choose the directory containing the unZIPped version of EmPubLiteStarter-Eclipse.zip.

This will change the wizard to show the project. Click on “EmPubLiteActivity” in the table, which will then become editable. Change EmPubLiteActivity to be EmPubLite:

TUTORIAL #2 - CREATING A STUB PROJECT

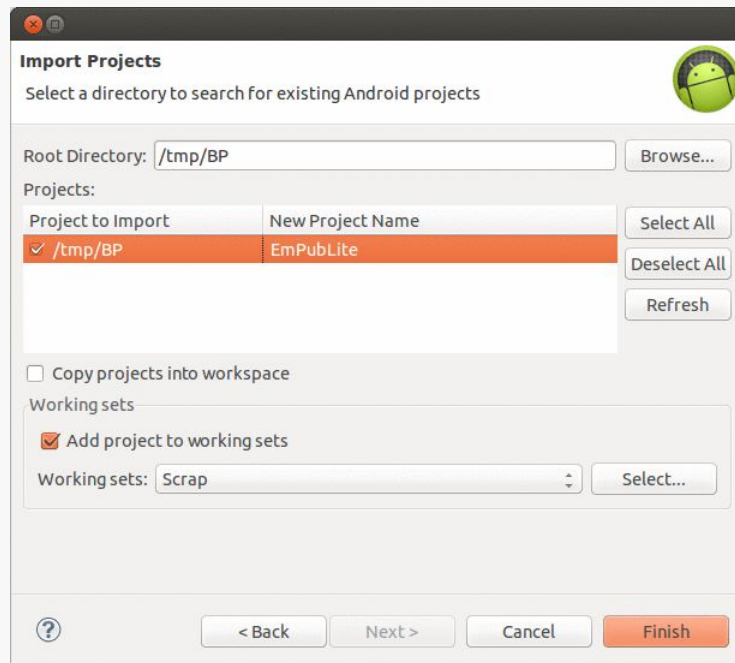

Figure 31: Eclipse Import Wizard, Second Page, After Directory Selected

If you want to have the contents of your chosen directory copied into your Eclipse workspace, click the “Copy projects into workspace” checkbox. Otherwise, Eclipse will keep the project files where they are.

If you are using Eclipse’s working sets, choose your working set (if you do not know what working sets are in Eclipse, you are not using them, and so you can safely ignore this option).

Then, click Finish. Afterwards, you should be able to find EmPubLite in the Eclipse Package Explorer:

TUTORIAL #2 - CREATING A STUB PROJECT

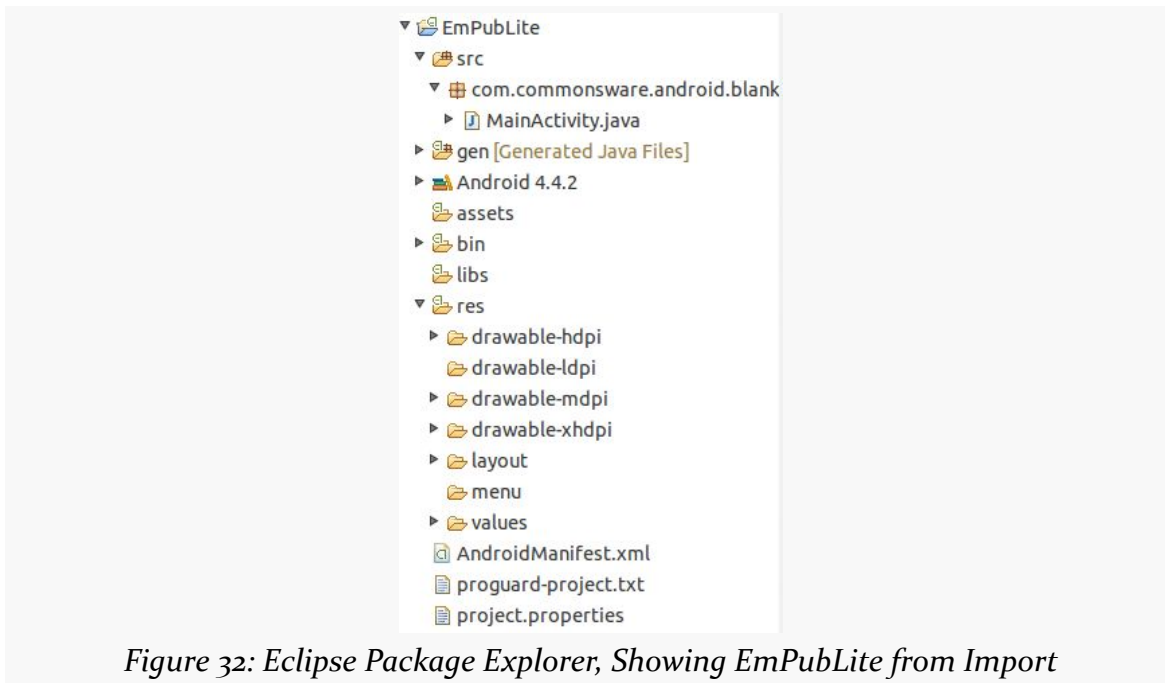

Figure 32: Eclipse Package Explorer, Showing EmPubLite from Import

You may encounter some problems, if the imported project is set to build with an Android SDK that you have not installed. To check your settings for this, right-click over the EmPubLite entry in the Package Explorer, and choose Properties. In the Properties dialog, click the Android entry in the list on the left:

TUTORIAL #2 - CREATING A STUB PROJECT

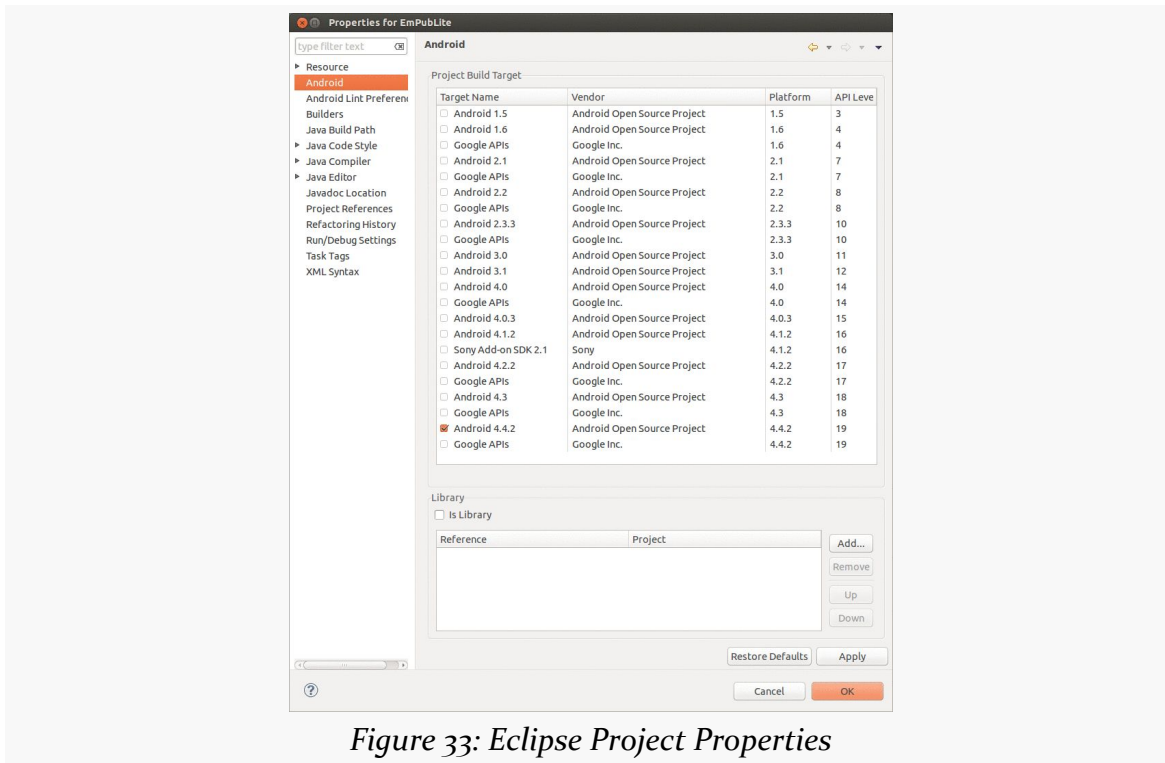

Figure 33: Eclipse Project Properties

If none of the entries in the API level checklist are checked, check the highest one that you have installed, if that is 15 or higher.

Step #2 - Set Up the Emulator

The Android tools include an emulator, a piece of software that pretends to be an Android device. This is very useful for development — not only does it mean you can get started on Android without a device, but the emulator can help test device configurations that you do not own.

Your first decision to make is whether or not you want to bother setting up an emulator image right now. If you have an Android device, you may prefer to start testing your app on it, and come back to set up the emulator at a later point.

Your second decision to make is whether you want to go ahead and set up the x86 emulator support. The vast majority of Android devices have ARM CPUs, while the vast majority of development machines have x86 CPUs. The ARM emulator is *slow* on x86 machines, as every ARM instruction must be translated into corresponding x86 instruction(s) before it can be executed. However, setting up the x86 emulator

TUTORIAL #2 - CREATING A STUB PROJECT

support is a bit complicated, and your development machine may not be able to support it. If you wish to try to set up the x86 emulator right away, there are instructions for doing that [later in the book](#) that you can review and follow.

The Android emulator can emulate one or several Android devices. Each configuration you want is stored in an “Android virtual device”, or AVD. The AVD Manager is where you create these AVDs.

Android Studio now has its own implementation of the AVD Manager that is separate from the one Android developers have traditionally used.

AVD Manager in Android Studio

To open the AVD Manager in Android Studio, choose Tools > Android > AVD Manager from the main menu. You should see a table of available virtual devices (AVDs), possibly including one already set up for you:

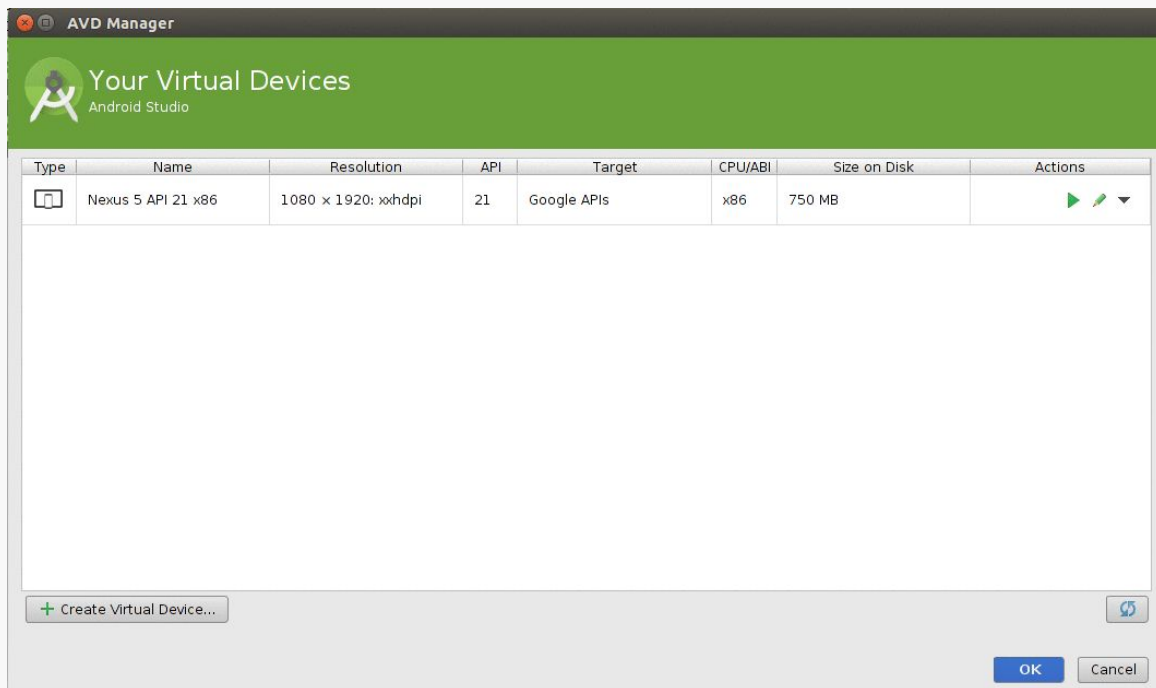

Figure 34: Android Studio AVD Manager, First Page

To define a new AVD, click the “Create Virtual Device” button in the AVD Manager, which brings up a “Virtual Device Configuration” wizard:

TUTORIAL #2 - CREATING A STUB PROJECT

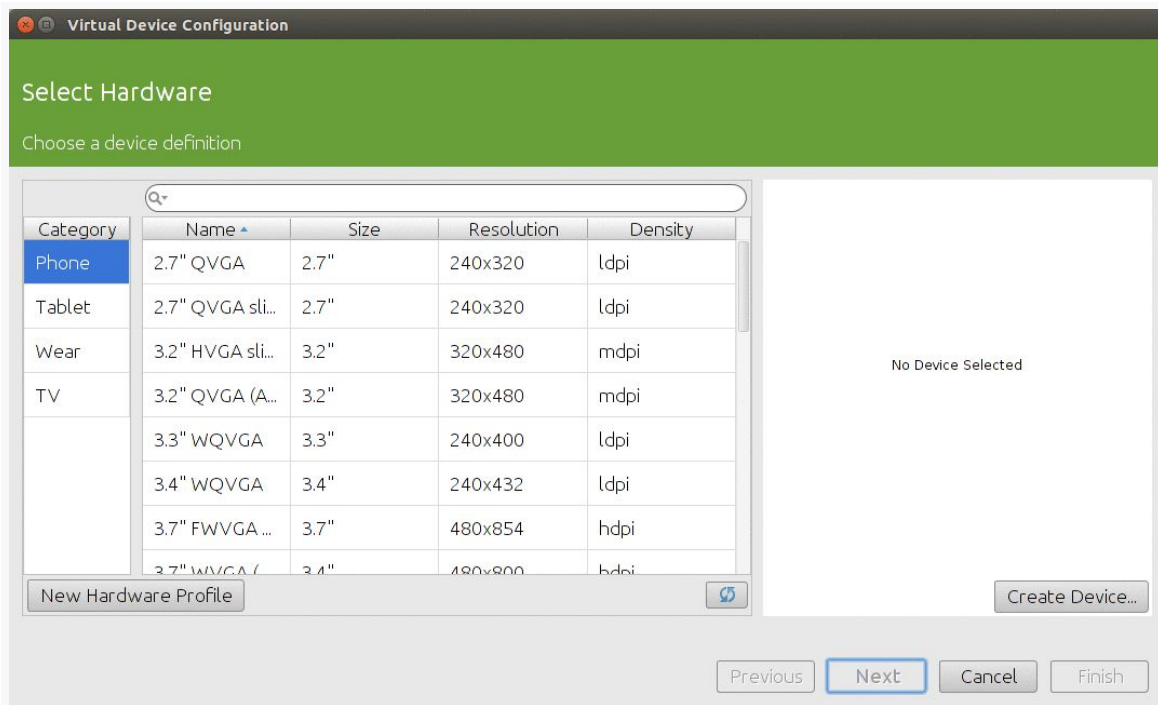

Figure 35: Android Studio Virtual Device Configuration Wizard, First Page

The first page of the wizard allows you to choose a device profile to use as a starting point for your AVD. The “New Hardware Profile” button allows you to define new profiles, if there is no existing profile that meets your needs.

Since emulator speeds are tied somewhat to the resolution of their (virtual) screens, you generally aim for a device profile that is on the low end but is not completely ridiculous. For example, an 800x480 phone would be considered by many people to be fairly low-resolution. However, there are plenty of devices out there at that resolution (or lower), and it makes for a reasonable starting emulator.

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 36: Android Studio Virtual Device Configuration Wizard, First Page, Nexus S Selected

If you want to create a new device profile based on an existing one — to change a few parameters but otherwise use what the original profile had – click the “Clone Device” button once you have selected your starter profile.

However, in general, at the outset, using an existing profile is perfectly fine.

Clicking “Next” allows you to choose an emulator image to use, based on the ones that you downloaded using the SDK Manager:

TUTORIAL #2 - CREATING A STUB PROJECT

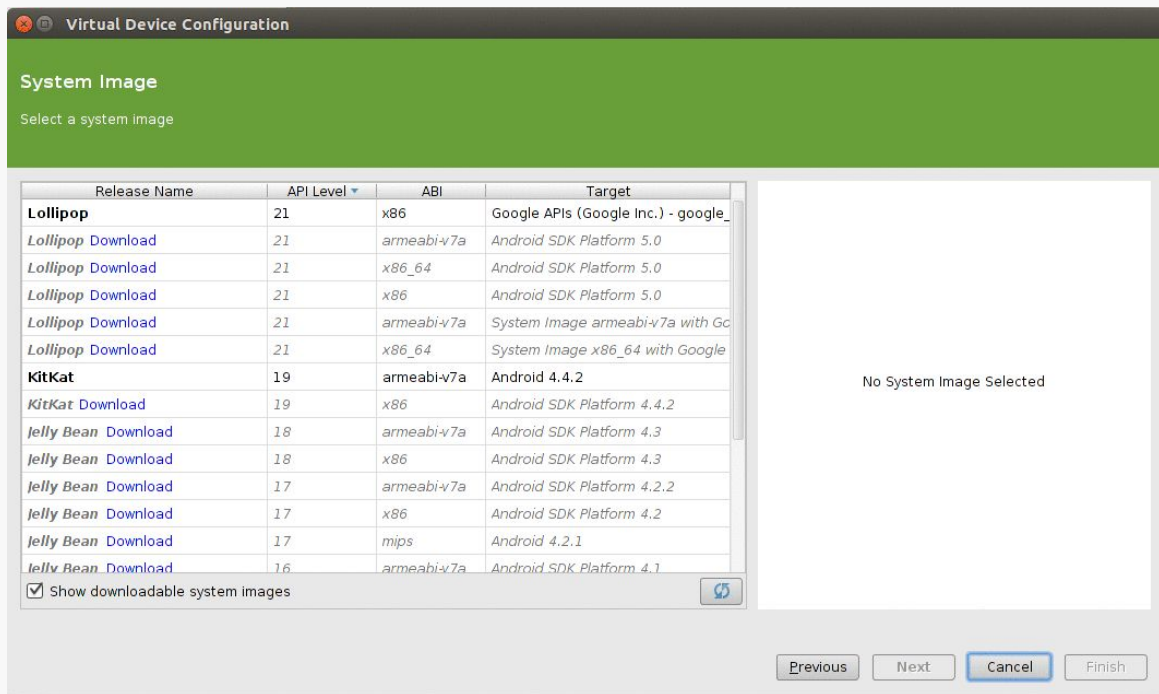

Figure 37: Android Studio Virtual Device Configuration Wizard, Second Page

For the tutorials in this book, you want an API Level 18 or 21 image, and for the armeabi-v7 CPU architecture (unless you have gone ahead and configured [x86 emulator support](#)). You do not need one with the “Google APIs” — those are for emulators that have Google Play Services in them and related apps like Google Maps. The ones with “Download” next to them will trigger a one-time download of the files necessary to create AVDs for that particular API level and CPU architecture combination.

Clicking “Next” allows you to finalize the configuration of your AVD:

TUTORIAL #2 - CREATING A STUB PROJECT

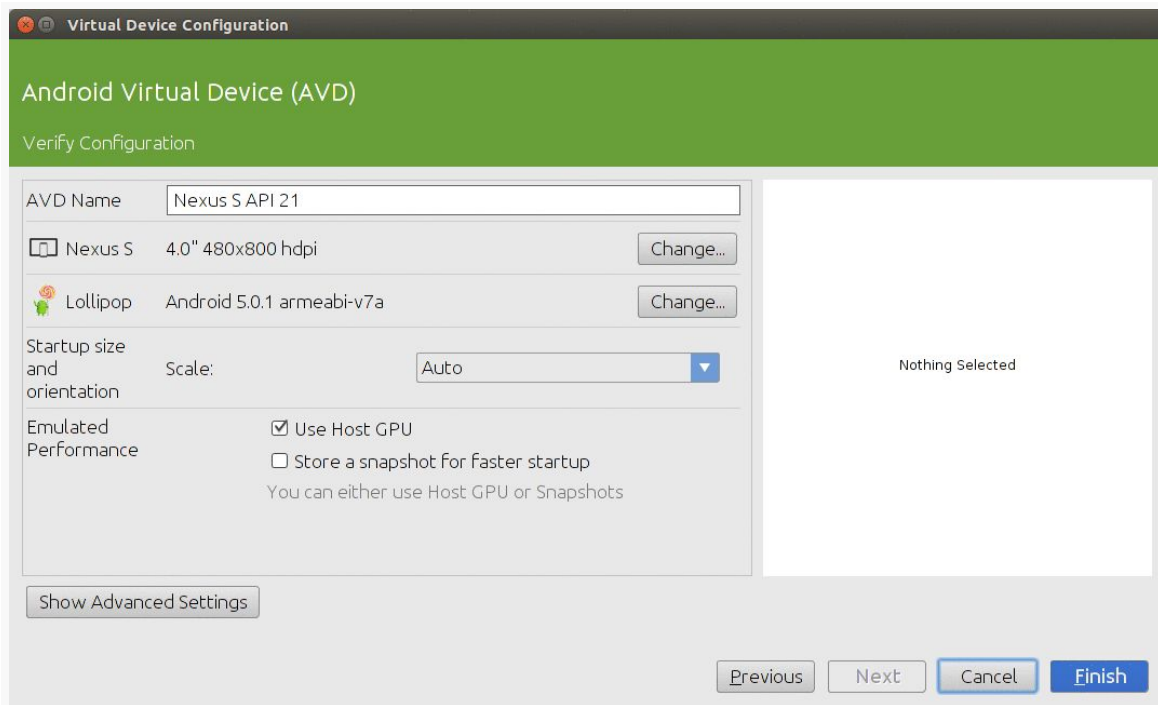

Figure 38: Android Studio Virtual Device Configuration Wizard, Third Page

A default name for the AVD is suggested, though you are welcome to replace this with your own value. The rest of the default values should be fine.

Clicking “Finish” will return you to the main AVD Manager, showing your new AVD. You can click “OK” to return to the main IDE window.

AVD Manager in Eclipse

To open the AVD Manager in Eclipse, choose Window > Android Virtual Device Manager from the main menu.

The AVD Manager starts up on a screen listing the AVDs you have available – initially, the list will be empty:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 39: AVD Manager, From Fresh Installation

You will notice that there is a “Device Definitions” tab. This provides a catalog of device hardware configurations that you can use as the starting point for your emulator:

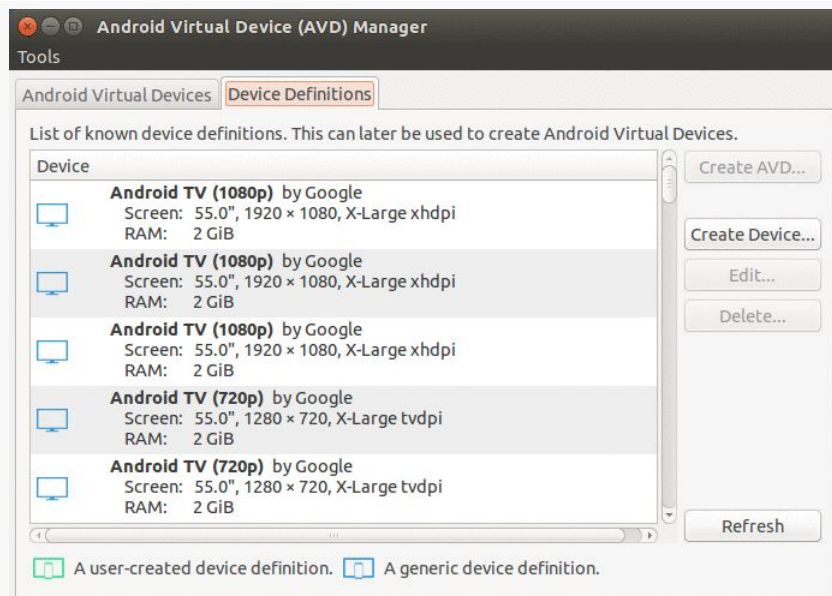

Figure 40: AVD Manager, Device Definitions Tab

TUTORIAL #2 - CREATING A STUB PROJECT

For now, though, on the “Android Virtual Devices” tab, click the New... button to create a new AVD file. This brings up a dialog where you can configure what this AVD should look and work like:

Figure 41: Adding a New AVD

You need to provide the following:

1. A name for the AVD. Since the name goes into files on your development machine, you will be limited by filename conventions for your operating system (e.g., no backslashes on Windows).
2. Which one of the available device templates from the “Device Definitions” tab you wish to use. Since the emulator runs slower with higher resolution screens, the Nexus S is a likely candidate, as it offers a not-too-unrealistic resolution and better emulator speed.
3. The Android version you want the emulator to run (a.k.a., the “target”). Choose one of the SDKs you installed via the drop-down list. Note that in addition to “pure” Android environments, you will have options based on the third-party add-ons you selected. For example, you probably have some options for setting up AVDs containing the Google APIs, and you will need such an AVD for testing an application that uses Google Maps.

TUTORIAL #2 - CREATING A STUB PROJECT

4. The CPU architecture your emulator will emulate. If you went ahead and set up x86 emulator support, choose your x86 emulator image here. Otherwise, choose your ARM emulator image.
5. Whether or not a hardware keyboard is present. Having this checked can ease your data entry on the emulator, as your development machine's keyboard will act as a keyboard for the emulated device.
6. Whether there should be a portion of the emulator window set aside to show hardware controls, such as a D-pad. This is usually a good idea, particularly while you are getting familiar with the Android environment.
7. Values for the memory and internal storage — the defaults are perfectly fine selections.
8. Details about the SD card the emulator should emulate. Since Android devices invariably have some form of “external storage”, you probably want to set up an SD card, by supplying a size in the associated field. However, since a file will be created on your development machine of whatever size you specify for the card, you probably do not want to create a 2GB emulated SD card. 32MB is a nice starting point, though you can go larger if needed.
9. Whether or not “snapshot” mode is enabled. This can speed up restarting the emulator at the cost of hard disk space. For now, leave it unchecked.
10. Whether or not you wish to use the development machine's graphics card (GPU) to accelerate the emulator's graphics. Usually, this helps emulator performance, so checking that is worth trying. If you encounter problems running the emulator, try editing the AVD definition and unchecking this value.

Click the OK button, and your AVD stub will be created.

To start the emulator, highlight it in the list and click “Start...”. You can skip the launch options for now and just click Launch. The first time you launch a new AVD, it will take a long time to start up. The second and subsequent times you start the AVD, it will come up a bit faster, and usually you only need to start it up once per day (e.g., when you start development). You do not need to stop and restart the emulator every time you want to test your application, in most cases. Also, Eclipse will automatically start an emulator if you do not have one started and you try running an application.

The emulator will go through a few startup phases, typically first with a plain-text “ANDROID” label (for pre-Android 4.0) or a blank screen (for Android 4.0+):

TUTORIAL #2 - CREATING A STUB PROJECT

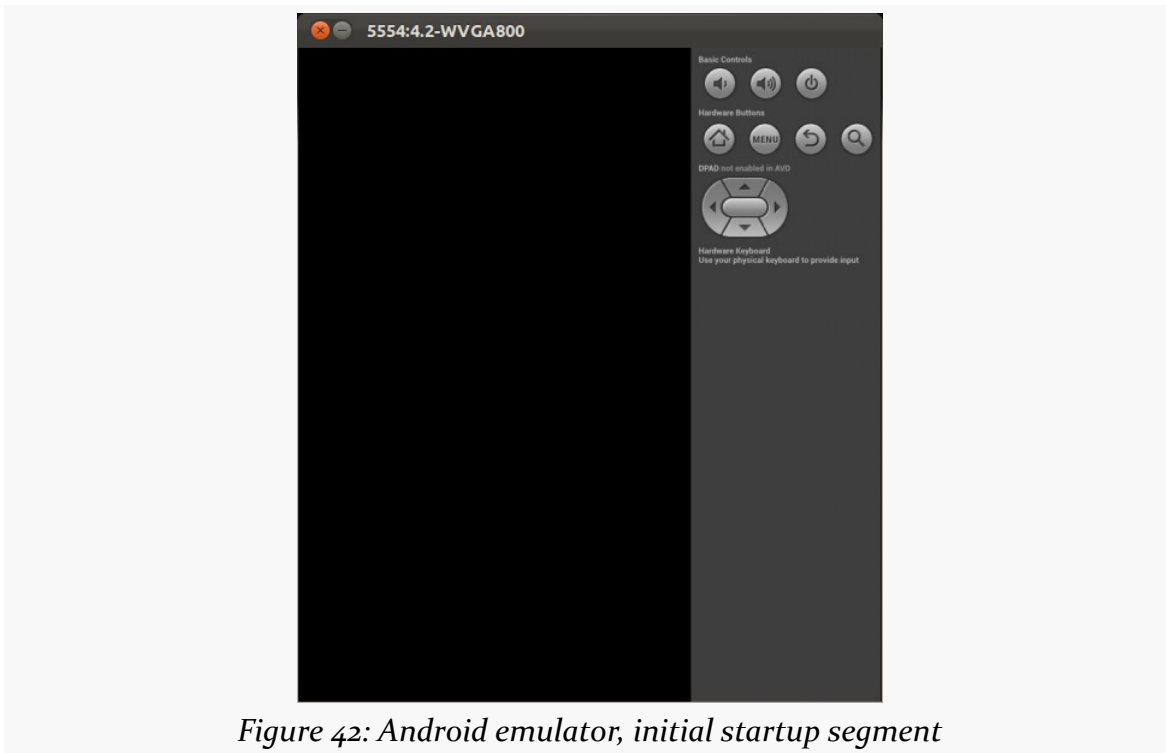

Figure 42: Android emulator, initial startup segment

... then a graphical Android logo:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 43: Android emulator, secondary startup segment

before eventually landing at the home screen, a welcome page (shown below, for Android 4.0), or the keyguard:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 44: Android 4.0 emulator welcome page

If you get the keyguard (shown below), press the MENU button, or slide the lock on the screen to the right, to get to the emulator's home screen:

Step #3 - Set Up the Device

You do not need an Android device to get started in Android application development. Having one is a good idea before you try to ship an application (e.g., upload it to the Play Store). And, perhaps you already have a device – maybe that is what is spurring your interest in developing for Android.

If you do not have an Android device that you wish to set up for development, skip this step.

The first step to make your device ready for use with development is to go into the Settings application on the device. What happens now depends a bit on your Android version:

- On Android 1.x/2.x, go into Applications, then into Development
- On Android 3.0 through 4.1, go into “Developer options” from the main Settings screen

TUTORIAL #2 - CREATING A STUB PROJECT

- On Android 4.2 and higher, go into About, tap on the build number seven times, then press BACK, and go into “Developer options” (which was formerly hidden)

Figure 46: Android device development settings

You may need to slide a switch in the upper-right corner of the screen to the “ON” position to modify the values on this screen.

Generally, you will want to enable USB debugging, so you can use your device with the Android build tools. You can leave the other settings alone for now if you wish, though you may find the “Stay awake” option to be handy, as it saves you from having to unlock your phone all of the time while it is plugged into USB.

Note that on Android 4.2.2 and higher devices, before you can actually use the setting you just toggled, you will be prompted to allow USB debugging with your *specific* development machine via a dialog box:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 47: Allow USB Debugging Dialog

This occurs when you plug in the device via the USB cable and have the driver appropriately set up. That process varies by the operating system of your development machine, as is covered in the following sections.

Windows

When you first plug in your Android device, Windows will attempt to find a driver for it. It is possible that, by virtue of other software you have installed, that the driver is ready for use. If it finds a driver, you are probably ready to go.

If the driver is not found, here are some options for getting one.

Windows Update

Some versions of Windows (e.g., Vista) will prompt you to search Windows Update for drivers. This is certainly worth a shot, though not every device will have supplied its driver to Microsoft.

Standard Android Driver

In your Android SDK installation, if you chose to install the “Google USB Driver” package from the SDK Manager, you will find an `extras/google/usb_driver/` directory, containing a generic Windows driver for Android devices. You can try pointing the driver wizard at this directory to see if it thinks this driver is suitable for your device. This will often work for Nexus devices.

Manufacturer-Supplied Driver

If you still do not have a driver, the [OEM USB Drivers](#) in the developer documentation may help you find one for download from your device manufacturer. Note that you may need the model number for your device, instead of the model

TUTORIAL #2 - CREATING A STUB PROJECT

name used for marketing purposes (e.g., GT-P3113 instead of “Samsung Galaxy Tab 2 7.0”).

OS X and Linux

Odds are decent that simply plugging in your device will “just work”. You can see if Android recognizes your device via running `adb devices` in a shell (e.g., OS X Terminal), where `adb` is in your `platform-tools/` directory of your SDK. If you get output similar to the following, the build tools detected your device:

```
List of devices attached
HT9CPP809576 device
```

If you are running Ubuntu (or perhaps other Linux variants), and this command did not work, you may need to add some udev rules. For example, here is a `51-android.rules` file that will handle the devices from a handful of manufacturers:

```
SUBSYSTEM=="usb", SYSFS{idVendor}=="0bb4", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="22b8", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="18d1", MODE="0666"
SUBSYSTEMS=="usb", ATTRS{idVendor}=="18d1", ATTRS{idProduct}=="0c01",
MODE="0666", OWNER="[me]"
SUBSYSTEM=="usb", SYSFS{idVendor}=="19d2", SYSFS{idProduct}=="1354", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="04e8", SYSFS{idProduct}=="681c", MODE="0666"
```

Drop that in your `/etc/udev/rules.d` directory on Ubuntu, then either reboot the computer or otherwise reload the udev rules (e.g., `sudo service udev reload`). Then, unplug and re-plug in the device and see if it is detected.

The CyanogenMod project maintains [a page on their wiki](#) with more on these udev rules, including rules from a variety of manufacturers and devices.

Step #4: Running the Project

Now, we can confirm that our project is set up properly by running it on a device or emulator. Once again, there are separate sections of instructions below for Android Studio versus Eclipse development — please follow the instructions that are appropriate for you.

Android Studio

Press the Run toolbar button (usually depicted as a green rightward-pointing triangle).

You will then be presented with a dialog indicating where you want the app to run: on some existing device or emulator, or on some newly-launched emulator:

Figure 48: Android Studio Device Chooser Dialog

If you do not have an emulator running, choose one from the drop-down menu towards the bottom of the dialog, then click OK. Android Studio will launch your emulator for you.

And, whether you start a new emulator instance or reuse an existing one, your app should appear on it.

Eclipse

Press the Run toolbar button (usually depicted as a white “play” triangle in a green circle). The first time you run the project, you will see a “Run As” dialog, prompting you to declare how you want to run the app:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 49: Eclipse Run As Dialog

Click on “Android Application” and click “OK” to proceed.

At this point, if you have a compatible running emulator or device, the app will be installed and run on it. If you have more than one, you will be given a dialog where you can choose what to use. Otherwise, Eclipse will start up a suitable emulator, from the AVDs you created [previously](#), then will install and run the app on it.

Results

You should see your app on the device or emulator:

TUTORIAL #2 - CREATING A STUB PROJECT

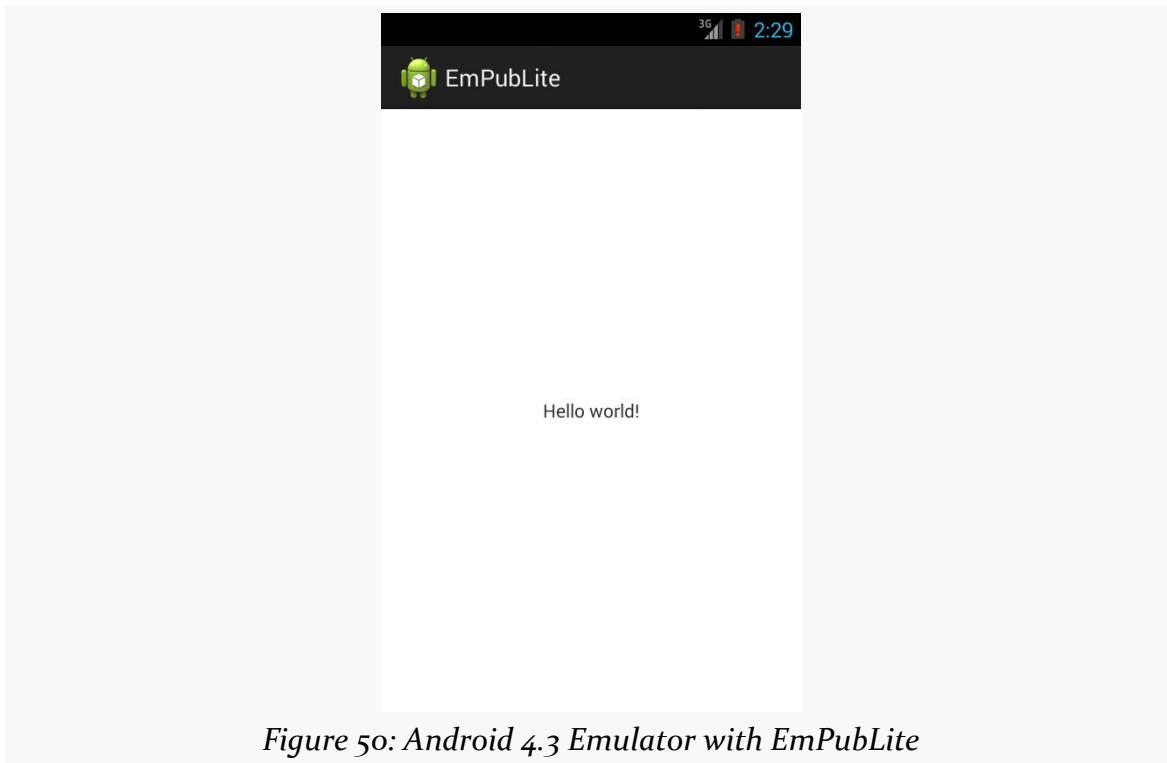

Figure 50: Android 4.3 Emulator with EmPubLite

Note that you will have to unlock your device or emulator to actually see the app running — it will not unlock automatically for you.

In Our Next Episode...

... we will [modify the AndroidManifest.xml file](#) of our tutorial project.

Getting Around Android Studio

Eclipse has been around for a very long time and has proven to be a very popular IDE. As a result, there is quite a bit of material written about it, from books and blogs to Stack Overflow questions and official project documentation.

Android Studio shares a lot of functionality with its parent, IntelliJ IDEA. However, IDEA itself has not achieved Eclipse's level of popularity, even though it has long been the IDE of choice for many “power developers”. And Android Studio's changes to IDEA are largely undocumented.

Hence, this chapter will serve as a quick tour of the Android Studio IDE, to help you get settled in. Other Android-specific capabilities of Android Studio will be explored in the chapters that follow.

Navigating The Project Explorer

After the main editing area — where you will modify your Java source code, your resources, and so forth — the piece of Android Studio you will spend the most time with is the project explorer, usually available on the left side of the IDE window:

Figure 51: Android Studio Project Explorer, Showing Android Project View

This explorer pane has two main “project views” that an Android developer will use: the Android project view and the classic project view.

Android Project View

By default, when you create or import a project, you will wind up in the Android project view.

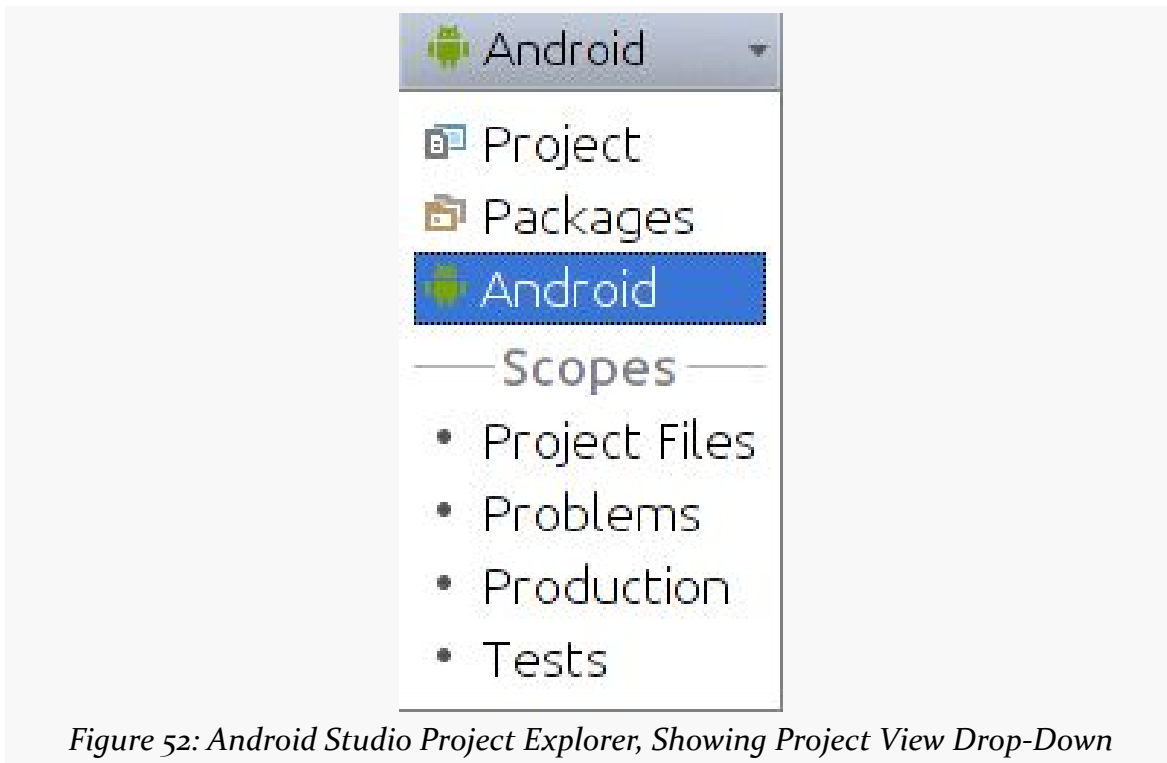

In theory, the Android project view is designed to simplify working with Android project files. In practice, it may do so, but only for some advanced developers. On the whole, it makes the IDE significantly more complicated for newcomers to Android, as it is rather difficult to see where things are and what relates to what.

We will return to the Android project view a bit later in the book and explain its benefits relative to [resources](#) and [Gradle’s sourcesets](#).

However, for most of the book — most importantly, for the tutorials – we will use the classic project view.

Classic Project View

To switch to the classic project view, click the drop-down just above the tree in the explorer, and choose Project:

This will change the contents of the tree to show you all of the files, in their associated directories:

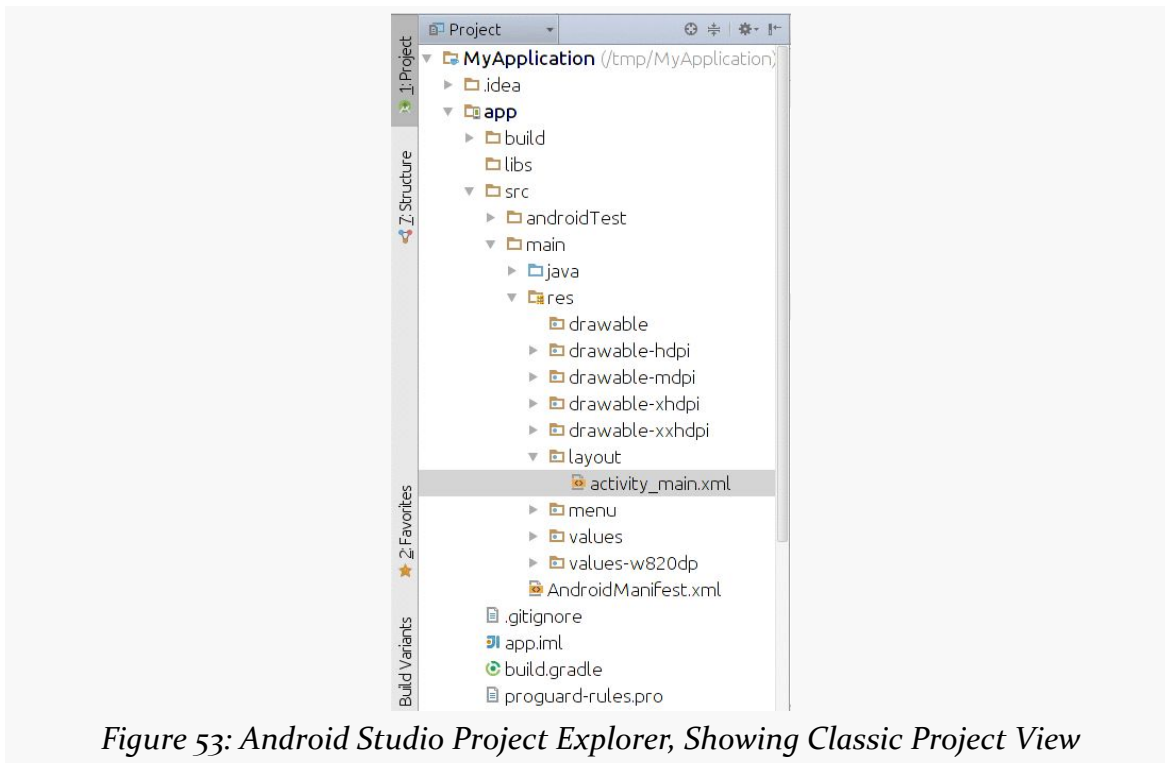

Figure 53: Android Studio Project Explorer, Showing Classic Project View

This project view is much like its equivalent in other IDEs, allowing you to find all of the pieces of your Android project. We will be exploring what those pieces are, and how their files are organized in our projects, in [the next chapter](#).

Context Menus in the Explorer

Right-clicking over a directory or file in the explorer will give you a context menu with a variety of options. Some of these will be typical of any sort of file manager, such as “cut”, “copy”, and/or “paste” options. Some of these will be organized according to how IntelliJ IDEA manages application development, such as the “Refactor” sub-menu, where you can rename or move files around. Yet others will be specific to Android Studio, such as the ability to invoke wizards to create certain types of Android components or other Java classes.

Running Projects

As noted in [Tutorial #2](#), to run your project, just press the Run toolbar button (usually depicted as a green rightward-pointing triangle). You will then be presented

with a dialog indicating where you want the app to run: on some existing device or emulator, or on some newly-launched emulator:

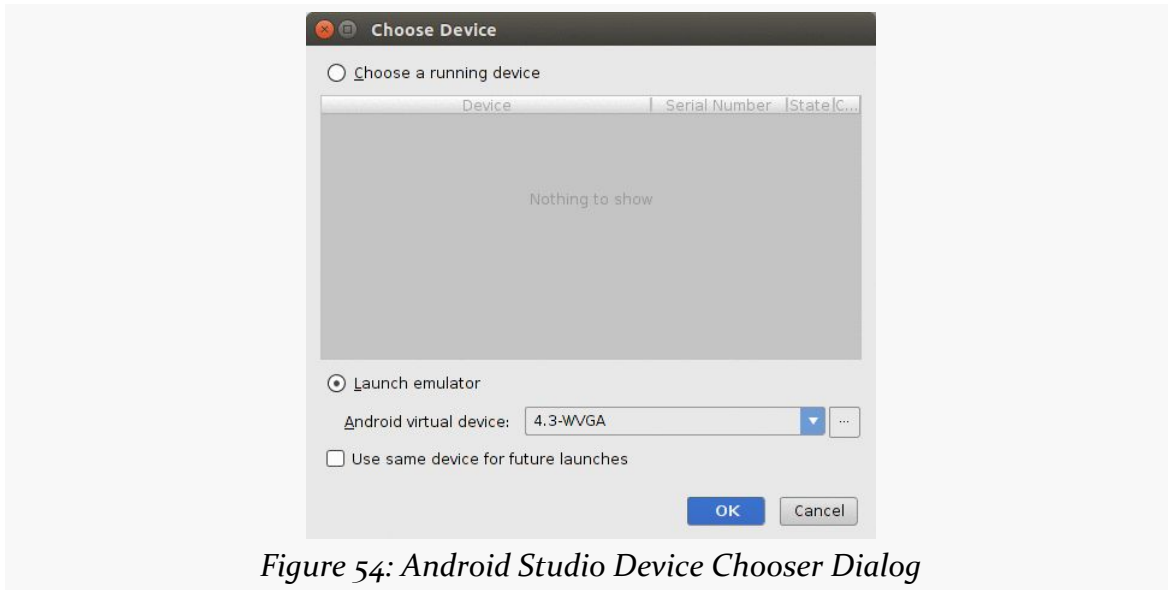

Figure 54: Android Studio Device Chooser Dialog

If you do not have an emulator running, choose one from the drop-down menu towards the bottom of the dialog, then click OK. Android Studio will launch your emulator for you. Whether you start a new emulator instance, reuse an existing one, or request that your app run on an attached Android device, your app should appear on it.

Viewing Output

Beyond your app itself, Android Studio will generate other sorts of diagnostic output, in the form of “console”-style transcripts of things that have occurred. The two of these that probably will matter most for you are the Gradle console and LogCat.

Gradle Console

By default, docked in the lower-right corner of your Android Studio window is a “Gradle Console” item. Tapping on that will open up a pane showing the output of attempts to build your application:

GETTING AROUND ANDROID STUDIO

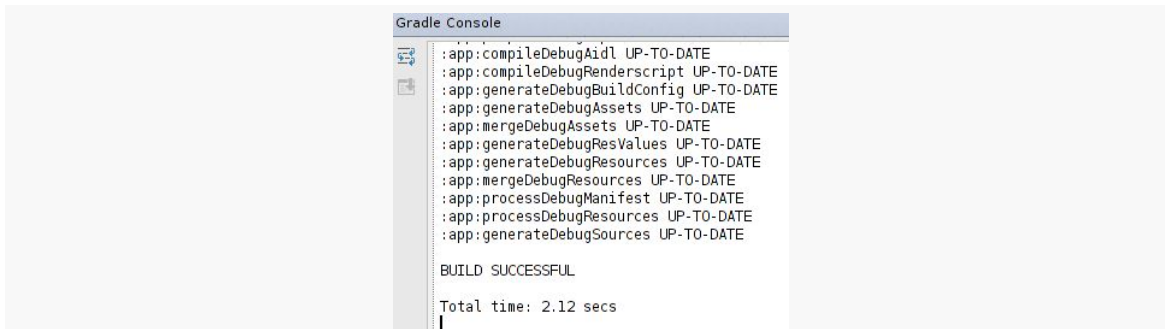

Figure 55: Android Studio Gradle Console

This may automatically appear from time to time, if specific build problems are detected, and you can always go examine it whenever you need.

Click on the “Gradle Console” item again to collapse the view and get it out of your way.

LogCat

Messages that appear at runtime — including the all-important Java stack traces triggered by bugs in your code — are visible in LogCat. The “Android” item docked towards the lower-left corner of your Android Studio window will display LogCat when tapped:

Figure 56: Android Studio LogCat View

LogCat is explained in greater detail [a bit later in this book](#).

Accessing Android Tools

Not everything related to Android is directly part of Android Studio itself. In some cases, tools need to be shared between users of Android Studio, users of Eclipse, and users of “none of the above”. In some cases, while the long term direction may be to

incorporate the tools' functionality directly into Android Studio, that work simply has not been completed to date.

Here are some noteworthy Android-related tools that you can access via the Tools > Android main menu option.

SDK and AVD Managers

As we saw in [Tutorial #1](#), the SDK Manager is Android's tool for downloading pieces of the Android SDK, including:

- “SDK Platform” editions, allowing us to compile against a particular API level
- ARM and (sometimes) x86 emulator images
- Documentation
- Updates to the core build tools
- Etc.

You can launch the SDK Manager via Tools > Android > SDK Manager from the Android Studio main menu, or by clicking on the “droid in a box” toolbar button:

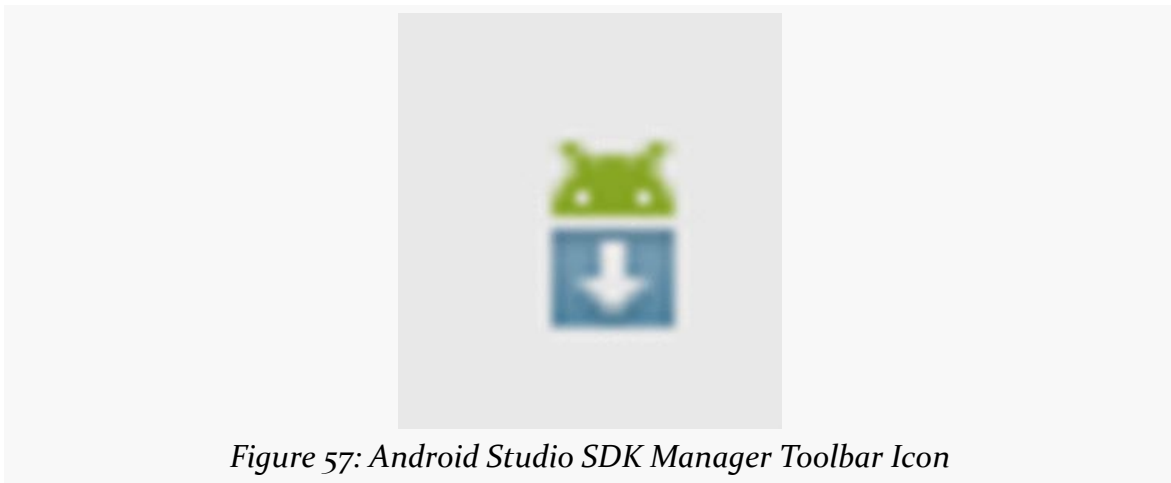

Figure 57: Android Studio SDK Manager Toolbar Icon

The AVD Manager is the tool for creating emulators that emulate certain Android environments, based upon API level, screen size, and other characteristics.

You can launch the AVD Manager via Tools > Android > AVD Manager from the Android Studio main menu, or by clicking the “droid and a screen” toolbar button:

Figure 58: Android Studio AVD Manager Toolbar Icon

Android Device Monitor

Elsewhere in this book, you will see references to tools associated with the Dalvik Device Monitor Service (DDMS), such as using it to help inspect your running apps for memory or threading issues. You will also see references to tools like Hierarchy View, for trying to make sense of your UI as it appears at runtime, after you have programmatically made lots of changes to it.

In Eclipse, DDMS and Hierarchy View are “perspectives”, added to Eclipse via the ADT plugin.

For everyone not using Eclipse — including Android Studio users — DDMS and Hierarchy View are available via the Android Device Monitor standalone tool. Android Studio users can launch the Monitor via Tools > Android > Android Device Monitor from the main menu.

This will first bring up a splash screen:

Figure 59: Android Device Monitor Splash Screen

followed by the Monitor itself:

Figure 60: Android Device Monitor, As Initially Opened

If you read about things available from DDMS or Hierarchy View online, such as in blog posts or Stack Overflow answers, most of those capabilities should be available to you via the Android Device Monitor.

Android Studio and Release Channels

When you install Android Studio for the first time, your installation will be set up to get updates on the “stable” release channel. Here, a “release channel” is a specific set of possible upgrades. The “stable” release channel means that you are getting full production-ready updates. Android Studio will check for updates when launched, and you can manually check for updates via Help > Check for Update... in the main menu.

If an update is available, you will be presented with a dialog box showing you details of the update:

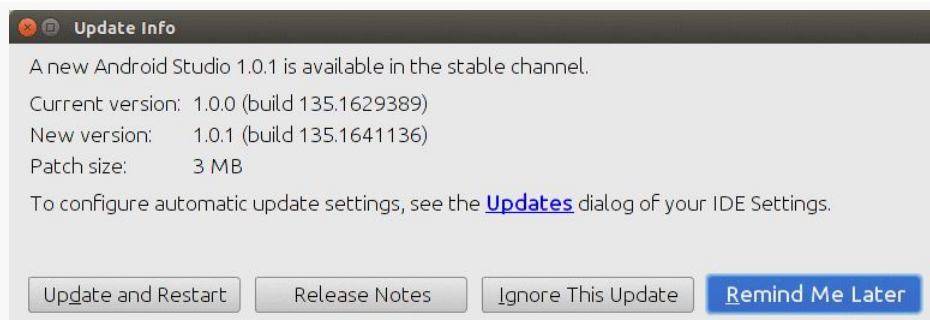

Figure 61: Android Studio Update Dialog

Choosing “Release Notes” will bring up a Web page with release notes for the new release. Clicking “Update and Restart” does pretty much what the button name suggests: it downloads the update and restarts the IDE, applying the update along the way.

Clicking the “Updates” hyperlink in the dialog brings up yet another dialog, allowing you to choose which release channel you want to subscribe to:

GETTING AROUND ANDROID STUDIO

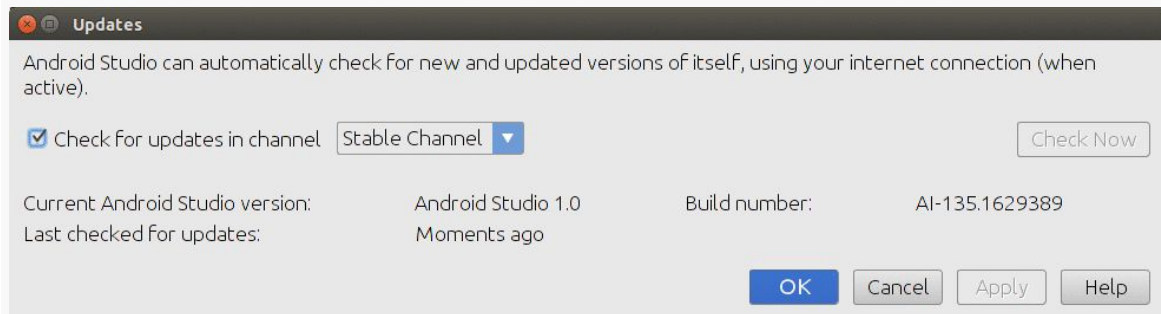

Figure 62: Android Studio Update Release Channel Dialog

You have four channels to choose from:

- Stable, which is appropriate for most developers
- Beta, which will get updates that are slightly ahead of stable
- Dev, which is even more ahead than is the beta channel
- Canary, which is updated *very* early (and the name, suggestive of a “canary in a coal mine”, indicates that you are here to help debug the IDE)

Contents of Android Projects

The Android build system is organized around a specific directory tree structure for your Android project, much like any other Java project. The specifics, though, are fairly unique to Android — the Android build tools do a few extra things to prepare the actual application that will run on the device or emulator.

Making things more complicated is that the default structure is different for the classic tools (e.g., Eclipse) and the new generation of tools (e.g., Android Studio).

Here is a quick primer on the project structure, to help you make sense of it all, particularly for the sample code referenced in this book.

What You Get, In General

The details of *exactly* what files are in your project depend upon your choice of IDE. However, regardless of whether you go with Android Studio or Eclipse, there are many elements in common.

The Manifest

`AndroidManifest.xml` is an XML file describing the application being built and what components — activities, services, etc. — are being supplied by that application. You can think of it as being the “table of contents” of what your application is about, much as a book has a “table of contents” listing the various parts, chapters, and appendices that appear in the book.

We will examine the manifest a bit more closely starting in [the next chapter](#). |

The Java

When you created the project, you supplied the fully-qualified class name of the “main” activity for the application (e.g., `com.commonware.android.SomeDemo`). You will then find that your project’s Java source tree already has the package’s directory tree in place, plus a stub Activity subclass representing your main activity (e.g., `src/com/commonware/android/SomeDemoActivity.java`). You are welcome to modify this file and add Java classes as needed to implement your application, and we will demonstrate that countless times as we progress through this book.

Elsewhere — in directories that you normally do not work with — the Android build tools will also be code-generating some source code for you each time you build your app. One of the code-generated Java classes (`R.java`) will be important for controlling our user interfaces from our own Java code, and we will see many references to this R class as we start building applications in earnest.

The Resources

You will also find that your project has a `res/` directory tree. This holds “resources” — static files that are packaged along with your application, either in their original form or, occasionally, in a preprocessed form. Some of the subdirectories you will find or create under `res/` include:

1. `res/drawable/` for images (PNG, JPEG, etc.)
2. `res/layout/` for XML-based UI layout specifications
3. `res/menu/` for XML-based menu specifications
4. `res/raw/` for general-purpose files (e.g., an audio clip, a CSV file of account information)
5. `res/values/` for strings, dimensions, and the like
6. `res/xml/` for other general-purpose XML files you wish to ship

Some of the directory names may have suffixes, like `res/drawable-hdpi/`. This indicates that the directory of resources should only be used in certain circumstances — in this case, the drawable resources should only be used on devices with high-density screens.

We will cover all of these, and more, later in this book.

The Build Instructions

The IDE needs to know how to take all of this stuff and come up with an Android APK file. Some of this is already “known” to the IDE based upon how the IDE was written. But some details are things that you may need to configure from time to time, and so those details are stored in files that you will edit, in one means or another, from your IDE.

In Android Studio, most of this knowledge is kept in one or more files named `build.gradle`. These are for a build engine known as [Gradle](#), that Android Studio uses to build APKs and other Android outputs.

In Eclipse, this knowledge is scattered among several files, some of which you might edit manually (e.g., `project.properties`) and some of which you would only change through Eclipse itself (e.g., `.classpath`).

The Contents of an Android Studio Project

An Android Studio project is significantly more complex than is an Eclipse project. That complexity is designed to give you more power when you become an expert Android developer.

In the short term, though, it may be a bit confusing.

The Root Directory

In the root directory of your project, the most important item is the `app/` directory, where your application code resides. We will look at that [in the next section](#).

Beyond the `app/` directory, the other noteworthy files in the root of your project include:

- `build.gradle`, which is part of the build instructions for your project, as is described above
- Various other Gradle-related files (`settings.gradle`, `gradle.properties`, and so forth)
- `local.properties`, which indicates where your Android SDK tools reside
- An `.iml` file, where Android Studio holds some additional metadata about your project

The App Directory

The `app/` directory, and its contents, are where you will spend most of your time as a developer. Rarely do you need to manipulate the files in the project root.

The most important thing in the `app/` directory is the `src/` directory, which is the root of your project's sourcesets, which will be described in [the next section](#).

Beyond the `src/` directory, there are a few other items of note in `app/`:

- A `build/` directory, which will hold the outputs of building your app, including your APK file
- A `build.gradle` file, where most of your project-specific Gradle configuration will go, to teach Android Studio how to build your app
- An `app.iml` file, containing more Android Studio metadata

The Sourcesets

Sourcesets are where the “source” of your project is organized. Here, “source” not only refers to programming language source code (e.g., Java), but other types of inputs to the build, such as your resources.

The sourceset that you will spend most of your time in is `main/`. You will also have a stub sourceset named `androidTest`, for use in creating unit tests, as will be covered [later in the book](#).

Inside of a sourceset, you can have:

- Java code, in a `java/` directory
- Resources, in a `res/` directory
- Assets, in an `assets/` directory, representing other static files you wish packaged with the application for deployment onto the device
- Your `AndroidManifest.xml` file

CONTENTS OF ANDROID PROJECTS

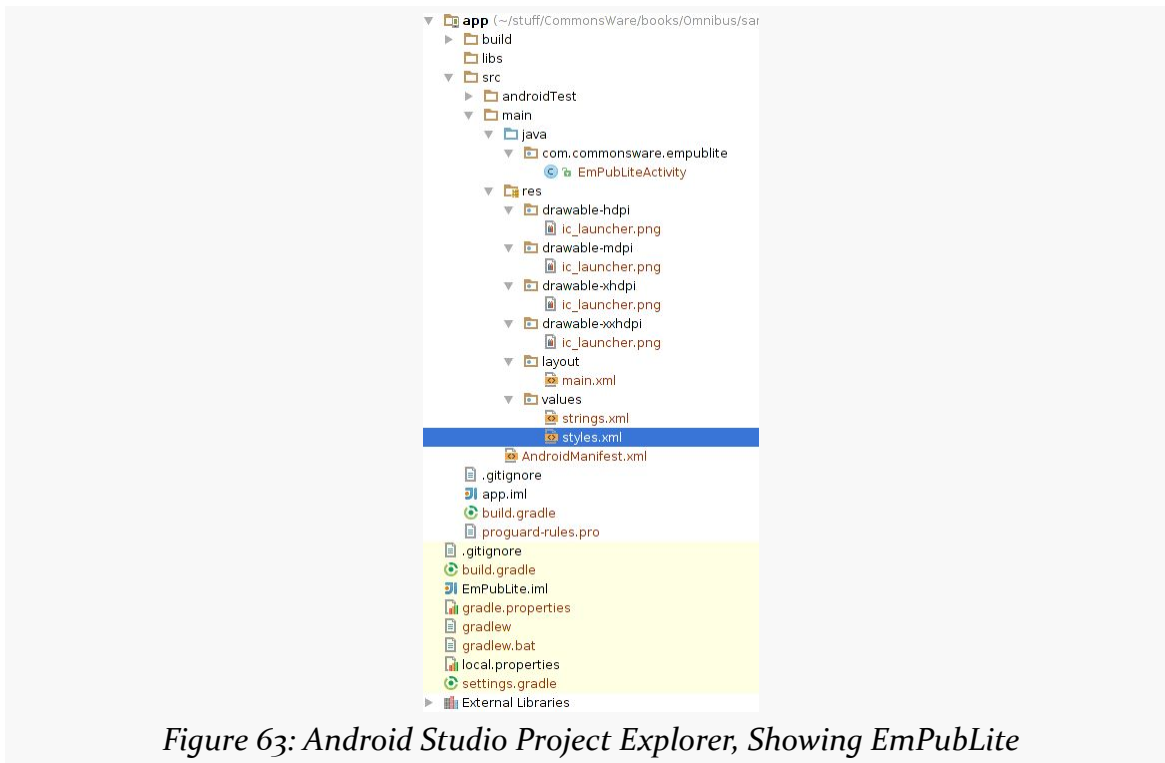

Figure 63: Android Studio Project Explorer, Showing EmPubLite

The Contents of an Eclipse Project

When you create a new Android project in Eclipse, you get several items in the project's root directory, including:

1. `AndroidManifest.xml`, as is described above
2. `bin/`, which holds the application once it is compiled (note: this directory will be created when you first build your application)
3. `res/`, which holds your resources, as is described above
4. `src/`, which holds the Java source code for the application

In addition to the files and directories shown above, you may find any of the following in Android projects:

1. `assets/`, which holds other static files you wish packaged with the application for deployment onto the device
2. `gen/`, where Android's build tools will place source code that they generate
3. `libs/`, which holds any third-party Java JARs your application requires
4. `*.properties`, containing configuration data for your builds

5. `proguard.cfg` or `proguard-project.txt`, which are used for integration with [ProGuard](#) for obfuscating your Android code
6. Hidden Eclipse project files (e.g., `.classpath`)

What You Get Out Of It

As part of running your app on a device or emulator, the IDE will generate an APK file. You will find this:

- in the `build/outputs/apk` directory of your Android Studio project, if the project has no modules (e.g., no `app/` directory), or
- in the `build/outputs/apk` directory of your module's directory, (e.g., `app/build/outputs/apk` for a traditional Android Studio project), or
- in the `bin/` directory of your Eclipse project

The APK file is a ZIP archive containing your compiled Java classes, the compiled edition of your resources (`resources.arsc`), any un-compiled resources (such as what you put in `res/raw/`), and the `AndroidManifest.xml` file. If you build a debug version of the application — which is the default — you will have `yourapp-debug.apk` as your APK, for an app named `yourapp`.

Introducing Gradle and the Manifest

In the discussion of Android Studio, this book has mentioned something called “Gradle”, without a lot of explanation.

In this chapter, the mysteries of Gradle will be revealed to you.

(well, OK, *some* of the mysteries...)

We also mentioned in passing in the previous chapter the concept of the “manifest”, as being a special file in our Android projects.

On the one hand, Gradle and the manifest are not strictly related. On the other hand, some (but far from all) of the things that we can set up in the manifest can be overridden in Gradle... for Android Studio users. Since Eclipse users are not using Gradle, their definitions will always be in the manifest itself.

So, in this chapter, we will review both what Gradle is, what the manifest is, what each of their roles are, and the basics of how they tie together.

Gradle: The Big Questions

First, let us “set the stage” by examining what this is all about, through a series of fictionally-asked questions (FAQs).

What is Gradle?

[Gradle](#) is software for building software, otherwise known as “build automation software” or “build systems”. You may have used other build systems before in other environments, such as `make` (C/C++), `rake` (Ruby), `Ant` (Java), `Maven` (Java), etc.

These tools know — via intrinsic capabilities and rules that you teach them — how to determine what needs to be created (e.g., based on file changes) and how to create them. A build system does not compile, link, package, etc. applications directly, but instead directs separate compilers, linkers, and packagers to do that work.

Gradle uses a domain-specific language (DSL) built on top of Groovy to accomplish these tasks.

What is Groovy?

There are many programming languages that are designed to run on top of the Java VM. Some of these, like JRuby and Jython, are implementations of other common programming languages (Ruby and Python, respectively). Other languages are unique, and [Groovy](#) is one of those.

Groovy scripts look a bit like a mashup of Java and Ruby. As with Java, Groovy supports:

- Defining classes with the `class` keyword
- Creating subclasses using `extends`
- Importing classes from external JARs using `import`
- Defining method bodies using braces (`{` and `}`)
- Objects are created via the `new` operator

As with Ruby, though:

- Statements can be part of a class, or simply written in an imperative style, like a scripting language
- Parameters and local variables are not typed
- Values can be automatically patched into strings, though using slightly different syntax ("Hello, \$name" for Groovy instead of "Hello, #{name}" for Ruby)

Groovy is an interpreted language, like Ruby and unlike Java. Groovy scripts are run by executing a `groovy` command, passing it the script to run. The Groovy runtime, though, is a Java JAR and requires a JVM in order to operate.

One of Groovy's strengths is in creating a [domain-specific language](#) (or DSL). Gradle, for example, is a Groovy DSL for doing software builds. Gradle-specific capabilities appear to be first-class language constructs, generally indistinguishable

from capabilities intrinsic to Groovy. Yet, the Groovy DSL is largely declarative, like an XML file.

To some extent, we get the best of both worlds: XML-style definitions (generally with less punctuation), yet with the ability to “reach into Groovy” and do custom scripting as needed.

What Does Android Have To Do with Gradle?

Google has published the Gradle for Android plugin, which gives Gradle the ability to build Android projects. Google is also using Gradle and Gradle for Android as the build system behind Android Studio.

Why Did We Move to Gradle?

Originally, when we would build an app, those builds were done using Eclipse and Ant. Eclipse was the IDE, while Ant was the command-line tool. Eclipse does not use Ant for building Android projects, but rather has its own build system. And we were successfully building a million-plus apps using these tools. Those tools still work today, though Ant support is fading fast.

So, why change?

There appear to be several contributing factors, including:

- Maintaining two separate build systems (Ant and Eclipse’s native approach) was becoming time-consuming, and would become worse with the advent of Android Studio and yet another build system. Hence, Google wishes to standardize on a single build system, based upon Gradle, for IDE and command-line scenarios.
- Getting Ant scripts to do everything that Google needed for builds was getting a bit creaky.
- Ant has no first-class support for “external artifacts” (e.g., libraries) and dependency management of those libraries. While there are ways to graft [Maven](#) onto Ant, or use Maven’s own build system, Google never endorsed that approach. Gradle offers much better support in this area than do Eclipse or Ant, and will help make it easier for developers to reliably consume libraries from a variety of authors.
- Gradle is designed to be integrated into IDEs as a library, much more than Ant is.

As to why Google chose Gradle over Maven... you would have to ask Google.

How Does Gradle Relate to Android Studio?

As noted above, Android Studio uses the new Gradle-based build system as its native approach for building Android projects. While the IntelliJ IDEA IDE that serves as Android Studio's core also has its own build system (much like Eclipse has one), IDEA is more amenable to replaceable build systems.

Over time, this will allow Google to focus on a single build system (Gradle) for all supported scenarios, rather than having to deal with a collection of independent build systems.

How Does Gradle Relate to Eclipse?

At the time of this writing, Eclipse has no ability to use Gradle for Android build scripts, either directly or as a source of project configuration data for imports. The Android Developer Tools (ADT) plugin for Eclipse does have the ability to [export a generated Gradle build file](#) for a project.

It is unclear to what extent that Eclipse will ever get Gradle for Android support. It is best to assume that this will not be possible any time soon.

Obtaining Gradle

As with any build system, to use it, you need the build system's engine itself.

If you will only be using Gradle in the context of Android Studio, the IDE will take care of getting Gradle for you. If, however, you are planning on using Gradle outside of Android Studio (e.g., command-line builds), you will want to consider where your Gradle is coming from. This is particularly important for situations where you want to build the app with no IDE in sight, such as using a continuous integration (CI) server, like Jenkins.

Direct Installation

What most developers looking to use Gradle outside of Android Studio will wind up doing is installing Gradle directly.

The [Gradle download page](#) contains links to ZIP archives for Gradle itself: binaries, source code, or both.

You can unZIP this archive to your desired location on your development machine.

Linux Packages

You may be able to obtain Gradle via a package manager on Linux environments. For example, there is [an Ubuntu PPA for Gradle](#).

The gradlew Wrapper

If you are starting from a project that somebody else has published, you may find a `gradlew` and `gradlew.bat` file in the project root, along with a `gradle/` directory. This represents [the “Gradle Wrapper”](#).

The Gradle Wrapper consists of three pieces:

- the batch file (`gradlew.bat`) or shell script (`gradlew`)
- the JAR file used by the batch file and shell script (in the `gradle/wrapper/` directory)
- the `gradle-wrapper.properties` file (also in the `gradle/wrapper/` directory)

Android Studio uses the `gradle-wrapper.properties` file to determine where to download Gradle from, for use in your project, from the `distributionUrl` property in that file:

```
#Wed Apr 10 15:27:10 PDT 2013
distributionBase=GRADLE_USER_HOME
distributionPath=wrapper/dists
zipStoreBase=GRADLE_USER_HOME
zipStorePath=wrapper/dists
distributionUrl=https\://services.gradle.org/distributions/gradle-2.2.1-all.zip
```

When you create or import a project, or if you change the version of Gradle referenced in the properties file, Android Studio will download the Gradle pointed to by the `distributionUrl` property and install it to a `.gradle/` directory (note the leading `.`) in your project. That version of Gradle will be what Android Studio uses.

RULE #1: Only use a `distributionUrl` that you trust.

If you are importing an Android project from a third party — such as the samples for this book — and they contain the `gradle/wrapper/gradle-wrapper.properties` file, examine it to see where the `distributionUrl` is pointing to. If it is loading from `services.gradle.org`, or from an internal enterprise server, it is probably trustworthy. If it is pointing to a URL located somewhere else, consider whether you really want to use that version of Gradle, considering that it may have been tampered with.

The batch file, shell script, and JAR file are there to support command-line builds. If you use `gradlew`, it will use a local copy of Gradle installed in `.gradle/` in the project. If there is no such copy of Gradle, `gradlew` will download Gradle from the `distributionUrl`, as does Android Studio. Note that Android Studio does not use `gradlew` for this role — that logic is built into Android Studio itself.

RULE #2: Only use a `gradlew` that you REALLY trust.

It is relatively easy to examine a `.properties` file to check a URL to see if it seems valid. Making sense of a batch file or shell script can be cumbersome. Decompiling a JAR file and making sense of it can be rather difficult. Yet, if you use `gradlew` that you obtained from somebody, that script and JAR are running on your development machine, as is the copy of Gradle that they install. If that code was tampered with, the malware has complete access to your development machine and anything that it can reach, such as servers within your organization.

Note that you do not have to use the Gradle Wrapper at all. If you would rather not worry about it, install a version of Gradle on your development machine yourself and remove the Gradle Wrapper files. You can use the `gradle` command to build your app (if your Gradle's `bin/` directory is in your `PATH`), and Android Studio will use your Gradle installation (if you teach it where to find it, such as via the `GRADLE_HOME` environment variable).

Versions of Gradle and Gradle for Android

The Gradle for Android plugin that we will use to give Gradle “super Android powers!” is updated periodically. Each update has its corresponding required version of Gradle.

[The rules, according to Google](#), are:

- Android Studio 1.x works with any Gradle for Android plugin version 1.x, where the values for “x” do not need to match.
- Gradle for Android 1.x should work with all Gradle 2.x versions

If you are using the Gradle Wrapper, you are using an installation of Gradle that is local to the project. So long as the version of Gradle in the project matches the version of Gradle for Android requested in the `build.gradle` file — as will be covered in the next chapter — you should be in fine shape.

If you are not using the Gradle Wrapper, you will need to decide when to take on a new Gradle for Android release and plan to update your Gradle installation and `build.gradle` files in tandem at that point.

Gradle Environment Variables

If you installed Gradle yourself, you will want to define a `GRADLE_HOME` environment variable, pointing to where you installed Gradle, and to add the `bin/` directory inside of Gradle to your `PATH` environment variable.

You may also consider setting up a `GRADLE_USER_HOME` environment variable, pointing to a directory in which Gradle can create a `.gradle` subdirectory, for per-user caches and related materials. By default, Gradle will use your standard home directory.

Examining the Gradle Files

An Android Studio project may have two `build.gradle` files, one at the project level and one at the “module” level (e.g., in the `app/` directory). That split is not required for single-module projects — those could just as easily have one `build.gradle` file for the module and nothing else.

Regardless of whether your `build.gradle` file is in one or two pieces, there are a few common elements that you will find, outlined in this section.

buildscript

The `buildscript` closure (i.e., code section wrapped in braces) in Gradle is where you configure the JARs and such that Gradle itself will use for interpreting the rest of

the file. Hence, here you are not configuring your *project* so much as you are configuring *the build itself*.

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}
```

The `repositories` closure inside the `buildscript` closure indicates where dependencies can come from, typically in the form of Maven-style repositories. Here, `mavenCentral()` is a built-in method that sets up the repository information for Maven Central, where Google is now publishing its required libraries.

The `dependencies` closure indicates what is required to be able to run the rest of the build script. `classpath 'com.android.tools.build:gradle:1.0.0'` is not especially well-documented by the Gradle team. However the `'com.android.tools.build:gradle:1.0.0'` portion means:

- Find the `com.android.tools.build` group of artifacts in a repository
- Find the gradle artifact within that group
- Ensure that we have version `1.0.0` of the artifact

The first time you run your build, with the `buildscript` closure as shown above, Gradle will notice that you do not have this dependency. It will then visit [Maven Central](#) and find [the com.android.tools.build group](#) and the gradle artifact within that group, then download version `1.0.0`.

Sometimes, the last segment of the version is replaced with a `+` sign (e.g., `1.0.+`). This tells Gradle to download the latest version, thereby automatically upgrading you to the latest patch-level (e.g., `1.0.3` at some point).

apply plugin

The `'com.android.tools.build:gradle:1.0.0'` dependency contains an implementation of the Gradle for Android plugin, to teach Gradle Android-specific constructs, such as those found in the `android` closure covered [later in this chapter](#). However, just downloading the dependency does not actually apply anything in it.

The `apply plugin: 'com.android.application'` statement actually adds the Gradle for Android plugin to Gradle for this build. In particular, it indicates that we are building an Android application.

dependencies

The `dependencies` closure in the `buildscript` closure specifies dependencies for the build script. The `dependencies` closure in the root of the `build.gradle` file, by contrast, specifies dependencies for the *app*.

However, the definition of “dependency” is largely the same: it is some library or similar artifact that we need in addition to our project’s source code.

We will get into the concept of these libraries [later in the book](#).

android

The `android` closure contains all of the Android-specific configuration information. This closure is what the Android plugin enables.

But before we get into what is in this closure, we should “switch gears” and talk about the manifest file, as what goes in the `android` closure is related to what goes in the manifest file.

Introducing the Manifest

The foundation for any Android application is the manifest file: `AndroidManifest.xml`. This will be in your project root for Eclipse projects and in your app module’s `src/main/` directory for classic Android Studio projects.

Here is where you declare what is inside your application — the activities, the services, and so on. You also indicate how these pieces attach themselves to the overall Android system; for example, you indicate which activity (or activities) should appear on the device’s main menu (a.k.a., launcher).

When you create your application, you will get a starter manifest generated for you. For a simple application, offering a single activity and nothing else, the auto-generated manifest will probably work out fine, or perhaps require a few minor modifications. On the other end of the spectrum, the manifest file for the Android

API demo suite is over 1,000 lines long. Your production Android applications will probably fall somewhere in the middle.

As mentioned previously, some items can be defined in both the manifest and in a `build.gradle` file. The approach of putting that stuff in the manifest still works, and for Eclipse it is the only option, as Eclipse is not looking at a `build.gradle` file. For Android Studio users, you will probably use the Gradle file and not have those common elements be defined in the manifest.

Things In Common Between the Manifest and Gradle

There are a few key items that can be defined in the manifest and can be overridden in `build.gradle` statements. These items are fairly important to the development and operation of our Android apps as well.

Package Name and Application ID

The root of all manifest files is, not surprisingly, a manifest element:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.empublite">
```

Note the android namespace declaration. You will only use the namespace on many of the attributes, not the elements (e.g., `<manifest>`, not `<android:manifest>`).

The biggest piece of information you need to supply on the `<manifest>` element is the package attribute.

The package attribute will always need to be in the manifest, even for Android Studio projects. The package attribute will control where some source code is generated for us, notably some `R` and `BuildConfig` classes that we will encounter later in the book.

Since the package value is used for Java code generation, it has to be a valid Java package name. Java convention says that the package name should be based off of a reverse domain name (e.g., `com.commonware.empublite`), where you own the domain in question. That way, it is unlikely that anyone else will accidentally collide with the same name.

The package also serves as our app's default "application ID". This needs to be a unique identifier, such that:

- no two apps can be installed on the same device at the same time with the same application ID
- no two apps can be uploaded to the Play Store with the same application ID (and other distribution channels may have the same limitation)

By default, the application ID is the package value, but Android Studio users can override it in their Gradle build files. Specifically, inside of the `android` closure can be a `defaultConfig` closure, and inside of there can be an `applicationId` statement:

```
android {  
    // other stuff  
  
    defaultConfig {  
        applicationId "com.commonware.empublite"  
        // more other stuff  
    }  
}
```

Not only can Android Studio users override the application ID in the `defaultConfig` closure, but there are ways of having different application ID values for different scenarios, such as a debug build versus a release build. We will explore that more [later in the book](#).

minSdkVersion and targetSdkVersion

Your manifest may also contain a `<uses-sdk>` element as a child of the `<manifest>` element, to specify what versions of Android you are supporting. It can contain, among other things, `android:minSdkVersion` and `android:targetSdkVersion` attributes. Eclipse projects will always have this element. Android Studio projects may not have this element, because the values are defined as `minSdkVersion` and `targetSdkVersion` properties in the `defaultConfig` closure, where `applicationId` can be defined.

Of the two, the more critical one is `minSdkVersion`. This indicates what is the oldest version of Android you are testing with your application. The value of the attribute is an integer representing the Android [API level](#). So, if you are only testing your application on Android 4.1 and newer versions of Android, you would set your `minSdkVersion` to be 16.

You can also specify a `targetSdkVersion`. This indicates what version of Android you are thinking of as you are writing your code. If your application is run on a newer version of Android, Android may do some things to try to improve compatibility of your code with respect to changes made in the newer Android. Nowadays, most Android developers should specify a target SDK version of 14 or higher. We will start to explore more about the `targetSdkVersion` as we get deeper into the book; for the moment, whatever your IDE gives you as a default value is probably a fine starting point.

The XML element looks like:

```
<uses-sdk android:minSdkVersion="14" android:targetSdkVersion="19" />
```

The corresponding entries in `build.gradle` go in the `defaultConfig` closure:

```
android {  
    // other stuff  
  
    defaultConfig {  
        applicationId "com.commonware.empublite"  
        minSdkVersion 15  
        targetSdkVersion 18  
        // more other stuff  
    }  
}
```

Version Code and Version Name

Your manifest can also specify `android:versionName` and `android:versionCode` attributes, up on the root `<manifest>` element. An Android Studio project, though, frequently skips those and defines them via `versionName` and `versionCode` properties in the `defaultConfig` closure.

These two values represent the versions of your application. The `versionName` value is what the user will see for a version indicator in the Applications details screen for your app in their Settings application:

Figure 64: Barcode Scanner App Screen in Settings, Showing Version 4.2

Also, the version name is used by the Play Store listing, if you are distributing your application that way. The version name can be any string value you want.

The versionCode, on the other hand, must be an integer, and newer versions must have higher version codes than do older versions. Android and the Play Store will compare the version code of a new APK to the version code of an installed application to determine if the new APK is indeed an update. The typical approach is to start the version code at 1 and increment it with each production release of your application, though you can choose another convention if you wish. During development, you can leave these alone, but when you move to production, these attributes will matter greatly.

Other Gradle Items of Note

You will always have at least two statements directly in the android closure: `compileSdkVersion` and `buildToolsVersion`.

```
android {  
    compileSdkVersion 19
```

INTRODUCING GRADLE AND THE MANIFEST

```
buildToolsVersion "21.1.2"
}
```

`compileSdkVersion` specifies the API level to be compiled against, usually as a simple API level integer (e.g., 19). An Eclipse project would pull this out of the `project.properties` file in the root of the project directory.

`buildToolsVersion` indicates the version of the Android SDK build tools that you wish to use with this project. While downloading the android plugin from Maven Central gives us parts of what is needed, it is not complete. The rest comes from the “Android SDK Build-tools” entry in the SDK Manager:

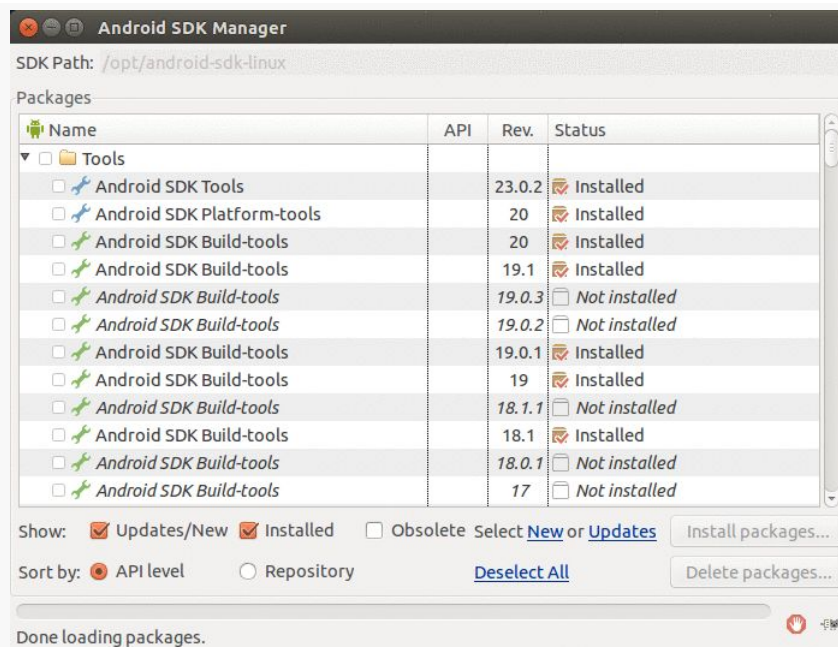

Figure 65: SDK Manager, Showing “Android SDK Build-tools”

Note that the SDK Manager will allow you to download the latest version of the build tools used by Gradle (appearing as 20 in the above screenshot) plus prior versions (e.g., 18.0.1 and 17 in the above screenshot). This corresponds with the `buildToolsVersion` in your `build.gradle` file.

So, your android closure could look like:

```
android {
    compileSdkVersion 19
    buildToolsVersion "20.0.0"
}
```

```
defaultConfig {  
    applicationId "com.commonware.empublite"  
    versionCode 1  
    versionName "1.0"  
    minSdkVersion 15  
    targetSdkVersion 18  
}
```

Eclipse does not really have the notion of a configurable build tools version, so there is no analogue for `buildToolsVersion` in an Eclipse project.

The Rest of the Manifest

Not everything in the manifest can be overridden in the Gradle build files. Here are a few key items that will always appear in the manifest, regardless of whether this project is to be built by Android Studio, Eclipse, or other means.

An Application For Your Application

In your initial project's manifest, the primary child of the `<manifest>` element is an `<application>` element.

By default, when you create a new Android project, you get a single `<activity>` element inside the `<application>` element:

```
<?xml version="1.0"?>  
<manifest xmlns:android="http://schemas.android.com/apk/res/android"  
    package="com.commonware.android.skeleton"  
    android:versionCode="1"  
    android:versionName="1.0">  
  
    <application>  
        <activity  
            android:name="Now"  
            android:label="Now">  
            <intent-filter>  
                <action android:name="android.intent.action.MAIN"/>  
  
                <category android:name="android.intent.category.LAUNCHER"/>  
            </intent-filter>  
        </activity>  
    </application>  
</manifest>
```

This element supplies `android:name` for the class implementing the activity, `android:label` for the display name of the activity, and (sometimes) an `<intent-filter>` child element describing under what conditions this activity will be displayed. The stock `<activity>` element sets up your activity to appear in the launcher, so users can choose to run it. As we'll see later in this book, you can have several activities in one project, if you so choose.

The `android:name` attribute, in this case, has a bare Java class name (`Now`). Sometimes, you will see `android:name` with a fully-qualified class name (e.g., `com.commonsware.android.skeleton.Now`). Sometimes, you will see a Java class name with a single dot as a prefix (e.g., `.Now`). Both `Now` and `.Now` refer to a Java class that will be in your project's package — the one you declared in the package attribute of the `<manifest>` element.

Supporting Multiple Screens

Android devices come with a wide range of screen sizes, from 2.8" tiny smartphones to 46" TVs. Android divides these into four buckets, based on physical size and the distance at which they are usually viewed:

1. Small (under 3")
2. Normal (3" to around 4.5")
3. Large (4.5" to around 10")
4. Extra-large (over 10")

By default, your application will support small and normal screens. It also will support large and extra-large screens via some automated conversion code built into Android.

To truly support all the screen sizes you want, you should consider adding a `<supports-screens>` element to your manifest. This enumerates the screen sizes you have explicit support for. For example, if you are providing custom UI support for large or extra-large screens, you will want to have the `<supports-screens>` element. So, while the starting manifest file works, handling multiple screen sizes is something you will want to think about.

You wind up with an element akin to:

```
<supports-screens
  android:largeScreens="true"
  android:normalScreens="true"
```

```
android:smallScreens="false"  
android:xlargeScreens="true" />
```

Much more information about providing solid support for all screen sizes, including samples of the `<supports-screens>` element, will be found later in this book as we cover large-screen strategies.

Other Stuff

As we proceed through the book, you will find other elements being added to the manifest, such as:

- `<uses-permission>`, to tell the user that you need permission to use certain device capabilities, such as accessing the Internet
- `<uses-feature>`, to tell Android that you need the device to have certain features (e.g., a camera), and therefore your app should not be installed on devices lacking such features
- `<meta-data>`, for bits of information needed by particular extensions to Android, such as the Google Play Services library.

These and other elements will be introduced elsewhere in the book.

Learning More About Gradle

This book will go into more about Gradle, both in the core chapters and in the trails. But, the focus will be on Gradle for Android, and Gradle itself offers a lot more than that. The Gradle Web site hosts [documentation](#), links to [Gradle-specific books](#), and links to [other Gradle educational resources](#).

At present, the Gradle for Android documentation is limited and mostly appears on [the Android tools site](#). Of note is [the top-level page about the new build system](#), and [the Gradle plugin user guide](#), though both may be out of date compared to the actual tools themselves.

Visit the Trails!

There are a few more chapters in this book getting into more details about the use of Gradle and Gradle for Android.

- [Gradle and Legacy Projects](#) is for developers who are looking to use Gradle with Eclipse-style projects
- [Gradle and Tasks](#) explains how we ask Gradle to do things on our behalf (“tasks”), such as compile our APK for us
- [Gradle and the New Project Structure](#) gets into why the project structure changed from what we used with Eclipse, and what capabilities we get as a result, including the ability to configure “build types” and “product flavors”
- [Gradle and Dependencies](#) covers more about the “artifacts” mentioned earlier in this chapter, as ways we can get packaged libraries automatically added to our projects via just a couple of lines in our build.gradle files

There is also the [“Advanced Gradle for Android Tips”](#) chapter for other Gradle topics, and [the chapter on manifest merging in Gradle](#).

Tutorial #3 - Changing Our Manifest (and Gradle File)

As we build EmPubLite, we will need to make a number of changes to our project's manifest. In this tutorial, we will take care of a couple of these changes, to show you how to manipulate the `AndroidManifest.xml` file. Future tutorials will make yet more changes.

Android Studio users will also get their first chance to work with the `build.gradle` file.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Some Notes About Relative Paths

In these tutorials, you will see references to relative paths, like `AndroidManifest.xml`, `res/layout/`, and so on.

Eclipse users should interpret these paths as being relative to the project root directory.

Android Studio users should interpret these paths as being relative to the `app/src/main/` directory within the project, except as otherwise noted. So, for example, Step

#1 below will ask you to open `AndroidManifest.xml` — that file can be found in `app/src/main/AndroidManifest.xml` from the project root.

Step #1: Supporting Screens

Our application will restrict its supported screen sizes. Tablets make for ideal ebook readers. Phones can also be used, but the smaller the phone, the more difficult it will be to come up with a UI that will let the user do everything that is needed, yet still have room for more than a sentence or two of the book at a time.

We will get into screen size strategies and their details [later in this book](#). For the moment, though, we will add a `<supports-screens>` element to keep our application off “small” screen devices (under 3” diagonal size).

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Double-click on `AndroidManifest.xml` in your project explorer.

As a child of the root `<manifest>` element, add a `<supports-screens>` element as follows:

```
<supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true"/>
```

Eclipse

In the Package Explorer view in Eclipse, find the `AndroidManifest.xml` entry and double-click on it.

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

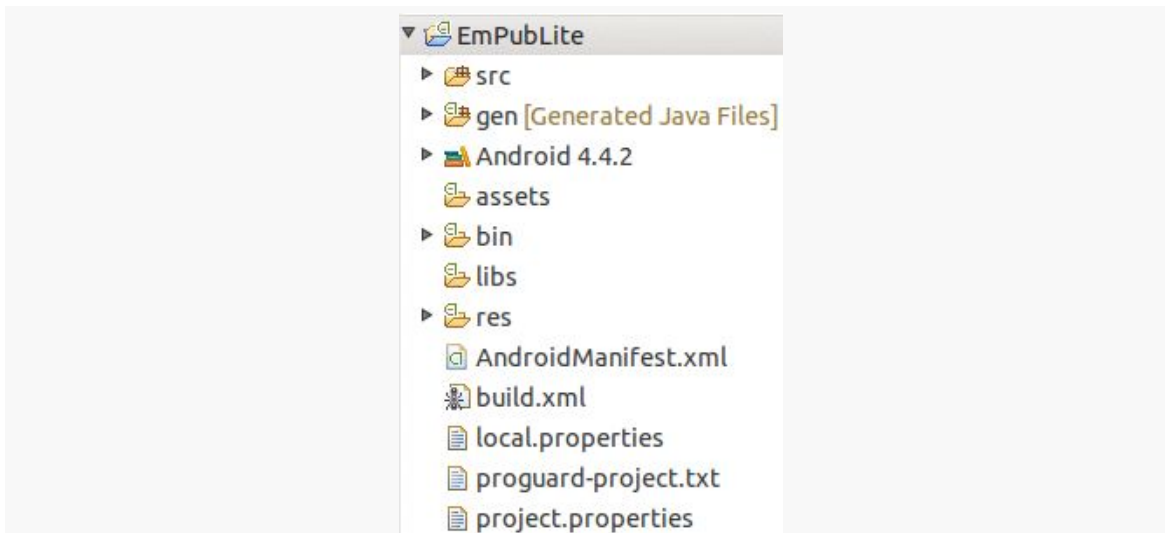

Figure 66: Eclipse Package Explorer, Showing EmPubLite

Double-clicking on the file will bring the file up in Eclipse's default editor for that type of file. In the case of `AndroidManifest.xml`, this will be a structured editor for manifest settings:

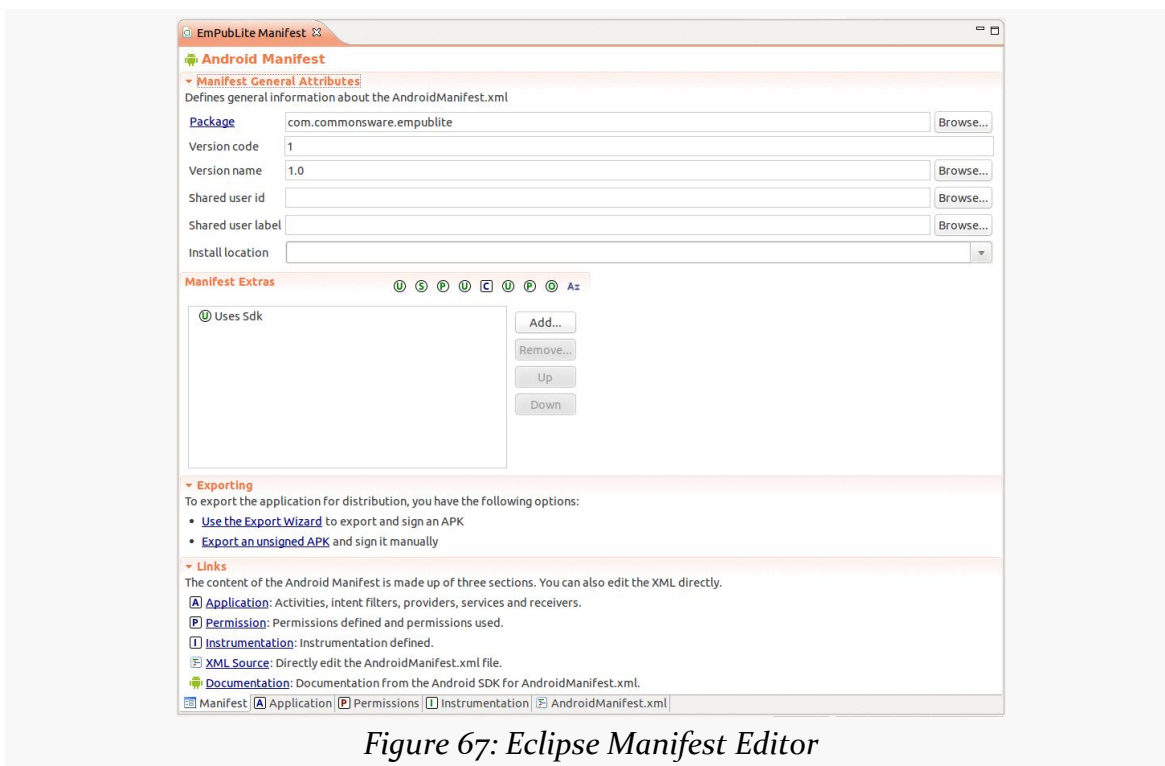

Figure 67: Eclipse Manifest Editor

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

You will notice that there is a series of sub-tabs at the bottom of the editor, labeled “Manifest”, “Application”, “Permissions”, and so on. These allow you to adjust different portions of the manifest file. The right-most sub-tab, “AndroidManifest.xml”, allows you to edit the raw XML of this file directly, if you so choose. This is a fairly typical pattern with the Eclipse editors: one or more sub-tabs providing a structured way of editing the data, and the right-most sub-tab providing raw access to the underlying XML.

In the “Manifest Extras” area of the “Manifest” sub-tab in our open manifest editor, click the “Add...” button to the right of the extras list, to bring up a dialog of what sort of extras we can add:

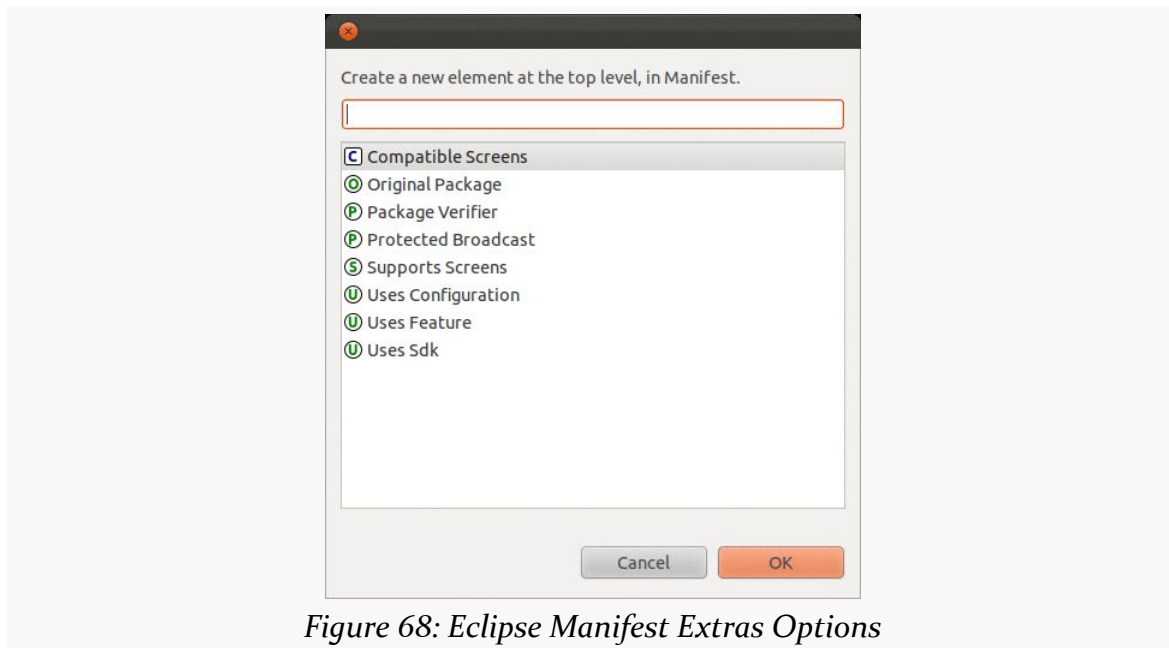

Figure 68: Eclipse Manifest Extras Options

Click on “Supports Screens”, then click “OK” to close the dialog and add a “Supports Screens” entry in the “Manifest Extras” list. That entry will be pre-selected by the editor, showing the available configuration options on the right:

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

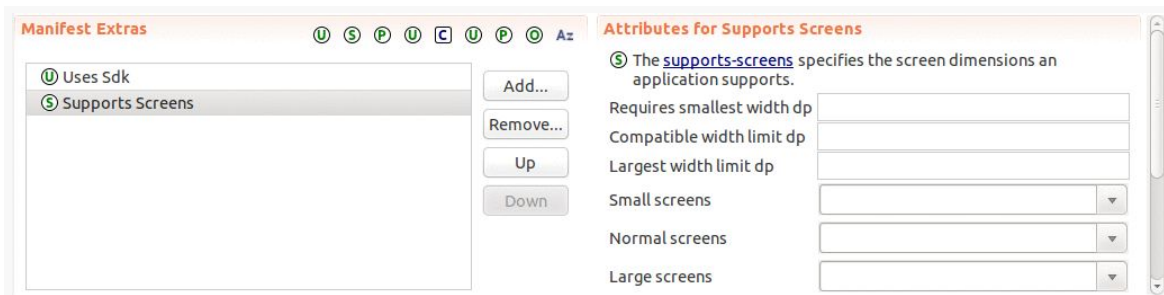

Figure 69: Eclipse Supports Screens Options

Note that the attributes list on the right may have vertical scrollbar, as there are several things we can stipulate on the `<supports-screens>` element, and not all can fit on the editor at once given the editor's design.

Using that scrollbar as needed, toggle the “Small screens” value to false and the “Normal screens”, “Large screens”, and “Xlarge screens” values to true:

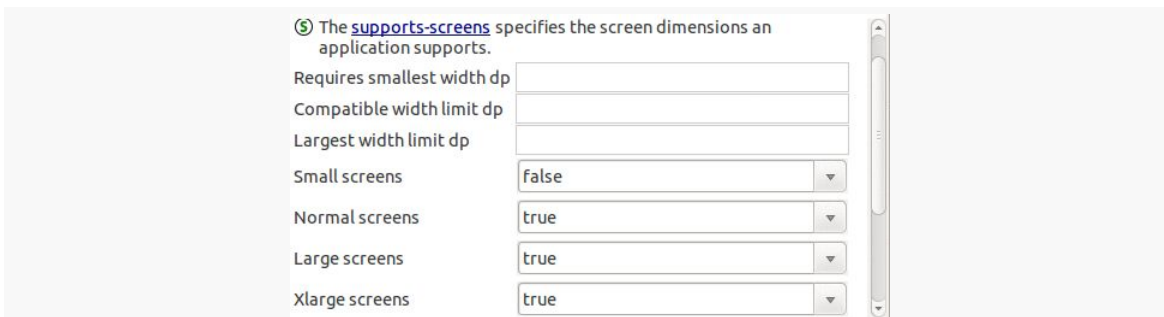

Figure 70: Eclipse Supports Screens Options, Adjusted

Then you can save the file, via the main menu, the Save toolbar icon, or `<Ctrl>-<S>`.

Step #2: Adding our Minimum and Target SDK Versions

We also need to teach our IDE our minimum SDK version (how old a version of Android we will support) and our target SDK version (what version of Android we were thinking of when writing our code).

Eclipse users will accomplish this by adding a `<uses-sdk>` element to the manifest. Android Studio users *could* do the same, but instead we will follow the Android Studio convention and add those values to `build.gradle`.

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Double-click on `app/build.gradle`, off of the project root, in the Project Explorer.

You should see in there a `defaultConfig` closure that looks like:

```
defaultConfig {  
    applicationId "com.commonware.empublite"  
    versionCode 1  
    versionName "1.0"  
}
```

Add the `minSdkVersion 15` and `targetSdkVersion 18` statements to it, so that it looks like:

```
defaultConfig {  
    applicationId "com.commonware.empublite"  
    versionCode 1  
    versionName "1.0"  
    minSdkVersion 15  
    targetSdkVersion 18  
}
```

You may get a yellow banner at the top of the editor, indicating that a “project sync” is requested. If you do, click the “Sync Now” link in that banner to synchronize the `*.iml` files with the changes you made to this `build.gradle` file.

Eclipse

You should already have the `AndroidManifest.xml` file open in Eclipse from Step #1 of this tutorial.

In the “Manifest Extras” area of the “Manifest” sub-tab in our open manifest editor, see if you already have a “Uses Sdk” entry. If yes, click it to fill in the details pane to the right. If you do not have a “Uses Sdk” entry, click the “Add...” button to the right of the extras list, choose “Uses Sdk”, then click “OK” to close the dialog and add a “Supports Screens” entry in the “Manifest Extras” list:

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

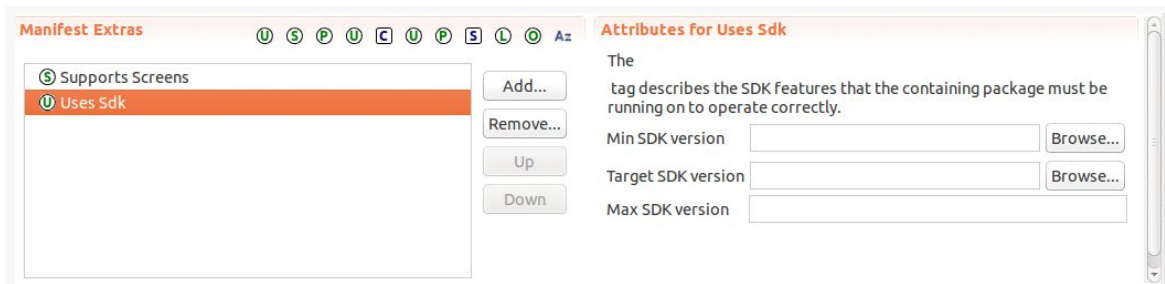

Figure 71: Eclipse Manifest Extras, Showing “Uses Sdk”

In the “Min SDK version” field, fill in 15, meaning that we will support Android 4.0.3 and higher.

In the “Target SDK version” field, fill in 18.

Leave the “Max SDK version” field blank, as that is unused in Android and most marketplaces.

Then you can save the file, via the main menu, the Save toolbar icon, or <Ctrl>-<S>.

In Our Next Episode...

... we will [make some changes to the resources](#) of our tutorial project

Some Words About Resources

It is quite likely that by this point in time, you are “chomping at the bit” to get into actually writing some code. This is understandable. That being said, before we dive into the Java source code for our stub project, we really should chat briefly about resources.

Resources are static bits of information held outside the Java source code. Resources are stored as files under the `res/` directory in your Android project layout (whether that is in the project root for Eclipse or in the `main/` sourceset for Android Studio). Here is where you will find all your icons and other images, your externalized strings for internationalization, and more.

These are not only separate from the Java source code because they are different in format. They are separate because you can have *multiple* definitions of a resource, to use in different circumstances. For example, with internationalization, you will have strings for different languages. Your Java code will be able to remain largely oblivious to this, as Android will choose the right resource to use, from all candidates, in a given circumstance (e.g., choose the Spanish string if the device’s locale is set to Spanish).

We will cover all the details of these resource sets [later in the book](#). Right now, we need to discuss the resources in use by our stub project, plus one more.

This chapter will refer to the `res/` directory. Android Studio users will find that in the `app/src/main/` directory of their project, while Eclipse users will find it in the project root directory.

String Theory

Keeping your labels and other bits of text outside the main source code of your application is generally considered to be a very good idea. In particular, it helps with internationalization (I18N) and localization (L10N). Even if you are not going to translate your strings to other languages, it is easier to make corrections if all the strings are in one spot instead of scattered throughout your source code.

Plain Strings

Generally speaking, all you need to do is have an XML file in the `res/values` directory (typically named `res/values/strings.xml`), with a `resources` root element, and one child `string` element for each string you wish to encode as a resource. The `string` element takes a `name` attribute, which is the unique name for this string, and a single text element containing the text of the string:

```
<resources>
  <string name="quick">The quick brown fox...</string>
  <string name="laughs">He who laughs last...</string>
</resources>
```

One tricky part is if the string value contains a quote or an apostrophe. In those cases, you will want to escape those values, by preceding them with a backslash (e.g., These are the times that try men\'s souls). Or, if it is just an apostrophe, you could enclose the value in quotes (e.g., "These are the times that try men's souls.").

For example, a project's `strings.xml` file could look like this:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <string name="app_name">EmPubLite</string>
  <string name="hello_world">Hello world!</string>

</resources>
```

We can reference these string resources from various locations, in our Java source code and elsewhere. For example, the `app_name` string resource often is used in the `AndroidManifest.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.empublite"
```

```
android:versionCode="1"
android:versionName="1.0">

<supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true"/>

<uses-sdk
    android:minSdkVersion="15"
    android:targetSdkVersion="18"/>

<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name="EmPubLiteActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

Here, the `android:label` attribute of the `<application>` element refers to the `app_name` string resource. This will appear in a few places in the application, notably in the list of installed applications in Settings. So, if you wish to change how your application's name appears in these places, simply adjust the `app_name` string resource to suit.

The syntax `@string/app_name` tells Android “find the string resource named `app_name`”. This causes Android to scan the appropriate `strings.xml` file (or any other file containing string resources in your `res/values/` directory) to try to find `app_name`.

Styled Text

Many things in Android can display rich text, where the text has been formatted using some lightweight HTML markup: ``, `<i>`, and `<u>`. Your string resources support this, simply by using the HTML tags as you would in a Web page:

```
<resources>
  <string name="b">This has <b>bold</b> in it.</string>
  <string name="i">Whereas this has <i>italics</i>!</string>
</resources>
```

CDATA. CDATA Run. Run, DATA, Run.

Since a strings resource XML file is an XML file, if your message contains <, >, or & characters (other than the formatting tags listed above), you will need to use a CDATA section:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of the TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
</string>
```

The Directory Name

Our string resources in our stub project are in the `res/values/strings.xml` file. Since this directory name (`values`) has no suffixes, the string resources in that directory will be valid for any sort of situation, including any locale for the device. We will need additional directories, with distinct `strings.xml` files, to support other languages. We will cover how to do that [later in this book](#).

Editing String Resources

If you double-click on a string resource file, like `res/values/strings.xml`, in Android Studio, you are presented the XML and edit it that way.

When you double-click on a string resource file in Eclipse, you will be greeted with a list of all the string resources that have been defined:

SOME WORDS ABOUT RESOURCES

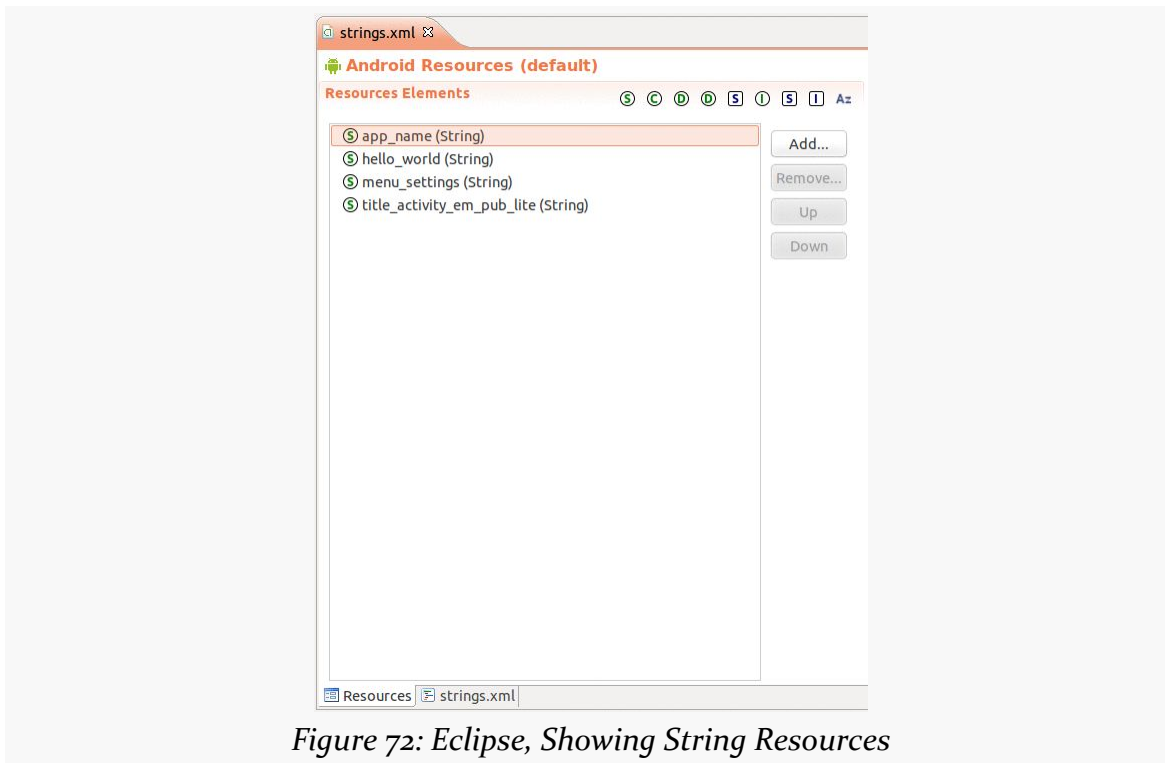

Figure 72: Eclipse, Showing String Resources

Clicking on a resource allows you to edit its name and value:

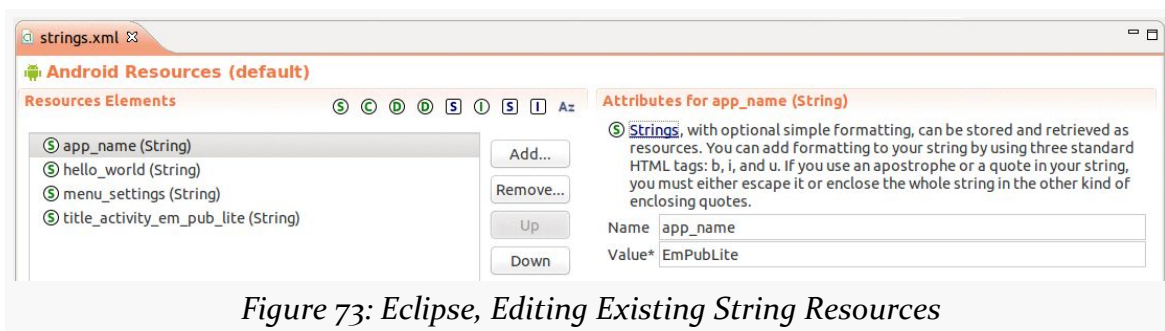

Figure 73: Eclipse, Editing Existing String Resources

Clicking the “Add...” button to the right of the list of strings brings up a dialog where you can add another resource to this file, typically a string:

SOME WORDS ABOUT RESOURCES

Figure 74: Eclipse, Add String Resource Dialog

Choosing “String” in that dialog and clicking OK will add another (empty) string resource to the list, where you can fill in the name and value.

You can always click on the `strings.xml` sub-tab to bring up an XML editor on the string resources if you prefer.

Got the Picture?

Android supports images in the PNG, JPEG, and GIF formats. GIF is officially discouraged, however; PNG is the overall preferred format. Android also supports some proprietary XML-based image formats, though we will not discuss those at length until later in the book.

The default directory for these so-called drawable resources is `res/drawable/`. Any images found in there can be referenced from Java code or from other places (such as the manifest), regardless of device characteristics.

However, your stub project does not have a `res/drawable/` directory.

Instead, it has directories like `res/drawable-mdpi/` and `res/drawable-hdpi/`.

SOME WORDS ABOUT RESOURCES

These refer to distinct resource sets. The suffixes (e.g., `-mdpi`, `-hdpi`) are filters, indicating under what circumstances the images stored in those directories should be used. Specifically, `-ldpi` indicates images that should be used on devices with low-density screens (around 120 dots-per-inch, or “dpi”). The `-mdpi` suffix indicates resources for medium-density screens (around 160dpi), `-hdpi` indicates resources for high-density screens (around 240dpi). `-xhdpi` indicates resources for extra-high-density screens (around 320dpi), `--xxhdpi` indicates extra-extra-high-density screens (around 480dpi), `-xxxhdpi` indicates extra-extra-extra-high-density screens (around 640dpi), and so on.

Inside each of those directories, you will see an `ic_launcher.png` file (along with perhaps other icons). This is the stock icon that will be used for your application in the home screen launcher. Each of the images is of the same icon, but the higher-density icons have more pixels. The objective is for the image to be roughly the same physical size on every device, using higher densities to have more detailed images.

For example, our `EmPubLite` tutorial project has directories like `res/drawable-hdpi/`, `res/drawable-xhdpi/`, and `res/drawable-mdpi/`. Each could contain a stock launcher icon (`ic_launcher.png`) tailored for that density.

Our `AndroidManifest.xml` file then references our `ic_launcher` icon in the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.empublite"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"
        android:xlargeScreens="true"/>

    <uses-sdk
        android:minSdkVersion="15"
        android:targetSdkVersion="18"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/AppTheme">
        <activity
            android:name="EmPubLiteActivity"
            android:label="@string/app_name">
```

```
<intent-filter>
  <action android:name="android.intent.action.MAIN"/>

  <category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
</activity>
</application>

</manifest>
```

Note that the manifest simply refers to `@drawable/ic_launcher`, telling Android to find a drawable resource named `ic_launcher`. The resource reference does not indicate the file type of the resource — there is no `.png` in the resource identifier. This means you cannot have `ic_launcher.png` and `ic_launcher.jpg` in the same project, as they would both be identified by the same identifier. You will need to keep the “base name” (filename sans extension) distinct for all of your images.

Also, the `@drawable/ic_launcher` reference does not mention what screen density to use. That is because *Android* will choose the right screen density to use, based upon the device that is running your app. You do not have to worry about it explicitly, beyond having multiple copies of your icon.

If Android detects that the device has a screen density for which you lack an icon, Android will take the next-closest one and scale it.

Getting Android Drawables

You may be a graphic designer. Or, you may know a graphic designer. In those cases, you can create your own icons, ideally following Google’s [design guidelines for iconography](#).

If you are not a graphic designer and do not have ready access to one, you will need to come up with your drawable resources by other means. There are plenty of icon libraries available from third parties, but the following sections outline some of Google’s solutions for putting icons in your app.

Android Icon Set Wizard

Both Android Studio and Eclipse offer an icon set wizard. This wizard is designed to take a starter image and give you icons, in a variety of densities, that use that image for a particular image role, such as your home screen launcher icon (the `ic_launcher.png` file we saw earlier in this chapter).

SOME WORDS ABOUT RESOURCES

We will explore how to use this wizard, for both Android Studio and Eclipse, in [the next tutorial](#).

Android Asset Studio

The same basic functionality found in the icon set wizard is available outside any IDE (but inside a Chrome browser) in the form of the [Android Asset Studio](#). As with the icon set wizard, you can choose a type of icon (e.g., launcher icons):

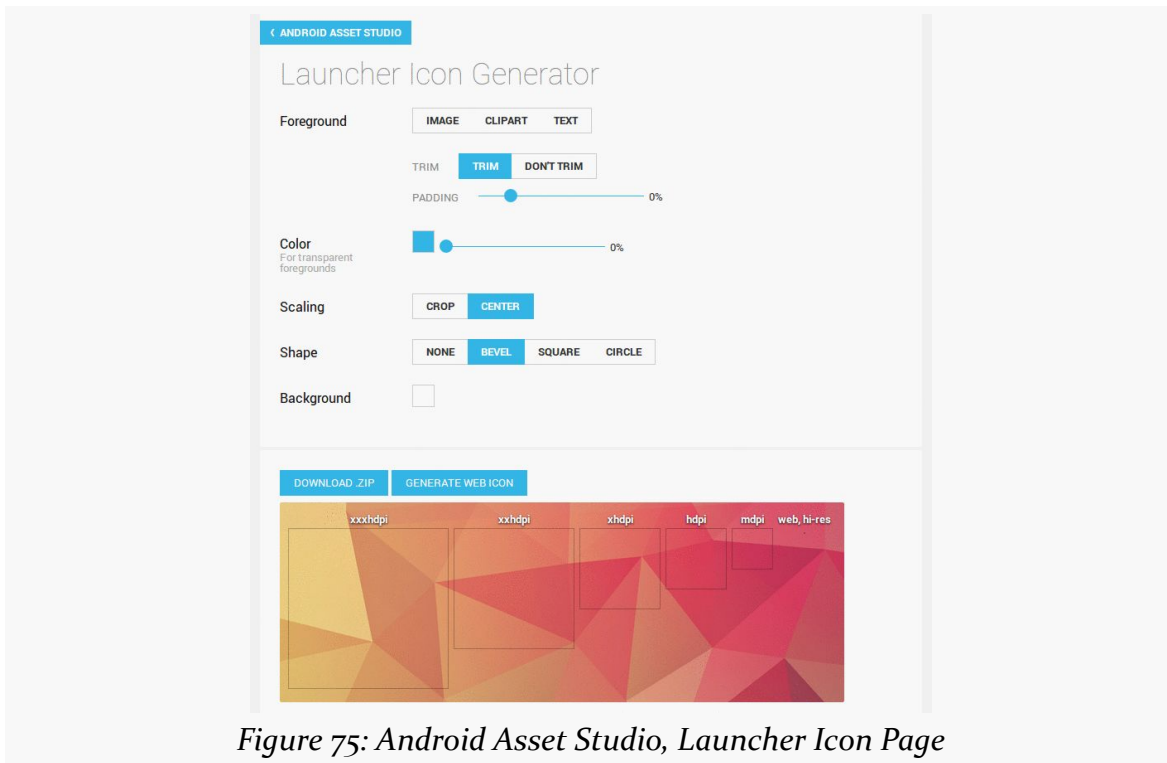

Figure 75: Android Asset Studio, Launcher Icon Page

Then you can specify the source of the base image (uploaded file, canned clipart, or free-form text) and other configuration data. The resulting images, in various densities, can be downloaded at the bottom of the page:

Figure 76: Android Asset Studio, Launcher Icon Page, with Icons

The Action Bar Icon Pack

Much of the clipart used by the icon set wizard and Android Asset Studio comes from Google's [Action Bar Icon Pack](#), which is a set of icons, at various densities, designed to be used as icons for toolbar-style buttons in the action bar. We will talk more about what the action bar is and how you use it [later in the book](#), and in [a subsequent tutorial](#) we will download and use icons from the Action Bar Icon Pack.

Editing Existing Drawable Resources

Neither Android Studio nor Eclipse ships with any sort of image editor that you could use for PNG and JPEG files. Hence, you will find yourself editing these images using other tools outside of your IDE.

Dimensions

Dimensions are used in several places in Android to describe distances, such as a widget's size. There are several different units of measurement available to you:

SOME WORDS ABOUT RESOURCES

1. px means hardware pixels, whose size will vary by device, since not all devices have the same screen density
2. in and mm for inches and millimeters, respectively, based on the actual size of the screen
3. pt for points, which in publishing terms is 1/72nd of an inch (again, based on the actual physical size of the screen)
4. dip (or dp) for density-independent pixels — one dip equals one hardware pixel for a ~160dpi resolution screen, but one dip equals two hardware pixels on a ~320dpi screen
5. sp for scaled pixels, where one sp equals one dip for normal font scale levels, increasing and decreasing as needed based upon the user's chosen font scale level in Settings

Dimension resources, by default, are held in a `dimens.xml` file in the `res/values/` directory that also holds your strings.

To encode a dimension as a resource, add a `dimen` element to `dimens.xml`, with a `name` attribute for your unique name for this resource, and a single child text element representing the value:

```
<resources>
  <dimen name="thin">10dip</dimen>
  <dimen name="fat">1in</dimen>
</resources>
```

In a layout, you can reference dimensions as `@dimen/...`, where the ellipsis is a placeholder for your unique name for the resource (e.g., `thin` and `fat` from the sample above). In Java, you reference dimension resources by the unique name prefixed with `R.dimen.` (e.g., `Resources.getDimension(R.dimen.thin)`).

While our stub project does not use dimension resources, we will be seeing them soon enough.

Editing Dimension Resources

As with most types of XML resources, Android Studio just has you edit the XML directly, when you double-click on the resource in the project explorer.

In Eclipse, much like editing string resources, when you double-click on a dimension resource file (e.g., `res/values/dimens.xml`), you will be presented with a list of existing dimensions. Clicking on one will let you change its definition:

SOME WORDS ABOUT RESOURCES

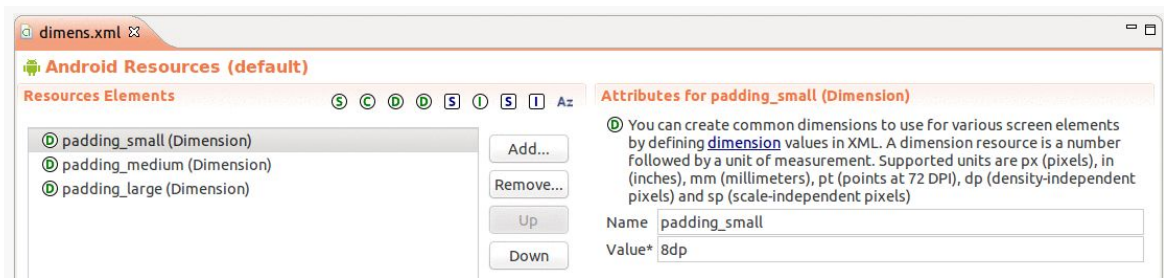

Figure 77: Eclipse, Editing Existing Dimension Resources

Clicking the “Add...” button to the right of the list of dimensions brings up a dialog where you can add another resource to this file, typically a dimension. Choosing “Dimension” and clicking “OK” will add an empty dimension resource to the file, for which you can supply the name and value.

And, as always, you can click on a sub-tab with the name of your file (e.g., `dimens.xml`) to bring up an XML editor on that resource’s content:

Figure 78: Eclipse, Dimension Resources in XML Editor

The Resource That Shall Not Be Named... Yet

Your stub project also has a `res/layout/` directory, in addition to the ones described above. That is for UI layouts, describing what your user interface should look like. We will get into the details of that type of resource as we start examining our user interfaces in [an upcoming chapter](#).

Tutorial #4 - Adjusting Our Resources

Our EmPubLite project has some initial resources. However, the defaults are not what we want for the long term. So, in addition to adding new resources in future tutorials, we will fix the ones we already have in this tutorial.

This is a continuation of the work we did in [the previous tutorial](#). |

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Changing the Name

Our application shows up everywhere as “EmPubLite”:

- In the title bar of our activity
- As the caption under our icon in the home screen launcher
- In the Application list in the Settings app
- And so on

We should change that to be “EmPub Lite”, adding a space for easier reading, and to illustrate that this is a “lite” version of the full EmPub application.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Double-click on the `res/values/strings.xml` file in your project explorer.

In the XML editor for the string resources, you will find an element that looks like:

```
<string name="app_name">EmPubLite</string>
```

Change the text node in this element to `EmPub Lite`. Then save your changes, giving you something like:

```
<resources>

  <string name="app_name">EmPub Lite</string>
  <string name="hello_world">Hello world!</string>

</resources>
```

Eclipse

In the Package Explorer, open up the `res/values/` folder — you should see a `strings.xml` file in there:

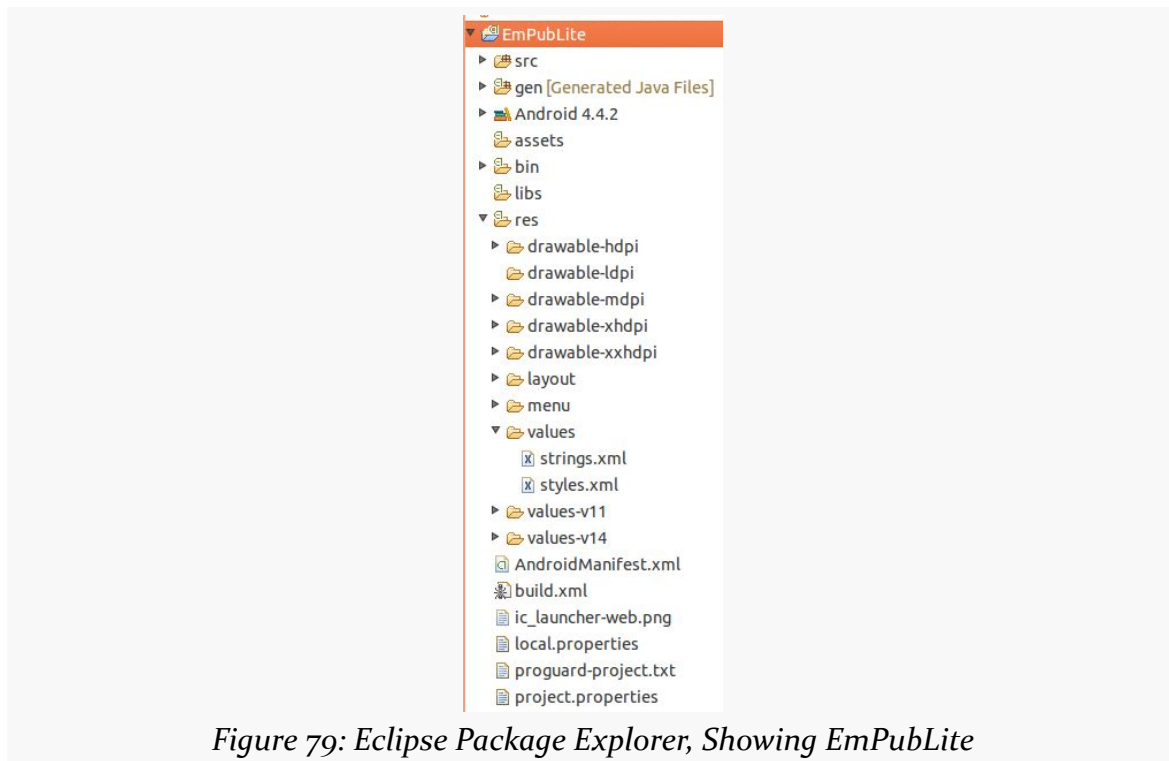

Figure 79: Eclipse Package Explorer, Showing EmPubLite

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Double-click on `strings.xml` to open it in the string resources editor:

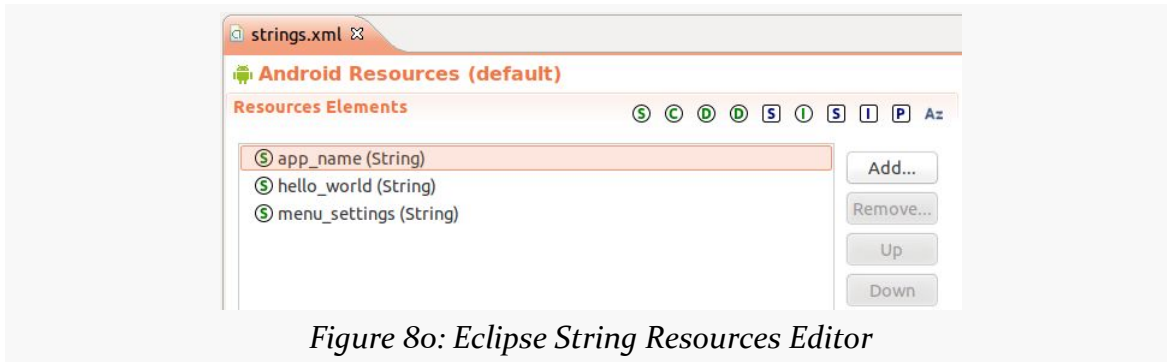

Figure 80: Eclipse String Resources Editor

This shows a list of the defined string resources (denoted by the green S in the circle) in this file.

Click the `app_name` resource, to bring up its details on the right:

Figure 81: Eclipse String Resources Editor with Details

The `app_name` name for the resource is fine, as that is how this string is referenced from the manifest. Change the value to be “EmPub Lite” (adding the space).

Step #2: Changing the Icon

The build tools provide us with a stock icon to use for the launcher — the actual image used varies by Android tools release. However, we can change it to something else. For example, we could use the icon portion of the CommonsWare logo:

Figure 82: CommonsWare

First, [download the original image](#) and save it somewhere on your development machine.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Click on the app/ entry in the project explorer, then choose File > New... from the main menu. This should pop up a small window for you to choose something new to create:

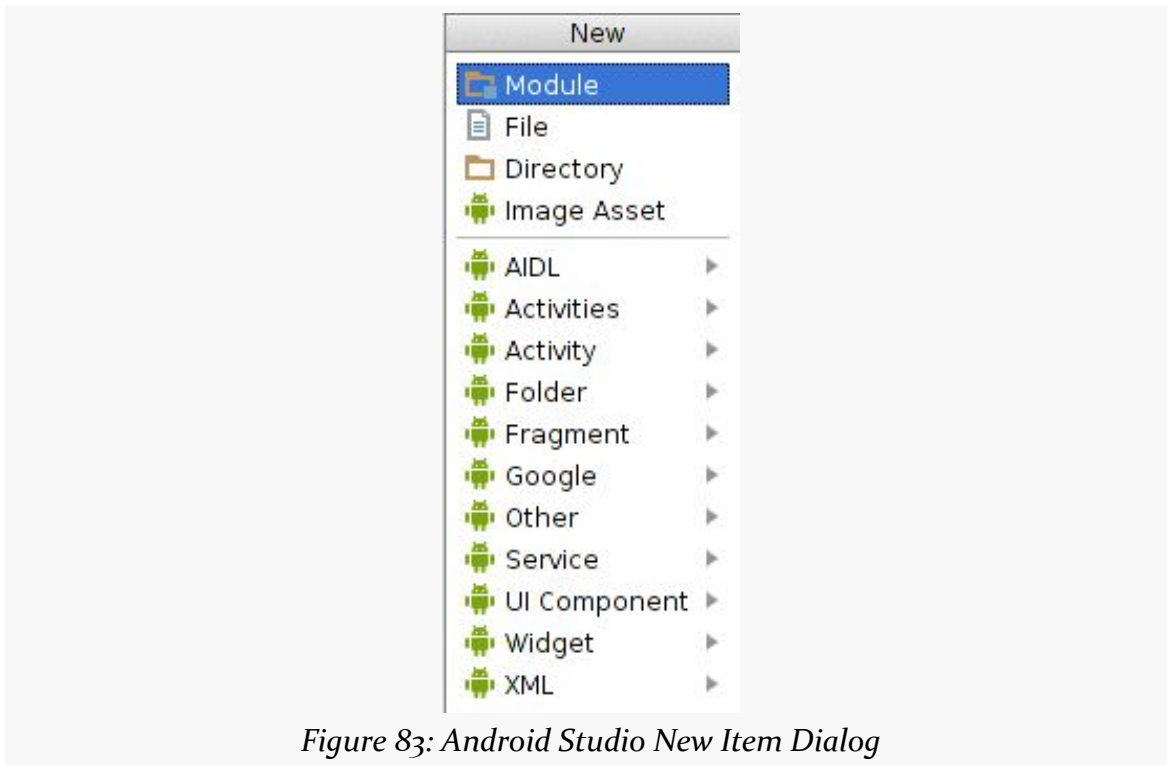

Figure 83: Android Studio New Item Dialog

In there, choose “Image Asset”. This will bring up an “Asset Studio” wizard for creating images:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

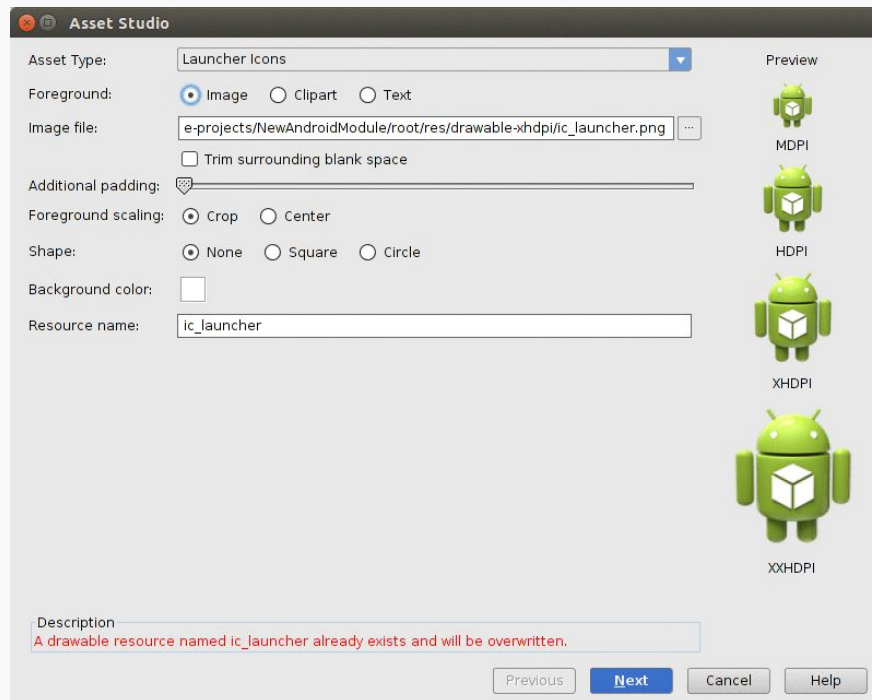

Figure 84: Android Studio “Asset Studio” Wizard, First Page

Ensure that the “Asset Type” drop-down is set to “Launcher Icons”, and the “Foreground” option is set to “Image”. Then, use the “...” button next to the “Image file” field to choose the image that you downloaded above.

Then, set the “Foreground scaling” to “Center”, leaving you with a wizard page that should resemble:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

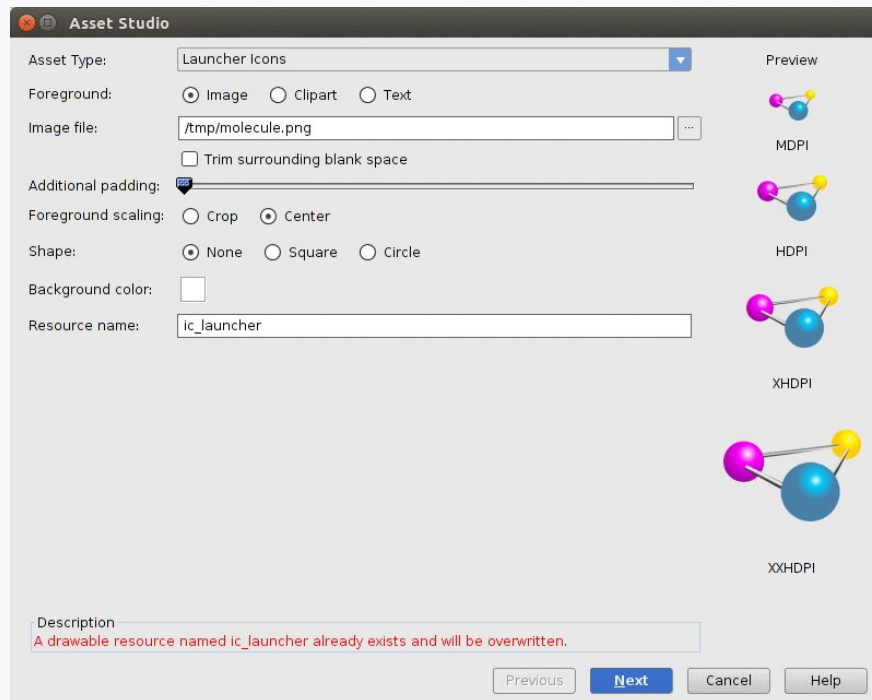

Figure 85: Android Studio “Asset Studio” Wizard, First Page, Filled In

Click “Next” to bring up the second page of the wizard, which is there to confirm where you want the images written and what images will be created:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

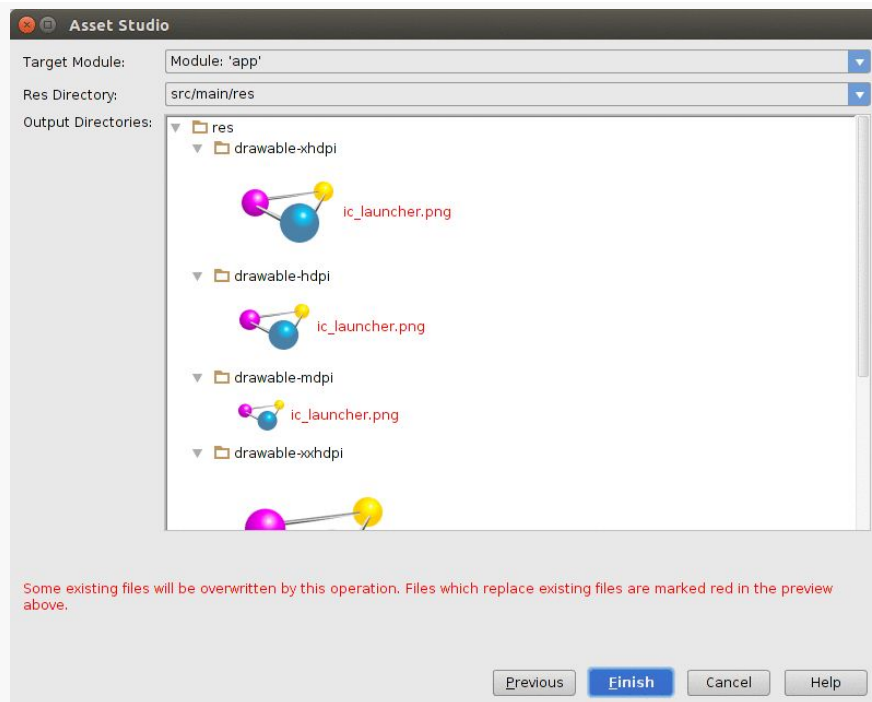

Figure 86: Android Studio “Asset Studio” Wizard, Second Page

Click “Finish”, and your original icons will be replaced with ones based on your chosen image.

Eclipse

From the Eclipse main menu, choose File > New > Other > Android. In the resulting dialog, choose “Android Icon Set” and press Next.

TUTORIAL #4 - ADJUSTING OUR RESOURCES

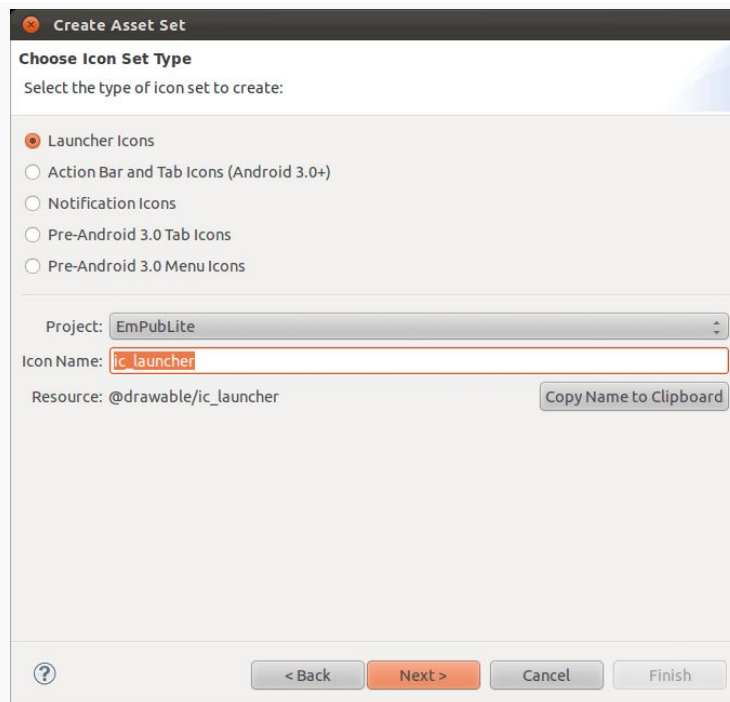

Figure 87: Eclipse Icon Set Wizard, First Page

The defaults on the first page of the icon set wizard are to create launcher icons, with a file base name of `ic_launcher`, to be added to the `EmPubLite` project. If the values that you see in the wizard do not match that, adjust the wizard, then press **Next**.

TUTORIAL #4 - ADJUSTING OUR RESOURCES

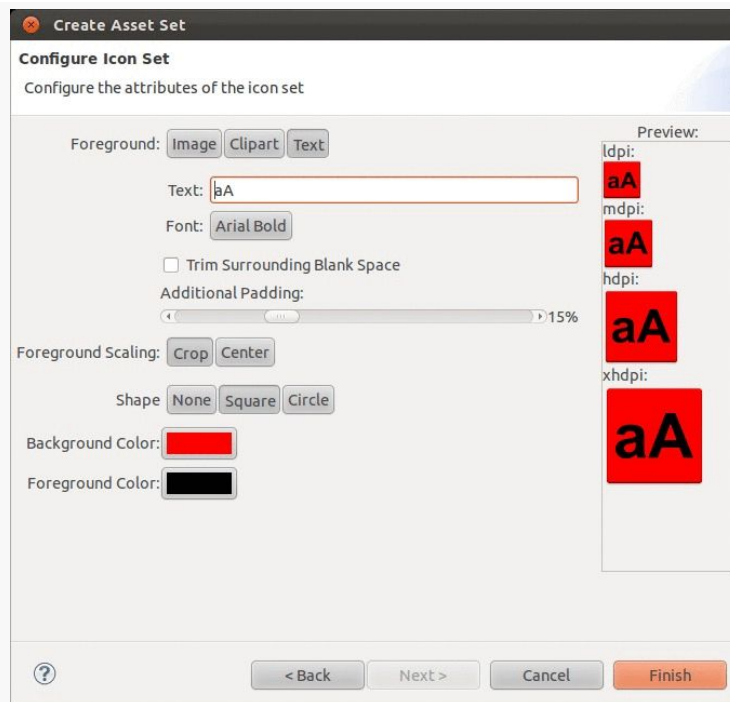

Figure 88: Eclipse Icon Set Wizard, Second Page

In the second page of the icon set wizard, click the “Image” button in the “Foreground” row. This will change the wizard slightly, giving you a space to supply the path to some image:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

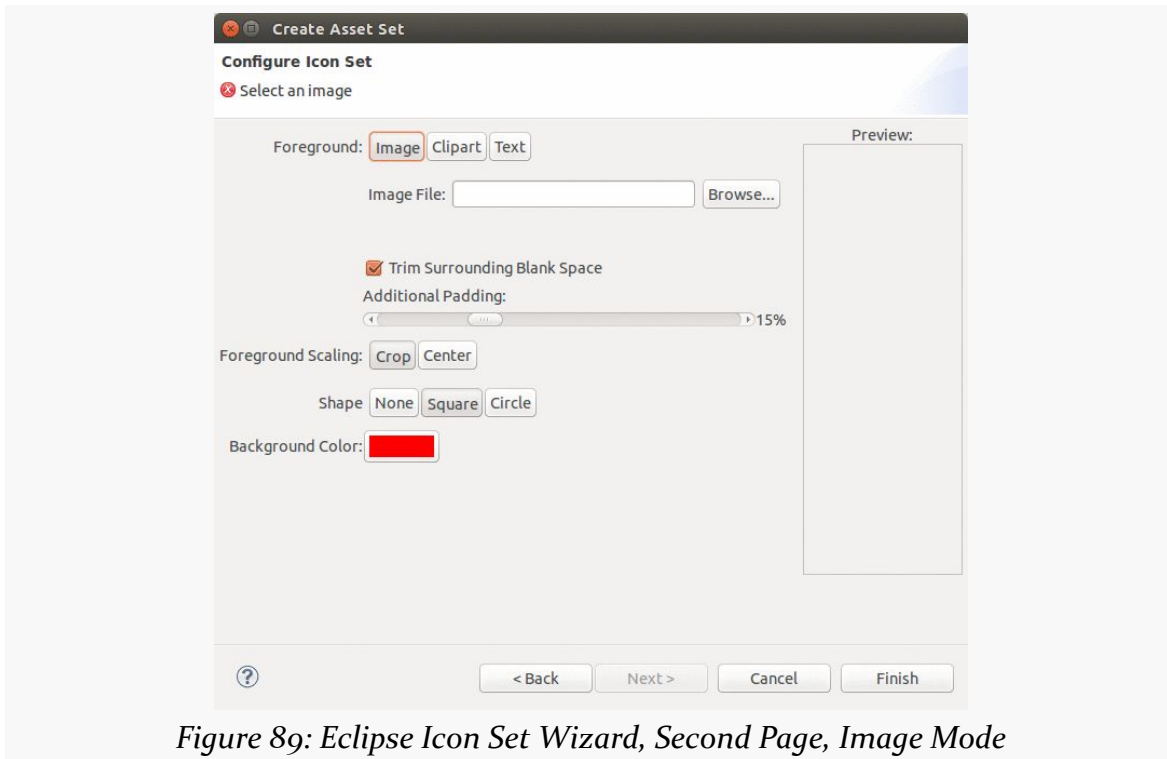

Figure 89: Eclipse Icon Set Wizard, Second Page, Image Mode

Click the “Browse...” button and open the `molecule.png` file you downloaded above. That will display the results in the wizard:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Figure 90: Eclipse Icon Set Wizard, Second Page, Image Mode, Showing Molecule

Click the “None” button in the “Shape” row, to remove the square background. Then, click Finish. You will be prompted for whether you want to overwrite the existing images — click “Yes to All”.

You may wind up with a bunch of error markers on your project for all of the new images in the Package Explorer. If this occurs, choose Project > Clean from the Eclipse main menu, ensure that EmPubLite is checked in the project list, and choose OK. This should get rid of those error markers.

Step #3: Running the Result

If you run the resulting app, you will see that it shows up with the new name and icon, such as in the launcher:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Figure 91: EmPubLite with New Icons

However, Eclipse users may encounter some problems in running the result. When you wish to run an Android project from Eclipse, you must pay close attention to what part of the Eclipse UI has the focus. The focus *cannot* be on an editor for a resource. So, for example, had you gone back to the string resource editor, done some changes there, then attempted to run the project, nothing would have happened.

Instead, the focus has to be pretty much anywhere else for the Run option in the toolbar to work:

- On the manifest
- On some Java code
- On the Package Explorer

This is a bug, one that will hopefully get fixed someday. However, since that preceding sentence has been in this book for a couple of years, it is unlikely that the bug will be addressed any time soon.

In Our Next Episode...

... we will [add a progress indicator](#) to the UI of our tutorial project.

The Theory of Widgets

There is a decent chance that you have already done work with widget-based UI frameworks. In that case, much of this chapter will be review, though checking out the section on the [absolute positioning anti-pattern](#) should certainly be worthwhile.

There is a chance, though, that your UI background has come from places where you have not been using a traditional widget framework, where either you have been doing all of the drawing yourself (e.g., game frameworks) or where the UI is defined more in the form of a document (e.g., classic Web development). This chapter is aimed at you, to give you some idea of what we are talking about when discussing the notion of widgets and containers.

What Are Widgets?

Wikipedia has [a nice definition of a widget](#):

In computer programming, a widget (or control) is an element of a graphical user interface (GUI) that displays an information arrangement changeable by the user, such as a window or a text box. The defining characteristic of a widget is to provide a single interaction point for the direct manipulation of a given kind of data. In other words, widgets are basic visual building blocks which, combined in an application, hold all the data processed by the application and the available interactions on this data.

(quote from the 7 March 2014 version of the page)

Take, for example, this Android screen:

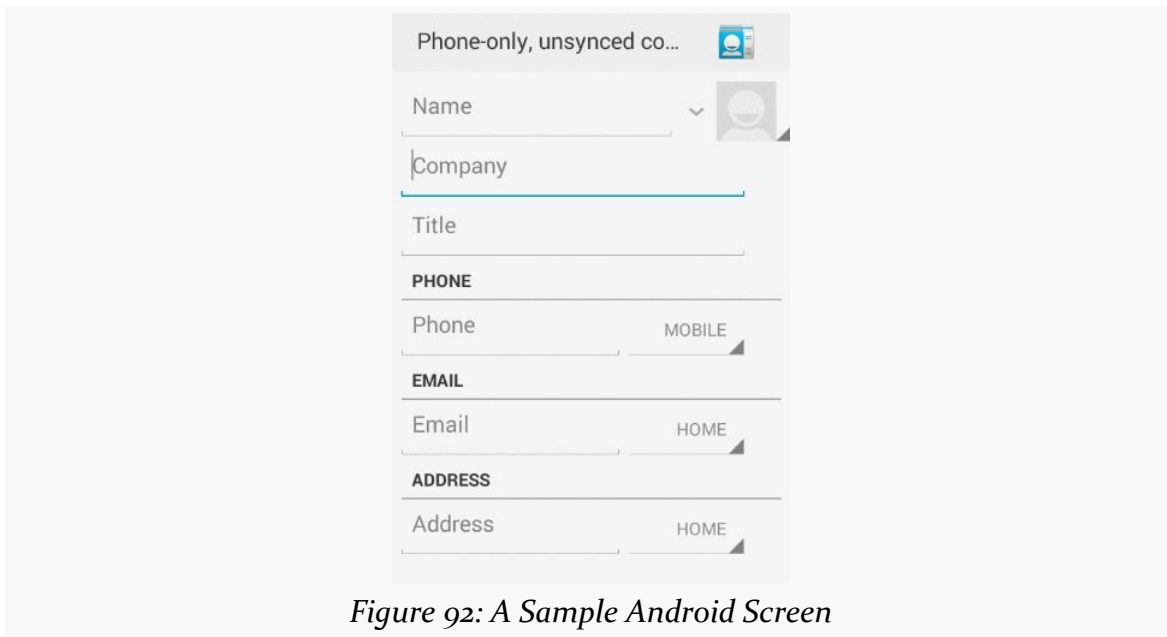

Figure 92: A Sample Android Screen

Here, we see:

- some text, like “Phone-only, unsynced co...” and “PHONE”
- an icon of a contact “Rolodex” card
- some data entry fields with hints like “Name” and “Company”
- some “spinner” drop-down lists (the items with the arrowheads pointing southeast)
- some gray divider lines

Everything listed above is a widget. The user interface for most Android screens (“activities”) is made up of one or more widgets.

This does not mean that you cannot do your own drawing. In fact, all the existing widgets are implemented via low-level drawing routines, which you can use for everything from your own custom widgets to games.

This also does not mean that you cannot use Web technologies. In fact, we will see later in this book [a widget designed to allow you to embed Web content](#) into an Android activity.

However, for most non-game applications, your Android user interface will be made up of several widgets.

Size, Margins, and Padding

Widgets have some sort of size, since a zero-pixel-high, zero-pixel-wide widget is not especially user-friendly. Sometimes, that size will be dictated by what is inside the widget itself, such as a label (TextView) having a size dictated by the text in the label. Sometimes, that size will be dictated by the size of whatever holds the widget (a “container”, described in the next section), where the widget wants to take up all remaining width and/or height. Sometimes, that size will be a specific set of dimensions.

Widgets can have margins. As with CSS, margins provide separation between a widget and anything adjacent to it (e.g., other widgets, edges of the screen). Margins are really designed to help prevent widgets from running right up next to each other, so they are visually distinct. Some developers, however, try to use margins as a way to hack “absolute positioning” into Android, which is an anti-pattern that we will examine [later in this chapter](#).

Widgets can have padding. As with CSS, padding provides separation between the contents of a widget and the widget’s edges. This is mostly used with widgets that have some sort of background, like a button, so that the contents of the widget (e.g., button caption) does not run right into the edges of the button, once again for visual distinction.

What Are Containers?

Containers are ways of organizing multiple widgets into some sort of structure. Widgets do not naturally line themselves up in some specific pattern — we have to define that pattern ourselves.

In most GUI toolkits, a container is deemed to have a set of children. Those children are widgets, or sometimes other containers. Each container has its basic rule for how it lays out its children on the screen, possibly customized by requests from the children themselves.

Common container patterns include:

- put all children in a row, one after the next
- put all children in a column, one below the next
- arrange the children into a table or grid with some number of rows and columns

- anchor the children to the sides of the container, according to requests made by those children
- anchor the children to other children in the container, according to requests made by those children
- stack all children, one on top of the next
- and so on

In the sample activity above, the dominant pattern is a column, with things laid out from top to bottom. Some of those things are rows, with contents laid out left to right. However, as it turns out, the area with most of those widgets is scrollable.

Android supplies a handful of containers, designed to handle most common scenarios, including everything in the list above. You are also welcome to create your own custom containers, to implement business rules that are not directly supported by the existing containers.

Note that containers also have size, padding, and margins, just as widgets do.

The Absolute Positioning Anti-Pattern

You might wonder why all of these containers and such are necessary. After all, can't you just say that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, and so on?

Many developers have taken that approach — known as absolute positioning — over the years, to their eventual regret.

For example, many of you may have used Windows apps, back in the 1990's, where when you would resize the application window, the app would not really react all that much. You would expand the window, and the UI would not change, except to have big empty areas to the right and bottom of the window. This is because the developers simply said that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, **regardless of the actual window size**.

In modern Web development, you see this in the debate over [fixed versus fluid Web design](#). The consensus seems to be that fluid designs are better, though frequently they are more difficult to set up. Fluid Web designs can better handle differing browser window sizes, whether those window sizes are because the user resized their browser window manually, or because those window sizes are dictated by the

screen resolution of the device viewing the Web page. Fixed Web designs — effectively saying that such-and-so element goes at such-and-so pixel coordinate and so on — tend to be easier to build but adapt more poorly to differing browser window sizes.

In mobile, particularly with Android, we have a wide range of possible screen resolutions, from QVGA (320x240) to beyond 1080p (1920x1080), and many values in between. Moreover, any device manufacturer is welcome to create a device with whatever resolution they so desire – there are no rules limiting manufacturers to certain resolutions. Hence, as developers, having the Android equivalent of fluid Web designs is critical, and the way you will accomplish that is by sensible use of containers, avoiding absolute positioning. The containers (and, to a lesser extent, the widgets) will determine how extra space is employed, as the screens get larger and larger.

The Theme of This Section: Themes

In Web development, we have had stylesheets for quite a while. Through such Cascading Style Sheets (CSS) files, we can stipulate various rules about how our Web pages should look. This includes:

- Establishing a default look for certain HTML tags by tag name (e.g., setting the font and size for all `<h1>` and `<h2>` elements)
- Establishing a look for specific HTML elements by class or ID (e.g., setting the width of a specific `<div>` to a certain number of CSS pixels)

In Android, the equivalent concepts can be found in styles and themes. Styles are a collection of values for properties (e.g., have a foreground color of red). These can be applied to specific widgets (e.g., this label should adopt this style), or they can be employed by “themes” that provide the default look for all sorts of widgets and other elements of our UI.

Of course, you do not have to declare any theme for your app. Android will give you a default look-and-feel without any specific theme. That look-and-feel has varied over the years, though, affecting the visual fundamentals of various Android widgets. These themes have names by which we refer to them: `Theme`, `Theme.Holo`, and `Theme.Material`.

In the Beginning, There Was “Theme”, And It Was Meh

Way back in Android 1.0, the default theme was known simply as Theme. Technically, all themes inherit from Theme, much as how later CSS stylesheets effectively “inherit” the settings established by prior stylesheets.

The Theme UI had a particular look to it:

Figure 93: Labels, Fields, and Buttons in Theme

For example:

- At the top of the screen, we had a thin gray “title bar” with the name of our app
- The focused field (an EditText widget) had a bright orange outline, whereas normally it was a plain white rectangle
- The buttons (“OK” and “Cancel”) were... well... buttons

Holo, There!

Android 3.0 (API Level 11) introduced a new default theme, Theme.Holo, with the so-called “holographic widget theme”. This changed the look of our UI somewhat:

Figure 94: Labels, Fields, and Buttons in Theme.Holo

Now:

- At the top of the screen, we have an “action bar”, containing our app’s logo and name
- The focused field has a blue “underbracket”, whereas normally it is gray
- The buttons are styled slightly differently, with a bigger font, alternative backgrounds, etc.

Considering the Material

Android 5.0 changed the default theme yet again, to `Theme.Material`:

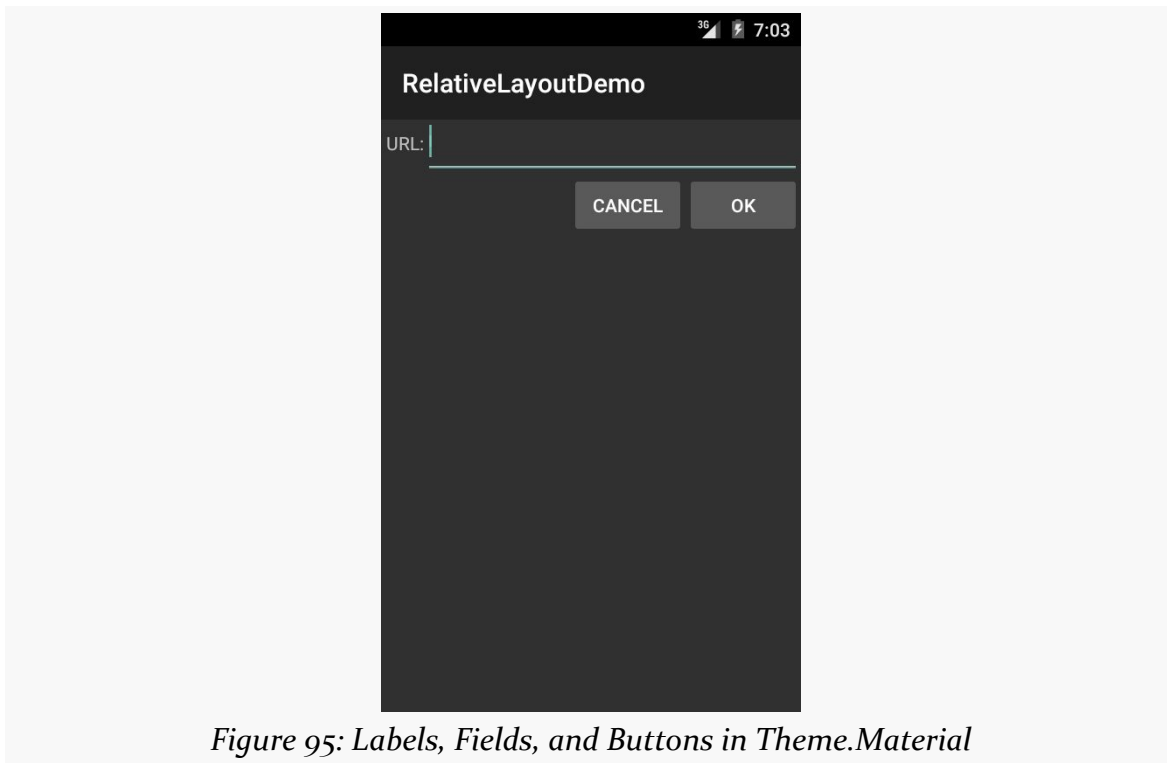

Figure 95: Labels, Fields, and Buttons in Theme.Material

Now:

- The action bar at the top of the screen no longer shows the app icon
- Our field is indicated by an underline, which is teal when focused or gray when unfocused
- The buttons are now forced into all-caps font, with a slightly smaller font size and subtly different background than we had with Theme.Holo

Doing More with Themes

Of course, we can do a lot more than just use these. There are other stock themes, with different characteristics. Furthermore, we can customize the themes, by defining our own (inheriting from a stock theme) and changing some of the properties (e.g., replacing the teal color with something else).

We will get much more into creating custom styles and themes [later in the book](#).

However, we will see the effects of Theme, Theme.Holo, and Theme.Material on stock widgets in [an upcoming chapter](#).

The Android User Interface

The project you created in [an earlier tutorial](#) was just the default files generated by the Android build tools — you did not write any Java code yourself. In this chapter, we will examine the basic Java code and resources that make up an Android activity.

The Activity

The Java source code that you maintain will be in a standard Java-style tree of directories based upon the Java package you chose when you created the project (e.g., `com.commonware.android` results in `com/commonware/android/`). Where those files reside depends upon what tools you are using:

- Android Studio will have that source, by default, in `app/src/main/java/` off of the top-level project root
- Eclipse will have that source be in `src/` off of the top-level project root

If you checked the checkbox in your IDE's new-project wizard to create an activity, you will have, in the innermost directory, a Java source file representing an activity class.

A very simple activity looks like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class EmPubLiteActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

```
        setContentView(R.layout.main);  
    }  
}
```

Dissecting the Activity

Let's examine this Java code piece by piece:

```
package com.commonware.empublite;  
  
import android.app.Activity;  
import android.os.Bundle;
```

By default, the package declaration is the same as the one you used when creating the project. And, like any other Java project, you need to import any classes you reference. Most of the Android-specific classes are in the android package.

Remember that not every Java SE class is available to Android programs! Visit the [Android class reference](#) to see what is and is not available.

```
public class EmPubLiteActivity extends Activity {
```

Activities are public classes, inheriting from the `android.app.Activity` base class (or, possibly, from some other class that itself inherits from `Activity`). You can have whatever data members you decide that you need, though the initial code has none.

```
    @Override  
    protected void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.main);  
    }
```

The `onCreate()` method is invoked when the activity is started. We will discuss the `Bundle` parameter to `onCreate()` [in a later chapter](#). For the moment, consider it an opaque handle that all activities receive upon creation.

The first thing you normally should do in `onCreate()` is chain upward to the superclass, so the stock Android activity initialization can be done. The only other statement in our stub project's `onCreate()` is a call to `setContentView()`. This is where we tell Android what the user interface is supposed to be for our activity.

This raises the question: what does `R.layout.main` mean? Where did this `R` come from?

To explain that, we need to start thinking about layout resources and how resources are referenced from within Java code.

Using XML-Based Layouts

As noted in the previous chapter, Android uses a series of widgets and containers to describe your typical user interface. These all inherit from an `android.view.View` base class, for things that can be rendered into a standard widget-based activity.

While it is technically possible to create and attach widgets and containers to our activity purely through Java code, the more common approach is to use an XML-based layout file. Dynamic instantiation of widgets is reserved for more complicated scenarios, where the widgets are not known at compile-time (e.g., populating a column of radio buttons based on data retrieved off the Internet).

With that in mind, it's time to break out the XML and learn how to lay out Android activity contents that way.

What Is an XML-Based Layout?

As the name suggests, an XML-based layout is a specification of its widgets' relationships to each other — and to containers — encoded in XML format. Specifically, Android considers XML-based layouts to be resources, and as such layout files are stored in the `res/layout/` directory inside your Android project (or, as we will see later, other layout resource sets, like `res/layout-land/` for layouts to use when the device is held in landscape). As has been noted elsewhere in this book, the location of `res/` is either in the project root for Eclipse or in `app/src/main/` for Android Studio.

Each XML file contains a tree of elements specifying a layout of widgets and containers that make up one `View`. The attributes of the XML elements are properties, describing how a widget should look or how a container should behave. For example, if a `Button` element has an attribute value of `android:textStyle = "bold"`, that means that the text appearing on the face of the button should be rendered in a boldface font style.

For example, here is a `res/layout/main.xml` file that could be used with the aforementioned activity:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
```

```
android:layout_width="match_parent"
android:layout_height="match_parent"
tools:context=".EmPubLiteActivity">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:text="@string/hello_world"/>

</RelativeLayout>
```

The class name of a widget or container — such as `RelativeLayout` or `TextView` — forms the name of the XML element. Since `TextView` is an Android-supplied widget, we can just use the bare class name. If you create your own widgets as subclasses of `android.view.View`, you would need to provide a full package declaration as well (e.g., `com.commonware.android.MyWidget`).

The root element needs to declare the Android XML namespace (`xmlns:android="http://schemas.android.com/apk/res/android"`). All other elements will be children of the root and will inherit that namespace declaration.

The attributes are properties of the widget or container, describing what it should look and work like. For example, the `android:layout_centerHorizontal="true"` attribute on the `TextView` element indicates that the `TextView` should be centered within its `RelativeLayout` parent.

We will get into details about these attributes, their possible values, and their uses, in upcoming chapters. Note that those attributes in the `tools` namespace (e.g., `tools:context`) are there solely to support the Android build tools, and do not affect the runtime execution of your project.

Android's SDK ships with a tool (`aapt`) which uses the layouts. This tool will be automatically invoked by your Android tool chain (e.g., Android Studio, Eclipse). Of particular importance to you as a developer is that `aapt` generates an `R.java` source file, allowing you to access layouts and widgets within those layouts directly from your Java code. In other words, this is where that magic `R` value used in `setContentView()` comes from. We will discuss that a bit more [later in this chapter](#).

XML Layouts and Your IDE

If you are using Android Studio or Eclipse, and you double-click on the `res/layout/main.xml` file in your project, you will not initially see that XML. Instead, you will be taken to the graphical layout editor:

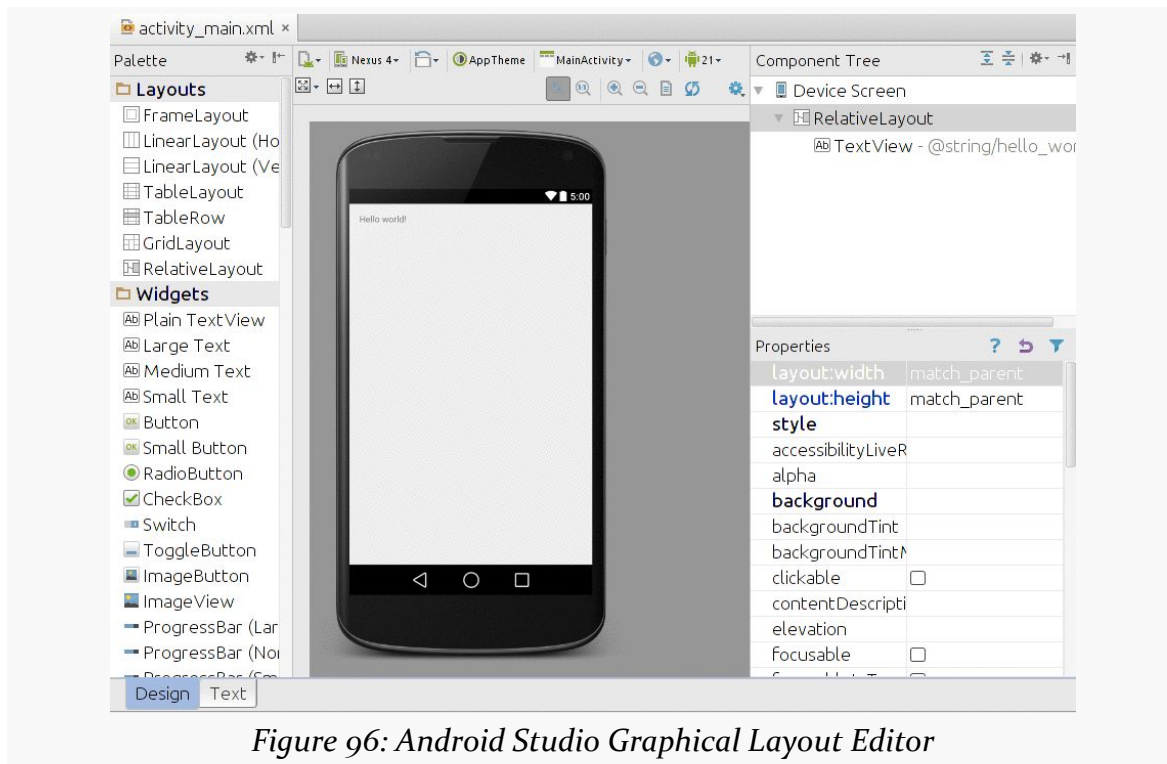

Figure 96: Android Studio Graphical Layout Editor

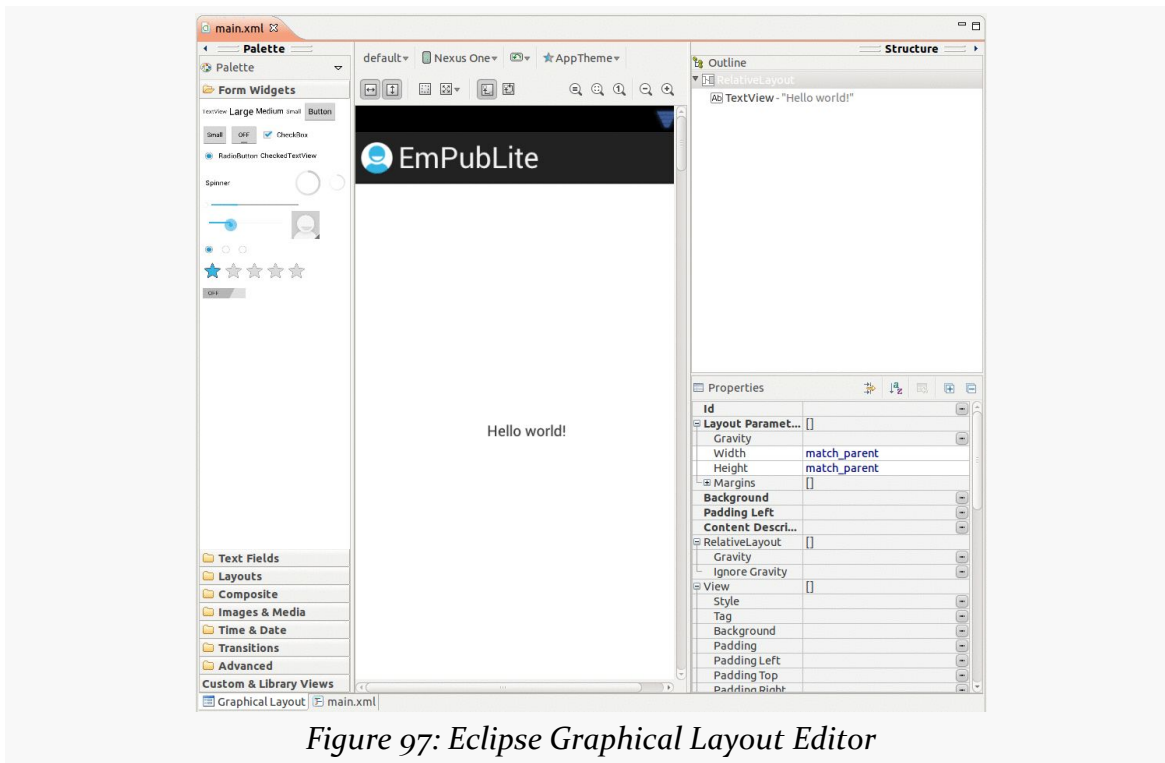

Figure 97: Eclipse Graphical Layout Editor

A sub-tab (e.g., “Text” on Android Studio) will show you the raw XML. The default “Design” or “Graphical Layout” sub-tab, though, shows you a preview of what your layout would look like, if it were to be used for an activity. The “Palette” on the left shows all sorts of widgets and containers, which you can drag into the preview area to add an instance of your chosen widget or container to your layout. Right-clicking over a widget or container will give you an extensive context menu to configure the item, and the toolbar immediately above the preview area will let you configure common properties of a selected widget or container.

We will go into much more detail about using the graphical layout editor in [an upcoming chapter](#), as we start to work more with specific widgets and containers.

Why Use XML-Based Layouts?

Almost everything you do using XML layout files can be achieved through Java code. For example, you could use `setText()` to have a button display a certain caption, instead of using a property in an XML layout. Since XML layouts are yet another file for you to keep track of, we need good reasons for using such files.

Perhaps the biggest reason is to assist in the creation of tools for view definition, such as the aforementioned graphical layout editors in Android Studio and Eclipse. Such GUI builders could, in principle, generate Java code instead of XML. The challenge is re-reading the definition in to support edits — that is far simpler if the data is in a structured format like XML than in a programming language. Moreover, keeping the generated bits separated out from hand-written code makes it less likely that somebody’s custom-crafted source will get clobbered by accident when the generated bits get re-generated. XML forms a nice middle ground between something that is easy for tool-writers to use and easy for programmers to work with by hand as needed.

Also, XML as a GUI definition format is becoming more commonplace. Microsoft’s [XAML](#), Adobe’s [Flex](#), Google’s [GWT](#), and Mozilla’s [XUL](#) all take a similar approach to that of Android: put layout details in an XML file and put programming smarts in source files (e.g., JavaScript for XUL). Many less-well-known GUI frameworks, such as [ZK](#), also use XML for view definition. While “following the herd” is not necessarily the best policy, it does have the advantage of helping to ease the transition into Android from any other XML-centered view description language.

Using Layouts from Java

Given that you have painstakingly set up the widgets and containers for your view in an XML layout file named `main.xml` stored in `res/layout/`, all you need is one statement in your activity’s `onCreate()` callback to use that layout, as we saw in our stub project’s activity:

```
setContentView(R.layout.main);
```

Here, `R.layout.main` tells Android to load in the layout (layout) resource (R) named `main.xml` (main).

Basic Widgets

Every GUI toolkit has some basic widgets: fields, labels, buttons, etc. Android's toolkit is no different in scope, and the basic widgets will provide a good introduction as to how widgets work in Android activities. We will examine a number of these in this chapter.

Common Concepts

There are a few core features of widgets that we need to discuss at the outset, before we dive into details on specific types of widgets.

Widgets and Attributes

As mentioned in [a previous chapter](#), widgets have attributes that describe how they should behave. In an XML layout file, these are literally XML attributes on the widget's element in the file. Usually, there are corresponding getter and setter methods for manipulating this attribute at runtime from your Java code.

If you visit the JavaDocs for a widget, such as [the JavaDocs for TextView](#), you will see an “XML Attributes” table near the top. This lists all of the attributes defined uniquely on this class, and the “Inherited XML Attributes” table that follows lists all those that the widget inherits from superclasses, such as `View`. Of course, the JavaDocs also list the fields, constants, constructors, and public/protected methods that you can use on the widget itself.

Those attributes can be modified by a “Properties” view in the graphical layout editor of the IDE:

BASIC WIDGETS

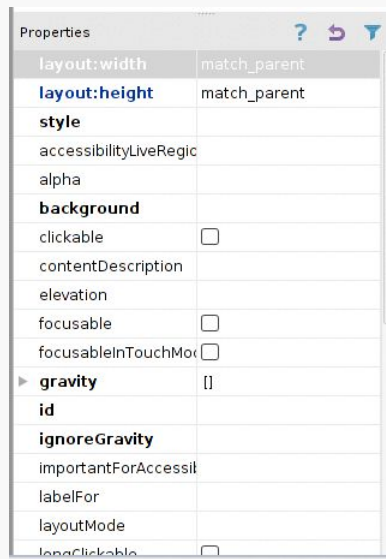

Figure 98: Properties View in Android Studio Graphical Layout Editor

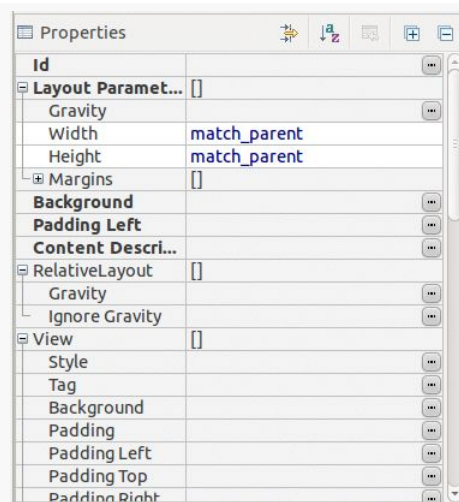

Figure 99: Properties View in Eclipse Graphical Layout Editor

This book does not attempt to explain each and every attribute on each and every widget. We will, however, cover the most popular widgets and the most commonly-used attributes on those widgets.

Referencing Widgets By ID

Many widgets and containers only need to appear in the XML layout file and do not need to be referenced in your Java code. For example, a static label (TextView) frequently only needs to be in the layout file to indicate where it should appear.

Anything you *do* want to use in your Java source, though, needs an `android:id`.

The convention is to use `@+id/...` as the `id` value, where the `...` represents your locally-unique name for the widget in question, for the first occurrence of a given `id` value in your layout file. The second and subsequent occurrences in the same layout file should drop the `+` sign.

Android provides a few special `android:id` values, of the form `@android:id/...` — we will see some of these in various chapters of this book.

To access our identified widgets, use `findViewById()`, passing it the numeric identifier of the widget in question. That numeric identifier was generated by Android in the `R` class as `R.id.something` (where `something` is the specific widget you are seeking).

This concept will become important as we try to attach listeners to our widgets (e.g., finding out when a checkbox is checked) or when we try referencing widgets from other widgets in a layout XML file (e.g., with `RelativeLayout`). All of this will be covered later in this chapter.

Size

Most of the time, we need to tell Android how big we want our widgets to be. Occasionally, this will be handled for us — we will see an example of that with `TableLayout` in [an upcoming chapter](#). But generally we need to provide this information ourselves.

To do that, you need to supply `android:layout_width` and `android:layout_height` attributes on your widgets in the XML layout file. These attributes' values have three flavors:

1. You can provide a specific dimension, such as `125dip` to indicate the widget should take up exactly a certain size (here, 125 density-independent pixels)

2. You can provide `wrap_content`, which means the widget should take up as much room as its contents require (e.g., a `TextView` label widget's content is the text to be displayed)
3. You can provide `match_parent`, which means the widget should fill up all remaining available space in its enclosing container

The latter two flavors are the most common, as they are independent of screen size, allowing Android to adjust your view to fit the available space.

Note that you will also see `fill_parent`. This is an older synonym for `match_parent`. `match_parent` is the recommended value going forward, but `fill_parent` will certainly work.

This chapter focuses on individual widgets. Size becomes much more important when we start combining multiple widgets on the screen at once, and so we will be spending more time on sizing scenarios in later chapters.

The `layout_` prefix on these attributes means that these attributes represent requests by the widget to its enclosing container. Whether those requests will be truly honored will depend a bit on what other widgets there are in the container and what *their* requests are.

Assigning Labels

The simplest widget is the label, referred to in Android as a `TextView`. Like in most GUI toolkits, labels are bits of text not editable directly by users. Typically, they are used to identify adjacent widgets (e.g., a “Name:” label before a field where one fills in a name).

In Java, you can create a label by creating a `TextView` instance. More commonly, though, you will create labels in XML layout files by adding a `TextView` element to the layout, with an `android:text` property to set the value of the label itself. If you need to swap labels based on certain criteria, such as internationalization, you may wish to use a string resource reference in `android:text` instead (e.g., `@string/label`).

For example, in [our last tutorial](#), we still are using the automatically-generated `res/layout/main.xml` file, containing, among other things, a `TextView`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
```

BASIC WIDGETS

```
android:layout_width="match_parent"
android:layout_height="match_parent"
tools:context=".EmPubLiteActivity">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:text="@string/hello_world"/>

</RelativeLayout>
```

Android Studio Graphical Layout Editor

The TextView widget is available in the “Widgets” category of the Palette in the Android Studio graphical layout editor:

Figure 100: Palette, “Plain TextView” in Widgets Category

The “Large Text”, “Medium Text”, and “Small Text” items beneath “Plain TextView” are also TextView widgets, with different default font sizes.

You can drag that TextView from the palette into a layout file in the main editing area to add the widget to the layout. Or, drag it over the top of some container you

BASIC WIDGETS

see in the Component Tree pane of the editor to add it as a child of that specific container:

Figure 101: Component Tree Pane

Clicking on the resulting TextView in the Component Tree pane, or in the preview area, will set up the Properties pane with the various attributes of the widget, ready for you to change as needed:

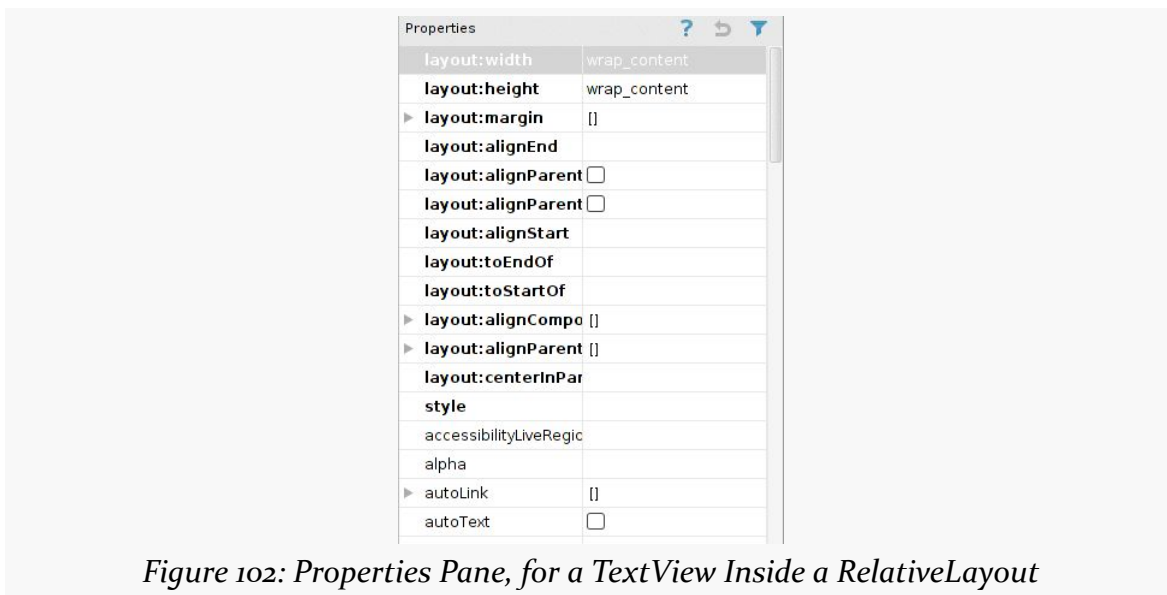

Figure 102: Properties Pane, for a TextView Inside a RelativeLayout

Editing the Text

The “Text” property will allow you to choose or define a string resource to serve as the text to be displayed:

BASIC WIDGETS

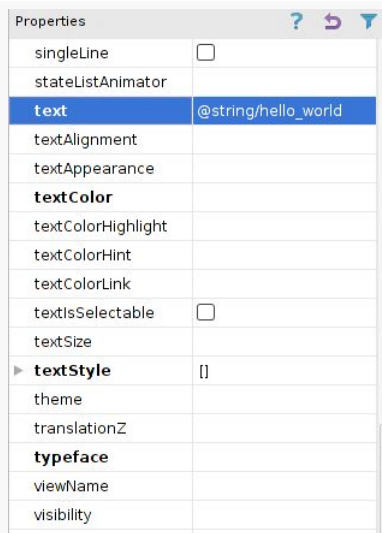

Figure 103: Properties Pane, with TextView “text” Property Selected

Clicking on the value will allow the property to be edited:

Figure 104: Properties Pane, with TextView “text” Property Editable

You can either type a literal string right in the Properties pane row, or you can click the “...” button to the right of the field to pick a string resource:

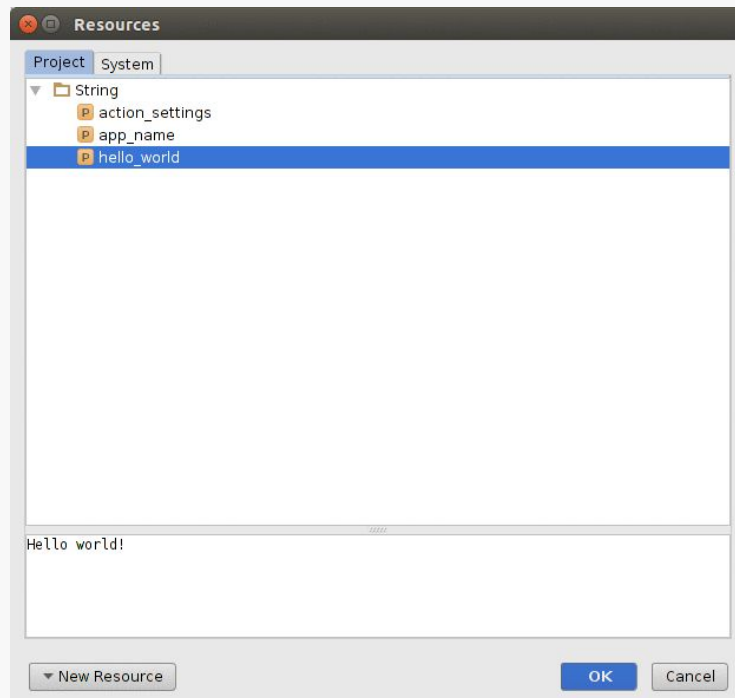

Figure 105: String Resources Dialog

You can highlight one of those resources and click “OK” to use it. Or, in the bottom of that dialog, there is a “New Resource” drop-down. When viewing string resources, that drop-down will contain a single command: “New String Value...”. Choosing it will allow you to define a new string resource via another dialog:

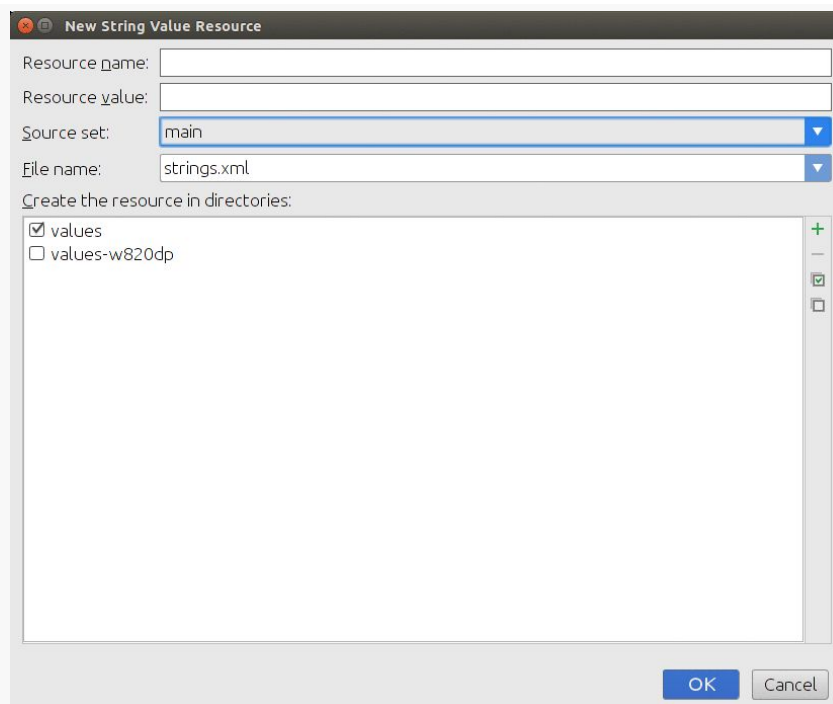

Figure 106: New String Resource Dialog

You can give your new string resource a name, the actual text of the string itself, the filename in which the string resource should reside (`strings.xml` by default), and which `values/` directory the string should go into (`values` by default). You will also choose the “source set” — for now, that will just be `main`. Once you accept the dialog, your new string resource will be applied to your `TextView`.

Editing the ID

The “id” property will allow you to change the `android:id` value of the widget:

BASIC WIDGETS

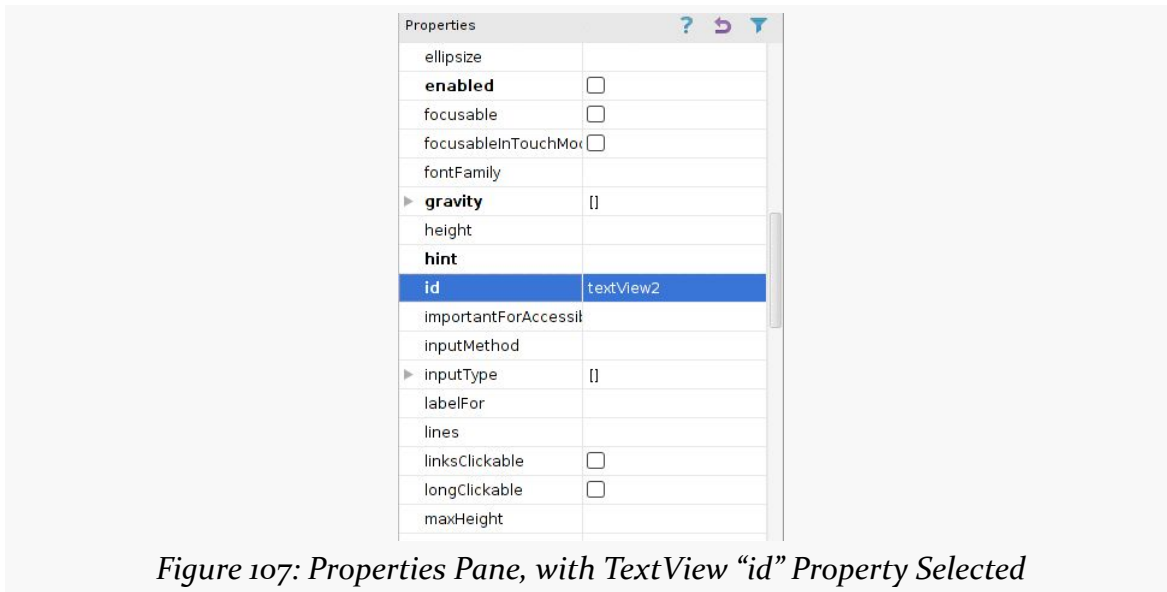

Figure 107: Properties Pane, with TextView “id” Property Selected

The value you fill in here is what goes after the `@+id/` portion (e.g., `textView2`).

Eclipse Graphical Layout Editor

The TextView widget is available in the “Form Widgets” portion of the Palette in the Eclipse graphical layout editor:

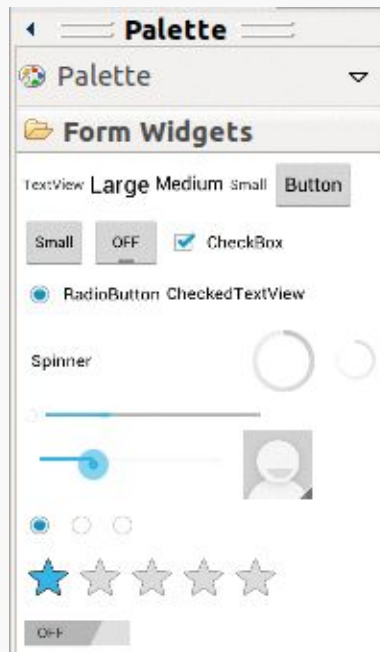

Figure 108: Form Widgets Palette, TextView in Upper Left

You can drag that TextView from the palette into a layout file in the main editing area to add the widget to the layout. Or, drag it over the top of some container you see in the Outline pane of the editor to add it as a child of that specific container:

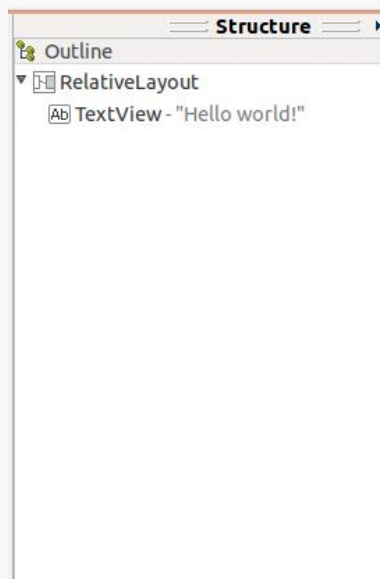

Figure 109: Outline Pane

BASIC WIDGETS

Clicking on the resulting `TextView` in the Outline pane, or in the preview area, will set up the Properties pane with the various attributes of the widget, ready for you to change as needed:

Figure 110: Properties Pane, for a TextView Inside a RelativeLayout

Editing the Text

The “Text” property will allow you to choose or define a string resource to serve as the text to be displayed. By default, it brings up a list of existing string resources:

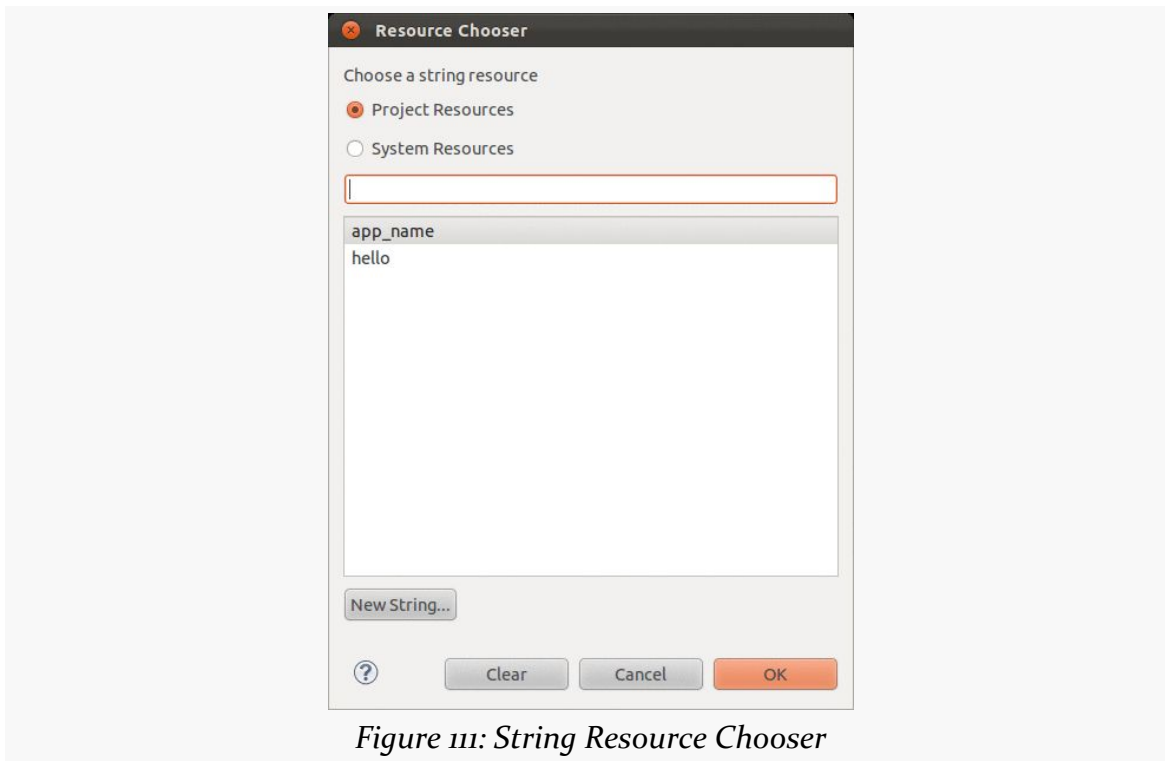

Figure 111: String Resource Chooser

You can highlight one of those resources and click “OK” to use it, or you can click the “New String...” button to define a brand-new string resource.

Editing the ID

The “Id” property will allow you to change the `android:id` value of the widget. Be sure to include the `@+id/` prefix, as Android will not add that automatically for you.

Notable TextView Attributes

TextView has numerous other attributes of relevance for labels, such as:

1. `android:typeface` to set the typeface to use for the label (e.g., monospace)
2. `android:textStyle` to indicate that the typeface should be made bold (bold), italic (italic), or bold and italic (bold_italic)
3. `android:textColor` to set the color of the label’s text, in RGB hex format (e.g., `#FF0000` for red) or ARGB hex format (e.g., `#88FF0000` for a translucent red)

These attributes, like most others, can be modified through the Properties pane.

For example, in the [Basic/Label](#) sample project, you will find the following layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/profound"
/>
```

Just that layout alone, with the stub Java source provided by Android's project builder (e.g., `android create project`) and appropriate string resources, gives you:

Figure 112: The LabelDemo Sample Application

A Commanding Button

Android has a `Button` widget, which is your classic push-button “click me and something cool will happen” widget. As it turns out, `Button` is a subclass of `TextView`, so everything discussed in the preceding section in terms of formatting the face of the button still holds.

For example, in the [Basic/Button](#) sample project, you will find the following layout file:

BASIC WIDGETS

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/button"/>

</LinearLayout>
```

Just that layout alone, with the stub Java source provided by Android's project builder (e.g., `android create project`) and appropriate string resources, gives you:

Figure 113: Button Widget, in Theme

BASIC WIDGETS

Figure 114: Button Widget, in Theme.Holo

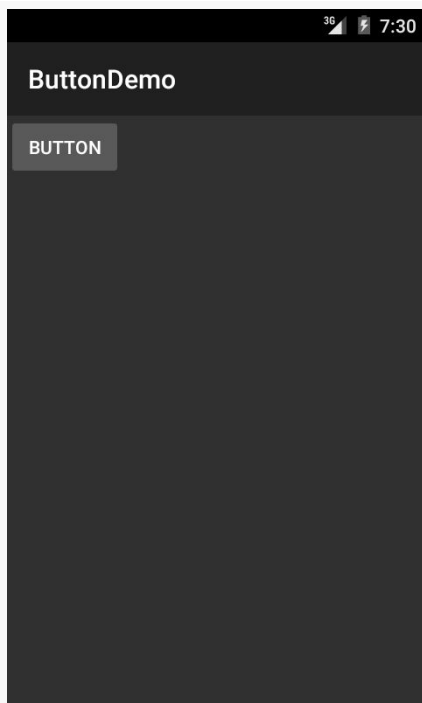

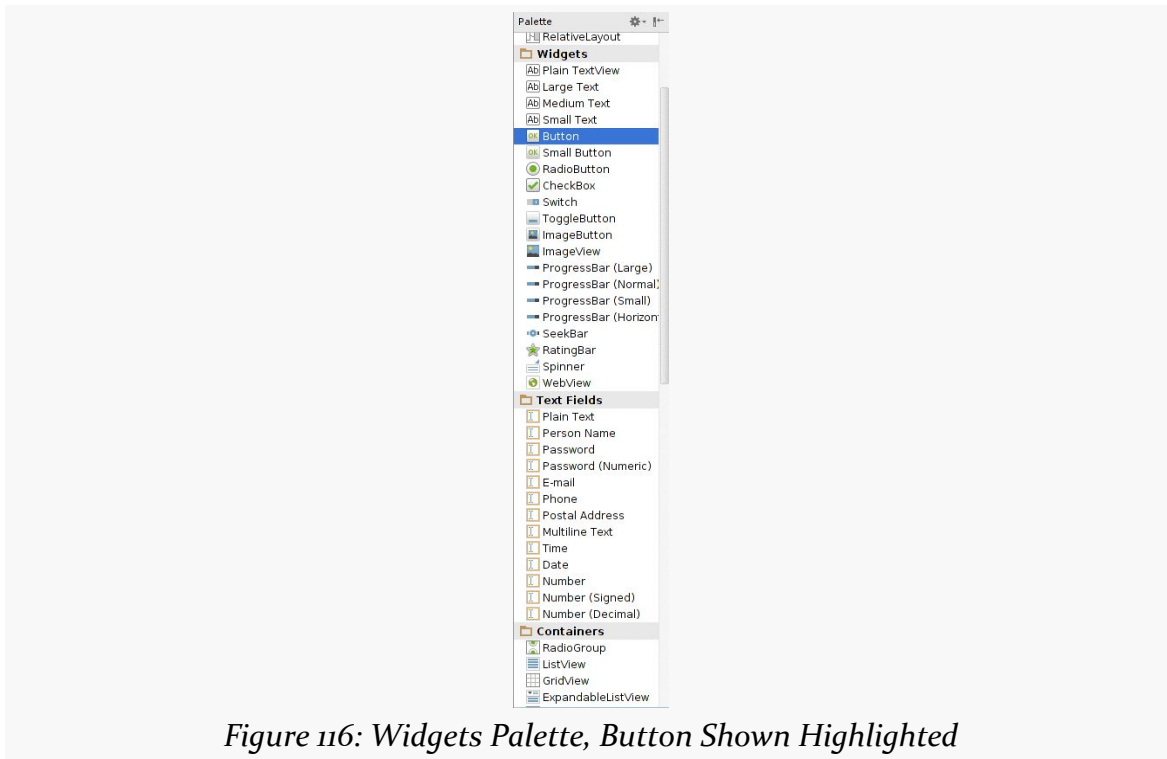

Figure 115: Button Widget, in Theme.Material

Android Studio Graphical Layout Editor

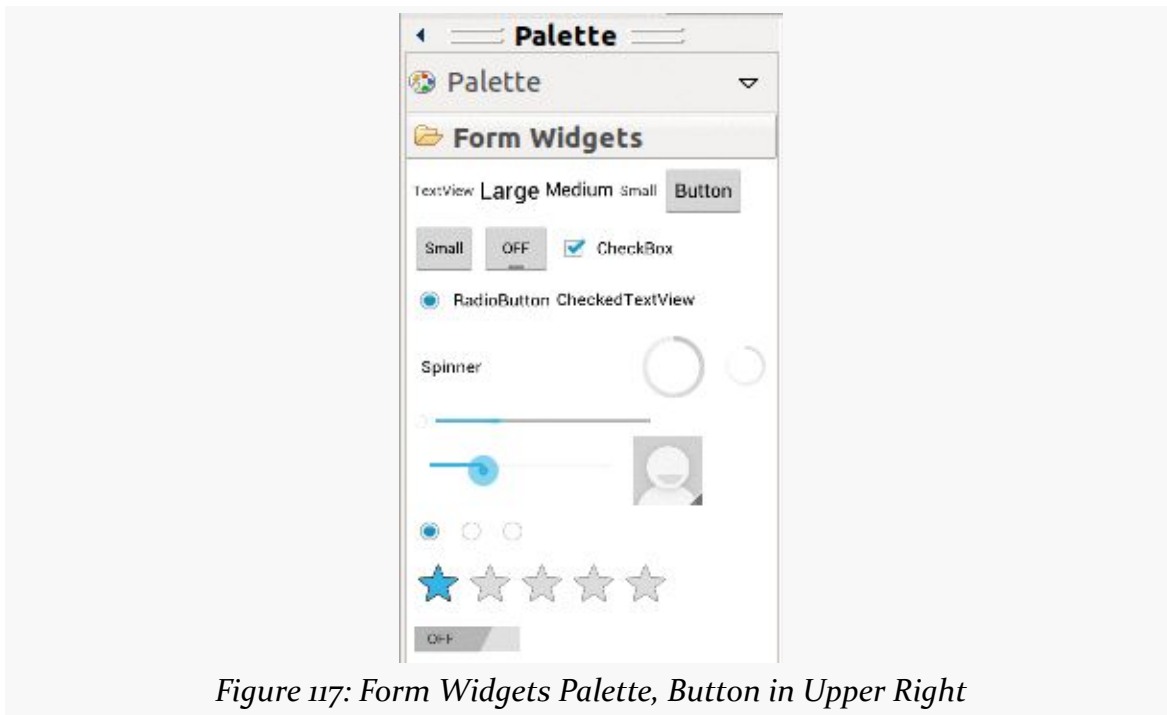

As with the TextView widget, the Button widget is available in the “Widgets” portion of the Palette in the Android Studio graphical layout editor:

You can drag that Button from the palette into a layout file in the main editing area to add the widget to the layout. The Properties pane will then let you adjust the various attributes of this Button. Since Button inherits from TextView, most of the options are the same (e.g., “Text”).

Eclipse Graphical Layout Editor

As with the TextView widget, the Button widget is available in the “Form Widgets” portion of the Palette in the Eclipse graphical layout editor:

You can drag that Button from the palette into a layout file in the main editing area to add the widget to the layout. The Properties pane will then let you adjust the various attributes of this Button. Since Button inherits from TextView, most of the options are the same (e.g., “Text”).

Tracking Button Clicks

Buttons are command widgets — when the user presses a button, they expect something to happen.

To define what happens when you click a Button, you can:

1. Define some method on your Activity that holds the button that takes a single View parameter, has a void return value, and is public
2. In your layout XML, on the Button element, include the `android:onClick` attribute with the name of the method you defined in the previous step

For example, we might have a method on our Activity that looks like:

```
public void someMethod(View theButton) {  
    // do something useful here  
}
```

Then, we could use this XML declaration for the Button itself, including `android:onClick`:

```
<Button
  android:onClick="someMethod"
  ...
/>
```

This is enough for Android to “wire together” the Button with the click handler. When the user clicks the button, `someMethod()` will be called.

Another approach is to skip `android:onClick`, instead calling `setOnClickListener()` on the Button object in Java code. When a Button is used directly by an activity, this is not typically used — `android:onClick` is a bit cleaner. However, when we start to [talk about fragments](#), you will see that `android:onClick` does not work that well with fragments, and so we will use `setOnClickListener()` at that point.

Fleeting Images

Android has two widgets to help you embed images in your activities: `ImageView` and `ImageButton`. As the names suggest, they are image-based analogues to `TextView` and `Button`, respectively.

Each widget takes an `android:src` attribute (in an XML layout) to specify what picture to use. These usually reference a drawable resource (e.g., `@drawable/icon`).

`ImageButton`, a subclass of `ImageView`, mixes in the standard `Button` behaviors, for responding to clicks and whatnot.

For example, take a peek at the `main.xml` layout from the [Basic/ImageView](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<ImageView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/icon"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:adjustViewBounds="true"
  android:src="@drawable/molecule"/>
```

The result, just using the code-generated activity, is simply the image:

Figure 118: The ImageViewDemo sample application

Android Studio Graphical Layout Editor

The `ImageView` widget can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor:

BASIC WIDGETS

Figure 119: Widgets Palette, ImageView Shown Highlighted

ImageButton appears alongside ImageView in that tool palette.

You can drag these into a layout file, then use the Properties pane to set their attributes. Like all widgets, you will have an “id” option to set the android:id value for the widget. Two others of importance, though, are more unique to ImageView and ImageButton:

- “src” allows you to choose a drawable resource to use as the image to be displayed
- “scaleType” opens a drop-down menu where you can choose how the image is to be scaled:

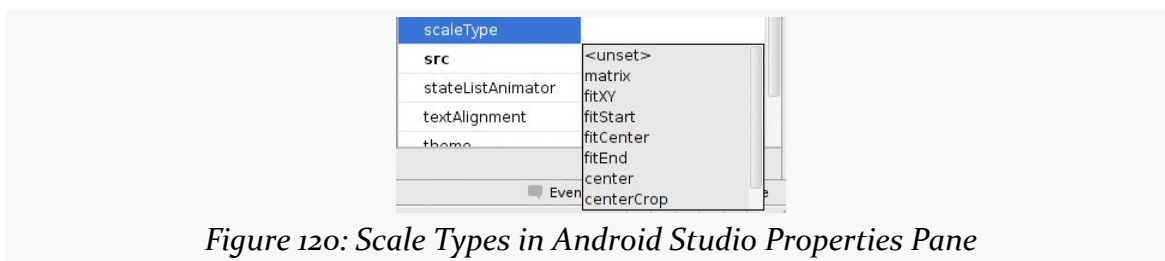

Figure 120: Scale Types in Android Studio Properties Pane

We will examine those scale types more [later in this chapter](#).

Eclipse Graphical Layout Editor

The ImageView widget can be found in the “Images & Media” portion of the Palette in the Graphical Layout editor:

The ImageButton widget is adjacent to the ImageView widget in the Palette.

You can drag these into a layout file, then use the Properties pane to set their attributes. Like all widgets, you will have an “Id” option to set the `android:id` value for the widget. Two others of importance, though, are more unique to ImageView and ImageButton:

- “Src” allows you to choose a drawable resource to use as the image to be displayed
- “Scale Type” opens a drop-down menu where you can choose how the image is to be scaled:

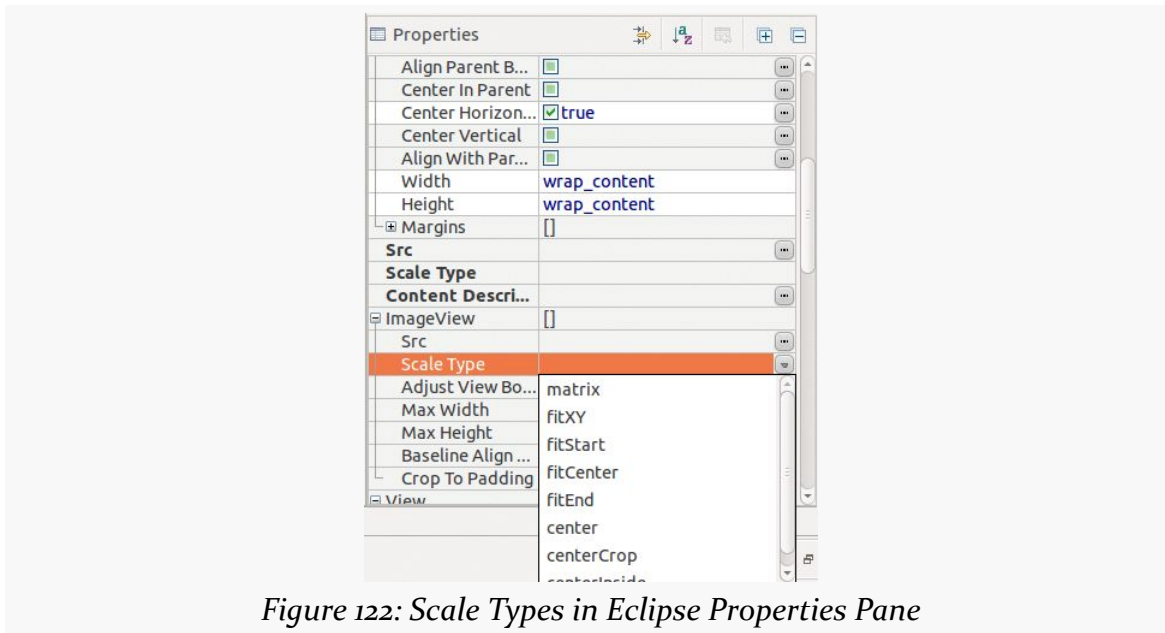

Figure 122: Scale Types in Eclipse Properties Pane

We will examine those scale types more in the next section.

Scaling Images

It is possible, perhaps even probable, that our `ImageView` size will not exactly match the size of the images that we are trying to display. `ImageView` supports a variety of “scale types” that indicate how Android should try to deal with the discrepancy between the size/aspect ratio of the image and the size/aspect ratio of the `ImageView` itself.

These values can be seen in the JavaDocs in [the `ImageView.ScaleType` class](#). The default (“fitCenter”) simply scales up the image to best fit the available space.

Of note, a choice of “center” will center the image in the available space but will not scale up the image:

Figure 123: The ImageViewDemo Sample, Set to center

A choice of “centerCrop” will scale the image so that its shortest dimension fills the available space and crops the rest:

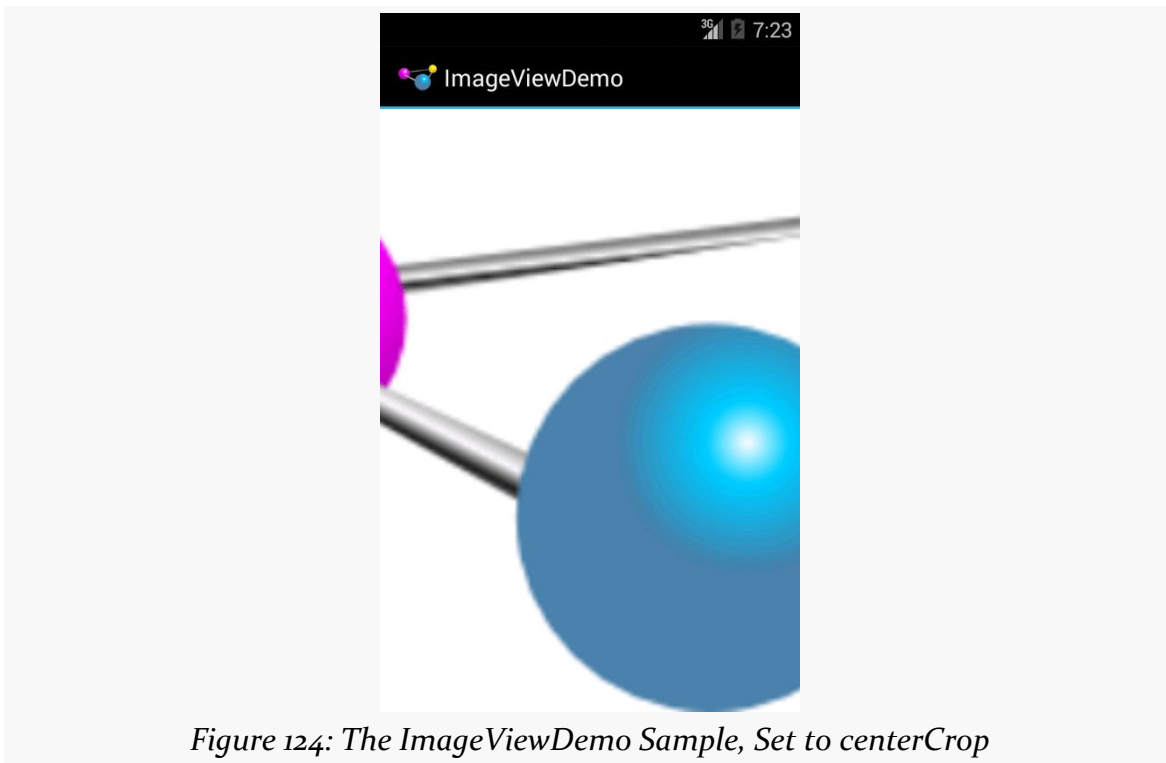

Figure 124: The ImageViewDemo Sample, Set to centerCrop

A choice of “fitXY” will scale the image to fill the space, ignoring the aspect ratio:

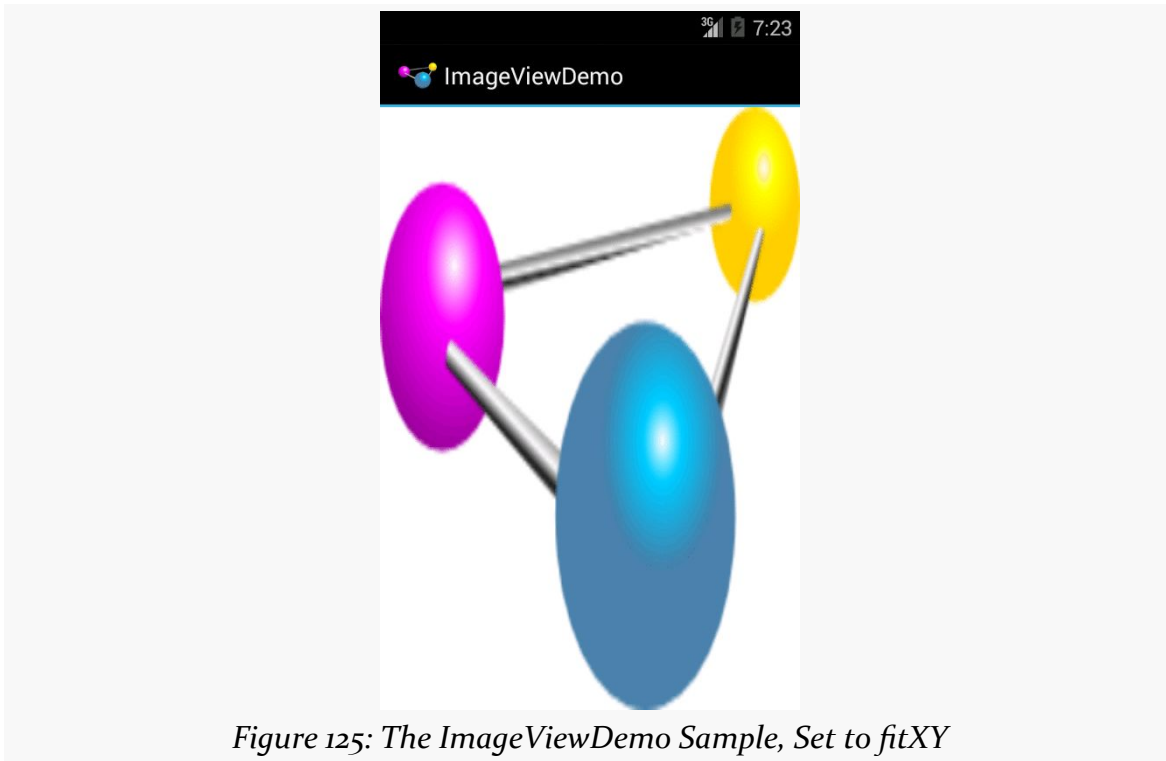

Figure 125: The ImageViewDemo Sample, Set to fitXY

Fields of Green. Or Other Colors.

Along with buttons and labels, fields are the third “anchor” of most GUI toolkits. In Android, they are implemented via the `EditText` widget, which is a subclass of the `TextView` used for labels.

Along with the standard `TextView` attributes (e.g., `android:textStyle`), `EditText` has others that will be useful for you in constructing fields, notably `android:inputType`, to describe what sort of input your `EditText` expects (numbers? email addresses? phone numbers?). A thorough explanation of `android:inputType` and its interaction with input method editors (a.k.a., “soft keyboards”) will be discussed in an [upcoming chapter](#).

For example, from the [Basic/Field](#) sample project, here is an XML layout file showing an `EditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/field"
    android:layout_width="match_parent"
```

BASIC WIDGETS

```
android:layout_height="match_parent"  
android:inputType="textMultiLine"  
android:text="@string/license"  
</>
```

Note that we have `android:inputType="textMultiLine"`, so users will be able to enter in several lines of text. We also have defined the initial text to be the value of a license string resource.

The result, once built and installed into the emulator, is:

Figure 126: FieldDemo, in Theme

Figure 127: FieldDemo, in Theme.Holo

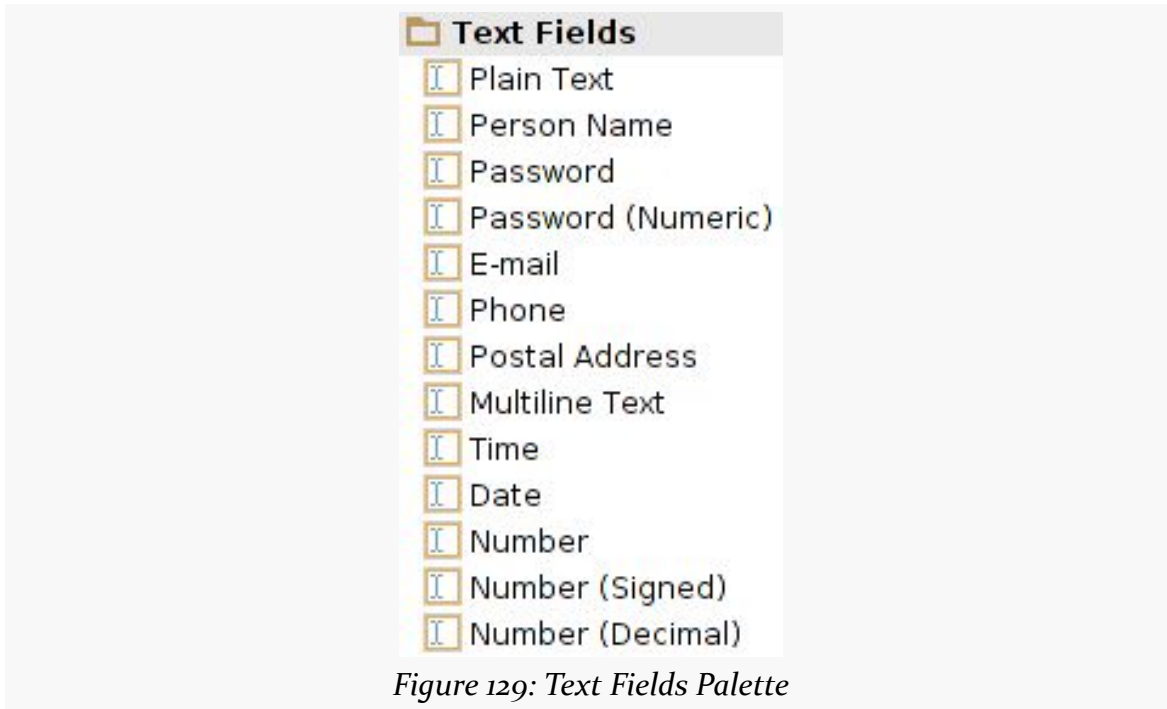

Figure 128: FieldDemo, in Theme.Material

Android Studio Graphical Layout Editor

The Android Studio Graphical Layout's Palette has a whole section dedicated primarily to `EditText` widgets, named "Text Fields":

The first entry is a general-purpose `EditText`. The rest come pre-configured for various scenarios, such as a person's name or a password.

You can drag any of these into your layout, then use the Properties pane to configure relevant attributes. The "Id" and "Text" attributes are the same as found on `TextView`, as are many other properties, as `EditText` inherits from `TextView`.

Eclipse Graphical Layout Editor

The Graphical Layout's Palette has a whole section dedicated primarily to `EditText` widgets, named "Text Fields":

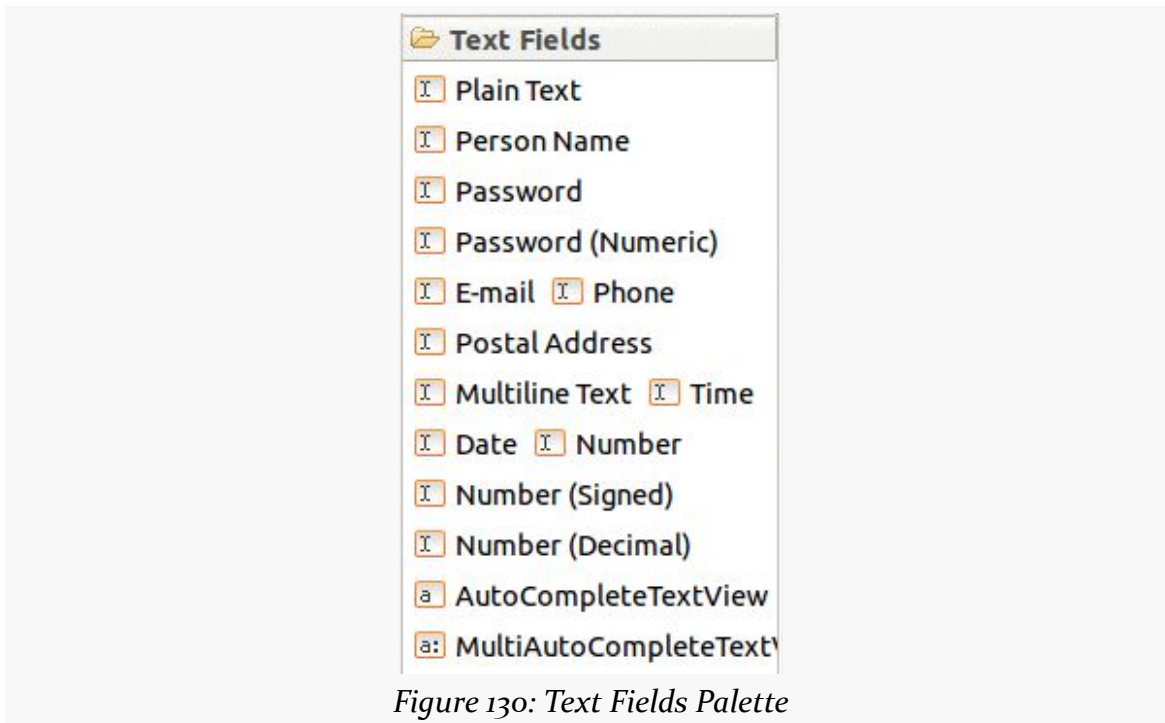

Figure 130: Text Fields Palette

The first entry is a general-purpose `EditText`. The rest come pre-configured for various scenarios, such as a person's name or a postal address.

You can drag any of these into your layout, then use the Properties pane to configure relevant attributes. The “Id” and “Text” attributes are the same as found on `TextView`, as are many other properties, as `EditText` inherits from `TextView`.

Notable `EditText` Attributes

The “Hint” item in the Properties pane allows you to set a “hint” for this `EditText`. The “hint” text will be shown in light gray in the `EditText` widget when the user has not entered anything yet. Once the user starts typing into the `EditText`, the “hint” vanishes. This might allow you to save on screen space, replacing a separate label `TextView`.

The “Input Type” item in the Properties pane allows you to describe what sort of input you are expecting to receive in this `EditText`, lining up with many of the types of fields you can drag from the Palette into the layout:

BASIC WIDGETS

Figure 131: Android Studio's Text Fields InputType Drop-Down

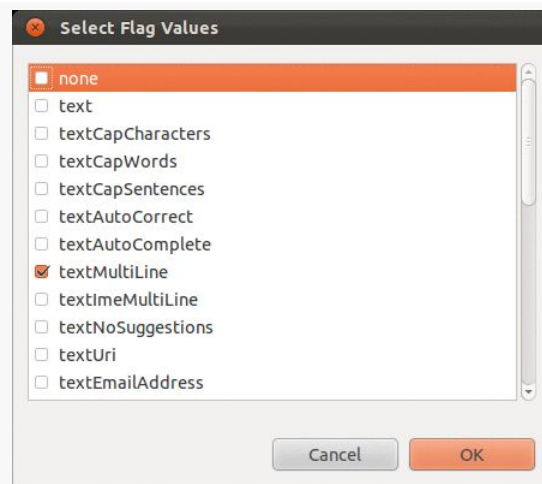

Figure 132: Eclipse's Text Fields InputType Dialog

The `inputType` attribute will be covered in greater detail in an [upcoming chapter](#).

More Common Concepts

All widgets, including the ones shown above, extend `View`. The `View` base class gives all widgets an array of useful attributes and methods beyond those already described.

Padding

Widgets have a minimum size, one that may be influenced by what is inside of them. So, for example, a `Button` will expand to accommodate the size of its caption. You can control this size using padding. Adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges of the widget.

Padding can be set once in XML for all four sides (`android:padding`) or on a per-side basis (`android:paddingLeft`, etc.). Padding can also be set in Java via the `setPadding()` method.

The value of any of these is a dimension — a combination of a unit of measure and a count. So, `10dip` is 10 density-independent pixels, `2mm` is 2 millimeters, etc.

Margins

By default, widgets are tightly packed, one next to the other. You can control this via the use of margins, a concept that is reminiscent of the padding described previously.

The difference between padding and margins comes in terms of the background. For widgets with a transparent background — like the default look of a `TextView` — padding and margins have similar visual effect, increasing the space between the widget and adjacent widgets. However, for widgets with a non-transparent background — like a `Button` — padding is considered inside the background while margins are outside. In other words, adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges, while adding margin increases the empty space between the edges and adjacent widgets.

Margins can be set in XML, either on a per-side basis (e.g., `android:layout_marginTop`) or on all sides via `android:layout_margin`. Once again, the value of any of these is a dimension — a combination of a unit of measure and a count, such as `5dp` for 5 density-independent pixels.

Colors

There are two types of color attributes in Android widgets. Some, like `android:background`, take a single color (or a drawable to serve as the background). Others, like `android:textColor` on `TextView` (and subclasses) can take a `ColorStateList`, including via the Java setter (in this case, `setTextColor()`).

A `ColorStateList` allows you to specify different colors for different conditions. For example, when you get to selection widgets in an upcoming chapter, you will see how a `TextView` has a different text color when it is the selected item in a list compared to when it is in the list but not selected. This is handled via the default `ColorStateList` associated with `TextView`.

If you wish to change the color of a `TextView` widget in Java code, you have two main choices:

- Use `ColorStateList.valueOf()`, which returns a `ColorStateList` in which all states are considered to have the same color, which you supply as the parameter to the `valueOf()` method. This is the Java equivalent of the `android:textColor` approach, to make the `TextView` always be a specific color regardless of circumstances.
- Create a `ColorStateList` with different values for different states, either via the constructor or via an XML drawable resource. This will be covered [much later in the book](#).

Other Useful Attributes

Some additional attributes on `View` most likely to be used include:

1. `android:visibility`, which controls whether the widget is initially visible
2. `android:nextFocusDown`, `android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`, which control the focus order if the user uses the D-pad, trackball, or similar pointing device
3. `android:contentDescription`, which is roughly equivalent to the `alt` attribute on an HTML `` tag, and is used by accessibility tools to help people who cannot see the screen navigate the application — this is very important for widgets like `ImageView`

We will see more about the focus attributes and `android:contentDescription` in [the chapter on focus management and accessibility](#), later in this book.

Useful Methods

You can toggle whether or not a widget is enabled via `setEnabled()` and see if it is enabled via `isEnabled()`. One common use pattern for this is to disable some widgets based on a `CheckBox` or `RadioButton` checked state. We will explore `CheckBox`, `RadioButton`, and similar sorts of widgets [a bit later in the book](#).

You can give a widget focus via `requestFocus()` and see if it is focused via `isFocused()`. You might use this in concert with disabling widgets as mentioned above, to ensure the proper widget has the focus once your disabling operation is complete.

To help navigate the tree of widgets and containers that make up an activity's overall view, you can use:

1. `getParent()` to find the parent widget or container
2. `findViewById()` to find a child widget with a certain ID
3. `getRootView()` to get the root of the tree (e.g., what you provided to the activity via `setContentView()`)

Visit the Trails!

You can learn more about Android's input method framework — what you might think of as soft keyboards — [in a later chapter](#).

Another chapter in the trails covers [the use of fonts](#), to tailor your `TextView` widgets (and those that inherit from them, like `Button`).

Yet another chapter in the trails covers [rich text formatting](#), both for presenting formatted text in a `TextView` (e.g., inline **boldface**) and for collecting formatted text from the user via a customized `EditText`.

Debugging Your App

Now that we are starting to manipulate layouts and Java code more significantly, the odds increase that we are going to somehow do it wrong, and our app will crash.

Figure 133: A Crash Dialog on Android 4.0.3

In this chapter, we will cover a few tips on how to debug these sorts of issues.

Get Thee To a Stack Trace

If you see one of those “Force Close” or “Has Stopped” dialogs, the first thing you will want to do is examine the Java stack trace that is associated with this crash. These are logged to a facility known as LogCat, on your device or emulator.

To view LogCat, you have three choices:

1. Use the `adb logcat` command at the command line (or something that uses `adb logcat`, such as various colorizing scripts available online)
2. Use the LogCat tab in the standalone Android Device Monitor utility (run `monitor` from the command line)
3. Use the LogCat view in your IDE (Eclipse or Android Studio)

There are also LogCat apps on the Play Store, such as aLogCat, that will display the contents of LogCat. However, for security and privacy reasons, on Jelly Bean and higher devices, such apps will only be able to show you *their* LogCat entries, not those from the system, your app, or anyone else. Hence, for development purposes, it is better to use one of the other alternatives outlined above.

LogCat in Android Studio

The LogCat view is available at any time, from pretty much anywhere in Android Studio, by means of clicking on the Android tool window entry, usually docked at the bottom of your IDE window:

Figure 134: Minimized Tool Windows in Android Studio, Showing Android Tool Window Entry

Tapping on that will bring up some Android-specific logs in an “Android DDMS” tool window, with a tab for “Devices | logcat”:

DEBUGGING YOUR APP

Figure 135: Android DDMS Tool Window, Showing LogCat

LogCat will show your stack traces, diagnostic information from the operating system, and anything you wish to include via calls to static methods on the `android.util.Log` class. For example, `Log.e()` will log a message at error severity, causing it to be displayed in red.

If you want to send something from LogCat to somebody else, such as via an issue tracker, just highlight the text and copy it to the clipboard, as you would with any text editor.

The “trash can” icon atop the tool strip on the right is the “clear log” tool. Clicking it will appear to clear LogCat. It definitely clears your LogCat view, so you will only see messages logged after you cleared it. Note, though, that this does not actually clear the logs from the device or emulator.

In addition, you can:

- Use the “Log level” drop-down to filter lines based on severity, where messages for your chosen severity or higher will be displayed
- Use the search field to the right of the “Log level” drop-down to filter items based on a search string
- Set up more permanent filters via the drop-down to the right of the search field

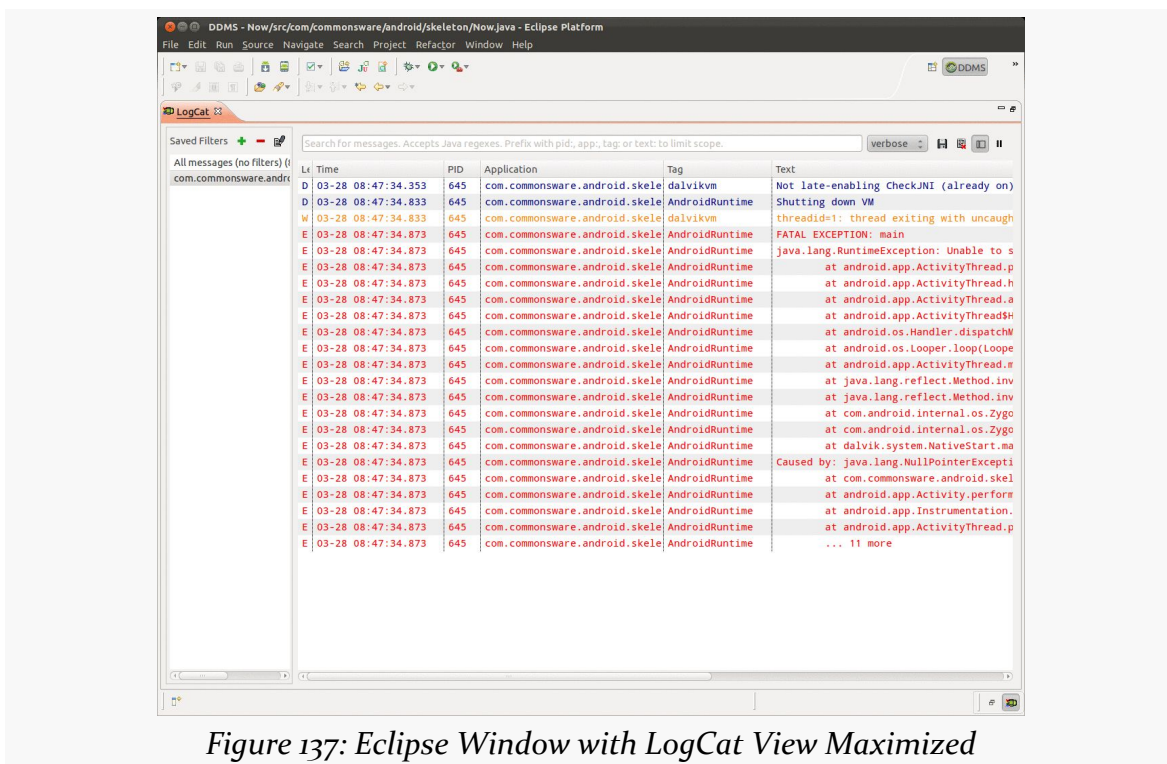

LogCat in Eclipse

The LogCat view is available at any time, from pretty much anywhere in Eclipse, by means of clicking on the LogCat icon in the status bar of your Eclipse window:

DEBUGGING YOUR APP

LogCat will show your stack traces, diagnostic information from the operating system, and anything you wish to include via calls to static methods on the `android.util.Log` class. For example, `Log.e()` will log a message at error severity, causing it to be displayed in red.

By default, when developing your app, if your app crashes, LogCat will display messages from your app alone, via a filter on the left, with the name of your app's package (e.g., `com.commonware.android.skeleton`). Switching the filter to "All messages (no filters)" will show all LogCat messages, regardless of origin.

DEBUGGING YOUR APP

There is a scrollbar towards the bottom of the main log area that will let you see more of your stack trace:

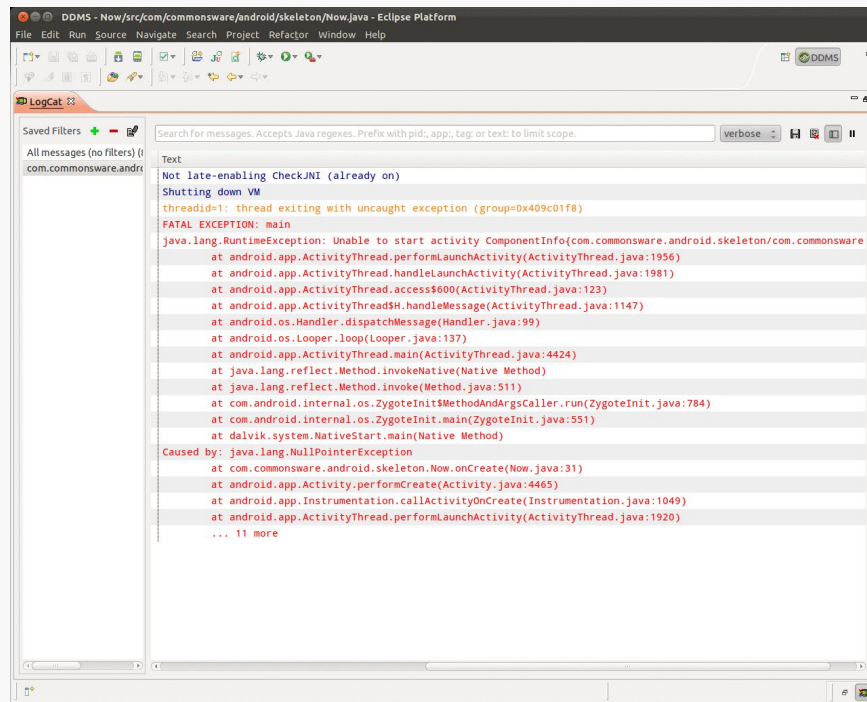

Figure 138: Eclipse Window with LogCat View Scrolled Right

Your stack trace will typically consist of two or more “stanzas”. Your own code will typically be in the last of these. So, in the screenshot above, we have `java.lang.RuntimeException: Unable to start activity...`, followed by `Caused by: java.lang.NullPointerException`, as a pair of stanzas. The point where our code crashed shows up in that second stanza (at `com.commonware.android.skeleton.Now.onCreate(Now.java:31)`).

If you double-click on a line in the stack trace corresponding with your code, you will be taken to a Java editor on that source file and line, so you can see what code triggered the exception.

If you wish to save one of these stack traces as a file, to attach to an issue in an issue tracker or something, highlight the lines you want in LogCat (click on the first line, then <Shift>-click on the last line), then click on the “Export Selected Items to Text File” icon (looks like a 3.5-inch floppy disk or a classic “save” icon). This will bring up your platform’s “Save As” dialog, where you can specify where to write out the file.

The icon immediately to the right is the “clear” icon:

Clicking it will appear to clear LogCat. It definitely clears your LogCat *view*, so you will only see messages logged after you cleared it. Note, though, that this does not actually clear the logs from the device or emulator.

The Case of the Confounding Class Cast

If you crash, the stack trace might suggest that there is a problem tied to your resources. One common flavor of this is a `ClassCastException` when you call `findViewById()`. For example, you might call `(Button)findViewById(R.id.button)`, yet get a `ClassCastException: android.widget.LinearLayout` as a result, indicating that while you thought your `findViewById()` call would return a `Button`, it really returned a `LinearLayout`.

Often times, this is not your fault. Sometimes, the R values get out of sync with pre-compiled classes from previous builds. This most often occurs just after you change your mix of resources (e.g., add a new layout).

To resolve this, you need to clean your project:

- In Android Studio, choose “Build > Clean Project” from the main menu
- In Eclipse, select the project, then choose Project > Clean from the main menu

So, if you get a strange crash that seems like it might be related to resources, clean your project. If the problem goes away, you are set — if the problem persists, you will need to do a bit more debugging.

Point Break

One of the hallmarks of Java IDEs is the ability to do real-time debugging, using breakpoints and the like. In that respect, Android Studio and Eclipse work for Android apps in the same way that IntelliJ IDEA and Eclipse work for Java apps. You can debug on an emulator or any Android device for which you enabled USB debugging (as you may have done in Tutorial #1).

Lacking any Android Studio-specific documentation, you will wind up referring to [the documentation for IntelliJ IDEA](#) to learn how to use its debugger. Similarly, you can turn to [the documentation for Eclipse](#) for details of how to use the Eclipse debugger.

Note that if you set up Eclipse to catch all unhandled exceptions, those exceptions will not be logged to LogCat unless you allow execution to proceed past the point of the exception. While this may not matter much to you during development, the LogCat stack trace is often easier for other developers to read, away from your Eclipse environment. So, if you wish to post a stack trace on an issue or on a support forum (e.g., Stack Overflow), use the LogCat stack trace.

LinearLayout and the Box Model

LinearLayout represents Android's approach to a box model — widgets or child containers are lined up in a column or row, one after the next.

Some GUI toolkits use the box as their primary unit of layout. If you want, you can use LinearLayout in much the same way, eschewing some of the other containers. Getting the visual representation you want is mostly a matter of identifying where boxes should nest and what properties those boxes should have, such as alignment with respect to other boxes.

Concepts and Properties

To configure a LinearLayout, you have four main areas of control besides the container's contents: the orientation, the fill model, the weight, the gravity.

Orientation

Orientation indicates whether the LinearLayout represents a row or a column. Just add the `android:orientation` property to your LinearLayout element in your XML layout, setting the value to be `horizontal` for a row or `vertical` for a column.

The orientation can be modified at runtime by invoking `setOrientation()` on the LinearLayout, supplying it either `HORIZONTAL` or `VERTICAL`.

Fill Model

The point behind a LinearLayout — or any of the Android container classes — is to organize multiple widgets. Part of organizing those widgets is determining how much space each gets.

LinearLayout takes an “eldest child wins” approach towards allocating space. So, if we have a LinearLayout with three children, the first child will get its requested space. The second child will get its requested space, if there is enough room remaining, and likewise for the third child. So if the first child asks for all the space (e.g., this is a horizontal LinearLayout and the first child has `android:layout_width="match_parent"`), the second and third children will wind up with zero width.

Weight

But, what happens if we have two or more widgets that should split the available free space? For example, suppose we have two multi-line fields in a column, and we want them to take up the remaining space in the column after all other widgets have been allocated their space.

To make this work, in addition to setting `android:layout_width` (for rows) or `android:layout_height` (for columns), you must also set `android:layout_weight`. This property indicates what proportion of the free space should go to that widget. If you set `android:layout_weight` to be the same non-zero value for a pair of widgets (e.g., 1), the free space will be split evenly between them. If you set it to be 1 for one widget and 2 for another widget, the second widget will use up twice the free space that the first widget does. And so on.

The weight for a widget is zero by default.

Another pattern for using weights is if you want to allocate sizes on a percentage basis. To use this technique for, say, a horizontal layout:

1. Set all the `android:layout_width` values to be 0 for the widgets in the layout
2. Set the `android:layout_weight` values to be the desired percentage size for each widget in the layout
3. Make sure all those weights add up to 100

If you want to have space left over, not allocated to any widget, you can add an `android:weightSum` attribute to the LinearLayout, and ensure that the sum of the `android:layout_weight` attributes of the children are less than that sum. The children will each get space allocated based upon the ratio of their `android:layout_weight` compared to the `android:weightSum`, not compared to the sum of the weights. And there will be empty space that takes up the rest of the room not allocated to the children.

To see `android:layout_weight` in action, take a look at the [Containers/LinearPercent](#) sample project. Here, we have a `res/layout/main.xml` file containing a vertical `LinearLayout` with three `Button` widgets as children:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="50"
        android:text="@string/fifty_percent"/>

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="30"
        android:text="@string/thirty_percent"/>

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="20"
        android:text="@string/twenty_percent"/>

</LinearLayout>
```

Each of the three `Button` widgets declares its height to be `0dip`. However, each also has an `android:layout_weight` attribute, with the top `Button` requesting a weight of 50, the middle `Button` a weight of 30, and the bottom `Button` a weight of 20.

The result is that the `Button` widgets' heights are allocated based solely upon those weights:

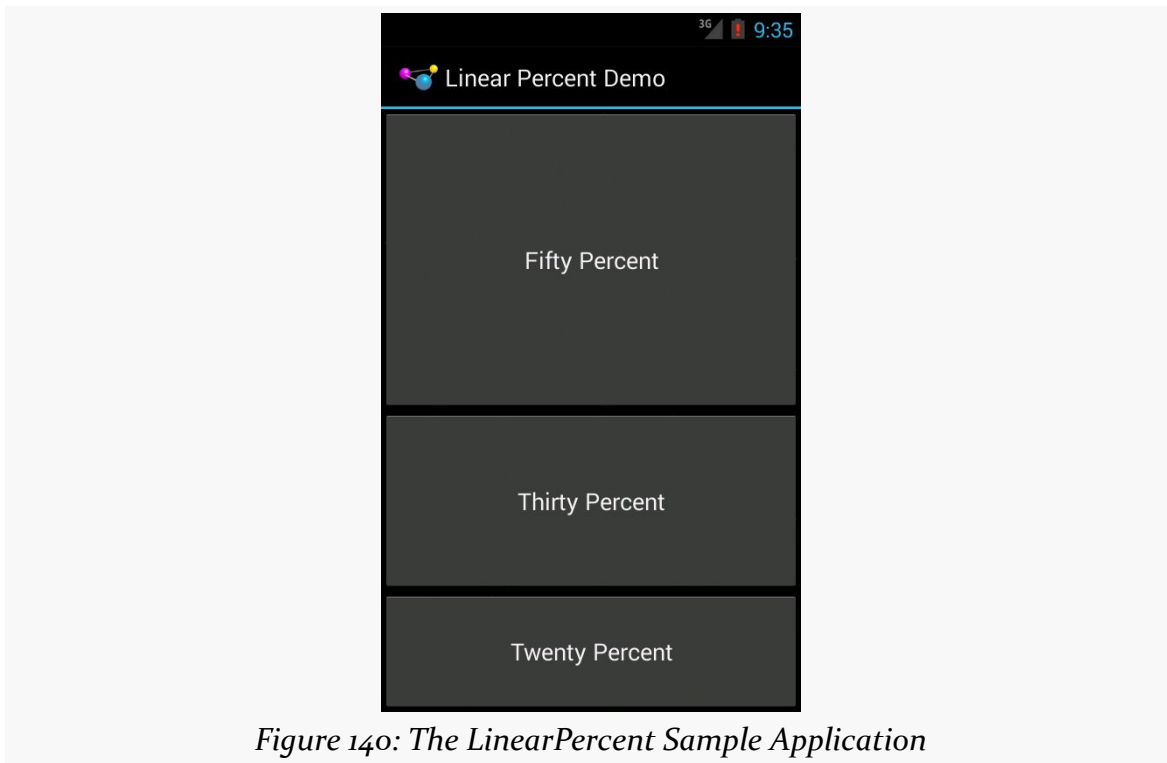

Figure 140: The LinearPercent Sample Application

Gravity

By default, everything in a `LinearLayout` is left- and top-aligned. So, if you create a row of widgets via a horizontal `LinearLayout`, the row will start flush on the left side of the screen.

If that is not what you want, you need to specify a gravity. Unlike the physical world, Android has two types of gravity: the gravity of a widget within a `LinearLayout`, and the gravity of the contents of a widget or container.

The `android:gravity` property of some widgets and containers — which also can be defined via `setGravity()` in Java — tells Android to slide the contents of the widget or container in a particular direction. For example, `android:gravity="right"` says to slide the contents of the widget to the right; `android:gravity="right|bottom"` says to slide the contents of the widget to the right and the bottom.

Here, “contents” varies. `TextView` supports `android:gravity`, and the “contents” is the text held within the `TextView`. `LinearLayout` supports `android:gravity`, and the “contents” are the widgets inside the container. And so on.

Children of a `LinearLayout` also have the option of specifying `android:layout_gravity`. Here, the child is telling the `LinearLayout` “if there is room, please slide me (and me alone) in this direction”. However, this only works in the direction *opposite* the orientation of the `LinearLayout` – the children of a vertical `LinearLayout` can use `android:layout_gravity` to control their positioning horizontally (left or right), but not vertically.

For a row of widgets, the default is for them to be aligned so their texts are aligned on the baseline (the invisible line that letters seem to “sit on”), though you may wish to specify a gravity of `center_vertical` to center the widgets along the row’s vertical midpoint.

Android Studio Graphical Layout Editor

The `LinearLayout` container can be found in the “Layouts” portion of the Palette of the Android Studio graphical layout editor:

Figure 141: Layouts Palette in Android Studio Graphical Layout Editor

You can drag either the “`LinearLayout (Vertical)`” or “`LinearLayout (Horizontal)`” into a layout XML resource, then start dragging in children to go into the container.

When your `LinearLayout` is the selected widget, a few new toolbar buttons will appear over the preview:

Figure 142: LinearLayout Toolbar Buttons

LINEARLAYOUT AND THE BOX MODEL

The left two buttons toggle the width and height between `match_parent` and `wrap_content`, while the third button changes the gravity of the `LinearLayout`.

When one of the *children* of the `LinearLayout` is the selected widget, the toolbar changes:

Figure 143: LinearLayout Toolbar Buttons, For Selected Child

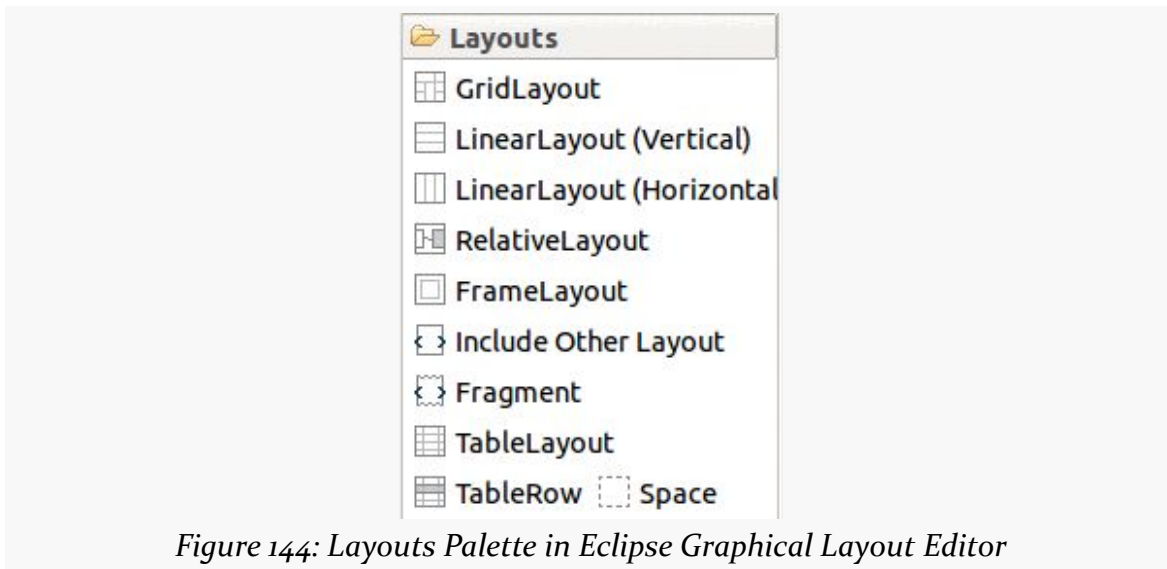

From left to right, the buttons:

- Toggle the parent `LinearLayout` between horizontal and vertical orientations
- Align the child widgets' baselines (where a "baseline" is the invisible line that text appears to sit upon)
- Change the `android:layout_gravity` value for the child
- Toggle the width between `match_parent` and `wrap_content`
- Toggle the height between `match_parent` and `wrap_content`
- Distribute the weights of the selected children evenly
- Assign this widget all of the weight, at the expense of other children of the `LinearLayout`
- Set the weight to a specific value
- Clear the weights from the children

The Properties pane for the selected widget also allows you to get to the `LinearLayout` container to make adjustments to its attributes.

Eclipse Graphical Layout Editor

The `LinearLayout` container can be found in the "Layouts" portion of the Palette of the Eclipse graphical layout editor:

You can drag either the “LinearLayout (Vertical)” or “LinearLayout (Horizontal)” into a layout XML resource, then start dragging in children to go into the container.

When your LinearLayout is the selected widget, a toolbar will appear over the preview:

The left two buttons toggle your LinearLayout between vertical and horizontal modes. The two immediately to the right of the divider toggle the width and height between match_parent and wrap_content.

When one of the *children* of the LinearLayout is the selected widget, the toolbar changes:

The left two buttons still toggle the orientation of the LinearLayout. The width and height buttons to their right toggle the width and height of the selected widget.

The right-most six buttons, from left to right, allow you to:

LINEARLAYOUT AND THE BOX MODEL

- Change the margins on the selected widget
- Change the gravity of the selected widget
- Give all widgets in the `LinearLayout` equal weight
- Give the selected widget all the weight
- Manually assign the weight to the selected widget
- Clear all weights from all widgets in the `LinearLayout`

The Properties pane for the selected widget also allows you to get to the `LinearLayout` container to make adjustments to its attributes.

Other Common Widgets and Containers

In [the chapter on basic widgets](#), we left out all of the classic “two-state” widgets, such as checkboxes and radio buttons. We will examine those and other related widgets in this chapter.

Beyond `LinearLayout`, Android supports a range of containers providing different layout rules. In this chapter, we will look at two other commonly-used containers: `RelativeLayout` (a rule-based model) and `TableLayout` (the grid model), along with `ScrollView` and `HorizontalScrollView`, containers that allow their contents to scroll. We will examine all of these containers in this chapter as well.

Just a Box to Check

The classic checkbox has two states: checked and unchecked. Clicking the checkbox toggles between those states to indicate a choice (e.g., “Add rush delivery to my order”).

In Android, there is a `CheckBox` widget to meet this need. It has `TextView` as an ancestor, so you can use `TextView` properties like `android:textColor` to format the widget.

Within Java, you can invoke:

1. `isChecked()` to determine if the checkbox has been checked
2. `setChecked()` to force the checkbox into a checked or unchecked state
3. `toggle()` to toggle the checkbox as if the user clicked upon it

OTHER COMMON WIDGETS AND CONTAINERS

Also, you can register a listener object (in this case, an instance of `OnCheckedChangeListener`) to be notified when the state of the checkbox changes.

For example, from [the Basic/CheckBox sample project](#), here is a simple checkbox layout:

```
<?xml version="1.0" encoding="utf-8"?>
<CheckBox xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/check"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/unchecked"/>
```

The corresponding `CheckBoxDemo.java` retrieves and configures the behavior of the checkbox:

```
package com.commonware.android.checkbox;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CheckBox;
import android.widget.CompoundButton;

public class CheckBoxDemo extends Activity implements
    CompoundButton.OnCheckedChangeListener {
    CheckBox cb;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        cb=(CheckBox)findViewById(R.id.check);
        cb.setOnCheckedChangeListener(this);
    }

    public void onCheckedChanged(CompoundButton buttonView,
        boolean isChecked) {
        if (isChecked) {
            cb.setText(R.string.checked);
        }
        else {
            cb.setText(R.string.unchecked);
        }
    }
}
```

Note that the activity serves as its own listener for checkbox state changes since it implements the `OnCheckedChangeListener` interface (set via `cb.setOnCheckedChangeListener(this)`). The callback for the listener is

OTHER COMMON WIDGETS AND CONTAINERS

`onCheckedChanged()`, which receives the checkbox whose state has changed and what the new state is. In this case, we update the text of the checkbox to reflect what the actual box contains.

The result? Clicking the checkbox immediately updates its text, as shown below:

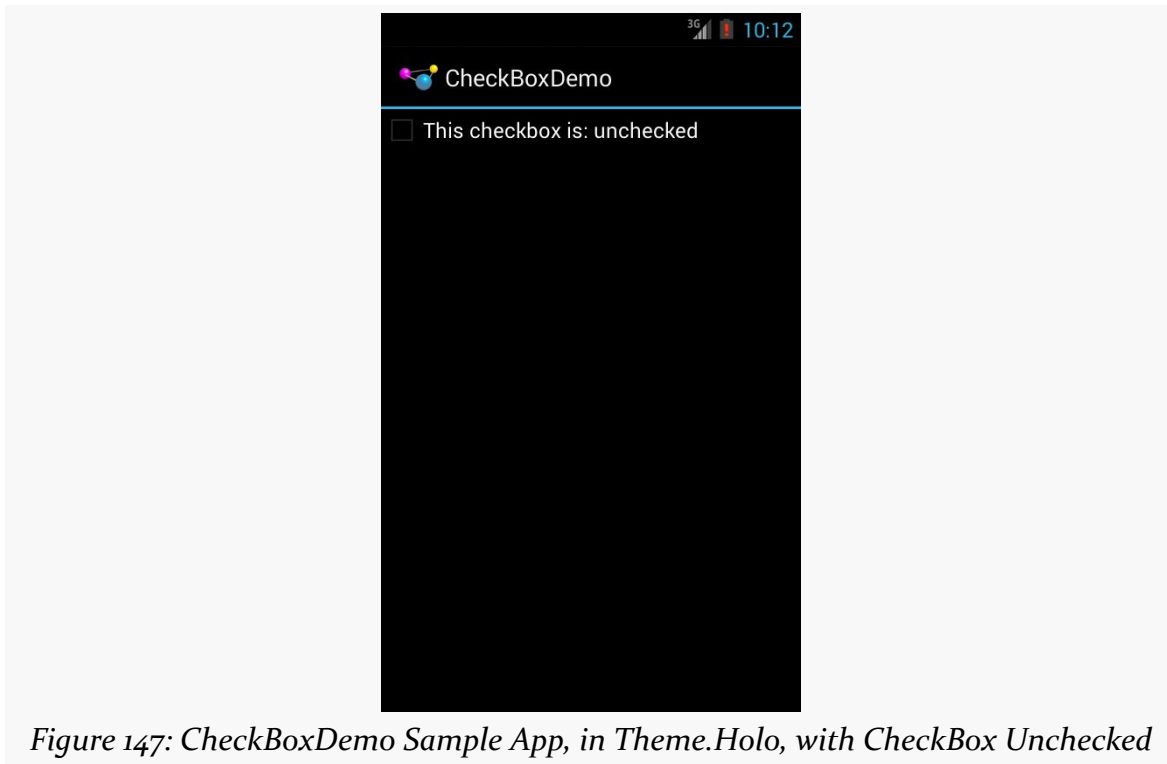

Figure 147: CheckBoxDemo Sample App, in Theme.Holo, with CheckBox Unchecked

Figure 148: CheckBoxDemo Sample App, in Theme.Holo, with CheckBox Checked

Figure 149: CheckBoxDemo Sample App, in Theme, with CheckBox Checked

Figure 150: CheckBoxDemo Sample App, in Theme.Material, with CheckBox Checked

Android Studio Graphical Layout Editor

The CheckBox widget can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor:

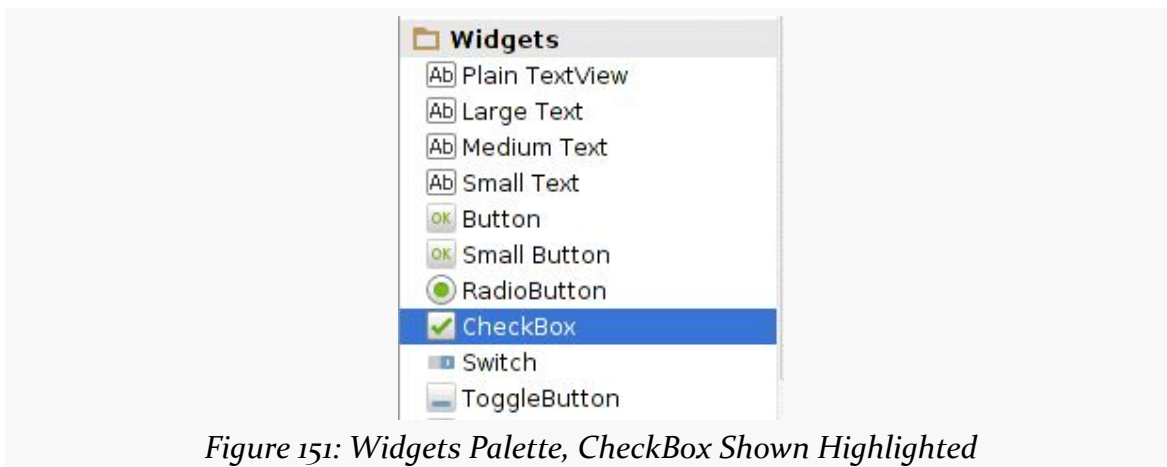

Figure 151: Widgets Palette, CheckBox Shown Highlighted

You can drag it into the layout and configure it as desired using the Properties pane. As `CheckBox` inherits from `TextView`, most of the settings are the same as those you would find on a regular `TextView`.

Eclipse Graphical Layout Editor

The `CheckBox` widget appears in the “Form Widgets” section of the Palette in the Graphical Layout editor. You can drag it into the layout and configure it as desired using the Properties pane. As `CheckBox` inherits from `TextView`, most of the settings are the same as those you would find on a regular `TextView`.

Don’t Like Checkboxes? How About Toggles or Switches?

A similar widget to `CheckBox` is `ToggleButton`. Like `CheckBox`, `ToggleButton` is a two-state widget that is either checked or unchecked. However, `ToggleButton` has a distinct visual appearance:

Figure 152: ToggleButtonDemo Sample, Unchecked, in Theme.Holo

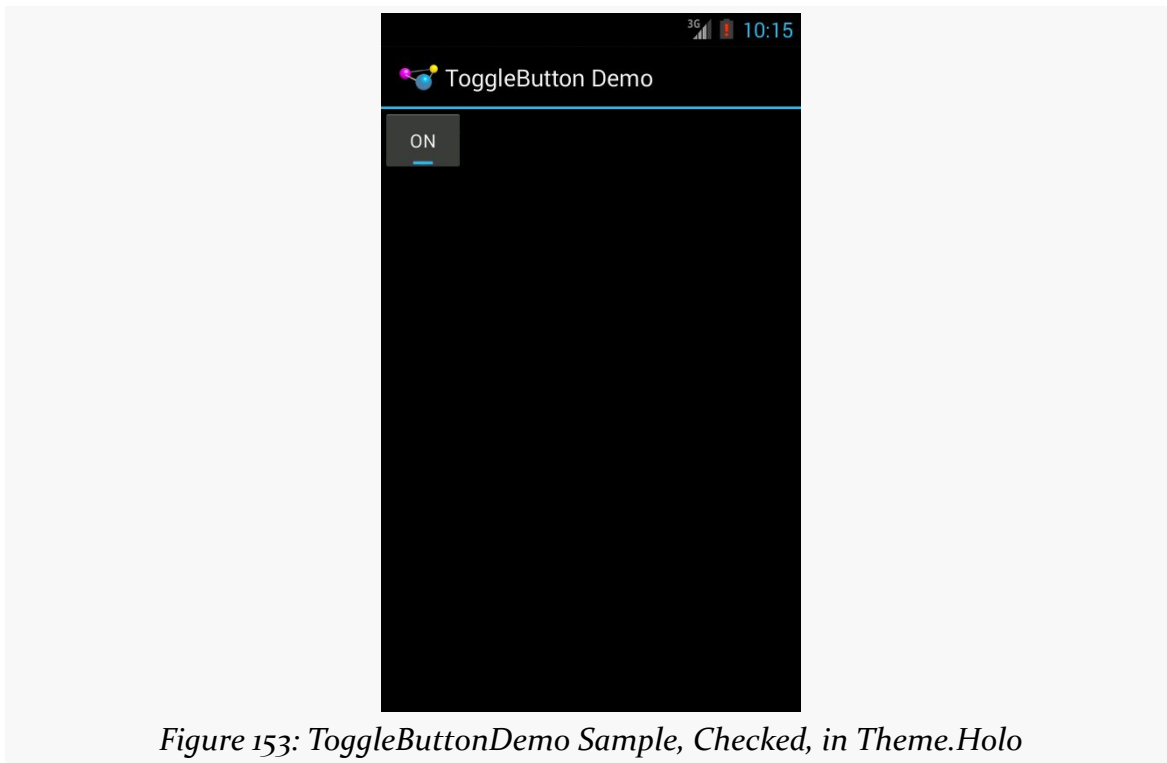

Figure 153: *ToggleButtonDemo Sample, Checked, in Theme.Holo*

Otherwise, `ToggleButton` behaves much like `CheckBox`. You can put it in a layout file, as seen in [the Basic/ToggleButton sample](#):

```
<?xml version="1.0" encoding="utf-8"?>
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

You can also set up an `OnCheckedChangeListener` to be notified when the user changes the state of the `ToggleButton`.

Similarly, Android has a `Switch` widget, showing the state via a small “ON/OFF” slider:

Figure 154: SwitchDemo Sample, Unchecked, in Theme.Holo

Figure 155: SwitchDemo Sample, Checked, in Theme.Holo

Figure 156: SwitchDemo Sample, Unchecked, in Theme.Material

Figure 157: SwitchDemo Sample, Checked, in Theme.Material

OTHER COMMON WIDGETS AND CONTAINERS

Switch, like CheckBox and ToggleButton, inherits from CompoundButton, and therefore shares a common API, for methods like `toggle()`, `isChecked()`, and `setChecked()`. And, as with the others, you can put it in a layout file, as seen in [the Basic/Switch sample](#):

```
<?xml version="1.0" encoding="utf-8"?>
<Switch xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

The biggest limitation with Switch is that it was only added to the Android SDK in API Level 14. If your `minSdkVersion` is set to 14 or higher, you are welcome to use Switch. If your `minSdkVersion` is set to something lower than 14, though, you will either need to choose something else or get into more complicated scenarios, like using a library that offers a backport of Switch. We will cover those more complicated scenarios later in the book; for now, it is simplest to only use Switch if your `minSdkVersion` is set to 14 or higher.

Android Studio Graphical Layout Editor

The ToggleButton and Switch widgets can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor, just beneath the CheckBox widget:

Figure 158: Widgets Palette, ToggleButton and Switch At Bottom

You can drag either widget into the layout and configure it as desired using the Properties pane.

Eclipse Graphical Layout Editor

Like `CheckBox`, the `ToggleButton` and `Switch` widgets appear in the “Form Widgets” section of the Palette in the Graphical Layout editor. You can drag either widget into the layout and configure it as desired using the Properties pane.

Turn the Radio Up

As with other implementations of radio buttons in other toolkits, Android’s radio buttons are two-state, like checkboxes, but can be grouped such that only one radio button in the group can be checked at any time.

`CheckBox`, `ToggleButton`, `Switch`, and `RadioButton` all inherit from `CompoundButton`, which in turn inherits from `TextView`. Hence, all the standard `TextView` properties for font face, style, color, etc. are available for controlling the look of radio buttons. Similarly, you can call `isChecked()` on a `RadioButton` to see if it is selected, `toggle()` to change its checked state, and so on, like you can with a `CheckBox`.

Most times, you will want to put your `RadioButton` widgets inside of a `RadioGroup`. The `RadioGroup` is a `LinearLayout` that indicates a set of radio buttons whose state is tied, meaning only one button out of the group can be selected at any time. If you assign an `android:id` to your `RadioGroup` in your XML layout, you can access the group from your Java code and invoke:

1. `check()` to check a specific radio button via its ID (e.g., `group.check(R.id.radio1)`)
2. `clearCheck()` to clear all radio buttons, so none in the group are checked
3. `getCheckedRadioButtonId()` to get the ID of the currently-checked radio button (or `-1` if none are checked)

Note that the mutual-exclusion feature of `RadioGroup` only applies to `RadioButton` widgets that are immediate children of the `RadioGroup`. You cannot have other containers between the `RadioGroup` and its `RadioButton` widgets.

For example, from [the Basic/RadioButton sample application](#), here is an XML layout showing a `RadioGroup` wrapping a set of `RadioButton` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RadioGroup
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
```

OTHER COMMON WIDGETS AND CONTAINERS

```
android:layout_width="match_parent"
android:layout_height="match_parent"
>
<RadioButton android:id="@+id/radio1"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/rock" />

<RadioButton android:id="@+id/radio2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/scissors" />

<RadioButton android:id="@+id/radio3"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/paper" />
</RadioGroup>
```

Using the stock Android-generated Java for the project and this layout, you get:

Figure 159: RadioButtonDemo, with “Scissors” Checked, in Theme

Figure 160: RadioButtonDemo, with “Scissors” Checked, in Theme.Holo

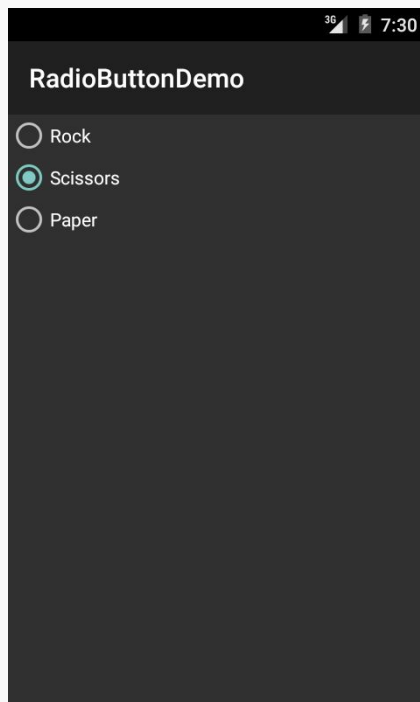

Figure 161: RadioButtonDemo, with “Scissors” Checked, in Theme.Material

Note that the radio button group is initially set to be completely unchecked at the outset. To preset one of the radio buttons to be checked, use either `setChecked()` on the `RadioButton` or `check()` on the `RadioGroup` from within your `onCreate()` callback in your activity. Alternatively, you can use the `android:checked` attribute on one of the `RadioButton` widgets in the layout file.

Android Studio Graphical Layout Editor

The `RadioGroup` container can be found in the “Containers” portion of the Palette in the Android Studio Graphical Layout editor:

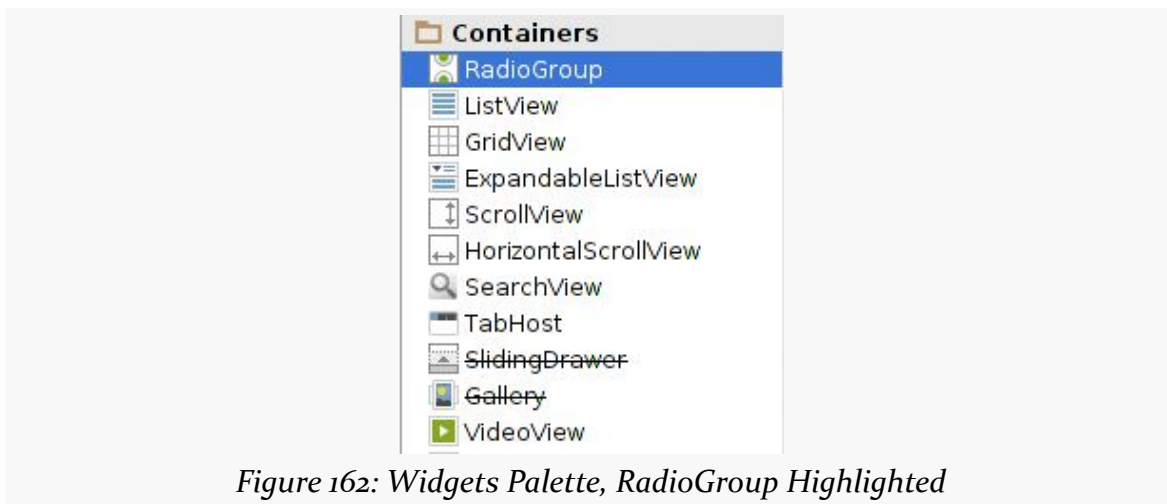

Figure 162: Widgets Palette, RadioGroup Highlighted

Dragging a `RadioGroup` into the preview works much like dragging a `LinearLayout` into the preview. You get a box into which you can drag other widgets, such as the `RadioButton` found in the “Widgets” section of the Palette.

Eclipse Graphical Layout Editor

Both `RadioButton` and `RadioGroup` appear in the “Form Widgets” section of the Palette in the Graphical Layout editor. The `RadioButton` widget has a radio button with the text “`RadioButton`” to the right. The `RadioGroup` widget looks like three radio buttons (sans text) side-by-side.

Since `RadioGroup` extends `LinearLayout`, when you drag it into the layout, you will get the same sorts of options as a vertical `LinearLayout`, such as setting the gravity. Note, though, that dragging a `RadioGroup` into a layout automatically gives you three

RadioButton child widgets — a departure from any other container in the Palette. You can configure those RadioButton widgets, delete them, add more, etc.

All Things Are Relative

RelativeLayout, as the name suggests, lays out widgets based upon their relationship to other widgets in the container and the parent container. You can place Widget X below and to the left of Widget Y, or have Widget Z's bottom edge align with the bottom of the container, and so on.

Concepts and Properties

To make all this work, we need ways to reference other widgets within an XML layout file, plus ways to indicate the relative positions of those widgets.

Positions Relative to Container

The easiest relations to set up are tying a widget's position to that of its container:

1. `android:layout_alignParentTop` says the widget's top should align with the top of the container
2. `android:layout_alignParentBottom` says the widget's bottom should align with the bottom of the container
3. `android:layout_alignParentLeft` says the widget's left side should align with the left side of the container
4. `android:layout_alignParentRight` says the widget's right side should align with the right side of the container
5. `android:layout_centerHorizontal` says the widget should be positioned horizontally at the center of the container
6. `android:layout_centerVertical` says the widget should be positioned vertically at the center of the container
7. `android:layout_centerInParent` says the widget should be positioned both horizontally and vertically at the center of the container

All of these properties take a simple boolean value (true or false).

Note that the padding of the widget is taken into account when performing these various alignments. The alignments are based on the widget's overall cell (combination of its natural space plus the padding).

Relative Notation in Properties

The remaining properties of relevance to `RelativeLayout` take as a value the identity of a widget in the container. To do this:

- Put identifiers (`android:id` attributes) on all elements that you will need to address
- Reference other widgets using the same identifier value

The first occurrence of an id value should have the plus sign (`@+id/widget_a`); the second and subsequent times that id value is used in the layout file should drop the plus sign (`@id/widget_a`). This allows the build tools to better help you catch typos in your widget id values — if you do not have a plus sign for a widget id value that has not been seen before, that will be caught at compile time.

For example, if Widget A appears in the `RelativeLayout` before Widget B, and Widget A is identified as `@+id/widget_a`, Widget B can refer to Widget A in one of its own properties via the identifier `@id/widget_a`.

Positions Relative to Other Widgets

There are four properties that control position of a widget *vis-à-vis* other widgets:

1. `android:layout_above` indicates that the widget should be placed above the widget referenced in the property
2. `android:layout_below` indicates that the widget should be placed below the widget referenced in the property
3. `android:layout_toLeftOf` indicates that the widget should be placed to the left of the widget referenced in the property
4. `android:layout_toRightOf` indicates that the widget should be placed to the right of the widget referenced in the property

Beyond those four, there are five additional properties that can control one widget's alignment relative to another:

1. `android:layout_alignTop` indicates that the widget's top should be aligned with the top of the widget referenced in the property
2. `android:layout_alignBottom` indicates that the widget's bottom should be aligned with the bottom of the widget referenced in the property
3. `android:layout_alignLeft` indicates that the widget's left should be aligned with the left of the widget referenced in the property

4. `android:layout_alignRight` indicates that the widget's right should be aligned with the right of the widget referenced in the property
5. `android:layout_alignBaseline` indicates that the baselines of the two widgets should be aligned (where the "baseline" is that invisible line that text appears to sit on)

The last one is useful for aligning labels and fields so that the text appears "natural". Since fields have a box around them and labels do not, `android:layout_alignTop` would align the top of the field's box with the top of the label, which will cause the text of the label to be higher on-screen than the text entered into the field.

So, if we want Widget B to be positioned to the right of Widget A, in the XML element for Widget B, we need to include `android:layout_toRightOf = "@id/widget_a"` (assuming `@id/widget_a` is the identity of Widget A).

Example

With all that in mind, let's examine a typical "form" with a field, a label, plus a pair of buttons labeled "OK" and "Cancel".

Here is the XML layout, pulled from [the Containers/Relative sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignBaseline="@+id/entry"
        android:layout_alignParentLeft="true"
        android:layout_marginLeft="4dip"
        android:text="@string/url"/>

    <EditText
        android:id="@+id/entry"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_alignParentTop="true"
        android:layout_toRightOf="@id/label"
        android:inputType="text"/>

    <Button
        android:id="@+id/ok"
```

```
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignRight="@id/entry"
        android:layout_below="@id/entry"
        android:text="@string/ok" />

<Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/ok"
    android:layout_toLeftOf="@id/ok"
    android:text="@string/cancel" />

</RelativeLayout>
```

First, we open up the `RelativeLayout`. In this case, we want to use the full width of the screen (`android:layout_width = "match_parent"`) and only as much height as we need (`android:layout_height = "wrap_content"`).

Next, we define the label as a `TextView`. We indicate that we want its left edge aligned with the left edge of the `RelativeLayout` (`android:layout_alignParentLeft="true"`) and that we want its baseline aligned with the baseline of the yet-to-be-defined `EditText`. Since the `EditText` has not been declared yet, we use the + sign in the ID (`android:layout_alignBaseline="@+id/entry"`).

After that, we add in the field as an `EditText`. We want the field to be to the right of the label, have the field be aligned with the top of the `RelativeLayout`, and for the field to take up the rest of this “row” in the layout. Those are handled by three properties:

1. `android:layout_toRightOf = "@id/label"`
2. `android:layout_alignParentTop = "true"`
3. `android:layout_width = "match_parent"`

Then, the OK button is set to be below the field (`android:layout_below = "@id/entry"`) and have its right side align with the right side of the field (`android:layout_alignRight = "@id/entry"`). The Cancel button is set to be to the left of the OK button (`android:layout_toLeft = "@id/ok"`) and have its top aligned with the OK button (`android:layout_alignTop = "@id/ok"`).

With no changes to the auto-generated Java code, the emulator gives us:

Figure 163: The RelativeLayoutDemo sample application

Overlap

RelativeLayout also has a feature that LinearLayout lacks — the ability to have widgets overlap one another. Later children of a RelativeLayout are “higher in the Z axis” than are earlier children, meaning that later children will overlap earlier children if they are set up to occupy the same space in the layout.

This will be clearer with an example. Here is a layout, [from the Containers/RelativeOverlap sample](#), with a RelativeLayout holding two Button widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:text="@string/big"
        android:textSize="120dip"
        android:textStyle="bold"/>

    <Button
```

```
android:layout_width="wrap_content"  
android:layout_height="wrap_content"  
android:layout_centerInParent="true"  
android:text="@string/small"/>
```

```
</RelativeLayout>
```

The first Button is set to fill the screen. The second Button is set to be centered inside the parent, but only take up as much space as is needed for its caption. Hence, the second Button will appear to “float” over the first Button:

Figure 164: The RelativeLayout sample application

Both Button widgets can still be clicked, though clicking on the smaller Button does not also click the bigger Button. Your clicks will be handled by the widget on top in the case of an overlap like this.

Android Studio Graphical Layout Editor

You will find RelativeLayout in the “Layouts” section of the Palette in the Android Studio Graphical Layout editor. You can drag that into your layout XML resource.

Figure 165: Layouts Section of Palette, RelativeLayout Highlighted

As you drag other widgets into your RelativeLayout, you will see a popup indicator of the RelativeLayout rules that will be applied if you were to drop the widget at the current mouse pointer position:

Figure 166: Dragging a Widget in a RelativeLayout

Getting the rules that you *want* may or may not be possible purely through drag-and-drop. You may need to just drop the widget into the RelativeLayout and manually adjust the rules, whether by using the Properties pane or by editing the XML directly.

NOTE: There is [a bug in the layout editor](#) that renders the `RelativeLayout` incorrectly on Android Studio, if your preview is set to API Level 21. If you drop the preview to API Level 19, the `RelativeLayout` renders correctly. And, running the app on a device shows that the `RelativeLayout` renders correctly, even on Android 5.0.

Eclipse Graphical Layout Editor

You will find `RelativeLayout` in the “Layouts” section of the Palette in the Eclipse Graphical Layout editor. You can drag that into your layout XML resource.

As with Android Studio, when you drag a widget into a `RelativeLayout`, a popup will indicate the `RelativeLayout` rules that will be applied if you drop the widget at the current location. Sometimes, you cannot get the rules that you really want, forcing you to modify the `RelativeLayout` XML directly via the other editor sub-tab or via the Properties pane to get it set up properly.

Tabula Rasa

If you like HTML tables, you will like Android’s `TableLayout`. It allows you to position your widgets in a grid to your specifications. You control the number of rows and columns, which columns might shrink or stretch to accommodate their contents, and so on.

`TableLayout` works in conjunction with `TableRow`. `TableLayout` controls the overall behavior of the container, with the widgets themselves poured into one or more `TableRow` containers, one per row in the grid.

Concepts and Properties

For all this to work, we need to figure out how widgets work with rows and columns, plus how to handle widgets that live outside of rows.

Putting Cells in Rows

Rows are declared by you, the developer, by putting widgets as children of a `TableRow` inside the overall `TableLayout`. You, therefore, control directly how many rows appear in the table.

The number of columns are determined by Android; you control the number of columns in an indirect fashion.

First, there will be at least one column per widget in your longest row. So if you have three rows, one with two widgets, one with three widgets, and one with four widgets, there will be at least four columns.

However, a widget can take up more than one column by including the `android:layout_span` property, indicating the number of columns the widget spans. This is akin to the `colspan` attribute one finds in table cells in HTML:

```
<TableRow>
  <TextView android:text="URL:" />
  <EditText
    android:id="@+id/entry"
    android:layout_span="3"/>
</TableRow>
```

In the above XML layout fragment, the field spans three columns.

Ordinarily, widgets are put into the first available column. In the above fragment, the label would go in the first column (column 0, as columns are counted starting from 0), and the field would go into a spanned set of three columns (columns 1 through 3). However, you can put a widget into a different column via the `android:layout_column` property, specifying the 0-based column the widget belongs to:

```
<TableRow>
  <Button
    android:id="@+id/cancel"
    android:layout_column="2"
    android:text="Cancel" />
  <Button android:id="@+id/ok" android:text="OK" />
</TableRow>
```

In the preceding XML layout fragment, the Cancel button goes in the third column (column 2). The OK button then goes into the next available column, which is the fourth column.

Non-Row Children of TableLayout

Normally, `TableLayout` contains only `TableRow` elements as immediate children. However, it is possible to put other widgets in between rows. For those widgets, `TableLayout` behaves a bit like `LinearLayout` with vertical orientation. The widgets

automatically have their width set to `match_parent`, so they will fill the same space that the longest row does.

Stretch, Shrink, and Collapse

By default, each column will be sized according to the “natural” size of the widest widget in that column (taking spanned columns into account). Sometimes, though, that does not work out very well, and you need more control over column behavior.

You can place an `android:stretchColumns` property on the `TableLayout`. The value should be a single column number (again, 0-based) or a comma-delimited list of column numbers. Those columns will be stretched to take up any available space yet on the row. This helps if your content is narrower than the available space.

Conversely, you can place an `android:shrinkColumns` property on the `TableLayout`. Again, this should be a single column number or a comma-delimited list of column numbers. The columns listed in this property will try to word-wrap their contents to reduce the effective width of the column — by default, widgets are not word-wrapped. This helps if you have columns with potentially wordy content that might cause some columns to be pushed off the right side of the screen.

You can also leverage an `android:collapseColumns` property on the `TableLayout`, again with a column number or comma-delimited list of column numbers. These columns will start out “collapsed”, meaning they will be part of the table information but will be invisible. Programmatically, you can collapse and un-collapse columns by calling `setColumnCollapsed()` on the `TableLayout`. You might use this to allow users to control which columns are of importance to them and should be shown versus which ones are less important and can be hidden.

You can also control stretching and shrinking at runtime via `setColumnStretchable()` and `setColumnShrinkable()`.

Example

The XML layout fragments shown above, when combined, give us a `TableLayout` rendition of the “form” we created for `RelativeLayout`, with the addition of a divider line between the label/field and the two buttons (found in [the Containers/Table demo](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">

    <TableRow>

        <TextView
            android:layout_marginLeft="4dip"
            android:text="@string/url"/>

        <EditText
            android:id="@+id/entry"
            android:layout_span="3"
            android:inputType="text"/>
    </TableRow>

    <View
        android:layout_height="2dip"
        android:background="#0000FF"/>

    <TableRow>

        <Button
            android:id="@+id/cancel"
            android:layout_column="2"
            android:text="@string/cancel"/>

        <Button
            android:id="@+id/ok"
            android:text="@string/ok"/>
    </TableRow>
</TableLayout>
```

When compiled against the generated Java code and run on the emulator, we get:

Figure 167: The TableLayoutDemo sample application

Android Studio Graphical Layout Editor

You will find TableLayout in the “Layouts” section of the Palette in the Android Studio Graphical Layout editor. You can drag that into your layout XML resource.

Figure 168: Layouts Section of Palette, TableLayout Highlighted

You might expect that you would then drag in TableRow containers as needed for your rows, then drag widgets into the TableRow containers. That’s not how Android Studio chose to implement the TableLayout drag-and-drop support.

OTHER COMMON WIDGETS AND CONTAINERS

Instead, you drag widgets directly into the `TableLayout`, which will switch to a “grid mode”, allowing you to indicate where in a table you want this widget to reside as a cell:

Figure 169: TableLayout Drag-and-Drop in Android Studio

Dropping the widget in a given cell position will:

- Add any necessary `TableRow` widgets, both for the row you requested and any prior rows that were not already set up, and
- Add the widget into the `TableRow`, with an `android:layout_column` value if needed to put the widget into the desired column in that row

For example, if you start with an empty `TableLayout`, then drag a `CheckBox` into “row 2, column 2”, you wind up with the following layout XML:

```
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:paddingLeft="@dimen/activity_horizontal_margin"
    android:paddingRight="@dimen/activity_horizontal_margin"
    android:paddingTop="@dimen/activity_vertical_margin"
    android:paddingBottom="@dimen/activity_vertical_margin"
```

```
tools:context=".MyActivity">

<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent"></TableRow>

<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent"></TableRow>

<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent">

    <CheckBox
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="New CheckBox"
        android:id="@+id/checkBox2"
        android:layout_column="2" />

</TableRow>
</TableLayout>
```

Three TableRow widgets were added (for rows 0, 1, and 2), and the CheckBox is given android:layout_column="2" to put it in column 2.

Eclipse Graphical Layout Editor

You will find TableLayout in the “Layouts” section of the Palette in the Eclipse Graphical Layout editor. You can drag that into your layout XML resource and start configuring it via the context menu, notably editing the android:stretchColumns and android:shrinkColumns values.

In addition, the toolbar above the layout will now sport an add-row button:

Figure 170: Eclipse Layout Toolbar for TableLayout

Clicking that adds a TableRow child to the TableLayout, though you will not necessarily see a visible change. However, now if you start dragging in other widgets, they will go in that row.

Once you have started to populate the row and can select it, you will get some more toolbar buttons:

Figure 171: Eclipse Layout Toolbar for TableLayout, with Row Selected

The icon immediately to the right of the add-row button will remove the selected row from the table. On the far right side of the toolbar are buttons to allow you to toggle the height and width of the row, plus toggle on and off baseline alignment for the contents of the row (enabled by default).

Scrollwork

Phone screens tend to be small, which requires developers to use some tricks to present a lot of information in the limited available space. One trick for doing this is to use scrolling, so only part of the information is visible at one time, the rest available via scrolling up or down.

ScrollView is a container that provides scrolling for its contents. You can take a layout that might be too big for some screens, wrap it in a ScrollView, and still use your existing layout logic. It just so happens that the user can only see part of your layout at one time, the rest available via scrolling.

For example, here is a ScrollView used in an XML layout file (from [the Containers/Scroll demo](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">
  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="0">
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#000000"/>
      <TextView android:text="#000000"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
```

```
<View
    android:layout_height="80dip"
    android:background="#440000" />
<TextView android:text="#440000"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
    <View
        android:layout_height="80dip"
        android:background="#884400" />
    <TextView android:text="#884400"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
    <View
        android:layout_height="80dip"
        android:background="#aa8844" />
    <TextView android:text="#aa8844"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
    <View
        android:layout_height="80dip"
        android:background="#ffaa88" />
    <TextView android:text="#ffaa88"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
    <View
        android:layout_height="80dip"
        android:background="#ffffaa" />
    <TextView android:text="#ffffaa"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
    <View
        android:layout_height="80dip"
        android:background="#ffffff" />
    <TextView android:text="#ffffff"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
</TableRow>
</TableLayout>
</ScrollView>
```

Without the `ScrollView`, the table would take up at least 560 density-independent pixels (7 rows at 80 dips each, based on the `View` declarations). There may be some devices with screens capable of showing that much information, but many will be

smaller. The `ScrollView` lets us keep the table as-is, but only present part of it at a time.

On the stock Android emulator, when the activity is first viewed, you see:

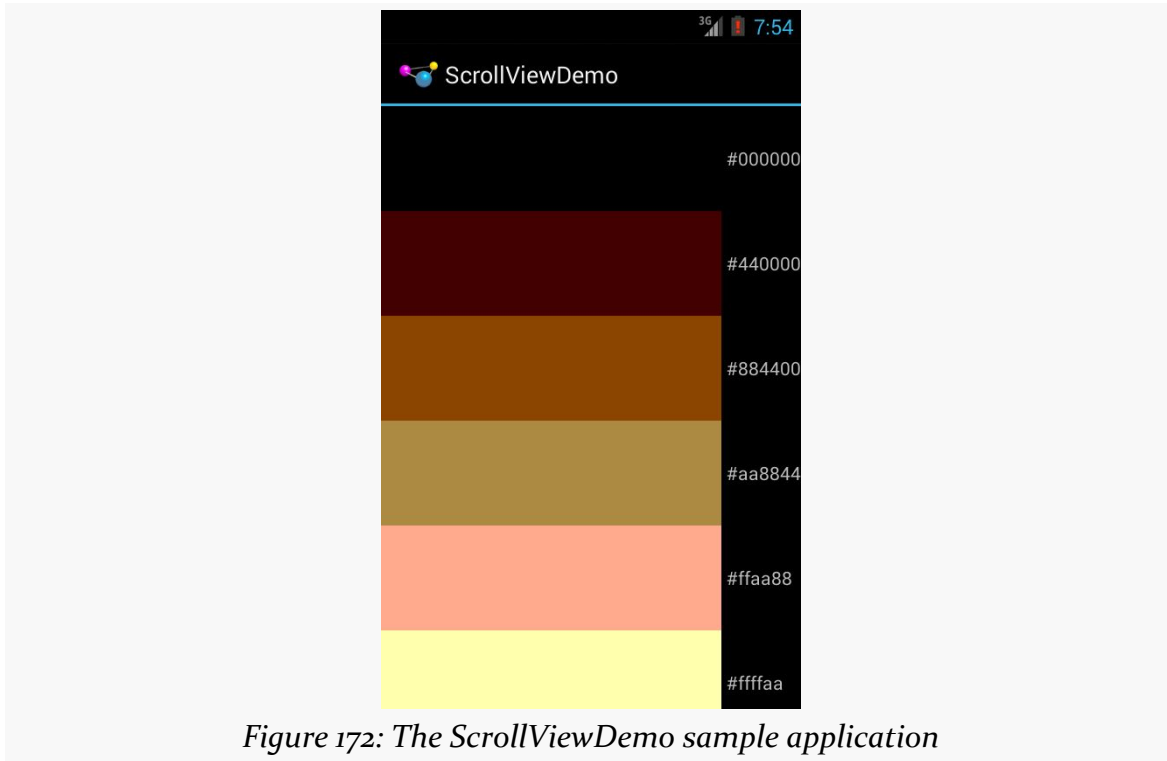

Figure 172: The ScrollViewDemo sample application

Notice how only five rows and part of the sixth are visible. You can scroll up and down to see the remaining rows. Also note how the right side of the content gets clipped by the scrollbar — be sure to put some padding on that side or otherwise ensure your own content does not get clipped in that fashion.

Android also has `HorizontalScrollView`, which works like `ScrollView`... just horizontally. This would be good for forms that might be too wide rather than too tall. Note that `ScrollView` only scrolls vertically and `HorizontalScrollView` only scrolls horizontally.

Also, note that you cannot put scrollable items into a `ScrollView`. For example, a `ListView` widget — which we will see in [an upcoming chapter](#) — already knows how to scroll. You do not need to put a `ListView` in a `ScrollView`, and if you were to try, it would not work very well.

And, a `ScrollView` or `HorizontalScrollView` can only have one child — if you want more than one, wrap the children in a suitable container class (e.g., a `LinearLayout`) and put that inside the `ScrollView` or `HorizontalScrollView`.

Android Studio Graphical Layout Editor

The `ScrollView` and `HorizontalScrollView` widgets appear in the “Containers” section of the Palette in the Graphical Layout editor. You can drag one of these into your layout XML resource, then drag *one* child into it.

Eclipse Graphical Layout Editor

The `ScrollView` and `HorizontalScrollView` widgets appear in the “Composite” section of the Palette in the Graphical Layout editor. You can drag one of these into your layout XML resource, then drag *one* child into it.

Making Progress with ProgressBars

If you are going to fork background threads to do work on behalf of the user, you will want to think about keeping the user informed that work is going on. This is particularly true if the user is effectively waiting for that background work to complete.

The typical approach to keeping users informed of progress is some form of progress bar, like you see when you copy a bunch of files from place to place in many desktop operating systems. Android supports this through the `ProgressBar` widget.

A `ProgressBar` keeps track of progress, defined as an integer, with 0 indicating no progress has been made. You can define the maximum end of the range — what value indicates progress is complete — via `setMax()`. By default, a `ProgressBar` starts with a progress of 0, though you can start from some other position via `setProgress()`.

If you prefer your progress bar to be indeterminate — meaning that it will show a general animated effect, rather than a specific amount of progress — use `setIndeterminate()`, setting it to `true`.

In your Java code, you can either positively set the amount of progress that has been made (via `setProgress()`) or increment the progress from its current amount (via

`incrementProgressBy()`). You can find out how much progress has been made via `getProgress()`.

We will see a `ProgressBar` in action in [the next chapter](#), another one of our tutorials.

Visit the Trails!

The trails portion of the book contains [a widget catalog](#), providing capsule descriptions and samples for a number of widgets not described elsewhere in this book.

You might also be interested in [GridLayout](#), which is an alternative to the classic `LinearLayout`, `RelativeLayout`, and `TableLayout` containers.

Tutorial #5 - Making Progress

When we actually get around to opening the digital book for display, there will be a slight delay as the HTML and other assets are read into memory. To help assure the user that their device has not frozen, we will add a `ProgressBar` to our user interface in this tutorial.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Removing The “Hello, World”

Right now, our user interface consists of a highly-sophisticated “Hello, World” string, shown in a `TextView`. While no doubt it is eligible for many design awards, this is not the user interface we need. So, we need to get rid of it.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Double-click on the `res/layout/main.xml` file. This should bring up the graphical layout editor on your initial layout:

TUTORIAL #5 - MAKING PROGRESS

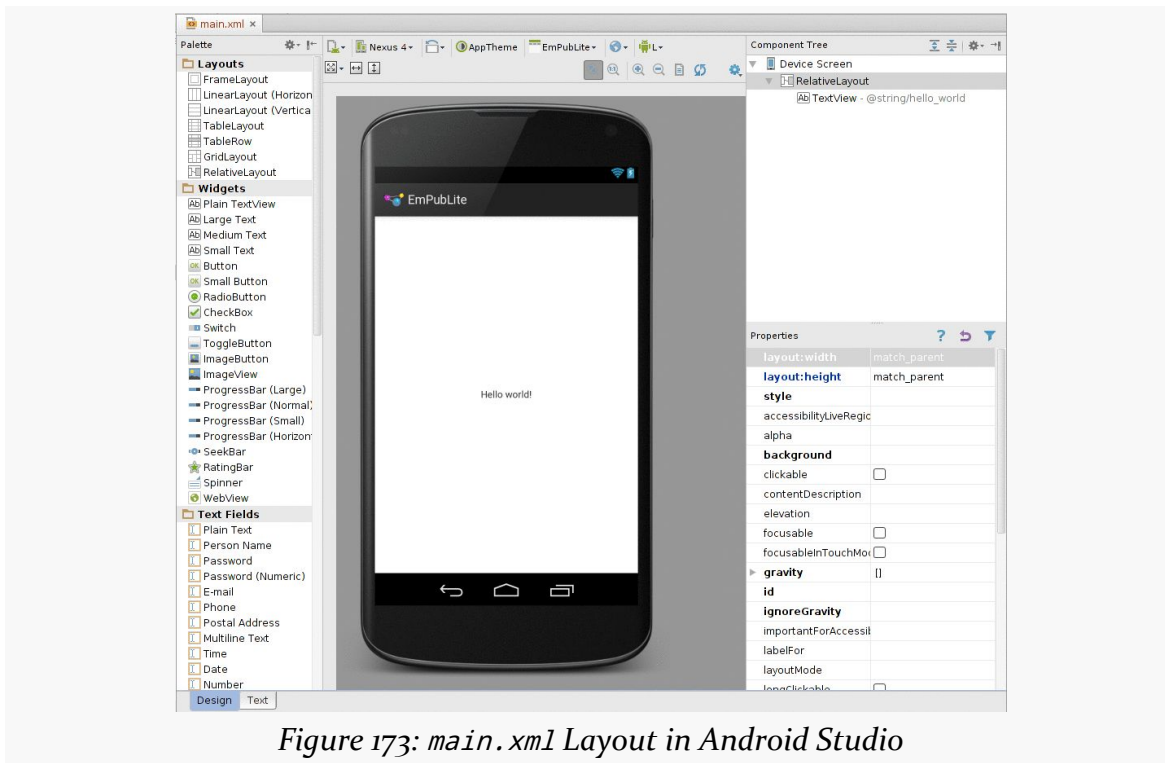

Figure 173: *main.xml* Layout in Android Studio

Click on the “Hello, world!” TextView in the middle of that layout to highlight it, then press the Delete key to delete it. At this point, you can save your file.

Also, we no longer need the `hello_world` string resource. To remove it, open the `res/values/strings.xml` file. Find the `<string>` element that has a name of `hello_world`, delete that element, and save the file.

The resulting XML should resemble:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <string name="app_name">EmPub Lite</string>

</resources>
```

Eclipse

Double-click on the `res/layout/main.xml` file in your project in Eclipse’s Package Explorer. If you do not have such a file, but you have some other layout resource (e.g., `res/layout/activity_main.xml`), rename it to `main.xml` by right-clicking over

TUTORIAL #5 - MAKING PROGRESS

the file in the Package Explorer and choosing Refactor > Rename from the right-mouse menu. Then double-click on the newly-renamed file.

This will bring up our current user interface:

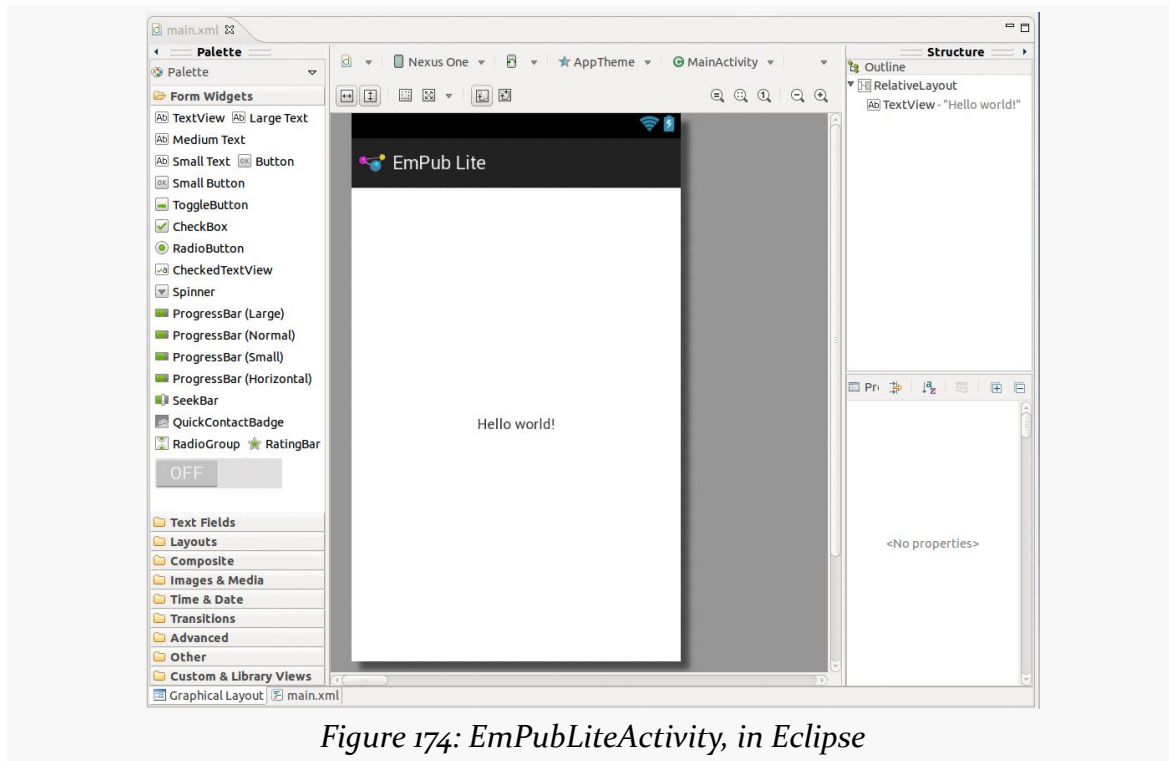

Figure 174: EmPubLiteActivity, in Eclipse

Click on the “Hello World!” string, then press the <Delete> key. You can now save your file (e.g., <Ctrl>-<S>).

Also, we no longer need the hello_world string resource. To remove it, double-click on the res/values/strings.xml file, select the hello_world string resource, click the “Remove...” button, click “Yes” on the confirmation dialog. Then you can save the file.

Step #2: Adding a ProgressBar

Now that the TextView is out of the way, we can add our ProgressBar in its place.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Go back to `res/layout/main.xml` in Android Studio. In the “Widgets” portion of the tool palette, you will see a few `ProgressBar` widget entries:

Drag the “Large” one out of the palette and onto the preview of our activity. You will see a tooltip pointing out the `RelativeLayout` rules that the drag-and-drop operation will apply if you drop the widget in its current location. Slide the `ProgressBar` around until you center it and the tooltip shows that it will use `centerHorizontal` and `centerVertical` rules. If you wind up with `centerInParent` instead of those other two settings, that is fine as well.

In the Properties list on the right, find the “id” row, and change the value for the “id” to `progressBar1` (to match what Eclipse’s drag-and-drop GUI builder uses, to keep the two sets of instructions synchronized).

At this point, you can save your file.

Eclipse

Go back to `res/layout/main.xml` in Eclipse. In the “Form Widgets” portion of the tool palette, you will see a few `ProgressBar` widget entries:

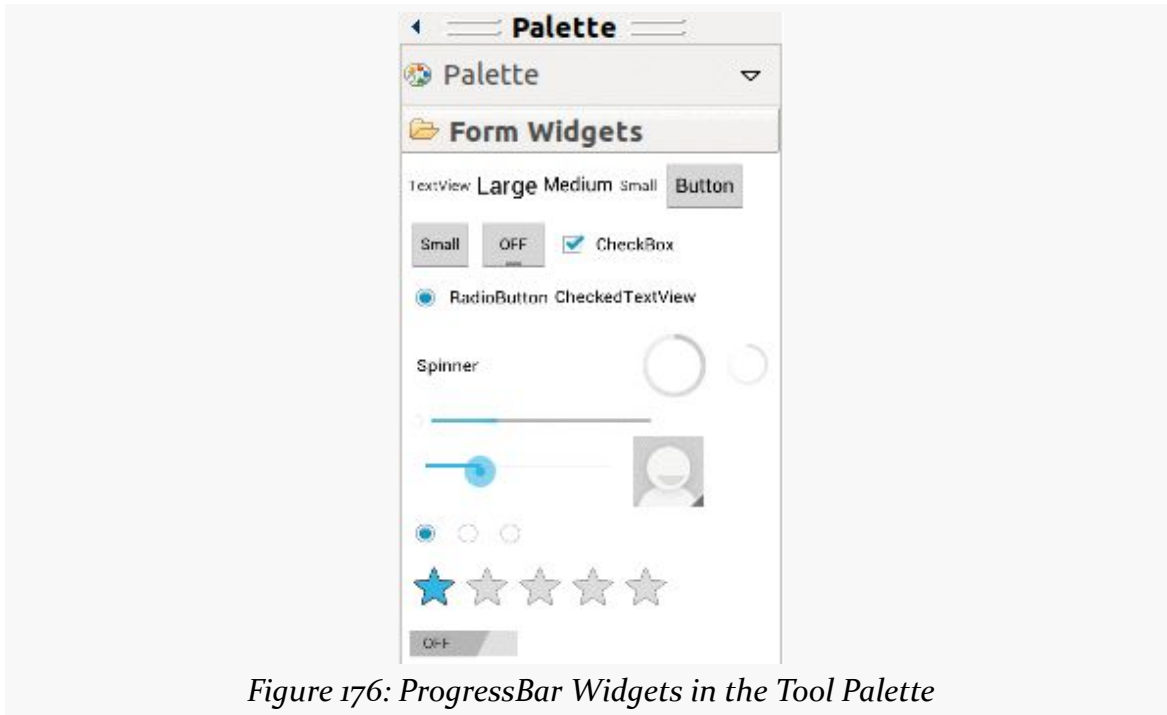

Figure 176: ProgressBar Widgets in the Tool Palette

Drag the “Large” one out of the palette and onto the preview of our activity. You will see a tooltip pointing out the `RelativeLayout` rules that the drag-and-drop operation will apply if you drop the widget in its current location. Slide the `ProgressBar` around until you center it and the tooltip shows that it will use `android:layout_centerHorizontal="true"` and `android:layout_centerVertical="true"`. If you wind up with `android:layout_centerInParent="true"` instead of those other two settings, that is fine as well.

If you are having difficulty centering it, drop it anywhere in the white part of the preview area. Then, from the toolbar above the preview, press the center-horizontal and center-vertical toolbar buttons in succession:

Figure 177: The Centering Toolbar Buttons (Third and Fourth from Right)

Then, you can save your file.

Step #3: Seeing the Results

If you run the app in a device or emulator, you will see your ProgressBar widget, sitting there, all alone, waiting for somebody to write more code in support of it:

Figure 178: EmPubLite, With ProgressBar

Note that if you have not yet set up the x86 emulator, you might wish to consider doing so, as we will become increasingly dependent upon the emulator, and the ARM emulator is slow. There is a section [later in the book](#) that covers how to set up the x86 emulator.

In Our Next Episode...

... we will [attach a third-party library](#) to our tutorial project.

GUI Building, Continued

If you are using an IDE, and you have been experimenting with the graphical layout editor and drag-and-drop GUI building, this chapter will cover some other general features of this editor that you may find useful.

Even if you are not using an IDE, you may want to at least skim this chapter, as you will find a few tricks that will be relevant for you as well.

Making Your Selection

Clicking on a widget makes it the selected widget, meaning that the toolbar buttons will affect that widget (or, sometimes, its container, depending upon the button). Selected widgets have a thin blue border with blue square “grab handles” for adjusting its size and position.

Figure 179: Android Studio, Selected Widget in Graphical Layout Editor

Clicking on a container also selects it. However, there may or may not be a blue border — in particular, containers that fill the screen (`match_parent` for width and height) do not seem to get the border.

Sometimes, though, you want to select a container that you cannot reach, because its contents are completely filled with widgets. That occurs with the `LinearPercent` sample from [a previous chapter](#) – the entire `LinearLayout` is filled with the three `Button` widgets. In these cases, click on the widget or container in the Component Tree (Android Studio) or Outline (Eclipse) pane to select it.

Including Includes

Sometimes, you have a widget or a collection of widgets that you want to reuse across multiple layout XML resources. Android supports the notion of an “include” that allows this. Simply create a dedicated layout XML resource that contains the widget(s) to reuse, then add them to your main layouts via an `<include>` element:

```
<include layout="@layout/thing_we_are_reusing" />
```

You can even assign the `<include>` element a width or height if needed, as if it were just a widget or container.

The IDE makes it easy for you to take widgets from an existing layout XML resource and extract them into a separate layout XML resource, replacing them with an `<include>` element.

In Android Studio, select the widget(s) that you want to reuse, then choose Refactor > Extract Layout from the context menu. This will display a dialog where you can fill in the file name of your resulting resource:

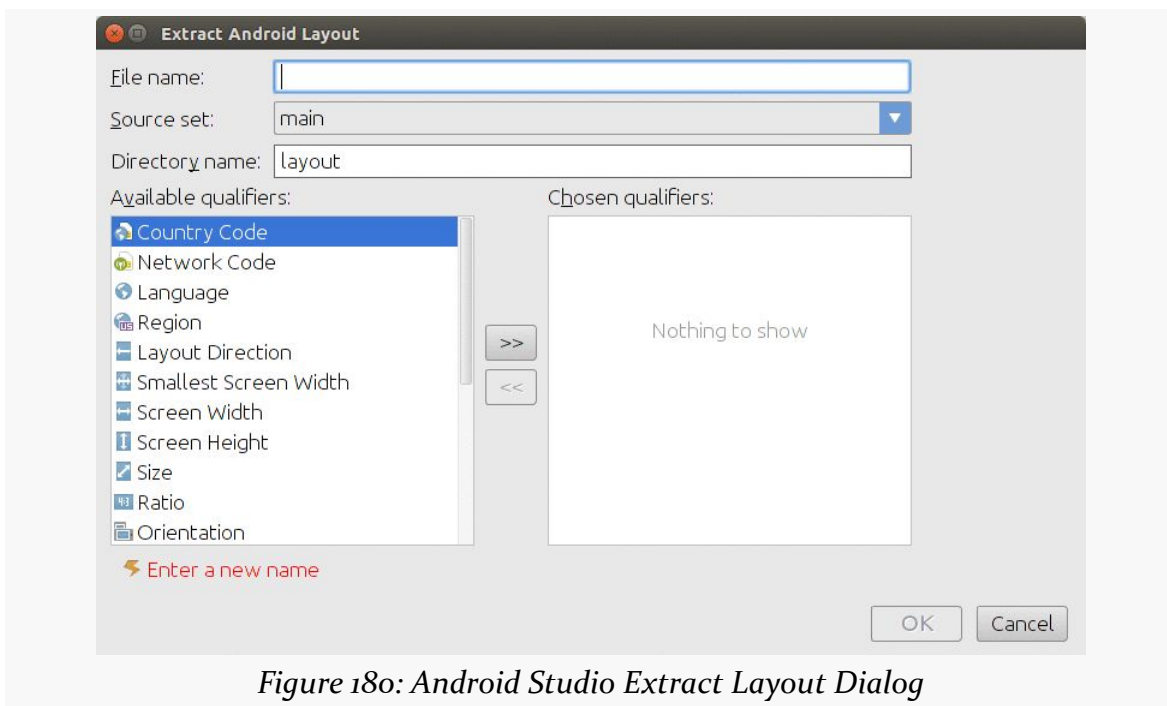

Figure 180: Android Studio Extract Layout Dialog

In Eclipse, select the widget(s) that you want to reuse, then right-click over them and choose “Extract Include” from the context menu. This will bring up a dialog where you can specify a name to give the new layout XML resource:

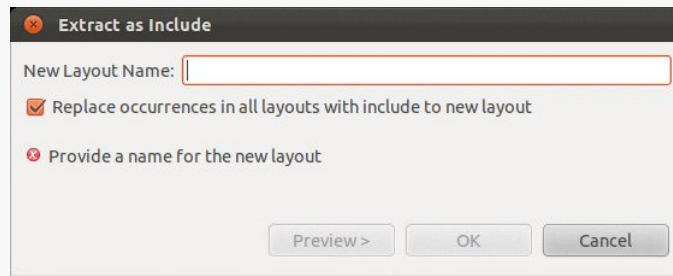

Figure 181: Extract as Include Dialog

By default, Eclipse will search *all* your layout files for these widgets and replace them with the `<include>`, though you can uncheck the checkbox to disable this behavior and only affect the layout XML resource you are presently editing.

If you are extracting multiple widgets that are not wrapped in their own container, the IDE will automatically wrap them in a `<merge>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <!-- widgets go here -->
</merge>
```

This is necessary purely from an XML standpoint — you cannot have multiple root elements in an XML file. When the `<merge>` is added to another layout via `<include>`, the `<merge>` element itself evaporates, leaving behind its children.

Wrap It Up (In a Container)

Sometimes, after you have added a widget to your layout, you later determine that you really needed it to be in some sort of container. For example, perhaps you thought you only needed one `TextView` but later decided to stack two `TextView` widgets in a vertical `LinearLayout`, in which case you somehow need to introduce this `LinearLayout` into the mix.

In Eclipse, the simplest way to do that is to right-click over the widget that needs a new container (in the preview pane or the Outline pane) and choose “Wrap In Container...” from the context menu. This will bring up a dialog allowing you to choose the class of the container (with a reasonable default pre-selected) and give the container an `android:id` value (which, for some strange reason, is mandatory).

Figure 182: Wrap In Container Dialog

Similarly, if a widget is wrapped in a container, where the container is no longer necessary, “Remove Container” will get rid of the container.

Note that Android Studio does not offer this feature.

Morphing Widgets

Occasionally, you might configure a widget, only to decide later on that you really want it to be a different type of widget. For example, perhaps you start with a `CheckBox` and later want to switch it to be a `ToggleButton`.

To do this in Android Studio, right-click over the widget (in the preview pane or the Component Tree pane) and choose Morphing from the context menu. This brings up a fly-out menu of possible alternative classes; choosing one will automatically convert your widget into the selected type.

To do this in Eclipse, right-click over the widget (in the preview pane or the Outline pane) and choose “Change Widget Type” from the context menu. This will bring up a dialog box for you to choose a replacement widget class, with a likely candidate pre-selected for you:

Figure 183: Change Widget Type

After making the selection, Eclipse will alter your element to the new widget type. Note that you may need to make other changes yourself, for attributes that you no longer need or now need to add.

Preview of Coming Attractions

At the top of the graphical layout editor, you will find a series of drop-downs that allow you to tailor what the preview looks like:

Figure 184: Android Studio Preview Controls

Figure 185: Eclipse Preview Controls

Your IDE will choose some likely defaults based upon your project settings, but you are welcome to change them as you see fit. Notable changes include:

- What version of Android is used for the preview (as widget styling changes from time to time in Android releases)
- What language is used for your string resources?
- What size and resolution of screen is used?
- Is it displayed in portrait or landscape?

These only affect the preview, so they show you (approximately) what your layout will look like under those conditions, but they do not modify anything about your layout XML itself.

AdapterViews and Adapters

If you want the user to choose something out of a collection of somethings, you could use a bunch of `RadioButton` widgets. However, Android has a series of more flexible widgets than that, ones that this book will refer to as “selection widgets”.

These include:

- `ListView`, which is your typical “list box”
- `Spinner`, which (more or less) is a drop-down list
- `GridView`, offering a two-dimensional roster of choices
- `ExpandableListView`, a limited “tree” widget, supporting two levels in the hierarchy

and many more.

At their core, these are ordinary widgets. You will find them in your tool palette of your IDE’s graphical layout editor, and can drag them and position them as you see fit.

The key is that these all have a common superclass: `AdapterView`, so named because they partner with objects implementing the `Adapter` interface to determine what choices are available for the user to choose from.

Adapting to the Circumstances

An `Adapter` is your bridge between your model data and that data’s visual representation in the `AdapterView`:

- an Adapter might “adapt” an Invoice into a View that would serve as a row in a `ListView`
- an Adapter might “adapt” a Book into a View that would serve as a cell in a `GridView`
- and so on

Android ships with several Adapter classes ready for your use, where the different adapter classes are designed to “adapt” different sorts of collections (e.g., arrays versus results of database queries). Android also has a `BaseAdapter` class that can serve as the foundation for your own Adapter implementation, if you need to “adapt” a collection of data that does not fit any of the Adapter classes supplied by Android.

Using ArrayAdapter

The easiest adapter to use is `ArrayAdapter` — all you need to do is wrap one of these around a Java array or `java.util.List` instance, and you have a fully-functioning adapter:

```
String[] items={"this", "is", "a", "really", "silly", "list"};
new ArrayAdapter<String>(this,
    android.R.layout.simple_list_item_1,
    items);
```

One flavor of the `ArrayAdapter` constructor takes three parameters:

1. The Context to use (typically this will be your activity instance)
2. The resource ID of a view to use (such as a built-in system resource ID, as shown above)
3. The actual array or list of items to show

By default, the `ArrayAdapter` will invoke `toString()` on the objects in the list and wrap each of those strings in the view designated by the supplied resource. `android.R.layout.simple_list_item_1` simply turns those strings into `TextView` objects. Those `TextView` widgets, in turn, will be shown in the list or spinner or whatever widget uses this `ArrayAdapter`. If you want to see what `android.R.layout.simple_list_item_1` looks like, you can find a copy of it in your SDK installation — just search for `simple_list_item_1.xml`.

We will see in a [later section](#) how to subclass an Adapter and override row creation, to give you greater control over how rows and cells appear.

Lists of Naughty and Nice

The classic listbox widget in Android is known as `ListView`. Include one of these in your layout, invoke `setAdapter()` to supply your data and child views, and attach a listener via `setOnItemSelectedListener()` to find out when the selection has changed. With that, you have a fully-functioning listbox.

However, if your activity is dominated by a single list, you might well consider creating your activity as a subclass of `ListActivity`, rather than the regular `Activity` base class. If your main view is just the list, you do not even need to supply a layout — `ListActivity` will construct a full-screen list for you. If you do want to customize the layout, you can, so long as you identify your `ListView` as `@android:id/list`, so `ListActivity` knows which widget is the main list for the activity.

For example, here is a layout pulled from [the Selection/List sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent" >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>
    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        />
</LinearLayout>
```

It is just a list with a label on top to show the current selection.

The Java code to configure the list and connect the list with the label is:

```
package com.commonware.android.list;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ListView;
import android.widget.TextView;
```

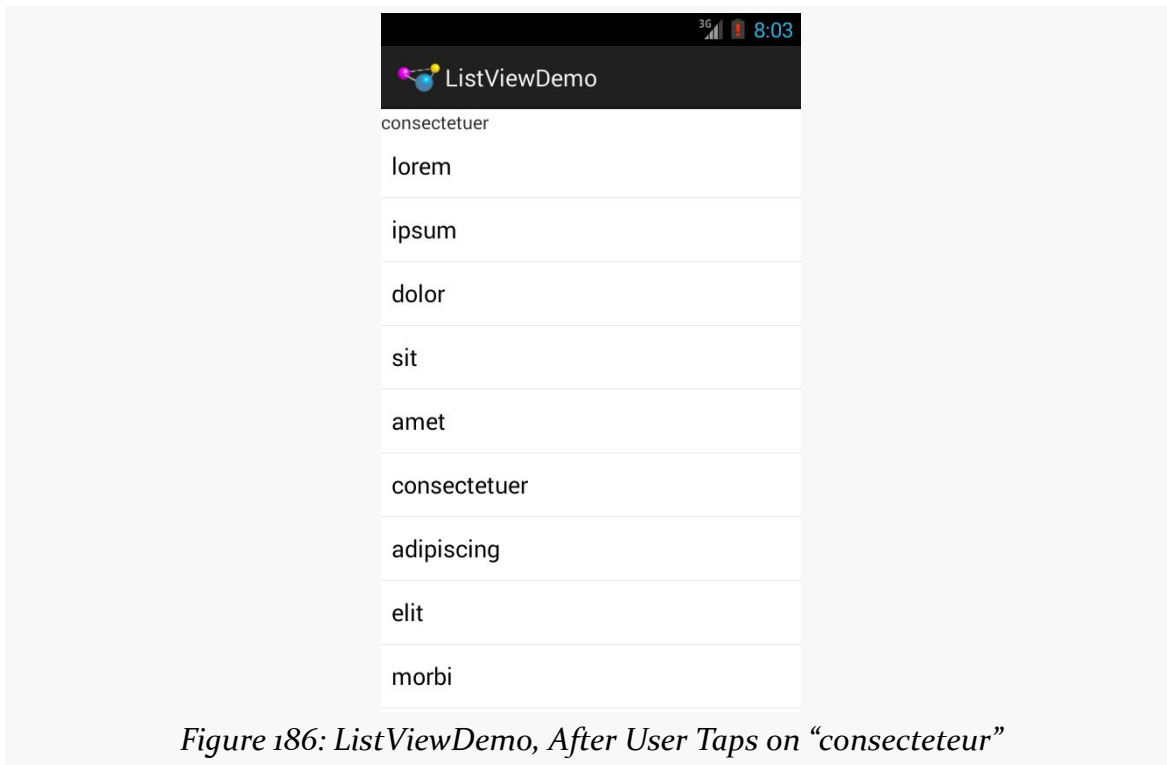

```
public class ListViewDemo extends ListActivity {
    private TextView selection;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            items));
        selection=(TextView)findViewById(R.id.selection);
    }

    @Override
    public void onItemClick(ListView parent, View v, int position,
        long id) {
        selection.setText(items[position]);
    }
}
```

With `ListActivity`, you can set the list adapter via `setListAdapter()` — in this case, providing an `ArrayAdapter` wrapping an array of Latin strings. To find out when the list selection changes, override `onItemClick()` and take appropriate steps based on the supplied child view and position (in this case, updating the label with the text for that position).

The results?

The second parameter to our ArrayAdapter — `android.R.layout.simple_list_item_1` — controls what the rows look like. The value used in the preceding example provides the standard Android list row: a big font with lots of padding to offer a large touch target for the user.

Clicks versus Selections

One thing that can confuse some Android developers is the distinction between clicks and selections. One might think that they are the same thing — after all, clicking on something selects it, right?

Well, no. At least, not in Android. At least not all of the time.

Android is designed to be used with touchscreen devices and non-touchscreen devices. Historically, Android has been dominated by devices that only offered touchscreens. However, there are various devices powered by Android and connected to TVs. Most TVs are not touchscreens, and so users of those TV-using Android devices will use some sort of remote control to drive Android. And some

Android devices offer both touchscreens and some other sort of pointing device — D-pad, trackball, arrow keys, etc.

To accommodate both styles of device, Android sometimes makes a distinction between selection events and click events. Widgets based off of the “spinner” paradigm — including `Spinner` — treat everything as selection events. Other widgets — like `ListView` and `GridView` — treat selection events and click events differently. For these widgets, selection events are driven by the pointing device, such as using arrow keys to move a highlight bar up and down a list. Click events are when the user either “clicks” the pointing device (e.g., presses the center D-pad button) or taps on something in the widget using the touchscreen.

Choice Modes

By default, `ListView` is set up simply to collect clicks on list entries. Sometimes, though, you want a list that tracks a user’s choice, or possibly multiple choices. `ListView` can handle that as well, but it requires a few changes.

First, you will need to call `setChoiceMode()` on the `ListView` in Java code to set the choice mode, classically supplying either `CHOICE_MODE_SINGLE` or `CHOICE_MODE_MULTIPLE` as the value. You can get your `ListView` from a `ListActivity` via `getListView()`. You can also declare this via the `android:choiceMode` attribute in your layout XML.

Then, rather than use `android.R.layout.simple_list_item_1` as the layout for the list rows in your `ArrayAdapter` constructor, you can use either `android.R.layout.simple_list_item_single_choice` or `android.R.layout.simple_list_item_multiple_choice` for single-choice or multiple-choice lists, respectively.

For example, here is an activity layout from [the Selection/Checklist sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<ListView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@android:id/list"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:drawSelectorOnTop="false"
  android:choiceMode="multipleChoice"
/>
```

It is a full-screen `ListView`, with the `android:choiceMode="multipleChoice"` attribute to indicate that we want multiple choice support.

Our activity just uses a standard `ArrayAdapter` on our list of Latin words, but uses `android.R.layout.simple_list_item_multiple_choice` as the row layout:

```
package com.commonware.android.checklist;

import android.app.ListActivity;
import android.os.Bundle;
import android.widget.ArrayAdapter;

public class ChecklistDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_multiple_choice,
            items));
    }
}
```

What the user sees is the list of words with checkboxes down the right edge:

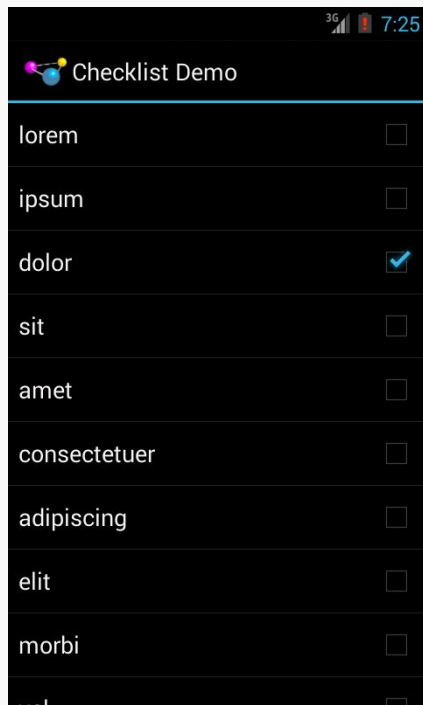

Figure 187: Multiple-Choice Mode

If we wanted, we could call methods like `getCheckedItemPositions()` on our `ListView` to find out which items the user checked, or `setItemChecked()` if we wanted to check (or un-check) a specific entry ourselves.

Clicks versus Selections, Revisited

If the user clicks a row in a `ListView`, a click event is registered, triggering things like `onListItemClick()` in an `OnItemClickListener`. If the user uses a pointing device to change a selection (e.g., pressing up and down arrows to move a highlight bar in the `ListView`), that triggers `onItemSelected()` in an `OnItemSelectedListener`.

Many times, particularly if the `ListView` is the entire UI at present, you only care about clicks. Sometimes, particularly if the `ListView` is adjacent to something else (e.g., on a TV, where you have more screen space *and* do not have a touchscreen), you will care more about selection events. Either way, you can get the events you need.

Spin Control

In Android, the Spinner is the equivalent of the drop-down selector you might find in other toolkits. Clicking the Spinner drops down a list for the user to choose an item from. You basically get the ability to choose an item from a list without taking up all the screen space of a `ListView`, at the cost of an extra click to make a change.

As with `ListView`, you provide the adapter for data and child views via `setAdapter()` and hook in a listener object for selections via `setOnItemSelectedListener()`.

To tailor the view used when displaying the drop-down perspective, you need to configure the adapter, not the Spinner widget. Use the `setDropDownViewResource()` method to supply the resource ID of the view to use.

For example, culled from [the Selection/Spinner sample project](#), here is an XML layout for a simple view with a Spinner:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
    <Spinner android:id="@+id/spinner"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
</LinearLayout>
```

This is the same view as shown in [a previous section](#), just with a Spinner instead of a `ListView`.

To populate and use the Spinner, we need some Java code:

```
public class SpinnerDemo extends Activity
    implements AdapterView.OnItemSelectedListener {
    private TextView selection;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
```

```
        "consectetuer", "adipiscing", "elit", "morbi", "vel",  
        "ligula", "vitae", "arcu", "aliquet", "mollis",  
        "etiam", "vel", "erat", "placerat", "ante",  
        "porttitor", "sodales", "pellentesque", "augue", "purus"};  
  
@Override  
public void onCreate(Bundle icle) {  
    super.onCreate(icle);  
    setContentView(R.layout.main);  
    selection=(TextView)findViewById(R.id.selection);  
  
    Spinner spin=(Spinner)findViewById(R.id.spinner);  
    spin.setOnItemSelectedListener(this);  
  
    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,  
                                                    android.R.layout.simple_spinner_item,  
                                                    items);  
  
    aa.setDropDownViewResource(  
        android.R.layout.simple_spinner_dropdown_item);  
    spin.setAdapter(aa);  
}  
  
@Override  
public void onItemSelected(AdapterView<?> parent,  
                           View v, int position, long id) {  
    selection.setText(items[position]);  
}  
  
@Override  
public void onNothingSelected(AdapterView<?> parent) {  
    selection.setText("");  
}  
}
```

Here, we attach the activity itself as the selection listener (`spin.setOnItemSelectedListener(this)`), as Spinner widgets only support selection events, not click events. This works because the activity implements the `OnItemSelectedListener` interface. We configure the adapter not only with the list of fake words, but also with a specific resource to use for the drop-down view (via `aa.setDropDownViewResource()`). Also note the use of `android.R.layout.simple_spinner_item` as the built-in View for showing items in the spinner itself. Finally, we implement the callbacks required by `OnItemSelectedListener` to adjust the selection label based on user input.

What we get is:

Figure 188: SpinnerDemo, as Initially Launched

Figure 189: SpinnerDemo, with Spinner Drop-Down List Displayed

Grid Your Lions (Or Something Like That...)

As the name suggests, `GridView` gives you a two-dimensional grid of items to choose from. You have moderate control over the number and size of the columns; the number of rows is dynamically determined based on the number of items the supplied adapter says are available for viewing.

There are a few properties which, when combined, determine the number of columns and their sizes:

1. `android:numColumns` spells out how many columns there are, or, if you supply a value of `auto_fit`, Android will compute the number of columns based on available space and the properties listed below.
2. `android:verticalSpacing` and `android:horizontalSpacing` indicate how much whitespace there should be between items in the grid.
3. `android:columnWidth` indicates how wide each column should be, in terms of some dimension value (e.g., `40dp` or `@dimen/grid_column_width`).
4. `android:stretchMode` indicates, for grids with `auto_fit` for `android:numColumns`, what should happen for any available space not taken up by columns or spacing — this should be `columnWidth` to have the columns take up available space or `spacingWidth` to have the whitespace between columns absorb extra space.

Otherwise, the `GridView` works much like any other selection widget — use `setAdapter()` to provide the data and child views, invoke `setOnItemClickListener()` to find out when somebody clicks on a cell in the grid, etc.

For example, here is an XML layout from [the Selection/Grid sample project](#), showing a `GridView` configuration:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
    <GridView
```

```
        android:id="@+id/grid"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:verticalSpacing="40dip"
        android:horizontalSpacing="5dip"
        android:numColumns="auto_fit"
        android:columnWidth="100dip"
        android:stretchMode="columnWidth"
        android:gravity="center"
    />
</LinearLayout>
```

For this grid, we take up the entire screen except for what our selection label requires. The number of columns is computed by Android (`android:numColumns = "auto_fit"`) based on our horizontal spacing (`android:horizontalSpacing = "5dip"`) and columns width (`android:columnWidth = "100dip"`), with the columns absorbing any “slop” width left over (`android:stretchMode = "columnWidth"`).

The Java code to configure the GridView is:

```
package com.commonware.android.grid;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.GridView;
import android.widget.TextView;

public class GridDemo extends Activity
    implements AdapterView.OnItemClickListener {
    private TextView selection;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icicle) {
        super.onCreate(icicle);
        setContentView(R.layout.main);
        selection=(TextView)findViewById(R.id.selection);

        GridView g=(GridView) findViewById(R.id.grid);
        g.setAdapter(new ArrayAdapter<String>(this,
            R.layout.cell,
            items));
        g.setOnItemClickListener(this);
    }
}
```

ADAPTERVIEWS AND ADAPTERS

```
}  
  
@Override  
public void onItemClick(AdapterView<?> parent, View v,  
                        int position, long id) {  
    selection.setText(items[position]);  
}  
}
```

The grid cells are defined by a separate `res/layout/cell.xml` file, referenced in our `ArrayAdapter` as `R.layout.cell`:

```
<?xml version="1.0" encoding="utf-8"?>  
<TextView  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="wrap_content"  
    android:layout_height="wrap_content"  
    android:textSize="14dip"  
</>
```

With the vertical spacing from the XML layout (`android:verticalSpacing = "40dip"`), the grid overflows the boundaries of the emulator's screen:

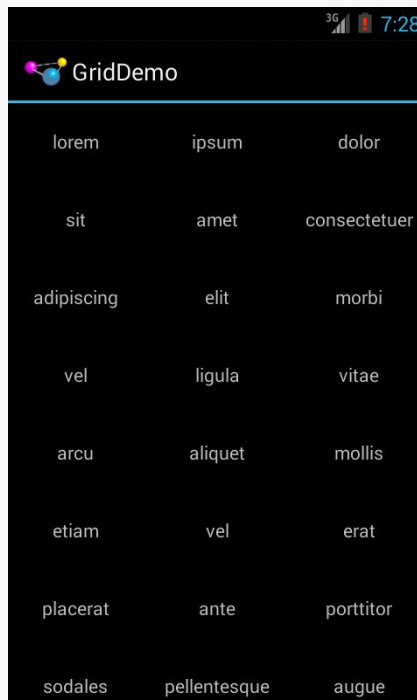

Figure 190: GridDemo, as Initially Launched

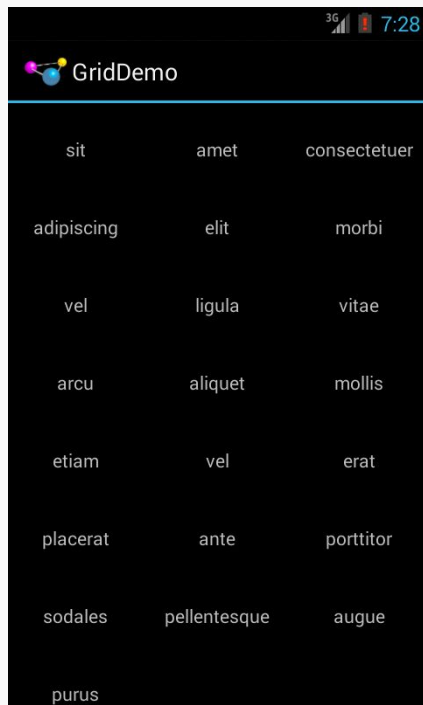

Figure 191: GridDemo, Scrolled to the Bottom of the Grid

GridView, like ListView, supports both click events and selection events. In this sample, we register an `OnItemClickListener` to listen for click events.

Fields: Now With 35% Less Typing!

The `AutoCompleteTextView` is sort of a hybrid between the `EditText` (field) and the `Spinner`. With auto-completion, as the user types, the text is treated as a prefix filter, comparing the entered text as a prefix against a list of candidates. Matches are shown in a selection list that folds down from the field. The user can either type out an entry (e.g., something not in the list) or choose an entry from the list to be the value of the field.

`AutoCompleteTextView` subclasses `EditText`, so you can configure all the standard look-and-feel aspects, such as font face and color.

In addition, `AutoCompleteTextView` has an `android:completionThreshold` property, to indicate the minimum number of characters a user must enter before the list filtering begins.

You can give `AutoCompleteTextView` an adapter containing the list of candidate values via `setAdapter()`. However, since the user could type something not in the list, `AutoCompleteTextView` does not support selection listeners. Instead, you can register a `TextWatcher`, like you can with any `EditText`, to be notified when the text changes. These events will occur either because of manual typing or from a selection from the drop-down list.

Below we have a familiar-looking XML layout, this time containing an `AutoCompleteTextView` (pulled from [the Selection/AutoComplete sample application](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    />
    <AutoCompleteTextView android:id="@+id/edit"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:completionThreshold="3"/>
</LinearLayout>
```

The corresponding Java code is:

```
package com.commonware.android.auto;

import android.app.Activity;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.widget.ArrayAdapter;
import android.widget.AutoCompleteTextView;
import android.widget.TextView;

public class AutoCompleteDemo extends Activity
    implements TextWatcher {
    private TextView selection;
    private AutoCompleteTextView edit;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
```

```
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);
    setContentView(R.layout.main);
    selection=(TextView)findViewById(R.id.selection);
    edit=(AutoCompleteTextView)findViewById(R.id.edit);
    edit.addTextChangedListener(this);

    edit.setAdapter(new ArrayAdapter<String>(this,
                                           android.R.layout.simple_dropdown_item_1line,
                                           items));
}

@Override
public void onTextChanged(CharSequence s, int start, int before,
                           int count) {
    selection.setText(edit.getText());
}

@Override
public void beforeTextChanged(CharSequence s, int start,
                              int count, int after) {
    // needed for interface, but not used
}

@Override
public void afterTextChanged(Editable s) {
    // needed for interface, but not used
}
}
```

This time, our activity implements `TextWatcher`, which means our callbacks are `onTextChanged()`, `beforeTextChanged()`, and `afterTextChanged()`. In this case, we are only interested in the first, and we update the selection label to match the `AutoCompleteTextView`'s current contents.

Here we have the results:

Figure 192: AutoCompleteDemo, as Initially Launched

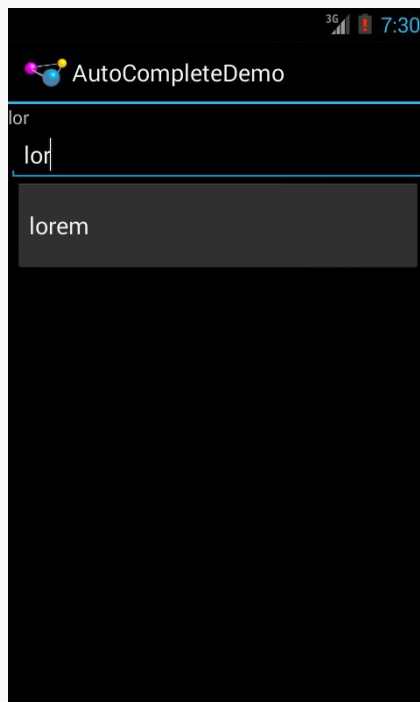

Figure 193: AutoCompleteDemo, After Entering a Few Matching Letters

Figure 194: AutoCompleteDemo, After Auto-Complete Value Was Selected

Note that the red underline in the preceding screenshot is due to spelling correction. Like `EditText`, `AutoCompleteTextView` supports hinting at spelling errors. The emulator's language is set to English, as there is no option in it for Latin.

Customizing the Adapter

The humble `ListView` is one of the most important widgets in all of Android, simply because it is used so frequently. Whether choosing a contact to call or an email message to forward or an ebook to read, `ListView` widgets are employed in a wide range of activities.

Of course, it would be nice if they were more than just plain text.

The good news is that they can be as fancy as you want, within the limitations of a mobile device's screen, of course. However, making them more elaborate takes some work.

Note that while this section will be using `ListView` as the `AdapterView`, the same techniques hold for *any* `AdapterView`.

The Single Layout Pattern

The simplest way of creating custom `ListView` rows (or `GridView` cells or whatever) is when they all have the same basic structure and can be created from the same layout XML resource. This does not mean they have to be strictly identical, but that you can make whatever changes you need just by configuring the widgets (e.g., make some things `VISIBLE` or `GONE`).

This is not especially difficult, though it does take a few more steps than what we have seen previously.

Step #0: Get Things Set Up Simply

First, create your activity (e.g., `ListActivity`), get your data (e.g., array of Java strings), and set up your `AdapterView` with a simple adapter following the steps outlined in the preceding sections.

Here, we will examine [the Selection/Dynamic sample project](#). We will use a simple `ListActivity` (taking the default layout of a full-screen `ListView`) and use the same list of 25 Latin words used in earlier samples. However, this time, we want to have a more elaborate row, taking into account the length of the Latin word.

Step #1: Design Your Row

Next, create a layout XML resource that will represent one row in your `ListView` (or cell in your `GridView` or whatever).

For example, our `res/layout/row.xml` resource will use a pair of nested `LinearLayout` containers to organize two `TextView` widgets and an `ImageView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:padding="2dip"
        android:src="@drawable/ok"
        android:contentDescription="@string/icon"/>
```

```
<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>
</LinearLayout>
```

The `ImageView` will use one of two drawable resources, one for short words, and another for long words.

Step #2: Extend `ArrayAdapter`

If you just used `R.layout.row` with a regular `ArrayAdapter`, it would work, insofar as it would not crash. However, `ArrayAdapter` only knows how to update a single `TextView` in a row, so it would ignore our other `TextView`, let alone the `ImageView`.

So, we need to create our own `ListAdapter`, by creating our own subclass of `ArrayAdapter`.

Since an `Adapter` is tightly coupled to the `AdapterView` that uses it, it is typically simplest to make the custom `ArrayAdapter` subclass be an inner class of whoever manages the `AdapterView`. Hence, in our sample, we will create an `IconicAdapter` inner class of our `ListActivity`.

Step #3: Override the Constructor and `getView()`

The `IconicAdapter` constructor can chain to the superclass and supply the necessary data, such as our Java array of Latin words. The real fun comes when we override `getView()`:

ADAPTERVIEWS AND ADAPTERS

```
package com.commonware.android.fancylists.three;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.TextView;

public class DynamicDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setListAdapter(new IconicAdapter());
    }

    class IconicAdapter extends ArrayAdapter<String> {
        IconicAdapter() {
            super(DynamicDemo.this, R.layout.row, R.id.label, items);
        }

        @Override
        public View getView(int position, View convertView,
            ViewGroup parent) {
            View row=super.getView(position, convertView, parent);
            ImageView icon=(ImageView)row.findViewById(R.id.icon);

            if (items[position].length()>4) {
                icon.setImageResource(R.drawable.delete);
            }
            else {
                icon.setImageResource(R.drawable.ok);
            }

            TextView size=(TextView)row.findViewById(R.id.size);

            size.setText(String.format(getString(R.string.size_template),
items[position].length()));

            return(row);
        }
    }
}
```

Our `getView()` implementation does three things:

- It chains to the superclass' implementation of `getView()`, which returns to us an instance of our row View, as prepared by `ArrayAdapter`. In particular, our word has already been put into one `TextView`, since `ArrayAdapter` does that normally.
- It finds our `ImageView` and applies a business rule to set which icon should be used, referencing one of two drawable resources (`R.drawable.ok` and `R.drawable.delete`).
- It finds our other `TextView` and populates it as well, by pulling in the value of a string resource and using `String.format()` to pour in our word length.

Note that we call `findViewById()` not on the activity, but rather on the row returned by the superclass' implementation of `getView()`. **Always call `findViewById()` on something that is guaranteed to give you a unique result.** In the case of an `AdapterView`, there will be many rows, cells, etc. — calling `findViewById()` on the activity might return widgets with the right name but from other rows or cells.

This gives us:

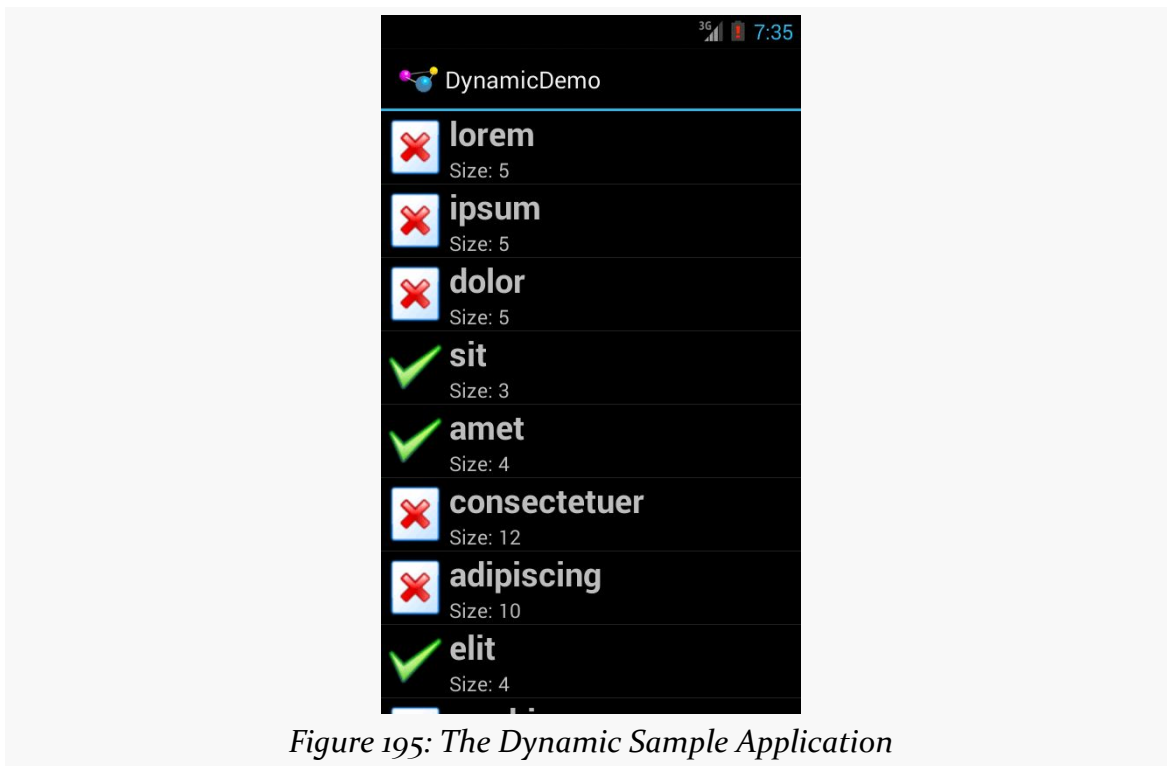

Figure 195: The Dynamic Sample Application

The approach of overriding `getView()` works for `ArrayAdapter`, but some other types of adapters would have alternatives. We will see that mostly with `CursorAdapter`, profiled in upcoming chapters.

Optimizing with the ViewHolder Pattern

A somewhat expensive operation we do a lot with more elaborate list rows is call `findViewById()`. This dives into our row and pulls out widgets by their assigned identifiers, so we can customize the widget contents (e.g., change the text of a `TextView`, change the icon in an `ImageView`). Since `findViewById()` can find widgets anywhere in the tree of children of the row's root `View`, this could take a fair number of instructions to execute, particularly if we keep having to re-find widgets we had found once before.

In some GUI toolkits, this problem is avoided by having the composite `View` objects, like our rows, be declared totally in program code (in this case, Java). Then, accessing individual widgets is merely the matter of calling a getter or accessing a field. And you can certainly do that with Android, but the code gets rather verbose. What would be nice is a way where we can still use the layout XML yet cache our row's key child widgets so we only have to find them once.

That's where the holder pattern comes into play, in a class we will call `ViewHolder`.

All `View` objects have `getTag()` and `setTag()` methods. These allow you to associate an arbitrary object with the widget. What the holder pattern does is use that "tag" to hold an object that, in turn, holds each of the child widgets of interest. By attaching that holder to the row `View`, every time we use the row, we already have access to the child widgets we care about, without having to call `findViewById()` again.

So, let's take a look at one of these holder classes (taken from [the Selection/ViewHolder sample project](#), a revised version of the Selection/Dynamic sample from before):

```
package com.commonware.android.fancylists.five;

import android.view.View;
import android.widget.ImageView;
import android.widget.TextView;

class ViewHolder {
    ImageView icon=null;
    TextView size=null;
}
```

```
ViewHolder(View row) {  
    this.icon=(ImageView)row.findViewById(R.id.icon);  
    this.size=(TextView)row.findViewById(R.id.size);  
}  
}
```

ViewHolder holds onto the child widgets, initialized via `findViewById()` in its constructor. The widgets are simply package-protected data members, accessible from other classes in this project... such as a `ViewHolderDemo` activity. In this case, we are only holding onto two widgets — the icon and the second label – since we will let `ArrayAdapter` handle our first label for us. In our case, we are holding onto the `TextView` and `ImageView` widgets that we want to populate in `getView()`.

Using `ViewHolder` is a matter of creating an instance whenever we inflate a row and attaching said instance to the row `View` via `setTag()`, as shown in this rewrite of `getView()`, found in `ViewHolderDemo`:

```
@Override  
public View getView(int position, View convertView,  
                    ViewGroup parent) {  
    View row=super.getView(position, convertView, parent);  
    ViewHolder holder=(ViewHolder)row.getTag();  
  
    if (holder==null) {  
        holder=new ViewHolder(row);  
        row.setTag(holder);  
    }  
  
    if (getModel(position).length()>4) {  
        holder.icon.setImageResource(R.drawable.delete);  
    }  
    else {  
        holder.icon.setImageResource(R.drawable.ok);  
    }  
  
    holder.size.setText(String.format(getString(R.string.size_template),  
items[position].length()));  
  
    return(row);  
}
```

If the call to `getTag()` on the row returns `null`, we know we need to create a new `ViewHolder`, which we then attach to the row via `setTag()` for later reuse. Then, accessing the child widgets is merely a matter of accessing the data members on the holder.

This takes advantage of the fact that rows in a `ListView` get *recycled* – a 25,000-row list does not create 25,000 rows. The recycling itself is handled for us by

ArrayAdapter, so we simply have to create our ViewHolder when needed and reuse the existing ViewHolder when a row gets recycled. The first time the ListView is displayed, all new rows need to be created, and we wind up creating a ViewHolder for each. As the user scrolls, rows get recycled, and we can reuse their corresponding ViewHolder widget caches. We will cover this recycling process in greater detail [in a later chapter](#).

Note that the `getModel()` method shown here retrieves our model String for a given position, by using `getListAdapter()` (to retrieve our `IconicAdapter` from the activity's `ListView`) and `getItem()` (to retrieve the data, held by the adapter, represented by the position):

```
private String getModel(int position) {  
    return(((IconicAdapter)getListAdapter()).getItem(position));  
}
```

Dealing with Multiple Row Layouts

The story gets significantly more complicated if our mix of rows is more complicated. For example, here is the Sound screen in the Settings application:

Figure 196: Sound Settings Screen

It may not look like it, but that is a `ListView`. However, not all the rows look the same:

- Some have one line of text (e.g., “Volumes”)
- Some have two lines of text (e.g., “Silent mode” plus “Off”)
- Some have one line of text and a `CheckBox` (e.g., “Vibrate and ring”)
- Some are headings with totally different text formatting (e.g., “RINGTONE & NOTIFICATIONS”)

This is handled by having more than one row layout XML resource used by the adapter. The complexity comes not only in managing those different resources and determining which to use when, but in just having more than one resource – after all, we only teach `ArrayAdapter` how to use one. We will examine how to handle this scenario [in a later chapter](#).

Visit the Trails!

To learn more about `ListView`, you can turn to [Advanced ListViews](#), which covers other tricks you can do with a `ListView`.

The WebView Widget

HTML has come a *long* way from Sir Tim Berners-Lee's original vision of using it to publish physics papers.

Not surprisingly, displaying HTML, CSS, and JavaScript in mobile applications is fairly popular, not only for creating full-fledged Web browsers, but for rendering HTML content from RSS/Atom feeds, from HTML-formatted email messages, ebooks (like the one you are reading), and so forth.

There are a couple of ways to display HTML in Android, with the most powerful being the WebView widget, the focus of this chapter.

Role of WebView

If your HTML is fairly limited in scope, such as what you might find in the body of a status update on Twitter, you can use the static `fromHtml()` method on the `Html` utility class to parse an HTML-formatted string into something that you can put into a `TextView`. `TextView` can render simple formatting like styles (bold, italic, etc.), font faces (serif, sans serif, etc.), colors, links, and so forth.

However, sometimes your needs for HTML transcend what `TextView` can handle. You will not be browsing Facebook using `TextView`, for example.

In those cases, `WebView` will be the more appropriate widget, as it can handle a *much* wider range of HTML tags. `WebView` can also handle CSS and JavaScript, which `Html.fromHtml()` would simply ignore. `WebView` can also assist you with common “browsing” metaphors, such as history list of visited URLs to support backwards and forwards navigation.

On the other hand, WebView is a much more expensive widget to use, in terms of memory consumption, than is TextView.

WebView and WebKit

The reason for the memory cost of WebView is the fact that WebView is powered by a fairly complete copy of [WebKit](#) (for Android 4.3 and older) or [Blink](#) (for Android 4.4+). WebKit is an open source Web rendering engine that forms the heart of major Web browsers, such as Safari, while Blink is used for Google's Chrome and Chromium browsers. While the version of WebKit/Blink that lives in Android is one optimized for mobile use, it still represents a fairly substantial code base, and rendering complex Web pages takes up a fair amount of RAM (as anyone with lots of browser tabs on their desktop knows all too well).

Because WebView is powered by WebKit/Blink, content that renders in Chrome and Safari *probably* renders the same in WebView. The emphasis on the word “probably” is for a few reasons:

- As mentioned, WebKit/Blink in Android is a mobile-optimized version, which introduces some differences compared to its desktop brethren
- WebKit/Blink, like any software project, has its own upgrade cycles and versioning, so different browsers (Chrome vs. Safari vs. WebView) will use different versions of the WebKit engine, introducing some differences
- Android has tweaked WebKit/Blink for its own purposes, introducing yet other potential differences

Adding the Widget

For simple stuff, WebView is not significantly different than any other widget in Android — pop it into a layout, tell it what URL to navigate to via Java code, and you are done.

As you can see in [the WebKit/Browser1 sample application](#), here is a simple layout with a WebView:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/webkit"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

As with any other widget, you need to tell it how it should fill up the space in the layout (in this case, it fills all remaining space).

And, just as with other widgets, you can add it using your IDE's graphical layout editor. An Android Studio user can drag a `WebView` out of the “Layouts” section of the tool palette, while an Eclipse user can drag a `WebView` out of the “Composite” section of the Eclipse tool palette.

Note that `WebView` knows how to scroll its own contents, so you do not need to put it in a `ScrollView` or `HorizontalScrollView`.

Loading Content Via a URL

There are a number of ways to load HTML content into a `WebView` widget.

The simplest is to use the `loadUrl()` method, which takes a URL and retrieves its contents over the Internet. For example, here is the activity source code for the `WebKit/Browser1` sample application:

```
package com.commonware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;

public class BrowserDemo1 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);

        browser.loadUrl("http://commonware.com");
    }
}
```

However, we also have to make one change to `AndroidManifest.xml`, adding a line where we request permission to access the Internet:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

If we fail to add this permission, the browser will refuse to load pages. We will discuss more about this “permission” concept [in a later chapter](#).

The resulting activity looks like a Web browser, just with hidden scrollbars:

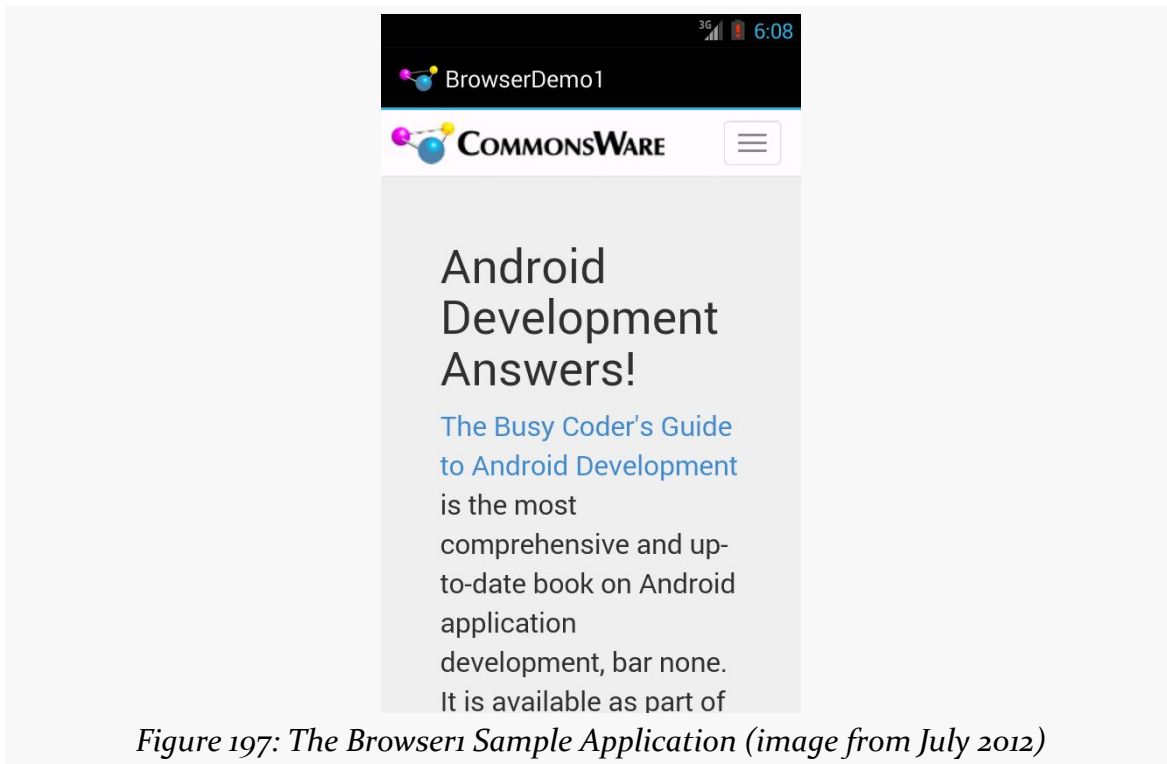

Figure 197: The Browser1 Sample Application (image from July 2012)

As with a regular Android Web browser, you can pan around the page by dragging it, while the directional pad moves you around all the focusable elements on the page.

What is missing is all the extra stuff that make up a Web browser, such as a navigational toolbar. `WebView` does not provide any of that — if you want those sorts of UI features, you will need to implement those yourself (e.g., use an `EditText` or `AutoCompleteTextView` for a browser address bar).

Supporting JavaScript

Now, you may be tempted to replace the URL in the above source code with something else, such as Google's home page or something else that relies upon JavaScript. You will find that such pages do not work especially well by default. That is because, by default, JavaScript is turned off in `WebView` widgets.

If you want to enable JavaScript, call `getSettings().setJavaScriptEnabled(true);` on the `WebView` instance. At this point, any JavaScript referenced by your Web page should work normally.

There are some fancy tricks you can perform with `WebView` and JavaScript, such as having JavaScript call Java code or vice versa. These techniques will be covered [in a later chapter](#).

Alternatives for Loading Content

`loadUrl()` works with:

- `http://` and `https://` URLs
- `file://` URLs pointing to the local filesystem
- `file:///android_asset/` URLs pointing to one of your application's assets, as will be discussed [later in this book](#)
- `content://` URLs pointing to a `ContentProvider` that is publishing content available for streaming, as will be discussed [much later in this book](#)

Instead of `loadUrl()`, you can also use `loadData()`. Here, you supply the HTML for the `WebView` to display. You might use this to:

1. display a manual that was installed as a file with your application package
2. display snippets of HTML you retrieved as part of other processing, such as the description of an entry in an Atom feed
3. generate a whole user interface using HTML, instead of using the Android widget set

There are two flavors of `loadData()`. The simpler one allows you to provide the content, the MIME type, and the encoding, all as strings. Typically, your MIME type will be `text/html` and your encoding will be UTF-8 for ordinary HTML.

For example, if you replace the `loadUrl()` invocation in the previous example with the following:

```
browser.loadData("<html><body>Hello, world!</body></html>",  
                "text/html", "UTF-8");
```

You get:

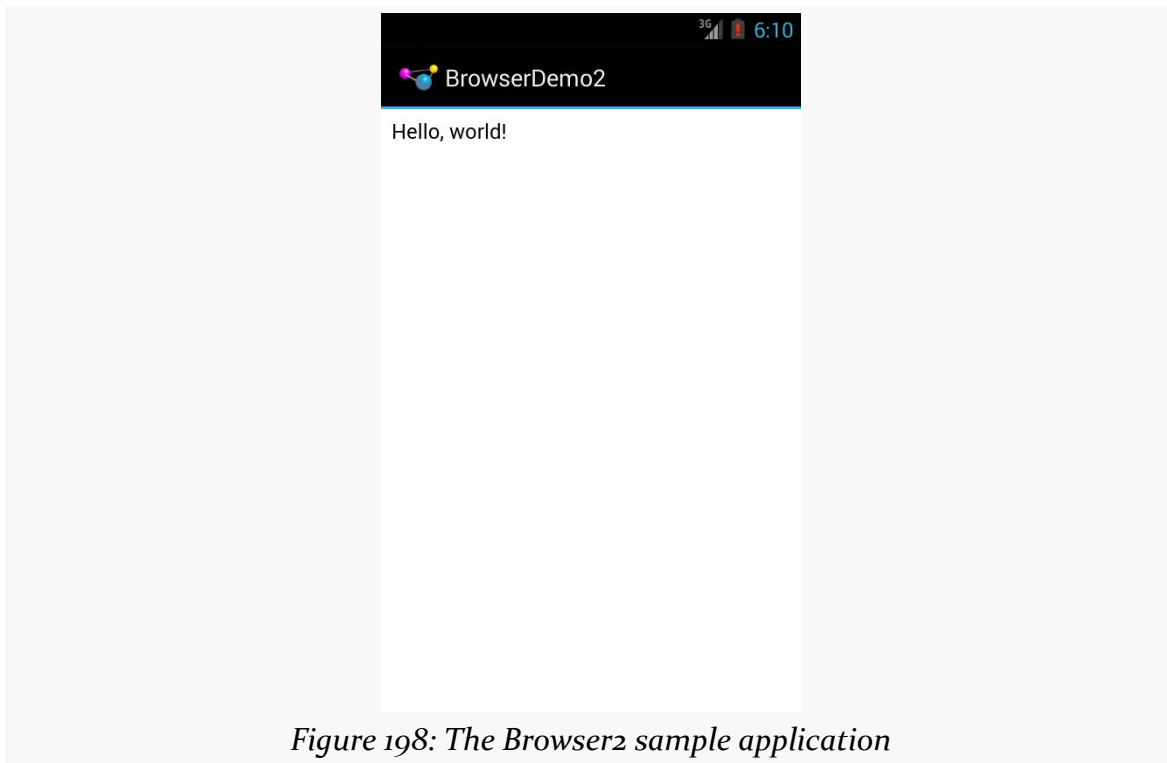

Figure 198: The Browser2 sample application

This is also available as a fully-buildable sample, as [WebKit/Browser2](#).

There is also a `loadDataWithBaseURL()` method. This takes, among other parameters, the “base URL” to use when resolving relative URLs in the HTML. Any relative URL (e.g., ``) will be interpreted as being relative to the base URL supplied to `loadDataWithBaseURL()`. If you find that you have content that refuses to load properly with `loadData()`, try `loadDataWithBaseURL()` with a null base URL, as sometimes that works better, for unknown reasons.

Listening for Events

Particularly if you are going to use the `WebView` as a local user interface (vs. browsing the Web), you will want to be able to get control at key times, particularly when users click on links. You will want to make sure those links are handled properly, either by loading your own content back into the `WebView`, by submitting an `Intent` to Android to open the URL in a full browser, or by some other means. We will discuss using an `Intent` to launch a Web browser [in a later chapter](#).

THE WEBVIEW WIDGET

One hook into the WebView activity is via `setWebViewClient()`, which takes an instance of a `WebViewClient` implementation as a parameter. The supplied callback object will be notified of a wide range of events, ranging from when parts of a page have been retrieved (`onPageStarted()`, etc.) to when you, as the host application, need to handle certain user- or circumstance-initiated events, such as:

1. `onTooManyRedirects()`
2. `onReceivedHttpAuthRequest()`
3. etc.

A common hook will be `shouldOverrideUrlLoading()`, where your callback is passed a URL (plus the `WebView` itself) and you return `true` if you will handle the request or `false` if you want default handling (e.g., actually fetch the Web page referenced by the URL). In the case of a feed reader application, for example, you will probably not have a full browser with navigation built into your reader, so if the user clicks a URL, you probably want to use an `Intent` to ask Android to load that page in a full browser. But, if you have inserted a “fake” URL into the HTML, representing a link to some activity-provided content, you can update the `WebView` yourself.

For example, let’s amend the first browser example to be an application that, upon a click, shows the current time.

From [WebKit/Browser3](#), here is the revised Java:

```
package com.commonware.android.webkit;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import java.util.Date;

public class BrowserDemo3 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);
        browser.setWebViewClient(new Callback());

        loadTime();
    }
}
```

```
void loadTime() {
    String page=
        "<html><body><a href='http://webview.used.to.be.less.annoying/clock'>"
        + DateUtils.formatDateTime(this, new Date().getTime(),
                                   DateUtils.FORMAT_SHOW_DATE
                                   | DateUtils.FORMAT_SHOW_TIME)
        + "</a></body></html>";

    browser.loadData(page, "text/html", "UTF-8");
}

private class Callback extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView view, String url) {
        loadTime();

        return(true);
    }
}
```

Here, we load a simple Web page into the browser (`loadTime()`) that consists of the current time, made into a hyperlink to a fake URL. We also attach an instance of a `WebViewClient` subclass, providing our implementation of `shouldOverrideUrlLoading()`. In this case, no matter what the URL, we want to just reload the `WebView` via `loadTime()`.

Running this activity gives us:

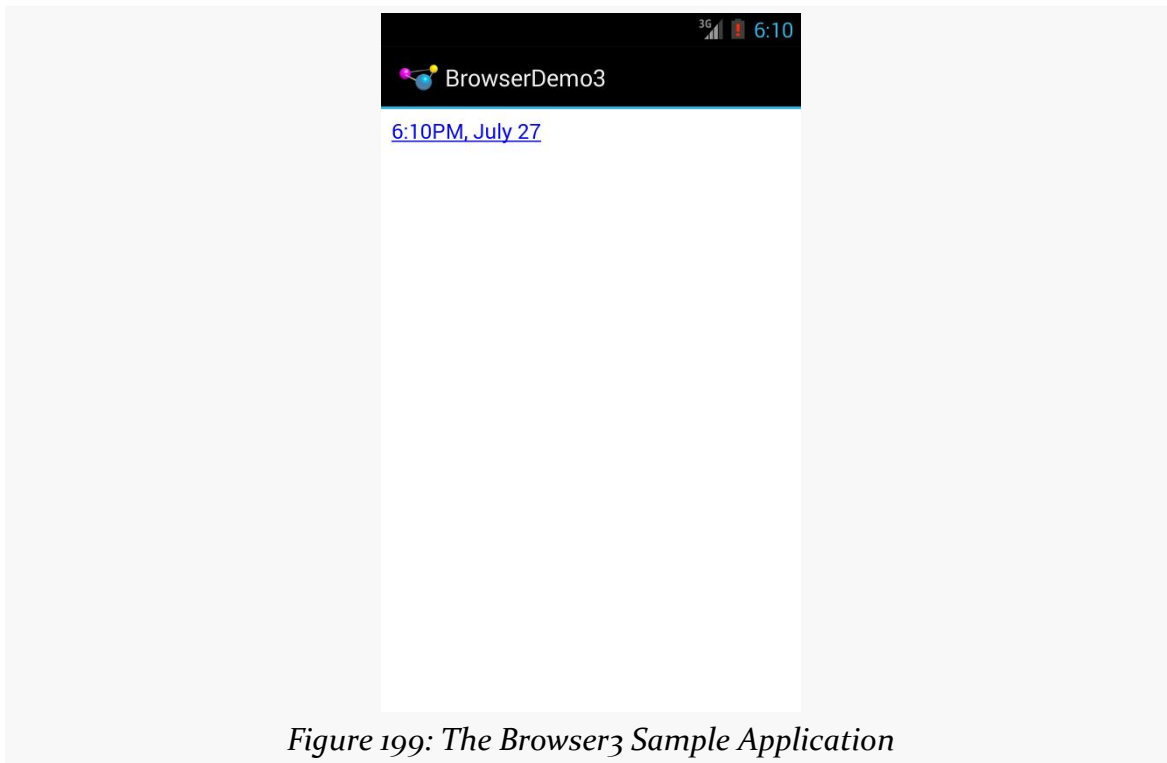

Figure 199: The Browser3 Sample Application

Clicking the link will cause us to rebuild the page with the new time.

Note that we are using a `DateUtils` utility class supplied by Android for formatting our date and time. The big advantage of using `DateUtils` is that this class is aware of the user's settings for how they prefer to see the date and time (e.g., 12- versus 24-hour mode).

There is also a `WebChromeClient` that you can register with a `WebView` via a call to `setWebChromeClient()`. This object will be called when various things occur in the `WebView` that might pertain to a browser's "chrome" (i.e., the things outside the HTML rendering area). For example, `onJSAlert()` will be called on your `WebChromeClient` when JavaScript code calls `alert()`.

WebView and Android 4.4

Historically, `WebView` was implemented using a version of `WebKit` independent from any other browser efforts by Google, such as `Chrome`.

As of Android 4.4, WebView is now based on Google's open source [Chromium project](#) and the Blink rendering engine. However, Blink was forked from WebKit, and so the two started from a common implementation.

At a high level, one WebKit-based HTML rendering engine should work similarly to another WebKit-based HTML rendering engine. However, the expression “the devil is in the details” certainly applies here, and there are [a variety of changes](#) in the way WebView renders content on Android 4.4 compared to prior versions. Some of these changes will be suppressed if your app has an `android:targetSdkVersion` set to 18 or lower.

It is highly recommended that you test your app thoroughly on both pre-4.4 and 4.4+ environments, and again when you eventually raise your `android:targetSdkVersion` to 19 or higher.

Visit the Trails!

You can learn more about powerful tricks with WebView, including integrating the Java and JavaScript environments, in [a later chapter](#).

You can also create apps that run totally in the browser using [HTML5](#), or app frameworks that use WebView to render their UI, such as [PhoneGap](#).

Defining and Using Styles

As noted in [an earlier chapter](#), Android offers styles and themes, filling the same sort of role that CSS does in Web development. In that earlier chapter, we covered the basic roles of styles and themes, plus introduced the three classic theme families:

- Theme
- Theme.Holo
- Theme.Material

In this chapter, we will take a slightly “deeper dive” into styles and themes, exploring how you can create your own and apply them to your app’s UI.

Styles: DIY DRY

The purpose of styles is to encapsulate a set of attributes that you intend to use repeatedly, conditionally, or otherwise wish to keep separate from your layouts proper. The primary use case is “don’t repeat yourself” (DRY) — if you have a bunch of widgets that look the same, use a style to use a single definition for “look the same”, rather than copying the look from widget to widget.

And that paragraph will make a bit more sense if we look at an example, specifically [the Styles/NowStyled sample project](#). This is a trivial project, with a full-screen button that shows the date and time of when the activity was launched or when the button was pushed. This time, though, we want to change the way the text on the face of the button appears, and we will do so using a style.

The `res/layout/main.xml` file in this project has a style attribute on the Button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
```

```
android:id="@+id/button"
android:text=""
android:layout_width="match_parent"
android:layout_height="match_parent"
style="@style/bigred"
/>
```

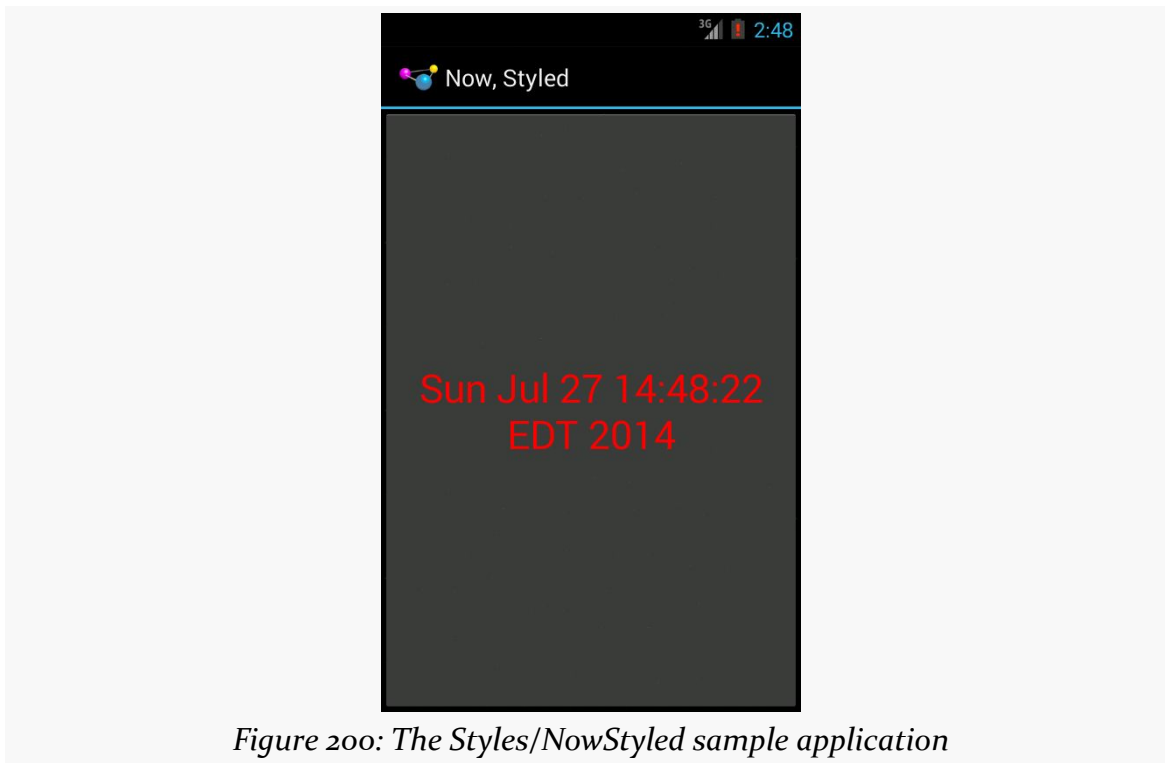

Note that the style attribute is part of stock XML and therefore is not in the android namespace, so it does not get the android: prefix.

The value, @style/bigred, points to a style resource. Style resources are values resources and can be found in the res/values/ directory in your project, or in other resource sets (e.g., res/values-v11/ for values resources only to be used on API Level 11 or higher). The convention is for styles resources to be held in a styles.xml file, such as the one from the NowStyled project:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="bigred">
    <item name="android:textSize">30sp</item>
    <item name="android:textColor">#FFFF0000</item>
  </style>
</resources>
```

The <style> element supplies the name of the style, which is what we use when referring to the style from a layout. The <item> children of the <style> element represent values of attributes to be applied to whatever the style is applied towards — in our example, our Button widget. So, our Button will have a comparatively large font (android:textSize set to 30sp) and have the text appear in red (android:textColor set to #FFFF0000).

Just defining the style and applying it to the widget gives us the desired results:

Elements of Style

There are four elements to consider when applying a style:

- Where do you put the style attributes to say you want to apply a style?
- What attributes can you define via a style?
- How do you inherit from a previously-defined style (one of your own or one from Android)?
- What values can those attributes have in a style definition?

Where to Apply a Style

The style attribute can be applied to a widget, to only affect that widget.

The style attribute can be applied to a container, to affect that container. However, doing this does not automatically style its children. For example, suppose `res/layout/main.xml` looked instead like this:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        style="@style/bigred">
    <Button
        android:id="@+id/button"
        android:text=""
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

The resulting UI would not have the Button text in a big red font, despite the style attribute. The style only affects the container, not the contents of the container.

You can also apply a style to an activity or an application as a whole, though then it is referred to as a “theme”, which will be covered [a bit later in this chapter](#).

The Available Attributes

When styling a widget or container, you can apply any of that widget’s or container’s attributes in the style itself. So, if it shows up in the “XML Attributes” or “Inherited XML Attributes” portions of the Android JavaDocs, you can put it in a style.

Note that Android will ignore invalid styles. So, had we applied the bigred style to the LinearLayout as shown above, everything would run fine, just with no visible results. Despite the fact that LinearLayout has no `android:textSize` or `android:textColor` attribute, there is no compile-time failure nor a runtime exception.

Also, layout directives, such as `android:layout_width`, can be put in a style.

Inheriting a Style

You can also indicate that you want to inherit style attributes from another style, by specifying a parent attribute on the `<style>` element.

For example, take a look at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <style name="activated" parent="android:Theme.Holo">
        <item name="android:background">?android:attr/
activatedBackgroundIndicator</item>
    </style>
</resources>
```

(note: in some renditions of this book, you may see the `<item>` element split over two lines — this is caused by word-wrapping, as this element should be all on one line)

Here, we are indicating that we want to inherit the `Theme.Holo` style from within Android. Hence, in addition to all of our own attribute definitions, we are specifying that we want all of the attribute definitions from `Theme.Holo` as well.

In many cases, this will not be necessary. If you do not specify a parent, your attribute definitions will be blended into whatever default style is being applied to the widget or container.

That `?android:attr` looks a bit bizarre, but we will get into what that syntax means in the next section.

The Possible Values

Typically, the value that you will give those attributes in the style will be some constant, like `30sp` or `#FFFF0000`.

Sometimes, though, you want to perform a bit of indirection — you want to apply some other attribute value from the theme you are inheriting from. In that case, you will wind up using the somewhat cryptic `?android:attr/` syntax, along with a few related magic incantations.

For example, let's look again at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/
activatedBackgroundIndicator</item>
  </style>
</resources>
```

Here, we are indicating that the value of `android:background` is not some constant value, or even a reference to a drawable resource (e.g., `@drawable/my_background`). Instead, we are referring to the value of some other attribute — `activatedBackgroundIndicator` — from our inherited theme. Whatever the theme defines as being the `activatedBackgroundIndicator` is what our background should be.

This portion of the Android style system is very under-documented, to the point where Google itself recommends you look at the [Android source code listing the various styles](#) to see what is possible.

This is one place where inheriting a style becomes important. In the example shown in this section, we inherited from `Theme.Holo`, because we specifically wanted the `activatedBackgroundIndicator` value from `Theme.Holo`. That value might not exist in other styles, or it might not have the value we want.

Themes: Would a Style By Any Other Name...

Themes are styles, applied to an activity or application, via an `android:theme` attribute on the `<activity>` or `<application>` element. If the theme you are applying is your own, just reference it as `@style/...`, just as you would in a style attribute of a widget. If the theme you are applying, though, comes from Android, typically you will use a value with `@android:style/` as the prefix, such as `@android:style/Theme.Holo.Dialog` or `@android:style/Theme.Holo.Light`.

In a theme, your focus is not so much on styling widgets, but styling the activity itself. For example, here is the definition of `@android:style/Theme.Holo.NoActionBar.Fullscreen`:

```
<!-- Variant of the default (dark) theme that has no title bar and  
fills the entire screen -->  
<style name="Theme.Holo.NoActionBar.Fullscreen">  
  <item name="android:windowFullscreen">true</item>  
  <item name="android:windowContentOverlay">@null</item>  
</style>
```

It specifies that the activity should take over the entire screen, removing the status bar on phones (`android:windowFullscreen` set to `true`). It also specifies that the “content overlay” — a layout that wraps around your activity’s content view — should be set to nothing (`android:windowContentOverlay` set to `@null`), having the effect of removing the title bar.

What Happens If You Have No Theme

Most of the sample apps that we have examined so far have not defined a theme, either at the `<application>` level or the `<activity>` level. What happens here then depends upon the device that your app runs upon:

- On an Android 1.x or 2.x device, you will get `Theme` as your theme
- On an Android 3.x or 4.x device, if your `minSdkVersion` or `targetSdkVersion` is 11 or higher, you will get `Theme.Holo` as your theme; otherwise, you will stick with `Theme` as your theme
- On an Android 5.0+ device, if your `targetSdkVersion` is 14 or higher, you will get `Theme.Material` as your theme; otherwise, your app behaves as in the 3.x/4.x scenario above

As a result, your app is far from “broken”, despite the lack of an explicit theme. It does mean, though, that your app will have a different look on those different Android OS levels, a look that will tend to have your app blend in more with other apps on that same device.

However, once you want to start customizing your theme, you will now run into a problem: having different themes for different OS versions. An Android 2.x device knows nothing about `Theme.Material`, for example, so you cannot simply create a custom theme based on `Theme.Material` and expect it to work. As we will see [in a later chapter](#), the solution winds up being *versioned resources*, where you have different theme definitions for different API levels.

Of course, if your `minSdkVersion` is high enough, resource versioning is less of an issue. For example, if your `minSdkVersion` is 21, all devices that your app runs upon should know about `Theme.Material`, just as if your `minSdkVersion` were 11 or higher, all devices that your app would run on would know about `Theme.Holo`.

JARs and Library Projects

Java has as many, if not more, third-party libraries than any other modern programming language. Here, “third-party libraries” refer to the innumerable JARs that you can include in a server or desktop Java application — the things that the Java SDKs themselves do not provide.

In the case of Android, the virtual machine (VM) at its heart is not precisely Java, and what it provides in its SDK is not precisely the same as any traditional Java SDK. That being said, many Java third-party libraries still provide capabilities that Android lacks natively and therefore may be of use to you in your project, for the ones you can get working with Android’s flavor of Java. This chapter explains what it will take for you to leverage such libraries and the limitations on Android’s support for arbitrary third-party code.

You might think that JARs are the primary model of code reuse within Android. That’s not really the case. The primary model of code reuse within Android is the Android library project. Many reusable components and frameworks are distributed as library projects, and we will see several in the course of this book.

The example described in this chapter is the Android Support package, a key piece of reusable code from Google itself, distributed partly as JARs and partly as an Android library project.

But first, let’s talk a bit more about Android and VMs.

The Dalvik VM, and a Bit of ART

When you are writing Android applications, you are writing Java source code. You might be thinking that your Android device is running Java bytecode, just as your Web browser might when it runs a Java applet.

Alas, you would be mistaken.

Android does not have a Java VM. Android has the Dalvik VM or ART.

The Dalvik VM is a virtual machine, along the lines of the Java VM, the Parrot VM (Perl), Microsoft's CLR, and so forth. Since each VM has its own bytecode, the Dalvik VM bytecode is not the same as the Java VM bytecode (or the Parrot VM bytecode, etc.).

When you build your project, your Java source code is initially compiled using the standard `javac` compiler. Then, however, the Java VM bytecodes created by `javac` are cross-compiled into Dalvik VM bytecodes, and it is *those* bytecodes that are packaged into your APK file and are executed by Android.

Most of the time, you will not notice the difference. Every now and then, though, you will encounter some issues related to Android's use of Dalvik, and the most prominent of these comes when you try repurposing existing Java code.

ART is a new runtime, available for developer testing in Android 4.4. ART still uses Dalvik bytecodes, but uses them as input for an ahead-of-time (AOT) compiler. Rather than relying on a just-in-time (JIT) compiler, as the Dalvik VM does, to translate Dalvik bytecodes into CPU-specific instructions, ART's AOT compiler converts *all* the bytecodes to instructions at installation time.

Getting the Library

You have two easy choices for integrating third-party Java code into your project: use JARs or use an artifact in a repository. The latter approach is for Android Studio users; any IDE can use JARs. The details vary by IDE.

Android Studio

Ideally, the documentation for the third-party library will tell you how to get it as an artifact and add it to your Android Studio project. Specifically, it should tell you a

JARS AND LIBRARY PROJECTS

line that you should add to your dependencies closure of your app's build.gradle file, such as `compile 'com.squareup.retrofit:retrofit:1.6.1'`. We will get into the details of what this line means [much later in the book](#).

The documentation should also indicate what artifact repository this artifact comes from. It may tell you that the artifact comes from “Maven” or “Maven Central”, in which case you will need a `mavenCentral()` line in your repositories closure:

```
repositories {  
    mavenCentral()  
}
```

Or, it may tell you something else to use, if the artifact is from another repository, such as:

```
repositories {  
    maven {  
        url "https://repo.commonsware.com.s3.amazonaws.com"  
    }  
}
```

So, for example, you might wind up with the following in your app's build.gradle file:

```
repositories {  
    mavenCentral()  
}  
  
dependencies {  
    compile 'com.squareup.retrofit:retrofit:1.6.1'  
}
```

If you have an artifact name (e.g., `com.squareup.retrofit:retrofit:1.6.1`), and you have no indication of where the artifact comes from, try the `mavenCentral()` option.

If all you have is a JAR file, put it in a `libs/` directory in your project's `app/` folder, and then make sure that your dependencies closure has the `compile fileTree...` line in it to pull JARs from `libs/`:

```
dependencies {  
    compile fileTree(dir: 'libs', include: ['*.jar'])  
}
```

Much more about Android Studio, Gradle, and dependencies can be found [later in the book](#), but this should help you get started.

Eclipse

If you choose to use an existing JAR, place the JAR in the `libs/` directory in your Android project. And that's it, at least for Eclipse. Your JAR will be automatically added to your build path, and your JAR will be automatically bundled into the APK file that is your Android application. Note that other IDEs might require other steps – please consult the documentation for that IDE.

Also note that the R22 version of the ADT plugin for Eclipse may force you to make some adjustments to the “Order & Export” portion of your project's build path. If it seems like your JAR is not being picked up (e.g., you try referring to classes from the JAR and you get runtime `ClassNotFoundException`s), then try this recipe:

- Right-click on the project in Eclipse's Package Explorer and choose Build Path > Configure Build Path from the context menu
- Switch to the “Order and Export” tab
- Check the “Android Private Libraries” entry in the list, if it is not already checked

The Outer Limits

Not all available Java code will work well with Android. There are a number of factors to consider, including:

- *Expected Platform APIs*: Does the code assume a newer JVM than the one Android is based on? Or, does the code assume the existence of Java APIs that ship with J2SE but not with Android, such as Swing?
- *Size*: Existing Java code designed for use on desktops or servers need not worry too much about on-disk size, or, to some extent, even in-RAM size. Android, of course, is short on both. Using third-party Java code, particularly when pre-packaged as JARs, may balloon the size of your application.
- *Performance*: Does the Java code effectively assume a much more powerful CPU than what you may find on many Android devices? Just because a desktop can run it without issue does not mean your average mobile phone will handle it well.
- *Interface*: Does the Java code assume a console interface? Or is it a pure API that you can wrap your own interface around?
- *Operating System*: Does the Java code assume the existence of certain console programs? Does the Java code assume it can use a Windows DLL?

- *Language Version*: Was the JAR compiled with an older version of Java (1.4.2 or older)? Was the JAR compiled with a different compiler than the official one from Sun (e.g., GCJ)? Was the JAR compiled with Java 8 and has Java 8 bytecodes rather than those compatible with Java 6?
- *Dependencies*: Does the Java code depend on other third-party JARs that might have some of these problems as well? Does the Java code depend upon third-party libraries (e.g., the `org.json` JSON library) that are built into Android, but the third party expects a different version of that library?

One trick for addressing some of these concerns is to use open source Java code, and actually work with the code to make it more Android-friendly. For example, if you are only using 10% of the third-party library, maybe it's worthwhile to recompile the subset of the project to be only what you need, or at least removing the unnecessary classes from the JAR. The former approach is safer, in that you get compiler help to make sure you are not discarding some essential piece of code, though it may be more tedious to do.

JAR Dependency Management

One challenge with reusing JARs is that JARs sometimes depend upon other JARs.

If you are using Android Studio, this is handled for you automatically, if you are using artifacts from a repository as the source of the JARs (e.g., pulling from Maven Central).

If you are using Eclipse, you will need to identify and download all relevant dependent JARs, placing them in `libs/` along with the JARs you originally obtained.

OK, So What is a Library Project?

An Android library project is a special type of Android project designed to share code and resources between Android application projects. It is specifically aimed at developers or teams creating multiple applications from the same code base. Library projects can also be used for reusable components, such as distributing custom widgets, activities, or frameworks to third parties.

The biggest difference between an Android library project and a JAR is that an Android library project is designed to distribute *resources* and *manifest entries* as well as Java code. If all you are looking to distribute is Java code, a JAR works just as

well as an Android library project. But if you need to distribute layouts, themes, activities, and the like, an Android library project is the better solution.

A [later chapter](#) will describe how to create an Android library project.

Using a Library Project

Given that you have a library project — or have identified one you want to use — you can attach it to a regular Android project, so the regular Android project has access to everything in the library. As you might expect, how you accomplish this depends upon your choice of IDE.

Android Studio

Hopefully, the library project that you are wishing to use is being distributed as an AAR — an Android archive file that contains a compiled version of the library's source code, along with the resources and, if supplied, manifest.

More specifically, hopefully the library project that you are wishing to use is being distributed as an AAR as an artifact in a repository. If so, you can integrate it using the same approach as is described [earlier in this chapter](#) for JARs — just add the necessary compile statement to the dependencies closure.

For example, to add [the CWAC-ColorMixer library project](#) to your Android Studio app, you would use:

```
repositories {  
    maven {  
        url "https://repo.commonware.com.s3.amazonaws.com"  
    }  
}  
  
dependencies {  
    compile 'com.commonware.cwac:colormixer:0.5.+'  
}
```

If the Android library project is being distributed in any other way, adding it to Android Studio becomes substantially more complicated. Those scenarios will be examined in greater detail in upcoming chapters on [library projects](#) and [Gradle dependencies](#). In that chapter, we will also go into more details about the structure of that compile statement and the versioning rules (e.g., 0.5.+).

Eclipse

To add a reference to an Android library project in Eclipse, you must first have it in your Eclipse workspace, such as via importing the project. Then, go into the project properties window (e.g., right-click on the project and choose Properties). Click on the Android entry in the list on the left, then click the “Add” button in the Library area. This will let you browse to the directory where your library project resides. You can add multiple libraries and control their ordering with the “Up” and “Down” buttons, or remove a library with the “Remove” button.

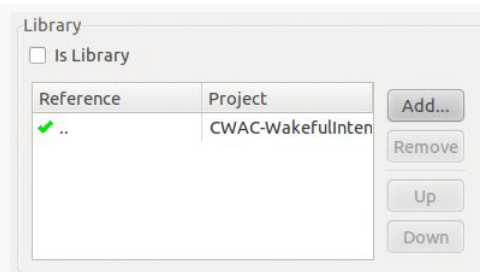

Figure 201: Android Library Project Consumer Properties, Library Section

Library Projects: What You Get

Now, if you build the main project, the Android build tools will:

- Include the `src/` directories of the main project and all of the libraries (`libs/`) in the source being compiled.
- Include all of the resources of the projects, with the caveat that if more than one project defines the same resource (e.g., `res/layout/main.xml`), the highest priority project’s resource is included. The main project is top priority, and the priority of the remainder are determined by their order as defined in the build rules (e.g., order in dependencies in Android Studio; order in `project.properties` for Eclipse).

This means you can safely reference `R.` constants (e.g., `R.layout.main`) in your library source code, as at compile time it will use the value from the main project’s generated `R` class(es).

You may also have some manifest entries automatically injected into your manifest, to add items from a manifest supplied by the library.

The Android Support Package

The Android Support package is distributed by Google, containing classes (in JARs and Android library projects) that are not part of the Android SDK, but are available to Android developers.

What's In There?

You can roughly divide the contents of the Android Support package into two major areas:

1. “Backports” of capabilities added to newer versions of Android and the Android SDK, so they can be used on older devices as well. By using the backported classes, you can get the same abilities on a wider range of devices than you could if you only used the classes in the Android SDK.
2. New widgets, containers, or other classes that are not going to be in the Android SDK (for ill-defined reasons) but that Google wishes to make available for Android developers.

More specifically, the most commonly-used pieces of the Android Support package include:

- support-v4, which contains backports and miscellaneous UI classes, working back to API Level 4
- support-v13, which is identical to support-v4 but *also* contains a few classes that only work on API Level 13 and higher
- appcompat-v7, which is a backport of the action bar, a concept that we will discuss [in an upcoming chapter](#)
- gridlayout-v7, which is a backport of [the GridLayout container](#)
- mediarouter-v7, which provides a re-implementation of [MediaRouter and related classes](#)

About the Names

What this book refers to as the “Android Support package” has many names.

It was originally referred to as the Android Compatibility Library, at a time when it only contained backports. Once Google started adding in things that were not strictly related to “compatibility”, they started changing the name to try to be more generic. Right now, “Android Support” seems to be fairly consistent, either used

standalone or in the form of “Android Support package” or “Android Support Library”.

For the purposes of this book, “Android Support package” refers to the entire family of these libraries.

-v4 Versus -v13

Any given project needs *either* support-v4 or support-v13 (or sometimes neither), not both. If your `minSdkVersion` is 13 or higher, choose the support-v13 library over the support-v4 library, as support-v13 is a clear superset of what is in support-v4.

Getting It

You will find the Android Support package in your SDK Manager, in the “Extras” category towards the bottom of the tree:

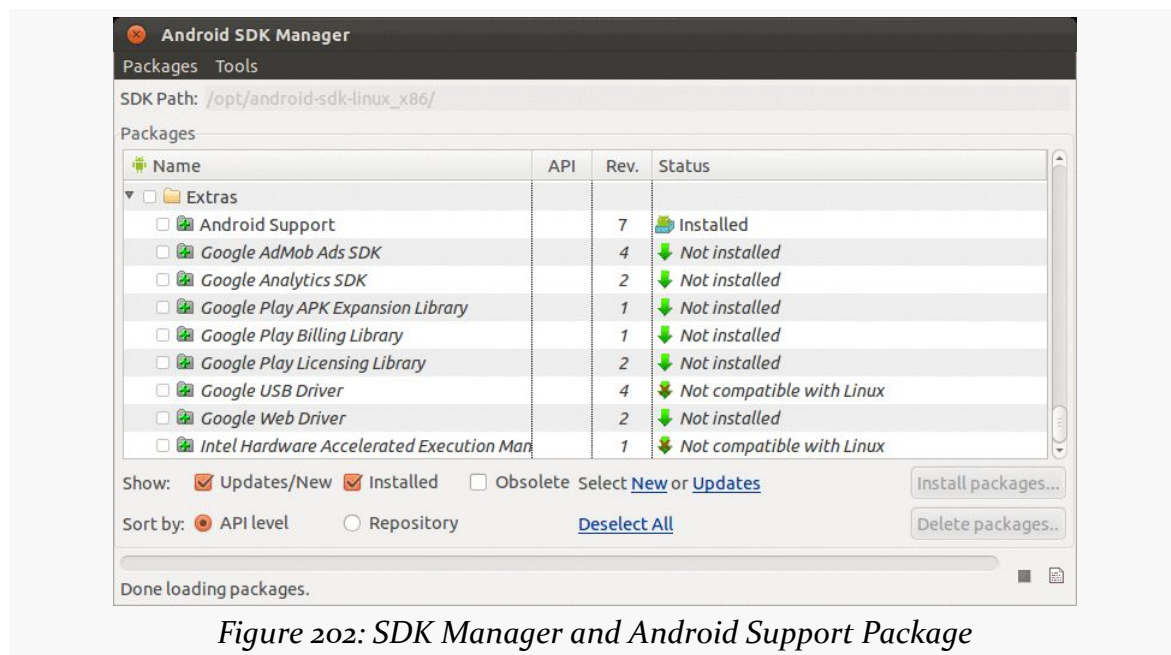

Figure 202: SDK Manager and Android Support Package

To install it, check the checkbox and click the “Install” button, just as you might install an SDK itself.

This will add an `extras/` directory to wherever your SDK installation resides, and the Android Support package will go into subdirectories inside of `extras/`.

Android Studio users will also want to download the “Android Repository” from the “Extras” area, as this makes the Android Support package’s libraries available to you in a local artifact repository, to simplify adding it to your project.

Attaching It To Your Project

As with many things in Android, how you attach Android Support package libraries to your app depends upon your choice of IDE.

Android Studio

You can add references to the Android Support package’s libraries — whether those libraries are simple JARs or Android library projects — via a few lines in your dependencies closure, referencing the artifacts from the Android Repository.

The easiest way at present to remember what the lines are is to visit [the “Gradle, please” Web site](#), which lists them at the top:

```
// Support Libraries
compile 'com.android.support:appcompat-v7:21.0.0'
compile 'com.android.support:cardview-v7:21.0.0'
compile 'com.android.support:gridlayout-v7:21.0.0'
compile 'com.android.support:leanback-v17:21.0.0'
compile 'com.android.support:mediarouter-v7:21.0.0'
compile 'com.android.support:palette-v7:21.0.0'
compile 'com.android.support:recyclerview-v7:21.0.0'
compile 'com.android.support:support-annotations:21.0.0'
compile 'com.android.support:support-v13:21.0.0'
compile 'com.android.support:support-v4:21.0.0'
```

Also, while you *could* add all of these to your project, that is not necessary. Only attach dependencies for libraries that you are actually using. Having unused libraries in your project just increases your APK size for no good reason. Hence, most projects will have only a subset of the aforementioned lines.

Eclipse

For support-v4 or support-v13, find the android-support-v4.jar or android-support-v13.jar file installed in your extras/ directory tree of your SDK installation and add a copy to your project’s libs/ directory.

JARS AND LIBRARY PROJECTS

The others are distributed as Android library projects. You will need to import the project(s) you want from the Android SDK's extras/ area, then attach them to your project as is described [earlier in this chapter](#).

Tutorial #6 - Adding a Library

We will want to use some third-party libraries in our project, to ease development of the app:

- the [Android Support library](#), specifically its android-support-v13 JAR
- greenrobot's [EventBus](#), for communication between various pieces of our app
- Google's [GSON](#) parser of JSON data
- Square's [Retrofit](#), for retrieving JSON data from Web services

Right now, we will just focus on arranging for our project to be able to use the libraries. Later in the book, we will actually put the libraries to use.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Attaching the Android Support Package

First, we need one of the pieces of the Android Support package, specifically the support-v13 library, for some classes that we will be using from it later on, such as ViewPager.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Open the `app/build.gradle` file, off of the project root directory. Find the dependencies closure, which should look like this:

```
dependencies {  
    compile fileTree(dir: 'libs', include: ['*.jar'])  
}
```

Replace that implementation with:

```
dependencies {  
    compile 'com.android.support:support-v13:21.0.3'  
}
```

This means that we will no longer be loading JAR files out of a `libs/`, so you can delete that `libs/` directory from the `app/` directory of your project. It also tells Android Studio to incorporate the `support-v13` library from your local Android Repository, which you installed back in [Tutorial #1](#).

Eclipse

In the directory where you installed the Android SDK, find the `extras/android/support/v13` directory, and the `android-support-v13.jar` file inside of there.

Your project should have an empty `libs/` directory. Copy that JAR file into the `libs/` directory. Ideally, you will want to drag-and-drop the file into the `libs/` directory shown in the Eclipse Package Explorer pane, as that not only will copy the file, but it will let Eclipse know about the copy.

Step #2: Downloading the Third-Party JARs

We also need some third-party components for our application eventually, but we can set them up now.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

The three third-party components we are going to set up now all are available from Maven Central. However, we need to teach Android Studio to be able to load dependencies from Maven Central. To do that, add the following code to your app/build.gradle file, above the dependencies closure:

```
repositories {  
    mavenCentral()  
}
```

Then, add three more lines to the dependencies closure, identifying the GSON, Retrofit, and EventBus components that we need:

```
dependencies {  
    compile 'de.greenrobot:eventbus:2.4.0'  
    compile 'com.google.code.gson:gson:2.3.1'  
    compile 'com.squareup.retrofit:retrofit:1.8.0'  
    compile 'com.android.support:support-v13:21.0.3'  
}
```

At this point, your app/build.gradle file should look something like:

```
apply plugin: 'com.android.application'  
  
android {  
    compileSdkVersion 19  
    buildToolsVersion "21.1.2"  
  
    defaultConfig {  
        applicationId "com.commonware.empublite"  
        versionCode 1  
        versionName "1.0"  
        minSdkVersion 15  
        targetSdkVersion 18  
    }  
}  
  
repositories {  
    mavenCentral()  
}  
  
dependencies {  
    compile 'de.greenrobot:eventbus:2.4.0'  
    compile 'com.google.code.gson:gson:2.3.1'  
    compile 'com.squareup.retrofit:retrofit:1.8.0'  
    compile 'com.android.support:support-v13:21.0.3'  
}
```

At this point, you can save your file.

You may get a yellow banner at the top of the editor, indicating that a “project sync” is requested. If you do, click the “Sync Now” link in that banner to synchronize the *.iml files with the changes you made to this build.gradle file.

Eclipse

The following URLs point to two JARs that we need (though some do a redirect first):

- [greenrobot’s EventBus](#)
- [Square’s Retrofit](#)
- [Google’s Gson](#)

Copy all three JARs into your libs/ directory. As before, Eclipse users will want to drag-and-drop the files into the libs/ directory shown in the Eclipse Package Explorer pane, as that not only will copy the files, but it will let Eclipse know about the copies.

At this point, the libs/ directory of your project should look like:

Figure 203: Eclipse libs/ Directory Contents

And that’s it. Now all four JARs (including the android-support-v13.jar) are available to us both at compile-time and at runtime.

In Our Next Episode...

... we will [configure the action bar](#) on our tutorial project

The Action Bar

The action bar — that bar that runs across the top of your activity — is the backbone of your UI. Here, you can provide actions for the user to perform related to the current activity (e.g., “edit the contact that you are viewing”) or related to the application as a whole (e.g., “here is the documentation”). Sometimes, these actions will appear as toolbar buttons or other widgets in the action bar. Sometimes, these actions will appear in the “overflow”, which amounts to a menu.

This chapter introduces the concept of the action bar and how to add actions to it.

Bar Hopping

Android has had many patterns for various “bars” as part of its UI. So, to help explain what an action bar is, it helps if we review the history and role of Android’s various bars.

Android 1.x/2.x

In the beginning, there was the status bar and the title bar.

The status bar was a thin strip across the top of the screen, used for things like the clock, signal strength, battery charge, and notification icons (for events like new unread email messages). This bar is technically part of the OS, not your app’s UI.

The title bar was a thin gray strip beneath the status bar that, by default, would hold the name of your application, much like the title bar of a browser might show the name of a Web site.

THE ACTION BAR

Figure 204: Status Bar and Title Bar

Android 3.0–4.1, Tablets

When official support for tablets arrived with Android 3.0 in February 2011, the story changed.

The status bar was replaced by the system bar, appearing at the bottom of the screen. This had all of the contents of the old status bar, but also had the soft keys for BACK, HOME, etc. Android 1.x and 2.x required that devices have off-screen affordances for those operations; now, device manufacturers could skip those and have the system bar offer them.

The action bar, by default, appears at the top of your activity, replacing the old title bar. You can define what goes in the action bar (icon, title, toolbar buttons, etc.).

THE ACTION BAR

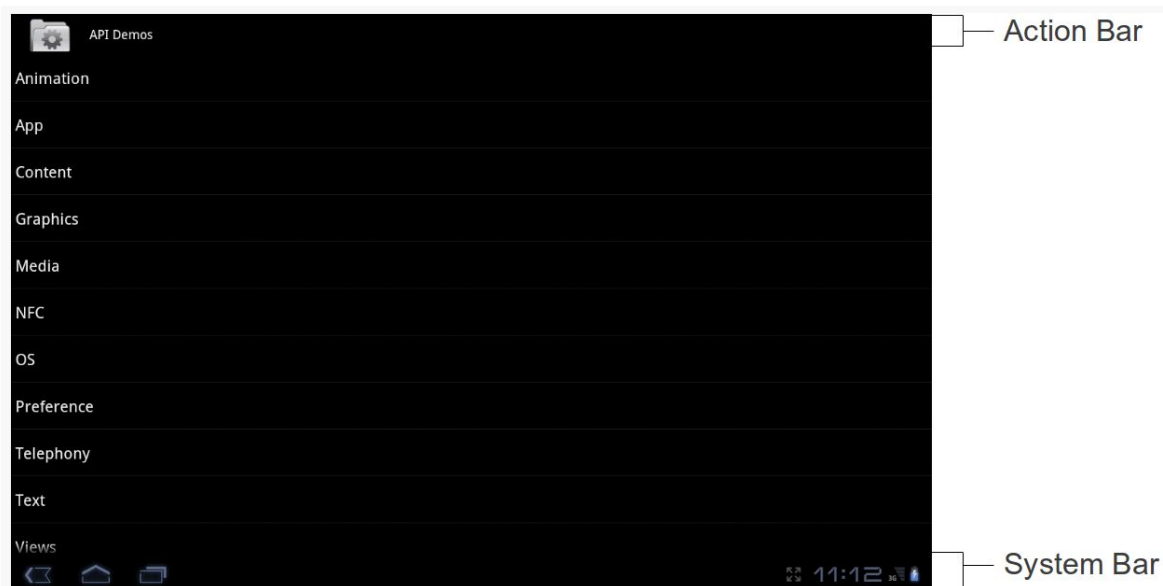

Figure 205: Action Bar and System Bar

The icon on the far left of the action bar also serves as a toolbar button, if you wish. A common pattern for using this is take the user back to the “main” or “home” activity of your application.

Sometimes, the far right side of the action bar will contain a “...” affordance. This is known as the “action overflow” or “overflow menu”:

Figure 206: Action Bar with Open Overflow Menu

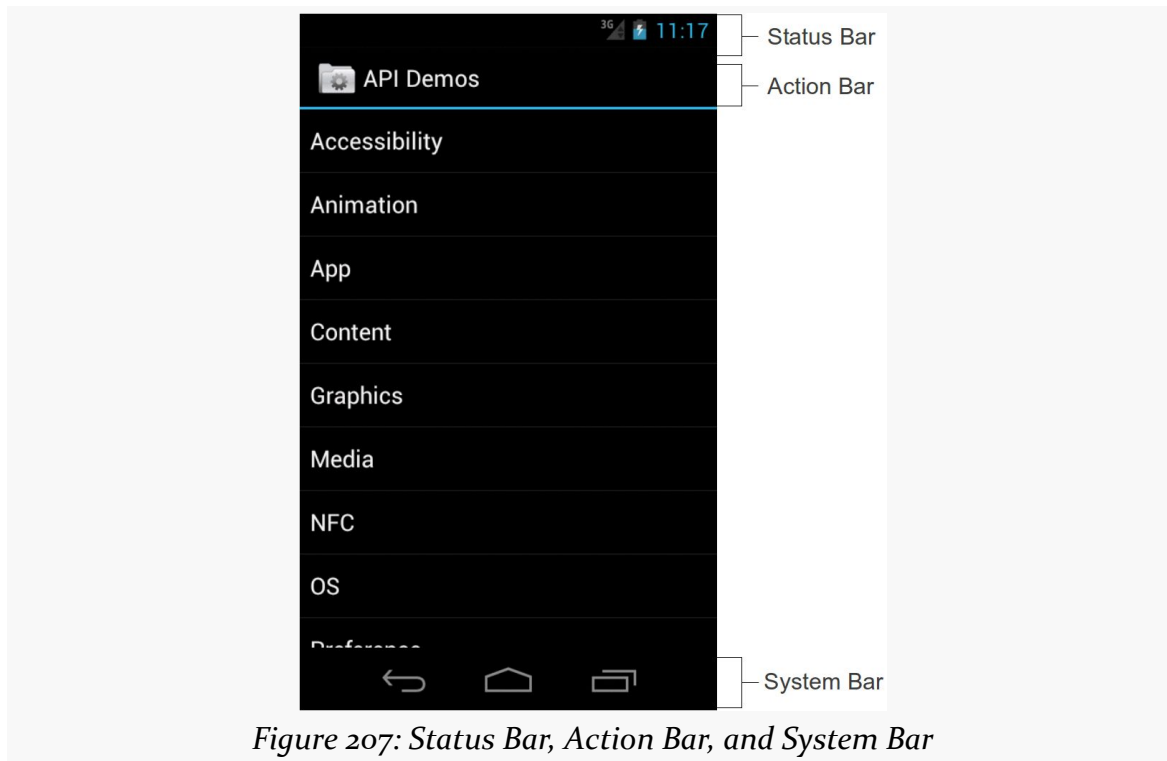

Tapping it will give the user access to actions that might have been toolbar buttons on a larger screen, but there was insufficient room. Also, low-priority actions may be tucked into the overflow, rather than clutter up the screen with too many toolbar buttons.

Android 4.0–4.4, Phones

Phone-sized devices were not supported by Android 3.x. They jumped from Android 2.3 to 4.0, and along the way adopted some of the Android 3.x UI features:

- Phone apps could have an action bar, like their tablet counterparts
- Device manufacturers could skip the BACK, HOME, etc. buttons and let a partial system bar handle those
- The status bar remained intact from the Android 2.x approach

THE ACTION BAR

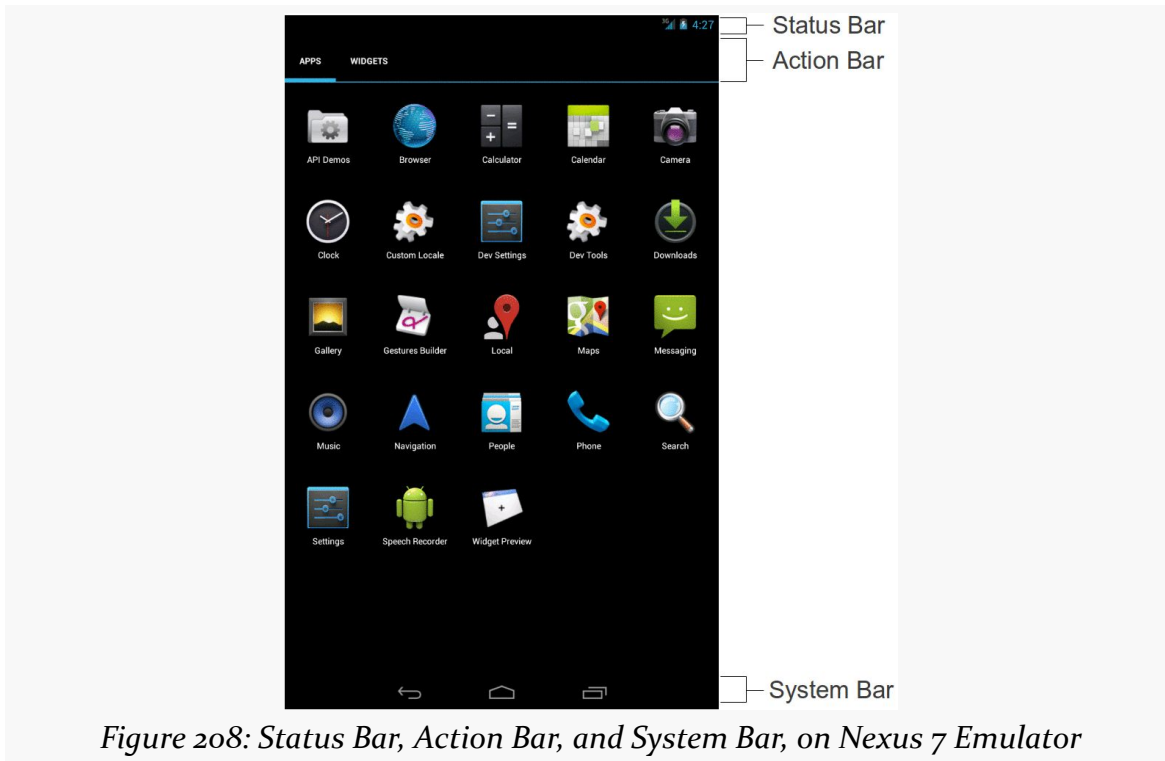

Android 4.2–4.4, Tablets

The Nexus 7, introduced in the summer of 2012, was a 7" tablet that did not follow the tablet UI structure that all other standard Android tablets used. Instead, it looked a bit like a really large phone, having a top status bar along with a bottom system bar solely for the navigation buttons (BACK, HOME, etc.). Apps, as before, could have an action bar as well.

Initially, it was thought that the Nexus 7 was going to be distinctive in that regard. Instead, with Android 4.2, Google switched all tablets to this model, restoring the status bar and relegating the system bar purely for navigation buttons.

THE ACTION BAR

Android 5.0+

Functionally, the action bar is much the same in Android 5.0 as it was in previous releases. However, aesthetically, it has dropped the icon and made other minor stylistic adjustments.

Figure 209: Action Bar on Android 5.0 Emulator

Yet Another History Lesson

Back in the dawn of Android time, referred to by some as “the year 2007”, we had options menus. These would rise up from the bottom of the screen based on the user pressing a MENU key:

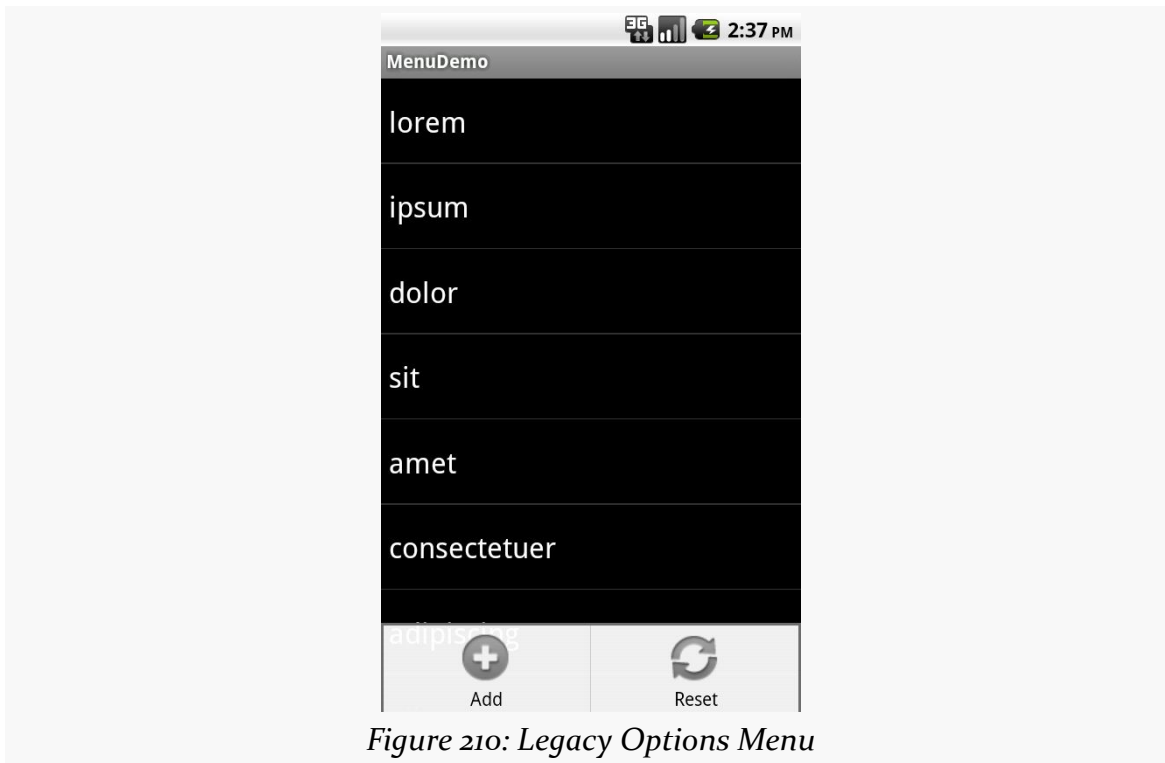

Figure 210: Legacy Options Menu

This is why you will see references to “options menu” scattered throughout the Android SDK.

The action bar pattern was first espoused by Google at the 2010 Google I/O conference. However, at the time, there was no actual implementation of this, except in scattered apps, and definitely not in the Android SDK.

Android 3.0 — a.k.a., API Level 11 — added the action bar to the SDK, and apps targeting that API level will get an action bar when running on such devices.

Your Action Bar Options

There are several implementations of the action bar floating about. You will probably be using the one that is part of Android itself, starting with API Level 11. However, there are a couple of backports of the action bar if you need them.

Pure Native

As mentioned above, devices running Android 3.0 and higher have support for the action bar as part of their firmware, and that support is exposed through the Android SDK. For example, there is an `ActionBar` class, and you can get an instance of it for your activity's action bar via `getActionBar()`.

However, this only works on devices running Android 3.0 and higher. If you try calling `getActionBar()` on an older device, you will crash with a `VerifyError` runtime exception. `VerifyError` is Android's way of telling you "while you compiled fine, something your compiled code refers to does not exist".

If your `minSdkVersion` is 11 or higher, you will be able to use the native action bar, and that approach will be used in most of this book.

Backports

If your `minSdkVersion` is lower than 11, you have three major choices:

1. Use the "menu" APIs in Android, which will add stuff to the action bar on newer devices, but will result in the classic "options menu" on older devices.
2. Use the `appcompat-v7` backport of the action bar, published by Google in the Android Support package in August 2013.
3. Use `ActionBarSherlock`, an independent backport of the action bar, published by Jake Wharton in 2011, after Android 3.0 was released.

This chapter assumes that your `minSdkVersion` is set to 11 or higher and you will use the native action bar. Separate chapters in the trails cover the use of [appcompat-v7](#) and [ActionBarSherlock](#).

Note that, as of October 2014, the `appcompat-v7` library not only backports the action bar, but also attempts to backport part of Google's Material Design styling. Normally, Material Design only comes from Android 5.0 and the use of `Theme.Material`. The [appcompat-v7 chapter](#) will cover the library's effects both to the action bar and to other aspects of your app's UI.

Setting the Target

If you want proper action bar support, you will want to target API Level 14 or higher at runtime. That involves setting the `targetSdkVersion` property in your

THE ACTION BAR

build.gradle file (for Android Studio users) or setting the `android:targetSdkVersion` attribute of the `<uses-sdk>` element of your manifest (for Eclipse users, or Android Studio users maintaining Eclipse compatibility with their projects).

We see this in the manifest of the [ActionBar/ActionBarDemoNative](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.inflation"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="10"
        android:targetSdkVersion="19"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name=".ActionBarDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Specifically, we have `android:targetSdkVersion` set to 19. While 11 or higher will give you an action bar, 14 or higher will solve a particular UI quirk related to menu choices. Some Android 4.0+ devices, but not all, will show *two* ways of getting at overflow menu items if you have your `android:targetSdkVersion` set to a value between 11 and 13. You will have the “...” item in the action bar itself *and* a second one in the system bar, on devices that have one. Setting `android:targetSdkVersion` to 14 or higher resolves this.

Doing nothing else but the preceding steps would give us an action bar, but one with no toolbar icons or action overflow menu. While perhaps visually appealing, this is not terribly useful for the user, so we need to do some more work to give the user actions to perform from the action bar.

Note that this manifest has a `minSdkVersion` of 10. This means that the app can run on Android 2.3.3 devices. On those devices, though, the app will not have an action bar, as the action bar did not exist then, and this app is not using a backport like `appcompat-v7`. Instead, the app will have an old-style options menu on API Level 10 devices. There is nothing intrinsically wrong with this, though it does mean that your app will look different on API Level 10 devices.

Defining the Resource

The easiest way to get toolbar icons and action overflow items into the action bar is by way of a menu XML resource. This is called a “menu” resource for historical reasons, as these resources originally were used for things like the options menu.

You can add a `res/menu/` directory to your project and place in there menu XML resources.

Through Eclipse, if you create a new file in there (e.g., `actions.xml`), you will be able to manipulate the menu items using a structured editor, using the “Add” to add a new item and configuring it via the options on the right:

THE ACTION BAR

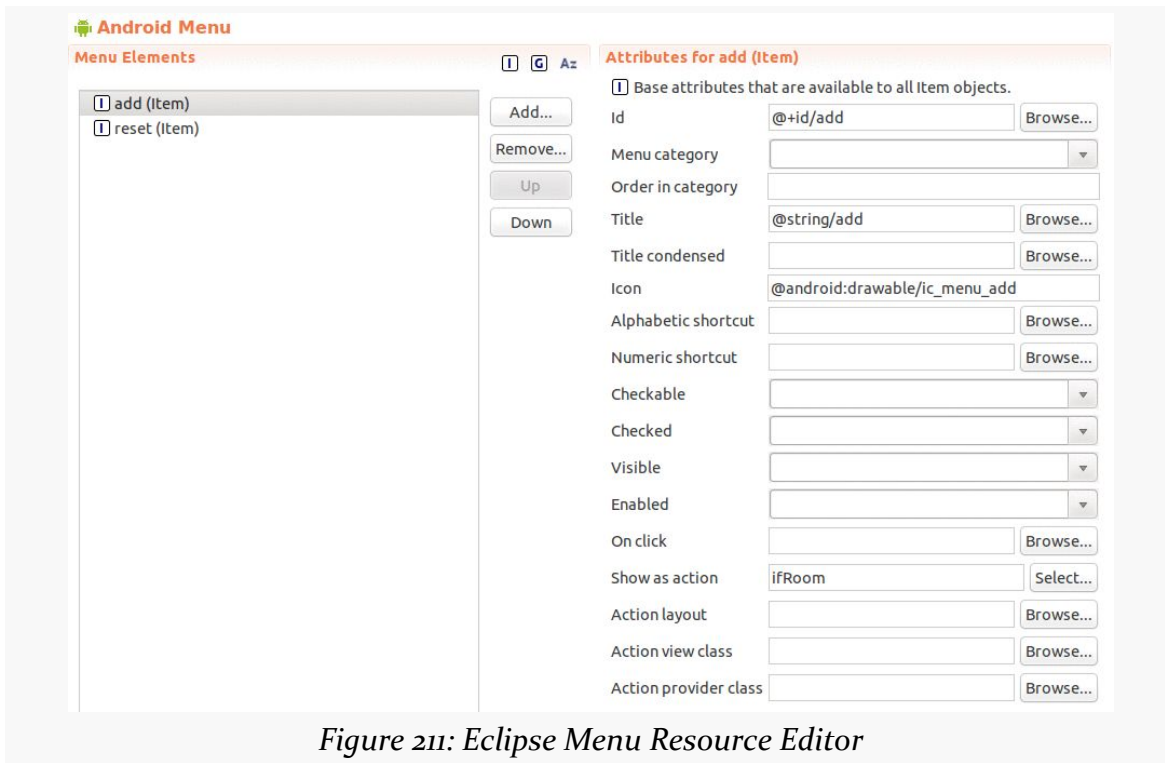

Figure 211: Eclipse Menu Resource Editor

Or, you can work with the raw XML, such as `res/menu/actions.xml` from `ActionBar/ActionBarDemoNative`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/add"
        android:icon="@drawable/ic_action_new"
        android:showAsAction="always"
        android:title="@string/add"/>
    <item
        android:id="@+id/reset"
        android:icon="@drawable/ic_action_refresh"
        android:showAsAction="always|withText"
        android:title="@string/reset"/>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        android:showAsAction="never"
        android:title="@string/about">
    </item>
</menu>
```

If you are using Android Studio, you will work with the XML directly.

There are four things you will want to configure on every menu item (<item> element in the XML):

1. The ID of the item (via the Id field in Eclipse or the `android:id` attribute in XML). This will create another `R.id` value, associated with this menu item, much like the `R.id` values for our widgets in our layouts. We will use this ID to determine when the user clicks on one of our toolbar buttons or action overflow items.
2. The title of the item (via the Title field in Eclipse or the `android:title` attribute in XML). If this item winds up in the action overflow menu, or optionally as part of its toolbar button, this text will appear. Also, this title will appear as a “tooltip” on the action item in the action bar itself, if the user long-presses on the icon (something few users know to do). Typically, you will use a string resource reference (e.g., `@string/add`), to better support internationalization.
3. The icon for the item (via the Icon field in Eclipse or the `android:icon` attribute in XML). If your item will appear as a toolbar button, this icon is used with that button.
4. Flags indicating how this item should be portrayed in the action bar (via the “Show as action” field in Eclipse or the `android:showAsAction` attribute in XML). You will choose to have it be always a toolbar button, only be a toolbar button `ifRoom`, or have it never be a toolbar button. You can also elect to append `|withText` to either `always` or `ifRoom`, to indicate that you want the toolbar button to be both the icon and the title, not just the icon. Note that `always` is not *guaranteed* to be a toolbar button — if you ask for 100 `always` items, you will not have room for all of them. However, `always` items get priority for space in the action bar over `ifRoom` items.

Applying the Resource

From your activity, you teach Android about these action bar items by overriding an `onCreateOptionsMenu()` method, such as this one from the `ActionBarDemoActivity` of the `ActionBar/ActionBarDemoNative` sample project:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

Here, we create a `MenuInflater` and tell it to inflate our menu XML resource (`R.menu.actions`) and pour them into the supplied `Menu` object. We then chain to the superclass, returning its result.

Responding to Events

To find out when the user taps on one of these things, you will need to override `onOptionsItemSelected()`, such as the `ActionBarDemoActivity` implementation shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.add:
            addWord();

            return(true);

        case R.id.reset:
            initAdapter();

            return(true);

        case R.id.about:
            Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
                .show();

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

You will be passed a `MenuItem`. You can call `getItemId()` on it and compare that value to the ones from your menu XML resource (`R.id.add` and `R.id.reset`). If you handle the event, return `true`; otherwise, return the value of chaining to the superclass' implementation of the method.

If you wish to respond to taps on your application icon, on the left of the action bar, compare `getItemId()` to `android.R.id.home`, as that will be the `MenuItem` used for that particular toolbar button. Note that if you have your `android:targetSdkVersion` set to 14 or higher, you will also need to call `setHomeButtonEnabled(true)` on the `ActionBar` (obtained via a call to `getActionBar()`) to enable this behavior. Note that this icon may not exist, particularly if you are using `Theme.Material` on Android 5.0+.

The Rest of the Sample Activity

So, what is it that we really are doing here in `ActionBarDemoActivity`?

In many respects, this is reminiscent of the `ListActivity` demos from [an earlier chapter](#). We have an array of 25 Latin words, and we want to display these in a list.

However, in this case, we are only showing five words at the outset. An “add” action bar item will add additional words out of the main roster of 25 words, until the `ListView` holds all 25. A “reset” action bar item will return us to the original 5 words.

`ActionBarDemoActivity` is a `ListActivity`. However, rather than set up our `ArrayAdapter` directly in the `onCreate()` method as some of the other samples have done, we delegate that work to an `initAdapter()` method. Moreover, that `initAdapter()` method does its work a bit differently than what those other samples did:

```
private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
        words.add(items[i]);
    }

    adapter=
        new ArrayAdapter<String>(this,
                                android.R.layout.simple_list_item_1,
                                words);

    setListAdapter(adapter);
}
```

Rather than create the `ArrayAdapter` straight out of the static `items` array, we create a fresh `ArrayList` and pour the 5 elements from `items` into it, then create the `ArrayAdapter` on the `ArrayList`. This may seem superfluous, but we will take advantage of this approach with our action bar items.

When the user clicks the “reset” item in the action bar, we call `initAdapter()` again, which gives our `ListActivity` a fresh set of 5 Latin words to display:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.add:
            addWord();
    }
}
```

```
        return(true);

    case R.id.reset:
        initAdapter();

        return(true);

    case R.id.about:
        Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
            .show();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

When the user clicks the “add” item in the action bar, we call an `addWord()` private method, which adds the next word out of the `items` array and appends it to the `ListView`:

```
private void addWord() {
    if (adapter.getCount() < items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}
```

The net result of all of this is that we have an activity with our customized action bar:

THE ACTION BAR

Among our action bar items is an “about” one that will always be in the overflow menu. This will have three possible visual outcomes.

First, on devices without an off-screen MENU key, the overflow menu is represented by a “...” button, which displays the overflow menu when clicked:

THE ACTION BAR

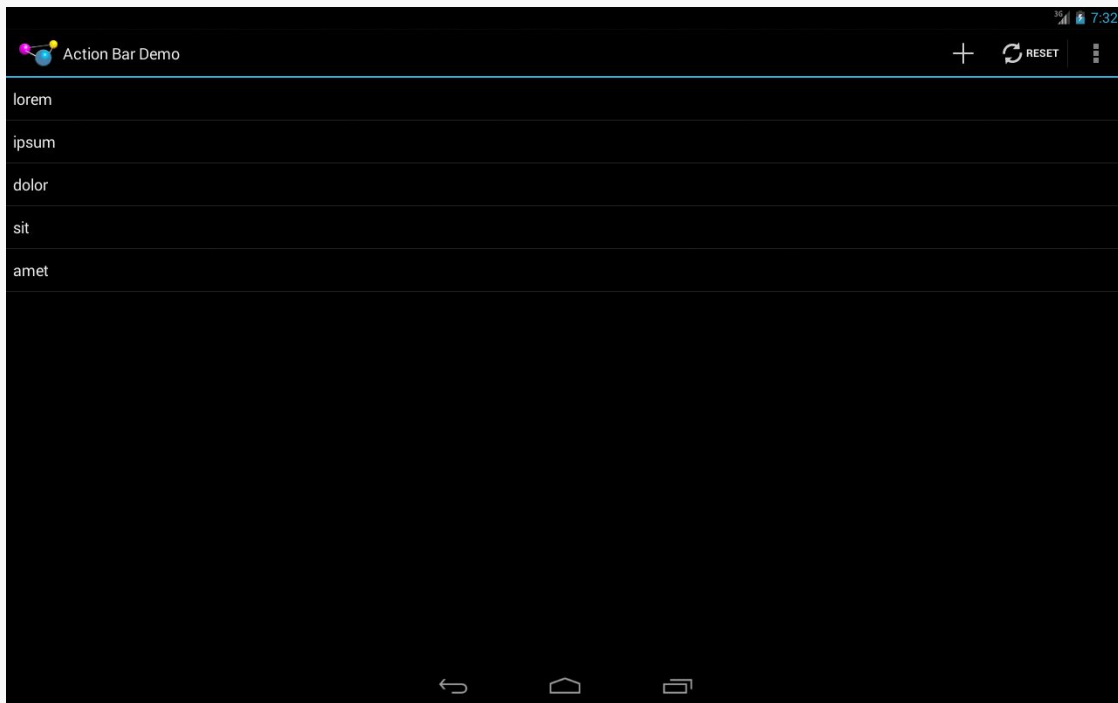

Figure 213: ActionBarDemo, on Android 4.3 Large Screen, with Overflow

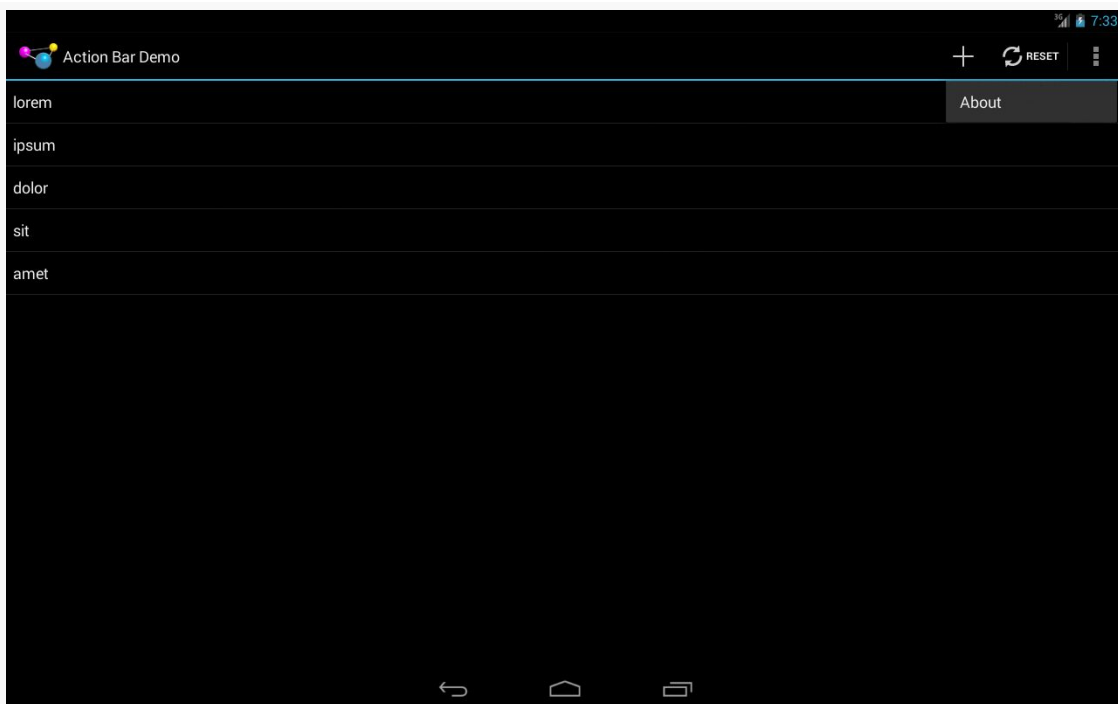

Figure 214: ActionBarDemo, on Android 4.3 Large Screen, with Overflow Open

THE ACTION BAR

On Android 4.x devices with an off-screen MENU key, pressing the MENU key will cause the overflow menu to rise up from the bottom of the screen:

Figure 215: ActionBarDemo, on Android 4.3 Normal Screen, with Overflow

Android 4.4+ devices should always have the “...” button, as is described in the next section.

Android 2.3 devices that run this app will have no action bar:

THE ACTION BAR

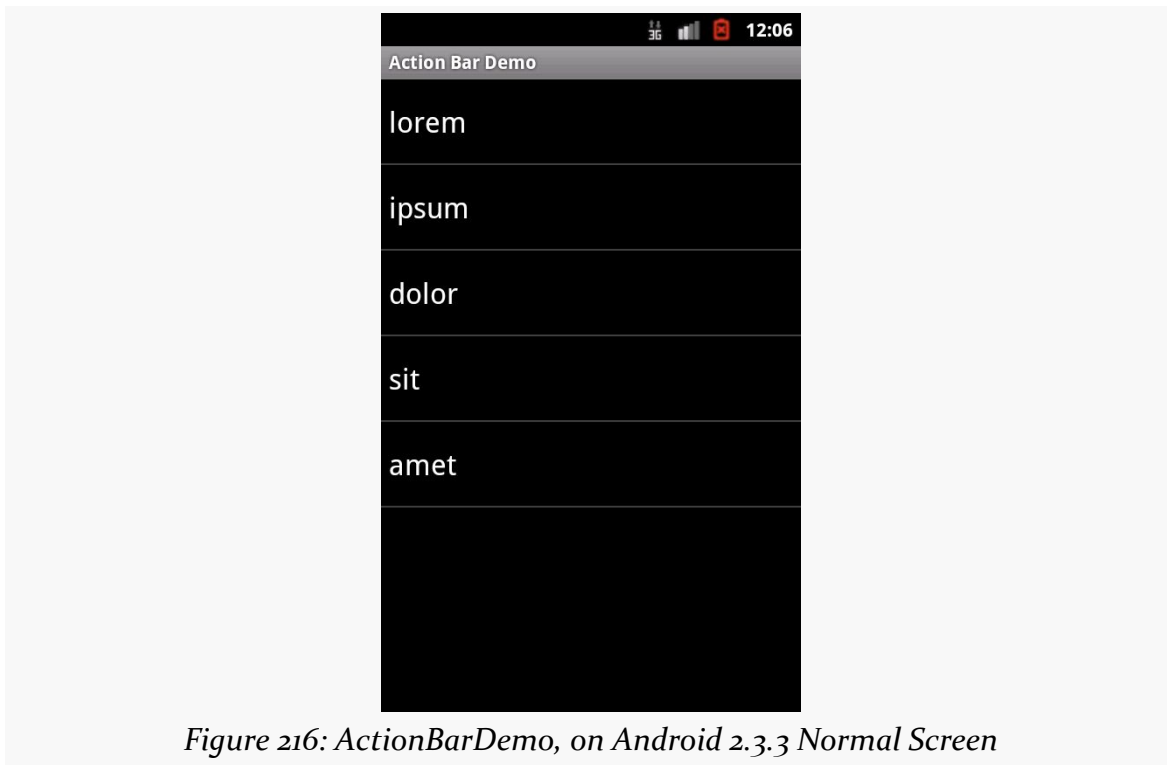

Figure 216: ActionBarDemo, on Android 2.3.3 Normal Screen

However, pressing the MENU button will bring up the old-style options menu, where our action items appear:

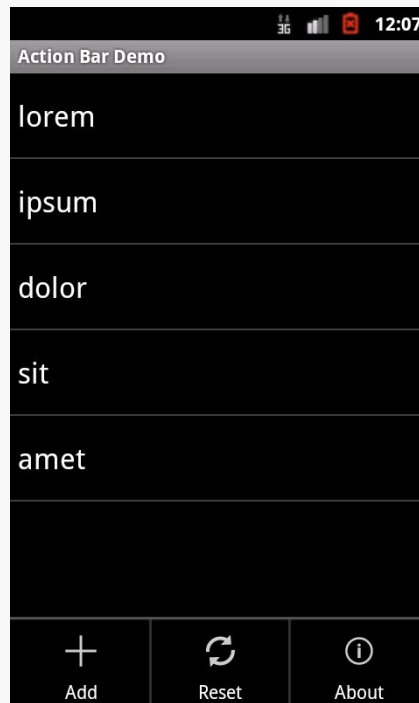

Figure 217: ActionBarDemo, on Android 2.3.3 Normal Screen, Showing the Options Menu

MENU Key, We Hardly Knew Ye

To expand upon the history lessons from earlier in this chapter, all Android 1.x and 2.x devices had a MENU key, used to bring up the options menu. With Android 3.0 and the advent of the system/navigation bar, device manufacturers no longer needed keys for HOME, BACK, and MENU. And, the action bar incorporated a “...” affordance for accessing the overflow, for items that would have been in the options menu and were not promoted to be toolbar buttons in the action bar itself.

Confusion began when we started having devices that *had* a MENU key *and* Android 3.0+. A few Android 2.x devices were upgraded to Android 4.0, and hundreds of millions of Android devices, from manufacturers like Samsung and HTC, shipped with Android 4.x and a MENU key.

To accommodate this, the device would report whether it had a “permanent menu key”, and the action bar would choose whether to show the “...” affordance based upon the existence of this key. Devices with a MENU key would not get the “...”, but instead would use the MENU key to display the overflow.

This irritated many developers, for much the same reason as why the MENU key irritated those developers back in Android 1.x/2.x: the existence of a menu was not very discoverable. Many users would eventually realize that tapping the MENU key might uncover useful stuff, but not all users would make this connection. However, now developers could see an obvious alternative, in the form of the “...” affordance, and so they sought ways to trick the action bar into showing the “...” even on devices that had a MENU key.

And that was how the world worked... up until Android 4.4.

An [unannounced change in Android 4.4](#) is that the “...” button should now *always* be shown in the action bar. The MENU key, if it exists, will still work, showing the overflow. Ideally, it shows the overflow as dropping down from the “...”, though that is not required. And [the Compatibility Definition Document for Android 4.4](#) more forcefully suggests that the MENU key is obsolete.

None of this should directly affect your code. However:

- When taking screenshots, bear in mind that they will vary between devices that have the “...” button and those that do not
- When writing documentation, or blog posts, or other instructional material, try to phrase references to the overflow that will work for both those users with a “...” button and those that do not

Action Bars, Live in Living Color!

On Android 4.0+, if you are using a Holo theme as a base, you may wish to adjust the colors used by your action bar.

On Android 5.0+, if you are using a Material theme as a base, you *will* want to adjust the colors used by your action bar. This is Google’s vision for how branding should work, in lieu of having your icon be in the action bar.

The following sections outline some ways to affect the colors of your action bar.

Material Tint Effects

Android 5.0 and Theme.Material make action bar colors easy to set up, as part of an overall “tinting” approach.

The [ActionBar/MaterialColor](#) sample project is a clone of the ActionBarDemoNative sample shown earlier in this chapter, but one where:

- Our `minSdkVersion` is set to 21, so the app will only run on Android 5.0+
- We set up a custom theme, with specific tinting rules, that affect our action bar colors

Color Resources

The theme will need to refer to colors, and the cleanest way to do that is to set up color resources. Like all of our other resources, we give color resources a name and a color value, usually in `#RRGGBB` or `#AARRGGBB` format. Color resources are “value” resources, held by default in `res/values/`, with the convention of using a `colors.xml` file for the actual colors.

For example, here is the `res/values/colors.xml` file from the MaterialColor sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#1a237e</color>
  <color name="accent">#ffee58</color>
</resources>
```

It defines three colors, `primary`, `primary_dark`, and `accent`, with different colors for each. In Android Studio, editing this file shows a tiny color swatch to help you visualize the colors:

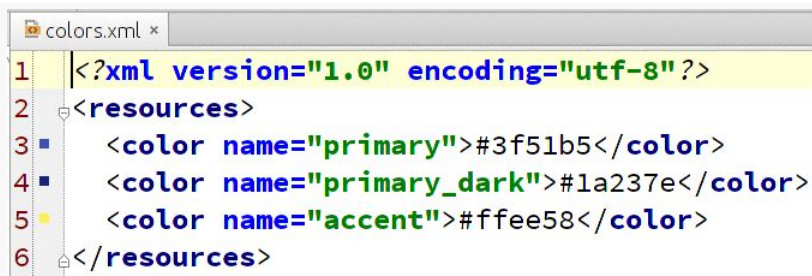

Figure 218: Color Resources in Android Studio

Tinting a Theme

Then, given that we have definitions of our colors, we can apply those colors to a custom theme, found in `res/values/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

Here, our `AppTheme` is inheriting from `Theme.Material` and is overriding three tints: `colorPrimary`, `colorPrimaryDark`, and `colorAccent`, referring to our three color resources in turn.

Note that we could have inherited from `Theme.Material.Light` had we wanted a light “content area” (where our widgets go), or even `Theme.Material.Light.DarkActionBar` for a light content area and a dark action bar (before we start tailoring the action bar colors).

Applying the Theme

The application’s manifest declares that we will use `AppTheme` as the default theme for our `<application>`, so all activities will use that theme unless overridden at the activity level:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.abmatcolor"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="21"
    android:targetSdkVersion="21"/>

  <application
    android:allowBackup="false"
```

THE ACTION BAR

```
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name="ActionBarDemoActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />

            <category android:name="android.intent.category.LAUNCHER" />
        </intent-filter>
    </activity>
</application>
</manifest>
```

Also note that here is where we specify that `minSdkVersion` is 21. An Android Studio project could do that in `build.gradle`, but since Eclipse does not work with Gradle, we have to define it in the manifest.

The Results

Everything else about the app is the same as the `ActionBarDemoNative` sample, including our activity and the `ListView` that we are populating.

However, when we run this edition on an Android 5.0+ device or emulator, our action bar takes on the requested colors, specifically the `colorPrimary` value for the background color of the action bar:

Figure 219: MaterialColor on Android 5.0 Emulator

The custom theme also affects the colors of certain widgets, as will be covered [later in the book](#).

Restoring the Icon (Sort Of)

While the Material Design philosophy skips the application icon that we used to have in the action bar, there is a way to add it back for a `Theme.Material` application, though it requires a little bit of work, as seen in the [ActionBar/MaterialLogo](#) sample project.

The key thing that you need to do is to call `setDisplayHomeAsUpEnabled(true)` on your `ActionBar` object, which you get by calling `getActionBar()` in your `Activity`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    getActionBar().setDisplayHomeAsUpEnabled(true);

    initAdapter();
}
```

THE ACTION BAR

This will use whatever icon is set for the `android:icon` attribute in your manifest as the “home” icon in your action bar:

Figure 220: MaterialLogo on Android 5.0 Emulator

If you would rather use a different icon, such as one that is scaled to fit the action bar a bit better, you can call `setIcon()` on your `ActionBar`, supplying the ID of a drawable resource (e.g., `R.drawable.action_bar_icon`) that should be used instead of the drawable specified in the `android:icon` attribute of your `<activity>` or `<application>` in the manifest.

Action Bar Style Generator

For `Theme.Holo` and `kin`, the tinting rules from `Theme.Material` will not apply. Instead, you will need to do a fair bit of tinkering to get the color scheme set up the way you want.

Or, you can use [Jeff Gilfelt's Action Bar Style Generator](#).

This is a Web site that allows you to design an action bar color scheme, where the site will then generate for you everything that you need to implement that color scheme.

THE ACTION BAR

Note that Mr. Gilfelt has marked this site as deprecated, with an eye towards people using Theme.Material or the appcompat-v7 edition of the action bar. The site works, but in all likelihood it will be discontinued at some future date.

Also note that the site works best with Google's Chrome or Chromium browsers, though in testing, a recent edition of Firefox worked as well. As the site indicates, "your mileage may vary with other browsers".

Designing the Scheme

The site is dominated by form for designing the color scheme and a preview area to show what the design will look like:

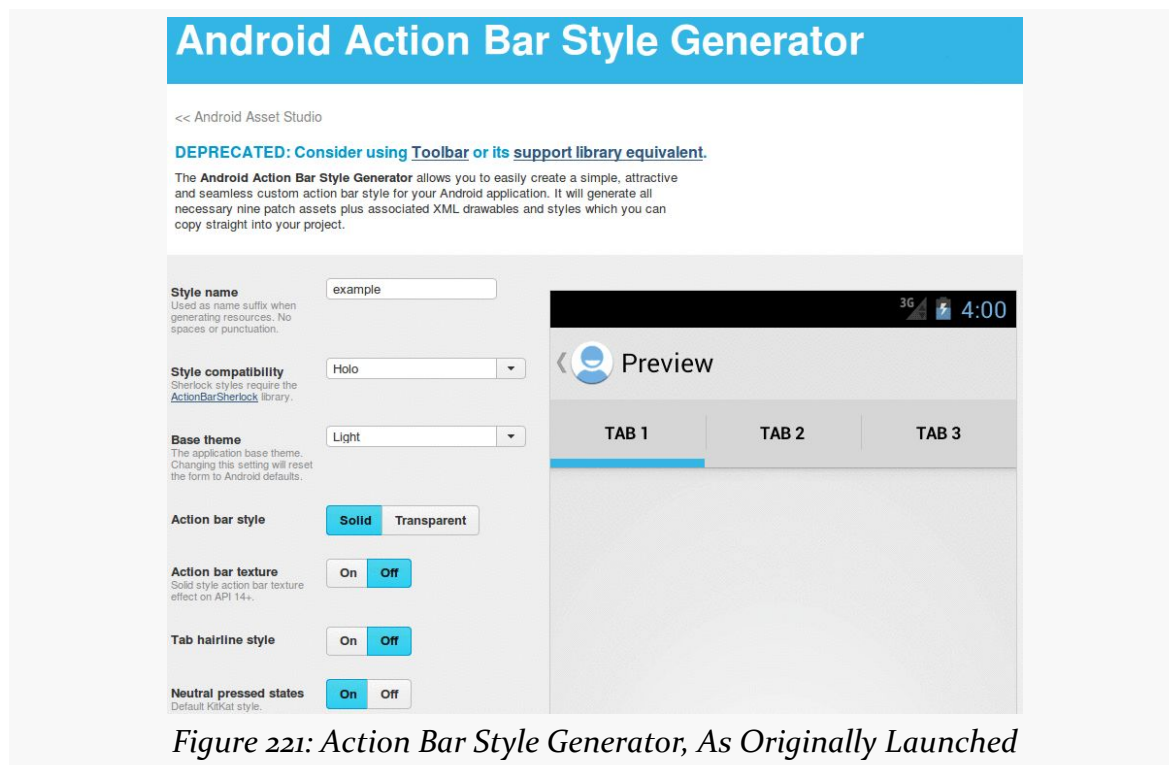

Figure 221: Action Bar Style Generator, As Originally Launched

In the "Style name" field, you can fill in the name you want to give your custom theme. Whatever you fill in will be converted into all lowercase with a leading capital letter, all following Theme.. So, for example, filling in AppTheme will result in a style resource named Theme.Apptheme.

For "Style compatibility", choose "Holo". For "Base theme", choose the base style you want:

THE ACTION BAR

- Light
- Dark
- Light with dark action bar

The next four options (“Action bar style”, “Action bar texture”, “Tab hairline style”, “Neutral pressed states”) are for advanced features and can be left at their defaults.

Scrolling further down the page, you will come to seven color pickers, allowing you to tailor the colors to be used in your action bar implementation. Each picker, when opened, allows you to choose a color based on a fixed palette, then refined using a gradient selector. Or, if you know specific colors (e.g., a graphic designer gave them to you), you can fill the color into the supplied field:

Figure 222: Action Bar Style Generator, Showing “Action bar color” Picker

As you change the colors, you will see what they impact on the preview.

At the bottom of the page is the “Output resources” frame:

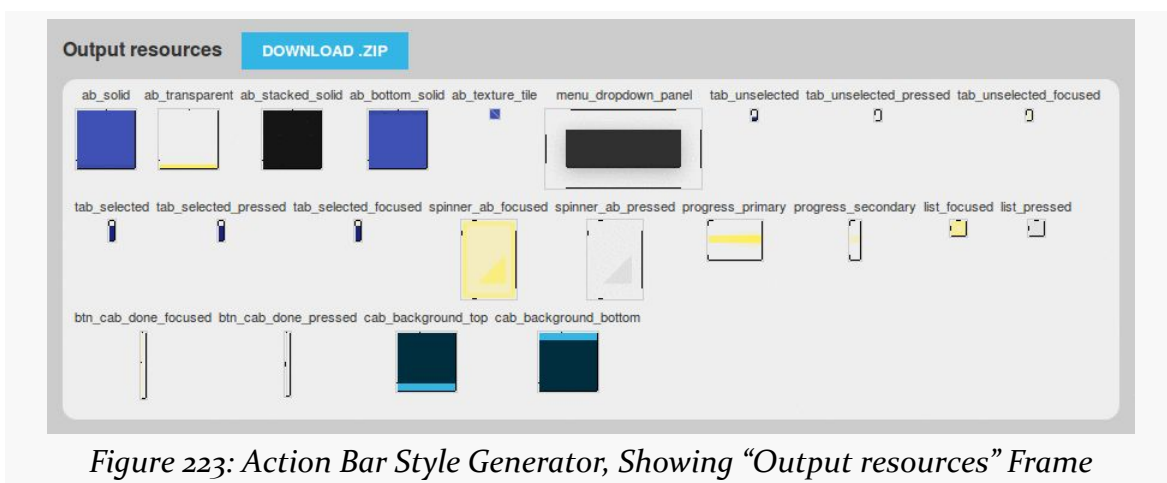

Figure 223: Action Bar Style Generator, Showing “Output resources” Frame

Here, you can click on the “DOWNLOAD .ZIP” button to download a ZIP archive containing your custom theme and all the associated resources required to implement it.

Implementing the Scheme

UnZIP the contents of that ZIP archive into your project’s `res/` directory (e.g., in a traditional Android Studio project, unZIP into `src/main/res/` in your app module). It will add a bunch of files, notably including a file in `res/values/` whose name is based upon the name you filled into the Web form for the theme name (e.g., `styles_apptheme.xml`).

If you look at that file, you will see that it defines a custom theme for you, named `Theme.` plus whatever you provided to that form (converted into a leading capital letter and the rest lowercase). That file will be rather lengthy, as it designates specific styles to use for various facets of the action bar (e.g., `android:actionBarStyle`).

Here is the theme’s primary `<style>` resource element, defining the theme itself:

```
<style name="Theme.Apptheme" parent="@android:style/Theme.Holo">
  <item name="android:actionBarItemBackground">@drawable/
selectable_background_apptheme</item>
  <item name="android:popupMenuStyle">@style/PopupMenu.Apptheme</item>
  <item name="android:dropDownListViewStyle">@style/
DropDownListView.Apptheme</item>
  <item name="android:actionBarTabStyle">@style/
ActionBarTabStyle.Apptheme</item>
  <item name="android:actionDropDownStyle">@style/
DropDownNav.Apptheme</item>
  <item name="android:actionBarStyle">@style/
ActionBar.Solid.Apptheme</item>
  <item name="android:actionModeBackground">@drawable/
cab_background_top_apptheme</item>
  <item name="android:actionModeSplitBackground">@drawable/
cab_background_bottom_apptheme</item>
  <item name="android:actionModeCloseButtonStyle">@style/
ActionButton.CloseMode.Apptheme</item>

</style>
```

To use this theme, just add an `android:theme` attribute to your `<application>` (or perhaps individual `<activity>` elements) in your manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
```

THE ACTION BAR

```
android:label="@string/app_name"
android:theme="@style/Theme.Apptheme">
<activity
    android:name="ActionBarDemoActivity"
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>
</application>
```

The resulting app will have a color scheme mirroring what you defined on the form:

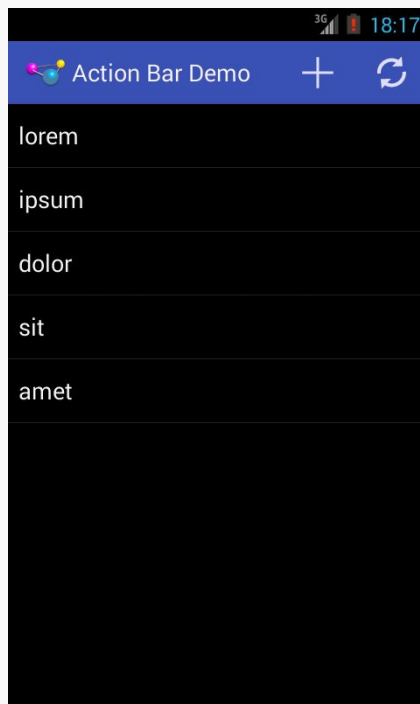

Figure 224: Results of the Action Bar Style Generator

This screenshot, and the code snippets, comes from the [ActionBar/HoloColor](#) sample project, which is the same as the base action bar sample app from this chapter with the custom theme applied.

Visit the Trails!

In addition to this chapter, you can [learn more about advanced action bar techniques](#) and [learn about action modes](#), which temporarily replace the action bar with new items for use with contextual operations.

Tutorial #7 - Setting Up the Action Bar

Next up is to configure the action bar to our EmPubLite application.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Starting in this tutorial, we will now begin editing Java source files. Eclipse users may wish to try to remember two useful shortcut key combinations (Windows/Linux syntax shown):

- <Ctrl>-<Shift>-<O> will organize your Java import statements, including finding imports for any classes or interfaces you have referenced in your code but have not yet imported. In Android Studio, this is <Ctrl>-<Alt>-<O>.
- <Ctrl>-<Shift>-<F> will reformat the Java or XML in the current editing window, in accordance with either the default styles in Eclipse or whatever you have modified them to via the Preferences window. In Android Studio, this is <Ctrl>-<Alt>-<L>.

Step #1: Acquiring Some Icons

As you noticed when running the previous versions of our app, our current action bar is very boring.

Very, very boring.

TUTORIAL #7 - SETTING UP THE ACTION BAR

To make it more useful and worthy of its screen space, we need to start adding some action items. And to do that, we will need some icons.

There are many sources of icons for use in Android apps, but few of them are part of the IDE. In particular, the IDE does not have many icons that are well-suited for use with action bar items. However, Google does publish the “Action Bar Icon Pack”, which contains a number of icons already set up for use in the action bar, with the appropriate styling and implementations in various screen densities.

Visit [the Design Downloads page](#) and download the “Action Bar Icon Pack”. You will find it convenient if you unZIP the archive somewhere on your development machine, though if you prefer to leave it ZIPped that is your choice.

Then, copy the `13_extra_actions_about` icons from the `Action Bar Icons/`
`holo_dark/` directory from the “Action Bar Icon Pack” into your project. In the `13_extra_actions_about` directory, you will see versions of this icon in various densities. Copy those icon files into their corresponding directories in your project. You can do this by dragging the file from your development desktop OS into the project explorer window and dropping it into the proper directory.

Finally, repeat the above process for `13_extra_actions_help`.

Be sure to hold onto the “Action Bar Icon Pack”, though, as we will be getting more icons from it in later tutorials.

Step #2: Defining Some Options

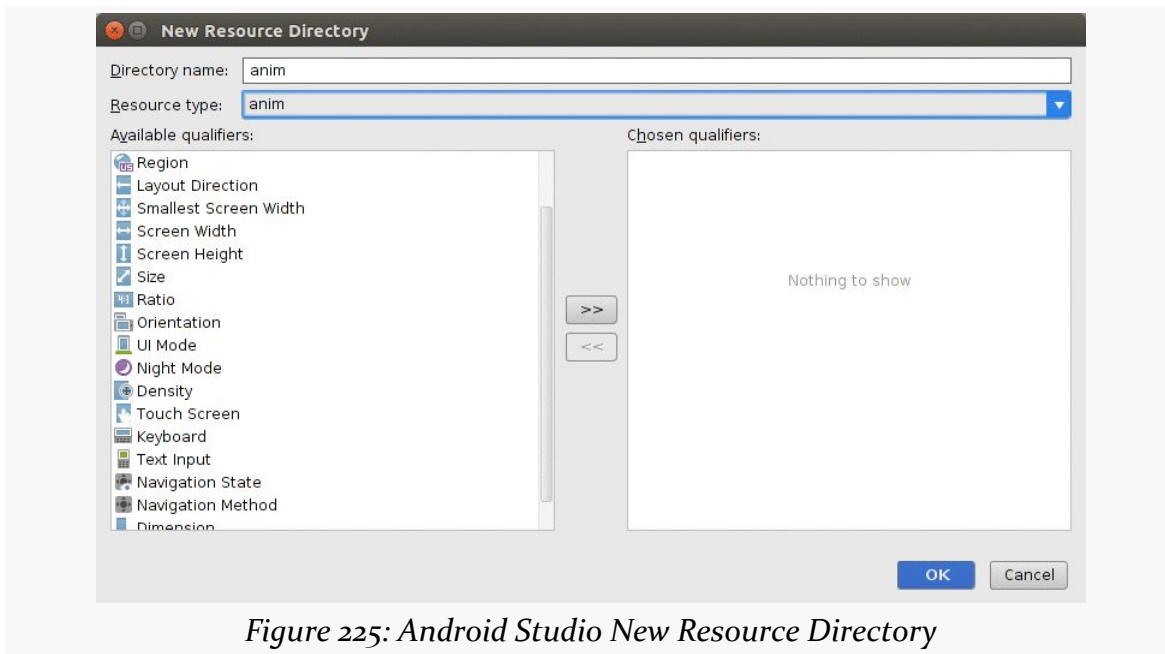

Next, we will add a couple of low-priority action items, for a help screen and an “about” screen.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right click over the `res/` directory in your project, and choose `New > “Android resource directory”` from the context menu. This will bring up a dialog to let you create a new resource directory:

TUTORIAL #7 - SETTING UP THE ACTION BAR

Change the “Resource type” drop-down to be “menu”, then click OK to create the directory.

Then, right-click over your new `res/menu/` directory and choose `New > “Menu resource file”` from the context menu. Fill in `options.xml` in the “New Menu Resource File” dialog:

Then click OK to create the file. It will open up into an XML editor, into which you can paste the following content:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/help"
        android:icon="@drawable/ic_action_help"
        android:title="@string/help">
    </item>
```

TUTORIAL #7 - SETTING UP THE ACTION BAR

```
<item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    android:title="@string/about">
</item>

</menu>
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Also, you will need to add string resources for help and about, by adding appropriate `<string>` elements to your existing `res/values/strings.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <string name="app_name">EmPub Lite</string>
    <string name="help">Help</string>
    <string name="about">About</string>
</resources>
```

Eclipse

Open the `res/menu/` folder in your project. Right-click over the menu folder and choose `New > Other` from the context menu. Choose “Android XML File” in the list of possible new-file templates and click `Next`. In the `File` field in the next page of the wizard, fill in options and click `Finish`.

This should open up the menu in the structured editor:

Figure 227: Eclipse Menu Editor

TUTORIAL #7 - SETTING UP THE ACTION BAR

However, the structured editor has multiple bugs. Hence, click the “options.xml” sub-tab to switch to the raw XML editor. Then, paste in the following content:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/help"
        android:icon="@drawable/ic_action_help"
        android:title="@string/help">
    </item>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        android:title="@string/about">
    </item>

</menu>
```

If you prefer, you can view this file’s contents in your Web browser via [this GitHub link](#).

Also, you will need to add string resources for help and about, by adding appropriate <string> elements to your existing res/values/strings.xml file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <string name="app_name">EmPub Lite</string>
    <string name="help">Help</string>
    <string name="about">About</string>

</resources>
```

Step #3: Loading and Responding to Our Options

Simply defining res/menu/options.xml is insufficient. We need to actually tell Android to use what we defined in that file, and we need to add code to respond to when the user taps on our items.

To do that, you will need to add an onCreateOptionsMenu() method and an onOptionsItemSelected() method to EmPubLiteActivity, as follows:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.options, menu);
    return(super.onCreateOptionsMenu(menu));
}
```

TUTORIAL #7 - SETTING UP THE ACTION BAR

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case android.R.id.home:
            return(true);
        case R.id.about:
            return(true);
        case R.id.help:
            return(true);
    }
    return(super.onOptionsItemSelected(item));
}
```

NOTE: Copying and pasting Java code may or may not work, depending on what you are using to read the book. For the PDF, some PDF viewers (e.g., Adobe Reader) should copy the code fairly well; others may do a much worse job.

In `onCreateOptionsMenu()`, we are inflating `res/menu/options.xml` and pouring its contents into the supplied `Menu` object, which will be used by Android to populate our action bar.

In `onOptionsItemSelected()`, we examine the supplied `MenuItem` and route to different branches of a switch statement based upon the item's ID. In addition to `R.id.about` and `R.id.help` — for the two items we defined in `res/menu/options.xml`, we also watch for `android.R.id.home`, which eventually will be triggered by a tap on our icon, on the left side of the action bar.

To get this to compile, you will need to add some imports as well:

```
import android.view.Menu;
import android.view.MenuItem;
```

Android Studio users can press `<Alt>-<Enter>` with the cursor in a class reference that is missing its import to add that import. Eclipse users can resolve all missing imports at one time using `<Ctrl>-<Shift>-<O>`.

If you run this in a device or emulator, you may see no initial difference. That would be for devices or emulators that have a MENU button and are running Android 4.3 or below. To display our options, you would need to press MENU:

TUTORIAL #7 - SETTING UP THE ACTION BAR

Figure 228: EmPubLite, With Options Via the MENU Button

Note that on an emulator, the MENU button is mapped to the PgUp key of your keyboard.

In other cases, the action bar will have a “...” icon on the action bar:

TUTORIAL #7 - SETTING UP THE ACTION BAR

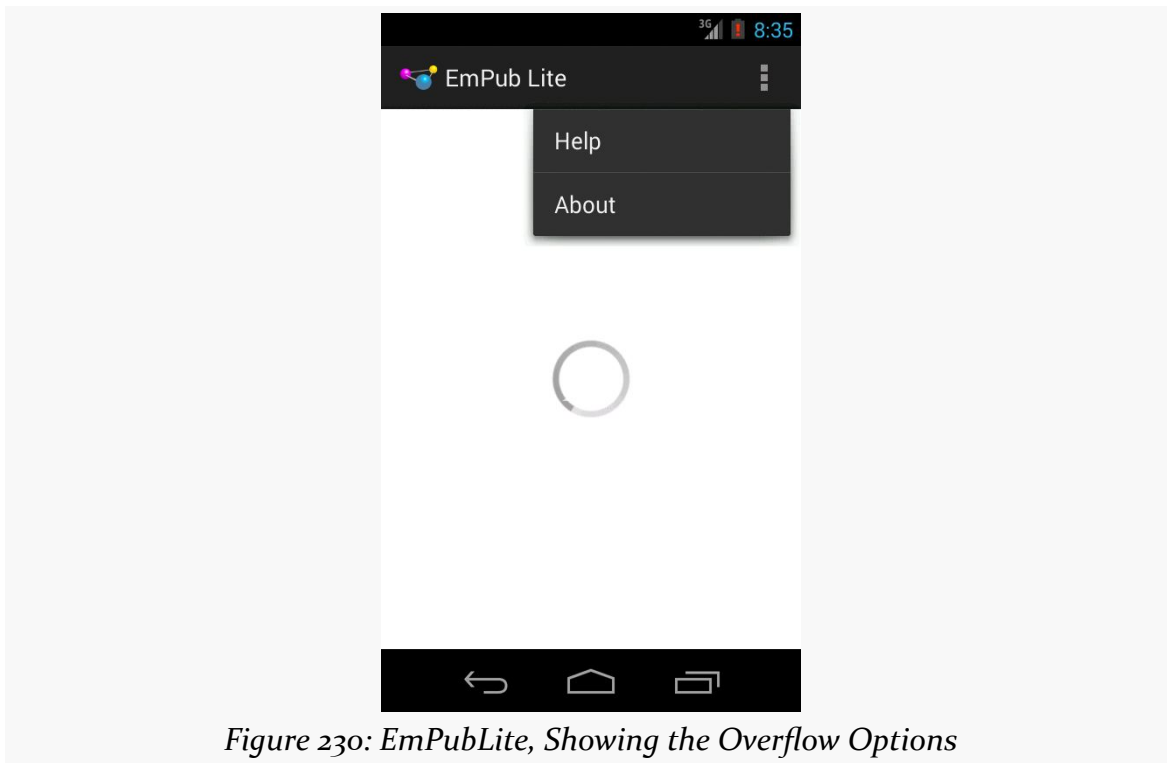

Figure 229: EmPubLite, Showing the ... Overflow Button

Pressing that brings up a menu showing our items:

In Our Next Episode...

... we will [define our first new activity](#) on the tutorial project.

Android's Process Model

So far, we have been treating our activity like it is our entire application. Soon, we will start to get into more complex scenarios, involving multiple activities and other types of components, like services and content providers.

But, before we get into a lot of that, it is useful to understand how all of this ties into the actual OS itself. Android is based on Linux, and Linux applications run in OS processes. Understanding a bit about how Android and Linux processes inter-relate will be useful in understanding how our mixed bag of components work within these processes.

When Processes Are Created

A user installs your app, goes to their home screen's launcher, and taps on an icon representing your activity. Your activity dutifully appears on the screen.

Behind the scenes, what happened is that Android forked a copy of a process known as the zygote. As a result of the way your process is forked from the zygote, your process contains:

- A copy of the VM (Dalvik or ART), shared among all such processes via Linux copy-on-write memory sharing
- A copy of the Android framework classes, like Activity and Button, also shared via copy-on-write memory
- A copy of your own classes, loaded out of your APK
- Any objects created by you or the framework classes, such as the instance of your Activity subclass

BACK, HOME, and Your Process

Suppose that you have an app with just one activity. From the home screen's launcher, the user taps on the icon associated with your app's activity. Then, with your activity in the foreground, the user presses BACK.

At this point, the user is telling the OS that she is done with your activity. Control will return to whatever preceded that activity — in this case, the home screen's launcher.

You might think that this would cause your process to be terminated. After all, that is how most desktop operating systems work. Once the user closes the last window of the application, the process hosting that application is terminated.

However, that is not how Android works. Android will *keep* your process around, for a little while at least. This is done for speed and power: if the user happens to want to return to your app sooner rather than later, it is more efficient to simply bring up another copy of your activity again in the existing process than it is to go set up a completely new copy of the process. This does not mean that your process will live forever; we will discuss when your process will go away later in this chapter.

Now, instead of the user pressing BACK, let's say that the user pressed HOME instead. Visually, there is little difference: the home screen re-appears. Depending on the home screen implementation there may be a visible difference, as BACK might return to a launcher whereas HOME might return to something else on the home screen. However, in general, they feel like very similar operations.

The difference is what happens to your activity.

When the user presses BACK, your foreground activity is *destroyed*. We will get into more of what that means [in the next chapter](#). However, the key feature is that the activity itself — the instance of your subclass of Activity — will never be used again, and hopefully is garbage collected.

When the user presses HOME, your foreground activity is *not* destroyed... at least, not immediately. It remains in memory. If the user launches your app again from the home screen launcher, and if your process is still around, Android will simply bring your existing activity instance back to the foreground, rather than having to create a brand-new one (as is the case if the user pressed BACK and destroyed your activity).

What HOME literally is doing is bringing the home screen activity back to the foreground, not otherwise directly affecting your process much.

Termination

Processes cannot live forever. They take up a chunk of RAM, for your classes and objects, and these mobile devices only have so much RAM to work with. Eventually, therefore, Android has to get rid of your process, to free up memory for other applications.

How long your process will stick around depends on a variety of factors, including:

- What else the device is doing, either in the foreground (user using apps) or in the background (e.g., automated checks for new email)
- How much memory the device has
- What is still running inside your process

Going back to the scenario from above, we have an application with a single activity launched from the home screen, where the user can return to the home screen either by pressing BACK or by pressing HOME. You might think that this has no difference at all on when the process would be terminated, but that would be incorrect. Pressing HOME would keep the process around perhaps a bit longer than would pressing BACK.

Why?

When the user presses BACK, your one and only activity is destroyed. When the user presses HOME, your activity is not destroyed. Android will tend to keep processes around longer if they have active (i.e., not destroyed) components in them.

The key word there is “tend”. Android’s algorithms for determining when to get rid of what processes are baked into the OS and are, at best, lightly documented. There is evidence to suggest that other criteria, such as process age, are also taken into account, and so there may be times when a process that has an activity running (but not in the foreground) might be terminated where a process with no running activity might not. However, in general, processes with active (not destroyed) components will stick around a bit longer than processes without such components.

Foreground Means “I Love You”

Just because Android terminates processes to free up memory does not mean that it will terminate just any process to free up memory. A foreground process – the most common of which is a process that has an activity in the foreground – is the least likely of all to be terminated. In fact, you can pretty much assume that if Android has to kill off the foreground process, that the phone is very sick and will crash in a matter of moments.

(and, fortunately, that does not happen very often)

So, if you are in the foreground, you are safe. It is only when you are not in the foreground that you are at risk of having the process be terminated.

You and Your Heap

Processes take up RAM. A significant chunk of that RAM represents the objects you create (a.k.a., “the heap”).

Those of you with significant Java backgrounds know that the Java VM loves RAM (“can’t get enough of it!”). Java VMs routinely grab 64MB or 128MB of heap space upon creating the process and will grow as big as you wish to let them (e.g., `-Xmx` switch to the `java` command).

Android heap sizes are not that big, because Android is designed to run on mobile devices with constrained amounts of RAM.

Your heap limit may be as low as 16MB, though values in the 32–48MB range are more typical with current-generation devices. How much the heap limit will be depends a bit on what version of Android is on the device. It depends quite a lot, though, on the screen size, as bigger screens will tend to want to display bigger bitmap images, and bitmap images can consume quite a bit of RAM.

The key is that the heap is small, and (generally speaking) you cannot adjust it yourself. It is what it is. Small applications will rarely run into a problem with heap space, but larger applications might. We will discuss tools and techniques for measuring and coping with memory problems later in this book.

Activities and Their Lifecycles

An Android application will have multiple discrete UI facets. For example, a calendar application needs to allow the user to view the calendar, view details of a single event, edit an event (including adding a new one), and so forth. And on smaller-screen devices, like most phones, you may not have room to squeeze all of this on the screen at once.

To handle this, you can have multiple activities. Your calendar application may have one activity to display the calendar, another to add or edit an event, one to provide settings for how the calendar should work, another for your online help, etc. Some of these activities might be private to your app, while others might be able to be launched by third parties, such as your “launcher” activity being available to home screens.

All of this implies that one of your activities has the means to start up another activity. For example, if somebody clicks on an event from the view-calendar activity, you might want to show the view-event activity for that event. This means that, somehow, you need to be able to cause the view-event activity to launch and show a specific event (the one the user clicked upon).

This can be further broken down into two scenarios:

- You know what activity you want to launch, probably because it is another activity in your own application
- You have a reference to... something (e.g., a Web page), and you want your users to be able to do... something with it (e.g., view it), but you do not know up front what the options are

This chapter will cover both of those scenarios.

In addition, frequently it will be important for you to understand when activities are coming and going from the foreground, so you can automatically save or refresh data, etc. This is the so-called “activity lifecycle”, and we will examine it in detail as well in this chapter.

Creating Your Second (and Third and...) Activity

Unfortunately, activities do not create themselves. On the positive side, this does help keep Android developers gainfully employed.

Hence, given a project with one activity, if you want a second activity, you will need to add it yourself. The same holds true for the third activity, the fourth activity, and so on.

The sample we will examine in this section is [Activities/Explicit](#). Our first activity, `ExplicitIntentsDemoActivity`, started off as just the default activity code generated by the build tools. Now, though, its layout contains a `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:textSize="20sp"
        android:text="@string/hello"
        android:onClick="showOther"/>

</LinearLayout>
```

That `Button` is tied to a `showOther()` method in our activity implementation, which we will examine shortly.

Defining the Class and Resources

To create your second (or third or whatever) activity, you first need to create the Java class. You need to create a new Java source file, containing a public Java class that extends `Activity` directly or indirectly. You have three basic ways of doing this:

- Just create the class and resources yourself
- Use the Android Studio new-activity wizard

- Use the Eclipse new-activity wizard

Android Studio New-Activity Wizard

Right-click on your `app/src/main/` sourceset directory in the project explorer, and go into the `New > Activity` portion of the context menu. This will give you a submenu of available activity templates — mostly the same roster of templates that we saw back when we created the project in the first place.

If you choose one of those templates, you will be presented with a one-page wizard in which to provide the details for this activity:

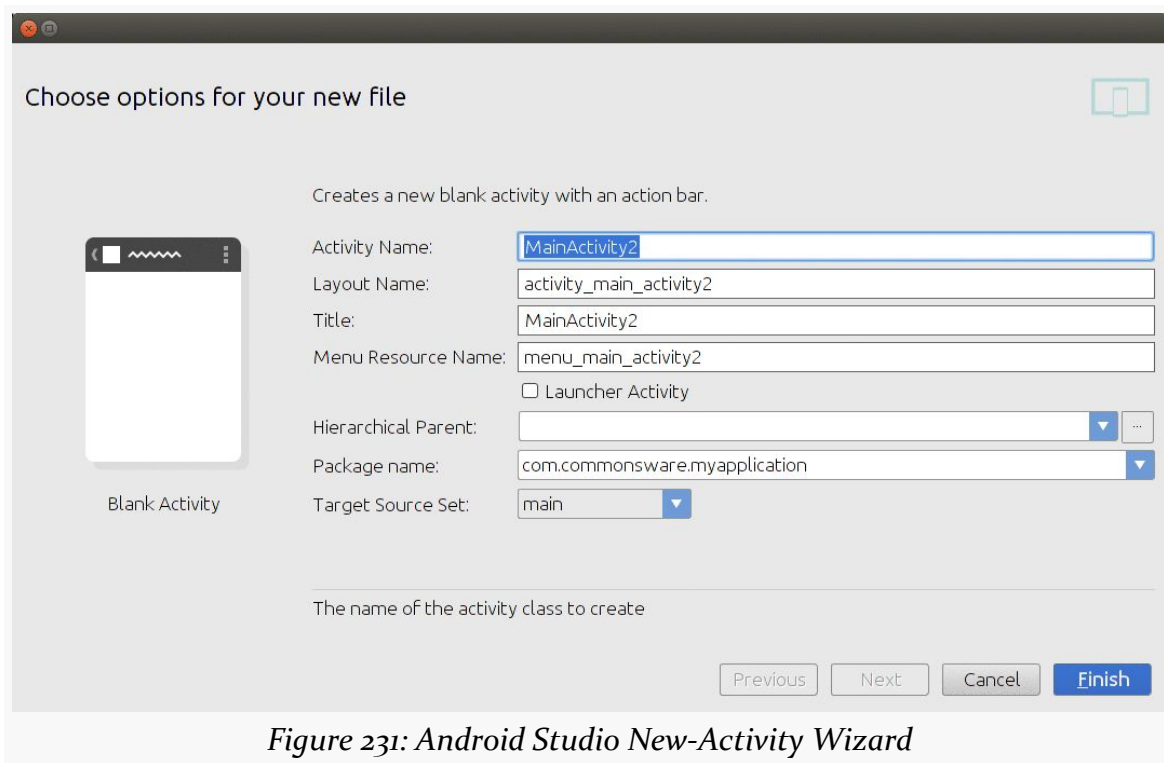

Figure 231: Android Studio New-Activity Wizard

The first few fields will be based upon the template you chose (e.g., activity name, layout XML resource name) and will mirror those we saw back in the new-project wizard. Others, though, are new to this wizard:

- the “Launcher Activity” checkbox which, if checked, will add the appropriate bits to the manifest to tell Android that this activity should get an icon in the home screen’s launcher

- the “Hierarchical Parent” drop-down, which presently is beyond the scope of this book
- the “Package name” drop-down, where you can choose the Java package name into which this activity’s class will be added
- the “Target Source Set” drop-down, where you can indicate the Gradle sourceset into which the generated code should go (for now, choose main)

Clicking “Finish” will then create the activity’s Java class, related resources, and manifest entry.

Eclipse New-Activity Wizard

Right-clicking over a project in the Package Explorer, and choosing New > Other from the context menu, brings up a list of things that you can add to your project. One of those, in the Android group, is “Android Activity”:

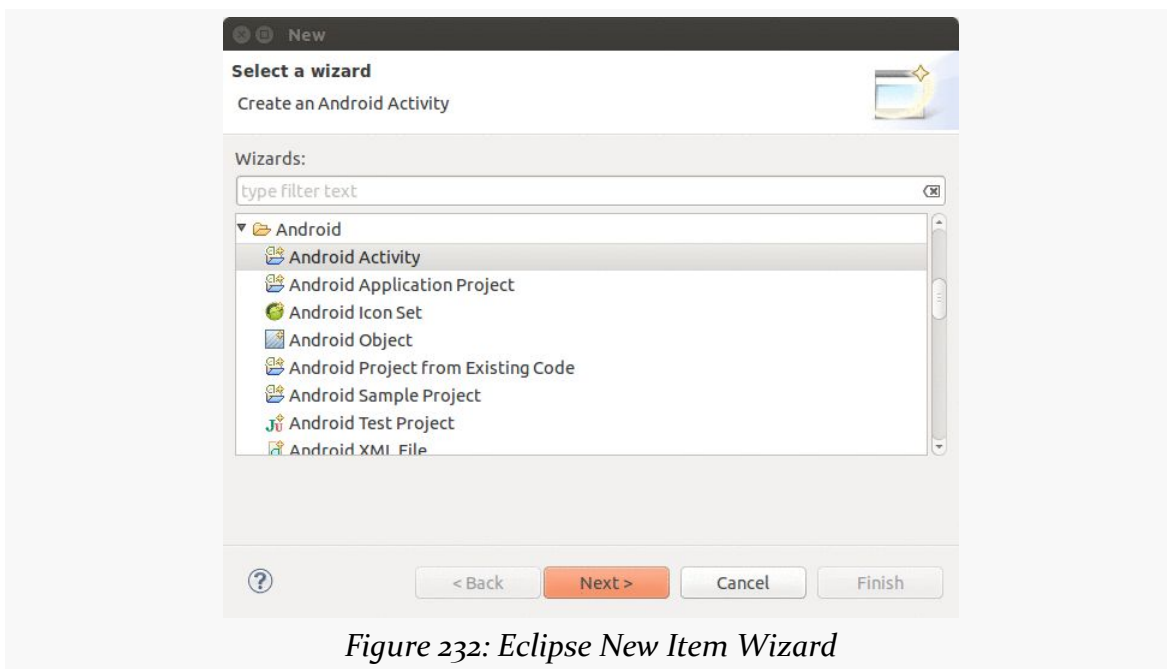

Figure 232: Eclipse New Item Wizard

Choosing “Android Activity” and clicking Next will give you a list of available activity templates:

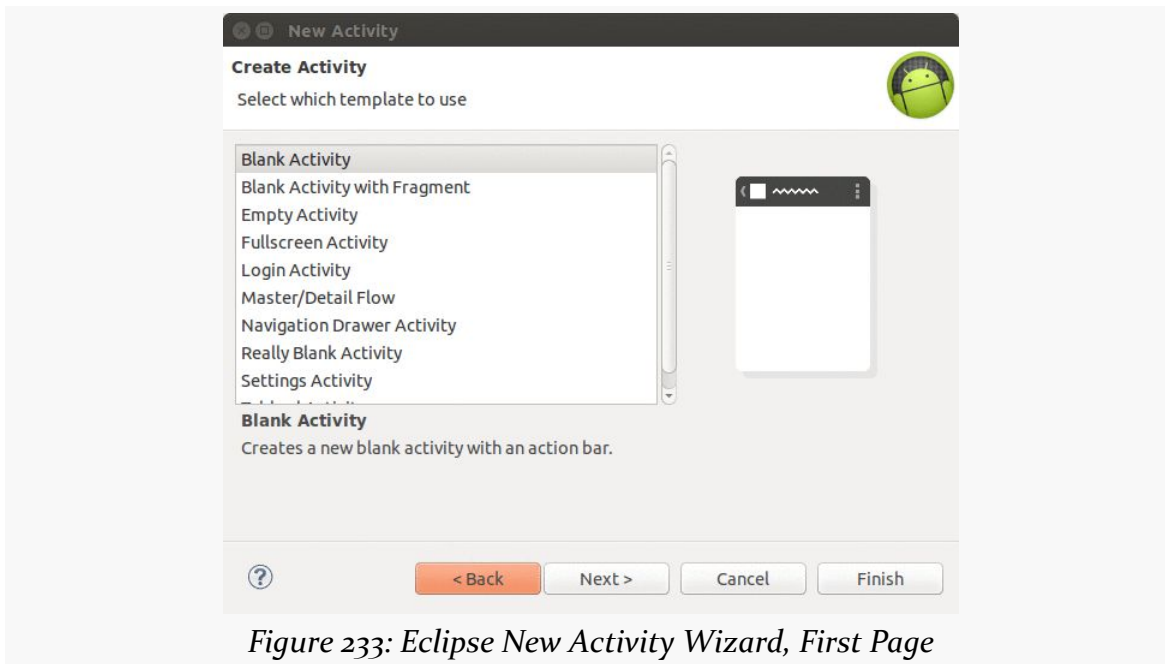

Figure 233: Eclipse New Activity Wizard, First Page

Choosing a template and clicking Next will bring up another wizard page, where you will need to provide additional information about the new activity:

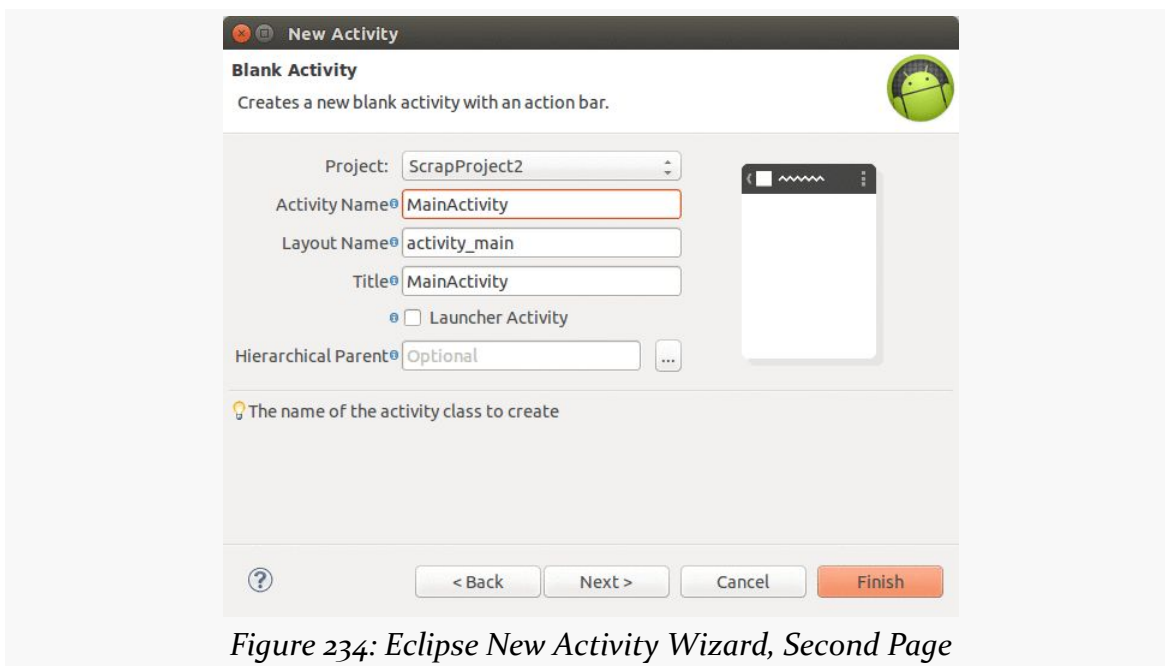

Figure 234: Eclipse New Activity Wizard, Second Page

In addition to the class name and layout name, as we saw in the new-project wizard, we are also asked for some more details:

- the project into which we want this activity created (defaults to the one we right-clicked over)
- the “Title” is the caption that will appear in the action bar for this activity
- the “Launcher Activity” checkbox which, if checked, will add the appropriate bits to the manifest to tell Android that this activity should get an icon in the home screen’s launcher
- the “Hierarchical Parent” drop-down, which presently is beyond the scope of this book

Clicking “Finish” will then create the activity’s Java class, related resources, and manifest entry.

Populating the Class and Resources

Once you have your stub activity set up, you can then add an `onCreate()` method to it (or edit an existing one created by the wizard), filling in all the details (e.g., `setContentView()`), just like you did with your first activity. Your new activity may need a new layout XML resource or other resources, which you would also have to create (or edit those created for you by the wizard).

In Activities/Explicit, our second activity is `OtherActivity`, with pretty much the standard bare-bones implementation:

```
package com.commonware.android.exint;

import android.app.Activity;
import android.os.Bundle;

public class OtherActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.other);
    }
}
```

and a similarly simple layout, `res/layout/other.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

```
        android:orientation="vertical">

        <TextView
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/other"
            android:textColor="#FFFF0000"
            android:textSize="20sp"/>

    </LinearLayout>
```

Augmenting the Manifest

Simply having an activity implementation is not enough. We also need to add it to our `AndroidManifest.xml` file. This is automatically handled for you by the IDEs' respective new-activity wizards. However, if you created the activity "by hand", you will need to add its manifest element, and over time you will need to edit this element in many cases.

Adding an activity to the manifest is a matter of adding another `<activity>` element to the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.exint"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="ExplicitIntentsDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
        <activity android:name="OtherActivity"/>
    </application>
</manifest>
```

```
</application>
</manifest>
```

You need the `android:name` attribute at minimum. Note that we do not include an `<intent-filter>` child element, the way the original activity has. For now, take it on faith that the original activity's `<intent-filter>` is what causes it to appear as a launchable activity in the home screen's launcher. We will get into more details of how that `<intent-filter>` works and when you might want your own [in a later chapter](#).

Warning! Contains Explicit Intents!

An Intent encapsulates a request, made to Android, for some activity or other receiver to do something.

If the activity you intend to launch is one of your own, you may find it simplest to create an explicit Intent, naming the component you wish to launch. For example, from within your activity, you could create an Intent like this:

```
new Intent(this, HelpActivity.class);
```

This would stipulate that you wanted to launch the `HelpActivity`. This activity would need to be named in your `AndroidManifest.xml` file.

In `Activities/Explicit`, `ExplicitIntentsDemoActivity` has a `showOther()` method tied to its Button widget's `onClick` attribute. That method will use `startActivity()` with an explicit Intent, identifying `OtherActivity`:

```
package com.commonware.android.exint;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExplicitIntentsDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        startActivity(new Intent(this, OtherActivity.class));
    }
}
```

```
}  
}
```

Our launched activity shows the button:

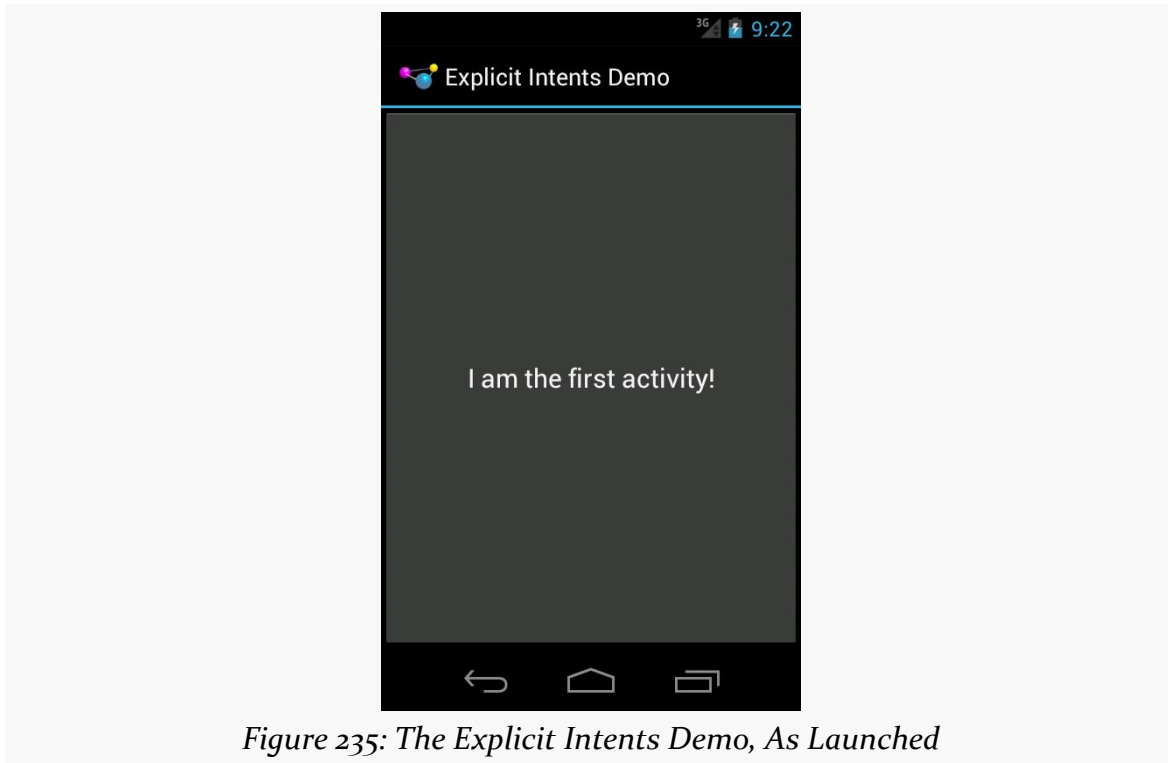

Figure 235: The Explicit Intents Demo, As Launched

Clicking the button brings up the other activity:

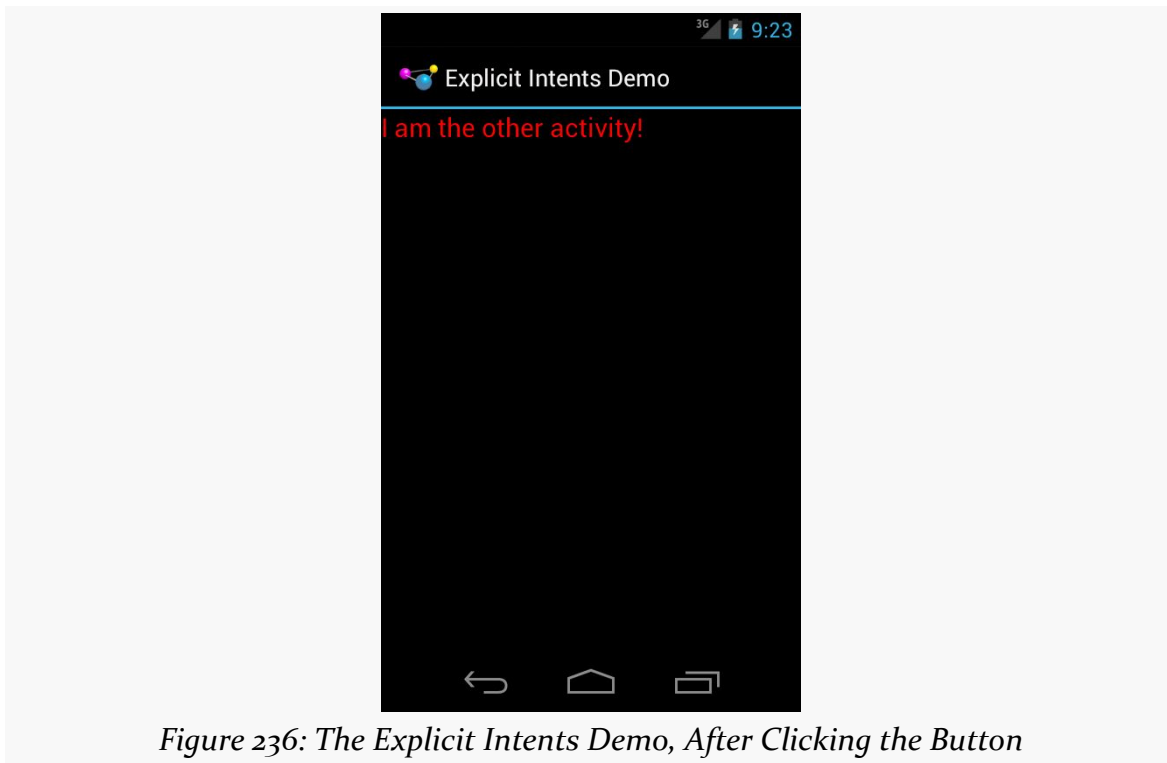

Figure 236: The Explicit Intents Demo, After Clicking the Button

Clicking BACK would return us to the first activity. In this respect, the BACK button in Android works much like the BACK button in your Web browser.

Using Implicit Intents

The explicit Intent approach works fine when the activity to be started is one of yours.

However, you can also start up activities from the operating system or third-party apps. In those cases, though, you will not have a Java Class object representing the other activity in your project, so you cannot use the Intent constructor that takes a Class.

Instead, you will use what are referred as the “implicit” Intent structure, which looks an *awful* lot like how the Web works.

If you have done any work on Web apps, you are aware that HTTP is based on verbs applied to URIs:

- We want to GET this image
- We want to POST to this script or controller
- We want to PUT to this REST resource
- Etc.

Android's implicit Intent model works much the same way, just with a *lot* more verbs.

For example, suppose you get a latitude and longitude from somewhere (e.g., body of a tweet, body of a text message). You decide that you want to display a map on those coordinates. There are ways that you can embed a Google Map directly in your app — and we will see how [in a later chapter](#) — but that is complicated and assumes the user wants Google Maps. It would be better if we could create some sort of generic “hey, Android, display an activity that shows a map for this location” request.

Or, in a simpler scenario: we get a URL to a Web page from some source (e.g., Web service call), and we want to open a Web browser on that page. This is illustrated in the [Activities/LaunchWeb](#) sample project.

We have a LaunchDemo activity that uses a layout containing a EditText widget and a Button, among other things:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:hint="@string/url"
        android:inputType="textUri"/>

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me"/>

</LinearLayout>
```

The Button is tied to a `showMe()` method on the activity itself, where we want to bring up a Web browser on the URL entered into the EditText widget:

ACTIVITIES AND THEIR LIFECYCLES

```
package com.commonware.android.activities;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
    }

    public void showMe(View v) {
        EditText url=(EditText)findViewById(R.id.url);

        startActivity(new Intent(Intent.ACTION_VIEW,
                                Uri.parse(url.getText().toString())));
    }
}
```

Just as HTTP uses a verb and a URI, Android uses an action and a `Uri`. We take the URL and convert it to a `Uri` via calling `Uri.parse()`. Then, we can use an action called `ACTION_VIEW` to try to display the desired Web page.

When launched, the user is presented with our data entry form:

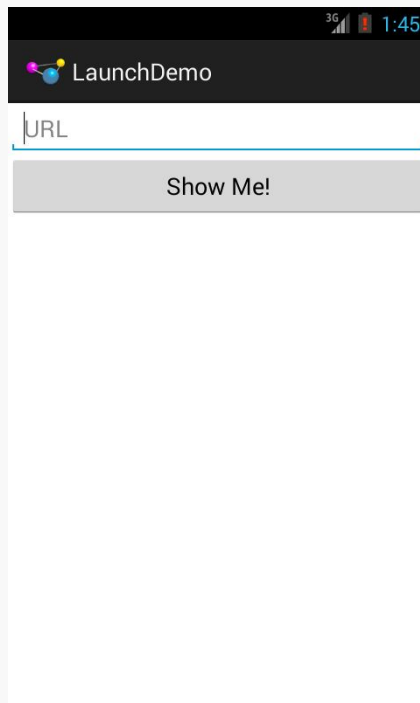

Figure 237: LaunchWeb Demo, As Initially Launched

We can fill in a URL:

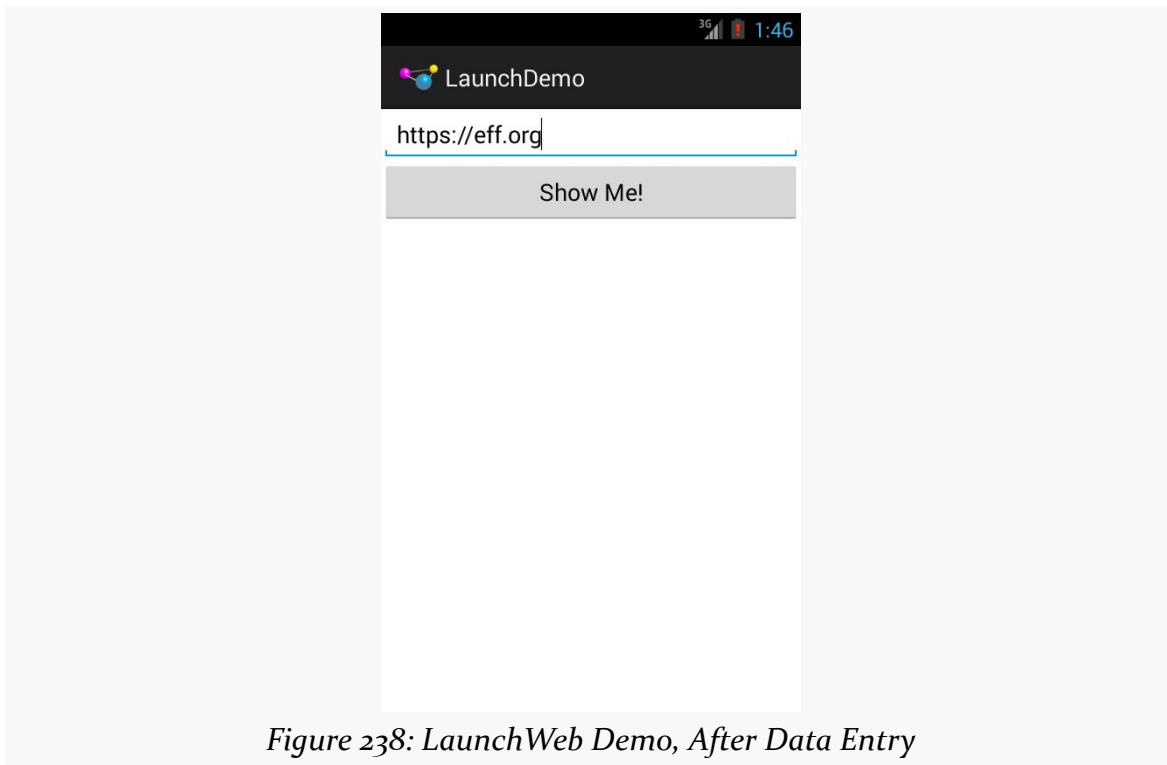

Figure 238: LaunchWeb Demo, After Data Entry

If the device has one app that responds to an ACTION_VIEW Intent on an https: scheme, clicking the “Show Me!” button will bring up that app, probably a Web browser:

ACTIVITIES AND THEIR LIFECYCLES

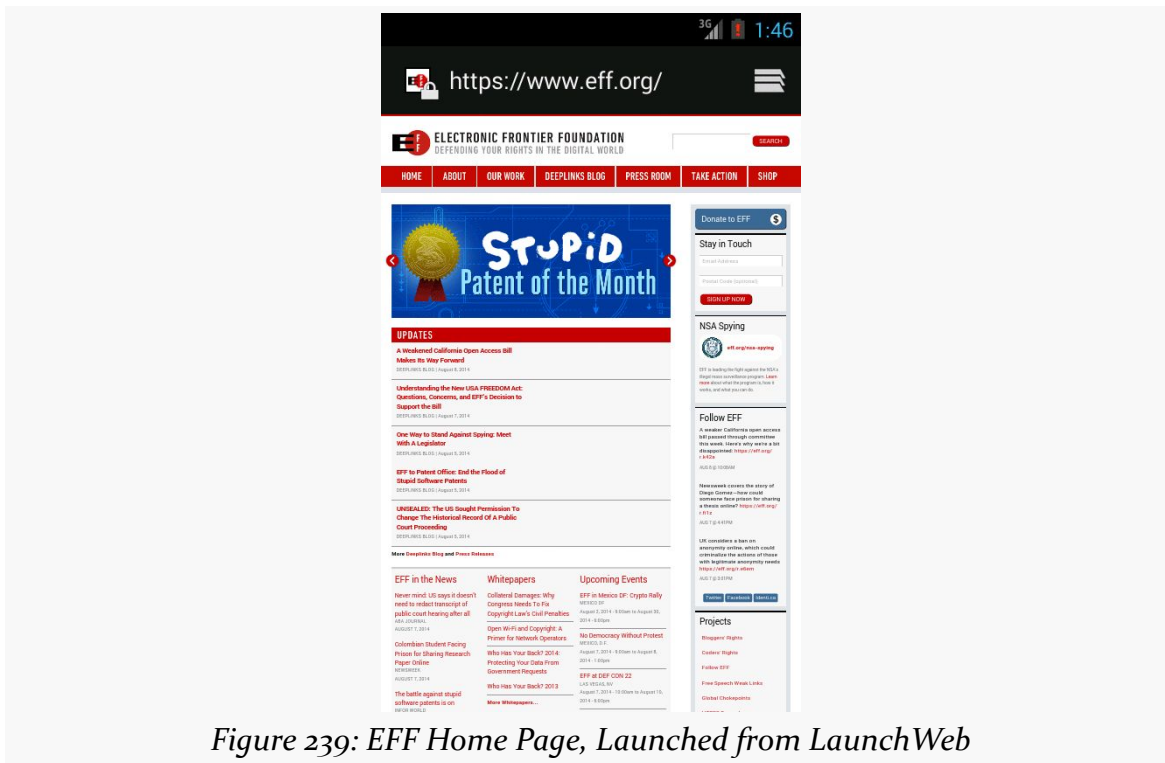

Figure 239: EFF Home Page, Launched from LaunchWeb

We will discuss what happens if there are no applications set up to handle this Intent, or if there is more than one, [in a later chapter](#).

Extra! Extra!

Sometimes, we may wish to pass some data from one activity to the next. For example, we might have a `ListActivity` showing a collection of our model objects (e.g., books) and we have a separate `DetailActivity` to show information about a specific model object. Somehow, `DetailActivity` needs to know which model object to show.

One way to accomplish this is via Intent extras.

There is a series of `putExtra()` methods on Intent to allow you to supply key/value pairs of data to be bundled into the Intent. While you cannot pass arbitrary objects, most primitive data types are supported, as are strings and some types of lists. The [next section](#) will explain a bit more about what can go in an Intent extra.

Any activity can call `getIntent()` to retrieve the `Intent` used to start it up, and then can call various forms of `get...` `Extra()` (with the ... indicating a data type) to retrieve any bundled extras.

For example, let's take a look at the [Activities/Extras](#) sample project.

This is mostly a clone of the `Activities/Explicit` sample from earlier in this chapter. However, this time, our first activity will pass an extra to the second:

```
package com.commonware.android.extra;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExtrasDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        Intent other=new Intent(this, OtherActivity.class);

        other.putExtra(OtherActivity.EXTRA_MESSAGE, getString(R.string.other));
        startActivity(other);
    }
}
```

We create the `Intent` as before, but then call `putExtra()`, supplying a key (a static string named `OtherActivity.EXTRA_MESSAGE`) and a value (the `R.string.other` string resource). Then, and only then, do we call `startActivity()`.

Our revised `OtherActivity` then retrieves that extra, along with the inflated `TextView` (via `findViewById()`) and pours that text in:

```
package com.commonware.android.extra;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class OtherActivity extends Activity {
    public static final String EXTRA_MESSAGE="msg";

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);
setContentView(R.layout.other);

TextView tv=(TextView)findViewById(R.id.msg);

tv.setText(getIntent().getStringExtra(EXTRA_MESSAGE));
}
```

Visually, the result is the same. Functionally, the text to be shown is passed from one activity to the next.

Pondering Parcelable

As noted above, Intent extras cannot handle arbitrary objects. That is because, most of the time, Intent extras get passed across process boundaries. Even when you are calling `startActivity()` to start up one of your own activities, that request passes from your process to a core OS process and back to your process. The Intent extras come along for the ride.

Hence, Intent extras need to be something that can be converted into a byte array, as part of the inter-process communication (IPC) that handles the passing around of Intent objects. You will see this come up in other flavors of Android IPC as well, such as [remote services](#).

However, there are two ways in which you can try to make your own objects work as Intent extras.

One approach is to implement `Serializable` on your class. This is a classic Java construct, designed to allow instances of your class, and other `Serializable` objects your instances hold onto, to be serialized into files and later read back in.

Another approach is to implement `Parcelable` on your class. This is an Android construct, one that is very similar to `Serializable`. However, `Serializable` is designed for *durable* storage of objects, where the file might be read back in months or years later. As such, `Serializable` has to deal with possible changes to the Java code implementing those classes, and as such needs to have hooks to help with converting old, saved objects into new objects. This adds overhead. `Parcelable` is only concerned with converting objects into byte arrays to pass across process boundaries. It can make the simplifying assumption that the class definition is not changing from when the object is turned into bytes and when the bytes are turned

back into an object. As a result, Parcelable is faster than Serializable for Android's IPC use.

You are welcome to implement Parcelable on your own classes if you wish, at which point they can be passed around via Intent extras. Beyond that, though, any Java classes you see in the Android JavaDocs that implement Parcelable can be put into Intent extras. So, for example, Uri implements Parcelable, and so you can put a Uri into an Intent extra. Not everything in the Android SDK is Parcelable, but some key classes like Uri are Parcelable.

Asynchronicity and Results

Note that `startActivity()` is asynchronous. The other activity will not show up until sometime after you return control of the main application thread to Android.

Normally, this is not much of a problem. However, sometimes one activity might start another, where the first activity would like to know some “results” from the second. For example, the second activity might be some sort of “chooser”, to allow the user to pick a file or contact or song or something, and the first activity needs to know what the user chose. With `startActivity()` being asynchronous, it is clear that we are not going to get that sort of result as a return value from `startActivity()` itself.

To handle this scenario, there is a separate `startActivityForResult()` method. While it too is asynchronous, it allows the newly-started activity to supply a result (via a `setResult()` method) that is delivered to the original activity via an `onActivityResult()` method. We will examine `startActivityForResult()` in greater detail [in a later chapter](#).

Schroedinger's Activity

An activity, generally speaking, is in one of four states at any point in time:

1. *Active*: the activity was started by the user, is running, and is in the foreground. This is what you are used to thinking of in terms of your activity's operation.
2. *Paused*: the activity was started by the user, is running, and is visible, but another activity is overlaying part of the screen. During this time, the user can see your activity but may not be able to interact with it. This is a

relatively uncommon state, as most activities are set to fill the screen, not have a theme that makes them look like some sort of dialog box.

3. *Stopped*: the activity was started by the user, is running, but it is hidden by other activities that have been launched or switched to.
4. *Dead*: the activity was destroyed, perhaps due to the user pressing the BACK button.

Life, Death, and Your Activity

Android will call into your activity as the activity transitions between the four states listed above.

Note that for all of these, you should chain upward and invoke the superclass' edition of the method, or Android may raise an exception.

onCreate() and onDestroy()

We have been implementing `onCreate()` in all of our Activity subclasses in all the examples. This will get called in two primary situations:

- When the activity is first started (e.g., since a system restart), `onCreate()` will be invoked with a `null` parameter.
- If the activity had been running and you have set up your activity to have different resources based on different device states (e.g., landscape versus portrait), your activity will be re-created and `onCreate()` will be called. We will discuss this scenario in greater detail later in this book.

Here is where you initialize your user interface and set up anything that needs to be done once, regardless of how the activity gets used.

On the other end of the lifecycle, `onDestroy()` may be called when the activity is shutting down, such as because the activity called `finish()` (which “finishes” the activity) or the user presses the BACK button. Hence, `onDestroy()` is mostly for cleanly releasing resources you obtained in `onCreate()` (if any), plus making sure that anything you started up outside of lifecycle methods gets stopped, such as background threads.

Bear in mind, though, that `onDestroy()` may not be called. This would occur in a few circumstances:

- You crash with an unhandled exception
- The user force-stops your application, such as through the Settings app
- Android has an urgent need to free up RAM (e.g., to handle an incoming phone call), wants to terminate your process, and cannot take the time to call all the lifecycle methods

Hence, `onDestroy()` is very likely to be called, but it is not guaranteed.

Also, bear in mind that it may take a long time for `onDestroy()` to be called. It is called quickly if the user presses BACK to finish the foreground activity. If, however, the user presses HOME to bring up the home screen, your activity is not immediately destroyed. `onDestroy()` will not be called until Android does decide to gracefully terminate your process, and that could be seconds, minutes, or hours later.

`onStart()`, `onRestart()`, and `onStop()`

An activity can come to the foreground either because it is first being launched, or because it is being brought back to the foreground after having been hidden (e.g., by another activity, by an incoming phone call).

The `onStart()` method is called in either of those cases. The `onRestart()` method is called in the case where the activity had been stopped and is now restarting.

Conversely, `onStop()` is called when the activity is about to be stopped. It too may not be called, for the same reasons that `onDestroy()` would not be called. However, `onStop()` is usually called fairly quickly after the activity is no longer visible, so the odds that `onStop()` will be called are even higher than that of `onDestroy()`.

`onPause()` and `onResume()`

The `onResume()` method is called just before your activity comes to the foreground, either after being initially launched, being restarted from a stopped state, or after a pop-up dialog (e.g., incoming call) is cleared. This is a great place to refresh the UI based on things that may have occurred since the user last was looking at your activity. For example, if you are polling a service for changes to some information (e.g., new entries for a feed), `onResume()` is a fine time to both refresh the current view and, if applicable, kick off a background thread to update the view (e.g., via a `Handler`).

Conversely, anything that takes over user input — mostly, the activation of another activity — will result in your `onPause()` being called. Here, you should undo anything you did in `onResume()`, such as stopping background threads, releasing any exclusive-access resources you may have acquired (e.g., camera), and the like.

Once `onPause()` is called, Android reserves the right to kill off your activity's process at any point. Hence, you should not be relying upon receiving any further events.

So, what is the difference between `onPause()` and `onStop()`? If an activity comes to the foreground that fills the screen, your current foreground activity will be called with `onPause()` and `onStop()`. If, however, an activity comes to the foreground that does *not* fill the screen, your current foreground activity will only be called with `onPause()`, as it is still visible.

Stick to the Pairs

If you initialize something in `onCreate()`, clean it up in `onDestroy()`.

If you initialize something in `onStart()`, clean it up in `onStop()`.

If you initialize something in `onResume()`, clean it up in `onPause()`.

In other words, stick to the pairs. For example, do not initialize something in `onStart()` and try to clean it up on `onPause()`, as there are scenarios where `onPause()` may be called multiple times in succession (i.e., user brings up a non-full-screen activity, which triggers `onPause()` but not `onStop()`, and hence not `onStart()`).

Which pairs of lifecycle methods you choose is up to you, depending upon your needs. You may decide that you need two pairs (e.g., `onCreate()/onDestroy()` and `onResume()/onPause()`). Just do not mix and match between them.

When Activities Die

So, what gets rid of an activity? What can trigger the chain of events that results in `onDestroy()` being called?

First and foremost, when the user presses the BACK button, the foreground activity will be destroyed, and control will return to the previous activity in the user's

navigation flow (i.e., whatever activity they were on before the now-destroyed activity came to the foreground).

You can accomplish the same thing by calling `finish()` from your activity. This is mostly for cases where some other UI action would indicate that the user is done with the activity (e.g., the activity presents a list for the user to choose from — clicking on a list item might close the activity). However, please do not artificially add your own “exit”, “quit”, or other menu items or buttons to your activity — just allow the user to use normal Android navigation options, such as the BACK button.

If none of your activities are in the foreground any more, your application’s process is a candidate to be terminated to free up RAM. As noted earlier, depending on circumstances, Android may or may not call `onDestroy()` in these cases (`onPause()` and `onStop()` would have been called when your activities left the foreground).

If the user causes the device to go through a “configuration change”, such as switching between portrait and landscape, Android’s default behavior is to destroy your current foreground activity and create a brand new one in its place. We will cover this more in [a later chapter](#).

And, if your activity has an unhandled exception, your activity will be destroyed, though Android will not call any more lifecycle methods on it, as it assumes your activity is in an unstable state.

Walking Through the Lifecycle

To see when these various lifecycle methods get called, let’s examine the [Activities/Lifecycle](#) sample project.

This project is the same as the Activities/Extras project, except that our two activities no longer inherit from Activity directly. Instead, we introduce a `LifecycleLoggingActivity` as a base class and have our activities inherit from it:

```
package com.commonware.android.lifecycle;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class LifecycleLoggingActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

```
    Log.d(getClass().getSimpleName(), "onCreate()");
}

@Override
public void onRestart() {
    super.onRestart();

    Log.d(getClass().getSimpleName(), "onRestart()");
}

@Override
public void onStart() {
    super.onStart();

    Log.d(getClass().getSimpleName(), "onStart()");
}

@Override
public void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(), "onResume()");
}

@Override
public void onPause() {
    Log.d(getClass().getSimpleName(), "onPause()");

    super.onPause();
}

@Override
public void onStop() {
    Log.d(getClass().getSimpleName(), "onStop()");

    super.onStop();
}

@Override
public void onDestroy() {
    Log.d(getClass().getSimpleName(), "onDestroy()");

    super.onDestroy();
}
}
```

All LifecycleLoggingActivity does is override each of the lifecycle methods mentioned above and emit a debug line to LogCat indicating who called what.

When we first launch the application, our first batch of lifecycle methods is invoked, in the expected order:

ACTIVITIES AND THEIR LIFECYCLES

```
04-01 11:47:21.437: D/ExplicitIntentsDemoActivity(1473): onCreate()
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onStart()
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onResume()
```

If we click the button on the first activity to start up the second, we get:

```
04-01 11:47:54.776: D/ExplicitIntentsDemoActivity(1473): onPause()
04-01 11:47:54.877: D/OtherActivity(1473): onCreate()
04-01 11:47:54.947: D/OtherActivity(1473): onStart()
04-01 11:47:54.974: D/OtherActivity(1473): onResume()
04-01 11:47:55.347: D/ExplicitIntentsDemoActivity(1473): onStop()
```

Notice that our first activity is paused before the second activity starts up, and that `onStop()` is delayed on the first activity until after the second activity has appeared.

If we press the BACK button on the second activity, returning to the first activity, we see:

```
04-01 11:48:54.807: D/OtherActivity(1473): onPause()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onRestart()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onStart()
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onResume()
04-01 11:48:55.257: D/OtherActivity(1473): onStop()
04-01 11:48:55.257: D/OtherActivity(1473): onDestroy()
```

Notice how, once again, going onto the screen happens in between `onPause()` and `onStop()` of the activity leaving the screen. Also notice that `onDestroy()` is called immediately after `onStop()`, because the activity was finished via the BACK button.

If we now press the HOME button, to bring the home screen activity to the foreground, we see:

```
04-01 11:50:30.347: D/ExplicitIntentsDemoActivity(1473): onPause()
04-01 11:50:32.227: D/ExplicitIntentsDemoActivity(1473): onStop()
```

There is a delay between `onPause()` and `onStop()` as the home screen does its display work, and there is no `onDestroy()`, because the application is still running

and nothing finished the activity. Eventually, the device will terminate our process, and if that happens normally, we would see the `onDestroy()` LogCat message.

Recycling Activities

Let us suppose that we have three activities, named A, B, and C. A starts up an instance of B based on some user input, and B later starts up an instance of C through some more user input.

Our “activity stack” is now A-B-C, meaning that if we press BACK from C, we return to B, and if we press BACK from B, we return to A.

Now, let’s suppose that from C, we wish to navigate back to A. For example, perhaps the user pressed the icon on the left of our action bar, and we want to return to the “home activity” as a result, and in our case that happens to be A. If C calls `startActivity()`, specifying A, we wind up with an activity stack that is A-B-C-A.

That’s because starting an activity, by default, creates a new instance of that activity. So, now we have two independent copies of A.

Sometimes, this is desired behavior. For example, we might have a single `ListActivity` that is being used to “drill down” through a hierarchical data set, like a directory tree. We might elect to keep starting instances of that same `ListActivity`, but with different extras, to show each level of that hierarchy. In this case, we would want independent instances of the activity, so the BACK button behaves as the user might expect.

However, when we navigate to the “home activity”, we may not want a separate instance of A.

How to address this depends a bit on what you want the activity stack to look like after navigating to A.

If you want an activity stack that is B-C-A — so the existing copy of A is brought to the foreground, but the instances of B and C are left alone — then you can add `FLAG_ACTIVITY_REORDER_TO_FRONT` to your Intent used with `startActivity()`:

```
Intent i=new Intent(this, HomeActivity.class);  
i.setFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT);  
startActivity(i);
```

If, instead, you want an activity stack that is just A — so if the user presses BACK, they exit your application — then you would add two flags:

FLAG_ACTIVITY_CLEAR_TOP and FLAG_ACTIVITY_SINGLE_TOP:

```
Intent i=new Intent(this, HomeActivity.class);  
i.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP | Intent.FLAG_ACTIVITY_SINGLE_TOP);  
startActivity(i);
```

This will finish all activities in the stack between the current activity and the one you are starting — in our case, finishing C and B.

Application: Transcending the Activity

Activity inherits from a class named Context. Many of the methods that we are calling on our activities, like startActivity(), are inherited from Context.

However, Activity is not the only relevant subclass of Context. We will see Service [later in the book](#), for example. And sometimes we will see plain Context objects, such as when we cover BroadcastReceiver [later in the book](#).

Another Context of note is Application. An instance of Application is created when our app starts up. The Application instance is a natural singleton; there should be exactly one instance of Application in our process.

Normally, this singleton is an instance of Application itself. However, we can subclass Application if we wish, then include a reference to our custom application class in an android:name attribute on the <application> element in the manifest. Then, when Android starts up our app, it will create an instance of our designated Application subclass, rather than creating an instance of the ordinary Application class.

We can retrieve the Application object at any point by calling getApplicationContext() on any Context object. getApplicationContext() will return a Context; if we need to reference Application or our specific Application subclass, we need to down-cast the returned Context to the appropriate type.

We can use Application in a few ways in Android apps.

First and foremost, if we need to hold onto some other object in a static data member, and that other object needs a Context, we *really* want it to be using the

Application, not an Activity, Service, etc. Because Application is a singleton, it is effectively “pre-leaked”. We cannot somehow leak it further by having another indirect static reference to it. In contrast, suppose we have a static data member holding onto an Activity. Now, when that Activity is destroyed, it (and all it holds, like widgets and listeners) cannot be garbage-collected. This represents a memory leak.

You could even take it one step further and have the Application manage this static data, rather than using separate singletons. There are pros and cons to this approach, but on the whole Google is not a big fan of it. That being said, Application has an `onCreate()` that is called shortly after it is instantiated, and your subclass of Application could override that and use it to initialize some “global” data.

However, while the JavaDocs indicate that there is an `onTerminate()` method on Application — suggesting that we find out when the Application is going away and our process is being terminated — that method is never called in practice.

Tutorial #8 - Setting Up An Activity

Of course, it would be nice if those “Help” and “About” menu choices that we added [in the previous tutorial](#) actually did something.

In this tutorial, we will define another activity class, one that will be responsible for displaying simple content like our help text and “about” details. And, we will arrange to start up that activity when those action bar items are selected. The activity will not actually display anything meaningful yet, as that will be the subject of the next few tutorials.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book’s GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Creating the Stub Activity Class and Manifest Entry

First, we need to define the Java class for our new activity, `SimpleContentActivity`.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click on your main/ sourceset directory in the project explorer, and choose New > Activity > Blank Activity from the context menu. This will bring up a new-activity wizard:

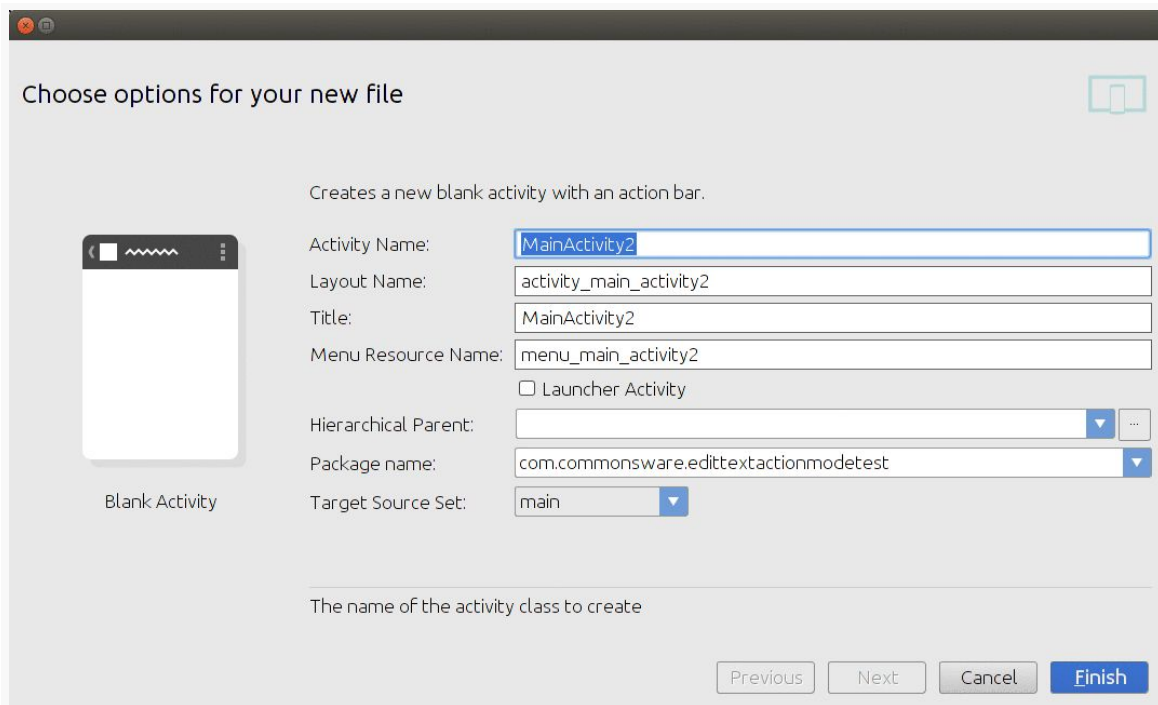

Figure 240: Android Studio New Activity Wizard

Fill in:

- SimpleContentActivity in the “Activity Name” field
- pleasedeleteme for the “Layout Name”
- @string/app_name for the “Title”
- pleasedeletemetoo for the “Menu Resource Name”

Leave the rest of the wizard at its defaults, then click on Finish.

In the SimpleContentActivity class that results, delete:

- the onCreateOptionsMenu() method
- the onOptionsItemSelected() method
- the setContentView() call from the onCreate() method

TUTORIAL #8 - SETTING UP AN ACTIVITY

At this point, your SimpleContentActivity class should look like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

At this point, you can delete the `res/layout/pleasedeleteme.xml` file, by right-clicking over it and choosing “Delete...” from the context menu. You can also delete the `res/menu/simple_content.xml` file, the `res/values/dimens.xml` file, the `res/values-820dp/` directory, and the `res/menu/pleasedeletemetoo.xml` file.

Next, go into `AndroidManifest.xml` and delete the `android:label` attribute of the `SimpleContentActivity` `<activity>` element.

Finally, you can open up the `res/values/strings.xml` file and delete the following string resources:

- `title_activity_simple_content`
- `hello_world`
- `action_settings`

Eclipse

Right-click over the EmPubLite project in the Package Explorer, then choose `New > Other` from the context menu. In the list of possible things to add to your project, choose “Android Activity” and click Next. In the list of templates, choose “Empty Activity” and click Next.

In the last page of the new-activity wizard, fill in:

- `SimpleContentActivity` in the “Activity Name” field
- `pleasedeleteme` for the “Layout Name”
- `pleasedeletemetoo` for the “Title”

Leave the rest of the wizard at its defaults, then click on Finish.

TUTORIAL #8 - SETTING UP AN ACTIVITY

In the `SimpleContentActivity` class that Android Studio generates, delete the `setContentView()` call from the `onCreate()` method.

You can also delete the `/res/layout/pleasedeleteme.xml` file, by right-clicking over it and choosing “Delete...” from the context menu.

Then, open up `AndroidManifest.xml`. In the XML sub-tab, go to the `<activity>` element added for `SimpleContentActivity` and remove the `android:label` attribute, so we inherit our label from the `<application>` element. At this point, you can save your changes to this file (e.g., `<Ctrl>-<S>`).

Finally, open up `res/values/strings.xml` and delete the `title_activity_simple_content` that the wizard added, which we are no longer using. At this point, you can save your changes to this file (e.g., `<Ctrl>-<S>`).

Step #2: Launching Our Activity

Now that we have declared that the activity exists and can be used, we can start using it.

Go into `EmPubLiteActivity` and modify `onOptionsItemSelected()` to add in some logic in the `R.id.about` and `R.id.help` branches, as shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case android.R.id.home:
            return(true);

        case R.id.about:
            Intent i=new Intent(this, SimpleContentActivity.class);
            startActivity(i);

            return(true);

        case R.id.help:
            i=new Intent(this, SimpleContentActivity.class);
            startActivity(i);

            return(true);
    }
    return(super.onOptionsItemSelected(item));
}
```

TUTORIAL #8 - SETTING UP AN ACTIVITY

In those two branches, we create an Intent, pointing at our new SimpleContentActivity. Then, we call `startActivity()` on that Intent. Right now, both help and about do the same thing — we will add some smarts to have them load up different content later in this book.

You will need to add an import for `android.content.Intent` to get this to compile.

If you run this app in a device or emulator, and you choose either the Help or About menu choices, what appears to happen is that the ProgressBar vanishes. In reality, what happens is that our SimpleContentActivity appeared, but empty, as we have not given it a full UI yet.

In Our Next Episode...

... we will [begin using fragments](#) in our tutorial project.

The Tactics of Fragments

Fragments are an optional layer you can put between your activities and your widgets, designed to help you reconfigure your activities to support screens both large (e.g., tablets) and small (e.g., phones).

This chapter will cover basic uses of fragments.

The Six Questions

In the world of journalism, the basics of any news story consist of six questions, [the Five Ws and One H](#). Here, we will apply those six questions to help frame what we are talking about with respect to fragments.

What?

Fragments are not activities, though they can be used by activities.

Fragments are not containers (i.e., subclasses of `ViewGroup`), though typically they create a `ViewGroup`.

Rather, you should think of fragments as being units of UI reuse. You define a fragment, much like you might define an activity, with layouts and lifecycle methods and so on. However, you can then host that fragment in one or several activities, as needed.

Android does not precisely implement UI architectures like Model-View-Controller (MVC), Model-View-Presenter (MVP), Model-View-ViewModel (MVVM), etc. To the extent that you wish to shove Android into the MVC architecture, fragments and activities combine to be the controller layer. Fragments serve as a local controller,

focused on their set of widgets, populating them from model data, and handling their events. Activities will serve as more of an orchestration layer, handling cross-fragment communications (e.g., a click in Fragment A needs to cause a change in what is displayed in Fragment B).

Functionally, fragments are Java classes, extending from a base Fragment class. As we will see, there are two versions of the Fragment class, one native to API Level 11 and one supplied by the Android Support package.

Where??

Since fragments are Java classes, your fragments will reside in one of your application's Java packages. The simplest approach is to put them in the same Java package that you used for your project overall and where your activities reside, though you can refactor your UI logic into other packages if needed.

Who?!?

Typically, you create fragment implementations yourself, then tell Android when to use them. Some third-party Android library projects may ship fragment implementations that you can reuse, if you so choose.

When?!?!?

Some developers start adding fragments from close to the outset of application development — that is the approach we will take in the tutorials. And, if you are starting a new application from scratch, defining fragments early on is probably a good idea. That being said, it is entirely possible to “retrofit” an existing Android application to use fragments, though this may be a lot of work. And, it is entirely possible to create Android applications without fragments at all.

Fragments were introduced with Android 3.0 (API Level 11, a.k.a., Honeycomb).

WHY?!?!?

Ah, this is the big question. If we have managed to make it this far through the book without fragments, and we do not necessarily need fragments to create Android applications, what is the point? Why would we bother?

THE TACTICS OF FRAGMENTS

The primary rationale for fragments was to make it easier to support multiple screen sizes.

Android started out supporting phones. Phones may vary in size, from tiny ones with less than 3" diagonal screen size (e.g., Sony Ericsson X10 mini), to monsters that are over 5" (e.g., Samsung Galaxy Note). However, those variations in screen size pale in comparison to the differences between phones and tablets, or phones and TVs.

Some applications will simply expand to fill larger screen sizes. Many games will take this approach, simply providing the user with bigger interactive elements, bigger game boards, etc. Any one of the ever-popular Angry Birds game series, when played on an tablet, gives you bigger birds and bigger pigs, not a phone-sized game area surrounded by ad banners.

However, another design approach is to consider a tablet screen to really be a collection of phone screens, side by side.

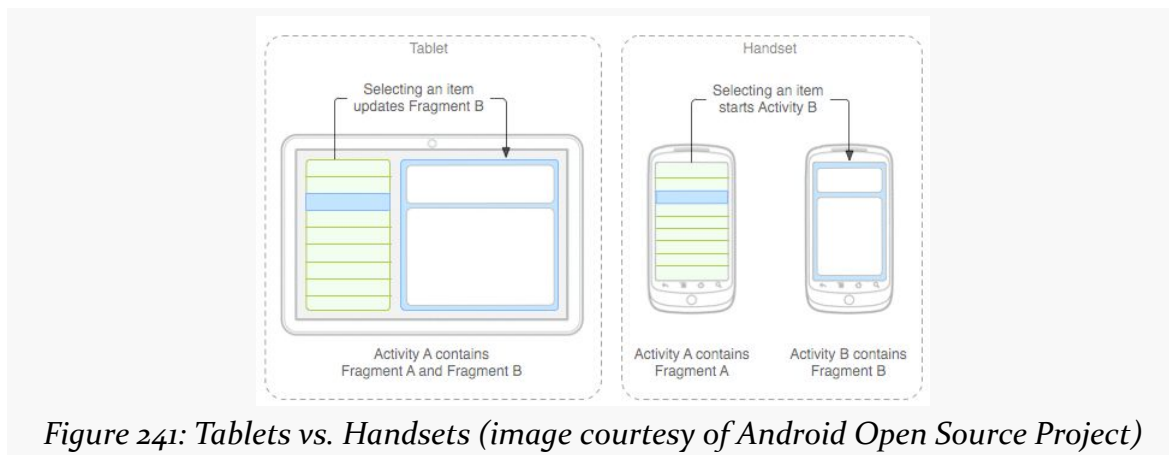

Figure 241: Tablets vs. Handsets (image courtesy of Android Open Source Project)

The user can access all of that functionality at once on a tablet, whereas they would have to flip back and forth between separate screens on a phone.

For applications that can fit this design pattern, fragments allow you to support phones and tablets from one code base. The fragments can be used by individual activities on a phone, or they can be stitched together by a single activity for a tablet.

Details on using fragments to support large screen sizes is a topic for [a later chapter in this book](#). This chapter is focused on the basic mechanics of setting up and using fragments.

OMGOMGOMG, HOW?!?!??

Well, answering that question is what the rest of this chapter is for, plus coverage of more advanced uses of fragments elsewhere in this book.

Where You Get Your Fragments From

Most developers will use the implementation of fragments that has been part of Android since API Level 11. You will use `android.app.Fragment` and have them be hosted by your regular activities.

However, there is a backport of the fragment system available in the Android Support package. This works back to API Level 4, so if your `minSdkVersion` is lower than 11 *and* you want to use fragments, the backport is something that you will wish to consider. You will need to add the `support-v4` JAR to your project (e.g., via `compile 'com.android.support:support-v4:...' in your dependencies in build.gradle`, for some value of ...). You will also need to use `android.support.v4.app.Fragment` instead of `android.app.Fragment`. Also, you will need to host those fragments in an activity inheriting from `android.support.v4.app.FragmentActivity` (as the regular `android.app.Activity` base class does not know about fragments prior to API Level 11).

This book focuses mostly on using the native API Level 11 implementation of fragments, with the occasional example of using the backport where the backport is necessary for one reason or another.

Your First Fragment

In many ways, it is easier to explain fragments by looking at an implementation, more so than trying to discuss them as abstract concepts. So, in this section, we will take a look at the [Fragments/Static](#) sample project. This is a near-clone of the [Activities/Lifecycle](#) sample project from [the previous chapter](#). However, we have converted the launcher activity from one that will host widgets directly itself to one that will host a fragment, which in turn manages widgets.

The Fragment Layout

Our fragment is going to manage our UI, so we have a `res/layout/mainfrag.xml` layout file containing our Button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/showOther"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/hello"
    android:textSize="20sp"/>
```

Note, though, that we do not use the `android:onClick` attribute. We will explain why we dropped that attribute from the previous editions of this sample shortly.

The Fragment Class

The project has a `ContentFragment` class that will use this layout and handle the Button.

As with activities, there is no constructor on a typical Fragment subclass. The primary method you override, though, is not `onCreate()` (though, as we will see later in this chapter, that is possible). Instead, the primary method to override is `onCreateView()`, which is responsible for returning the UI to be displayed for this fragment:

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.mainfrag, container, false);

    result.findViewById(R.id.showOther).setOnClickListener(this);

    return(result);
}
```

We are passed a `LayoutInflater` that we can use for inflating a layout file, the `ViewGroup` that will eventually hold anything we inflate, and the `Bundle` that was passed to the activity's `onCreate()` method. While we are used to framework classes loading our layout resources for us, we can “inflate” a layout resource at any time using a `LayoutInflater`. This process reads in the XML, parses it, walks the element tree, creates Java objects for each of the elements, and stitches the results together into a parent-child relationship.

Here, we inflate `res/layout/mainfrag.xml`, telling Android that its contents will eventually go into the `ViewGroup` but not to add it right away. While there are simpler flavors of the `inflate()` method on `LayoutInflater`, this one is required in

case the ViewGroup happens to be a RelativeLayout, so we can process all of the positioning and sizing rules appropriately.

We also use `findViewById()` to find our Button widget and tell it that we, the fragment, are its `OnClickListener`. `ContentFragment` must then implement the `View.OnClickListener` interface to make this work. We do this instead of `android:onClick` to route the Button click events to the fragment, not the activity.

Since we implement the `View.OnClickListener` interface, we need the corresponding `onClick()` method implementation:

```
@Override
public void onClick(View v) {
    ((StaticFragmentsDemoActivity) getActivity()).showOther(v);
}
```

Any fragment can call `getActivity()` to find the activity that hosts it. In our case, the only activity that will possibly host this fragment is `StaticFragmentsDemoActivity`, so we can cast the result of `getActivity()` to `StaticFragmentsDemoActivity`, so that we can call methods on our activity. In particular, we are telling the activity to show the other activity, by means of calling the `showOther()` method that we saw in the original `Activities/Lifecycle` sample (and will see again shortly).

That is really all that is needed for this fragment. However, `ContentFragment` also overrides many other fragment lifecycle methods, and we will examine these [later in this chapter](#).

The Activity Layout

Originally, the `res/layout/main.xml` used by the activity was where we had our Button widget. Now, the Button is handled by the fragment. Instead, our activity layout needs to account for the fragment itself.

In this sample, we are going to use a static fragment. Static fragments are easy to add to your application: just use the `<fragment>` element in a layout file, such as our revised `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.sfrag.ContentFragment"/>
```

Here, we are declaring our UI to be completely comprised of one fragment, whose implementation (`com.commonware.android.sfrag.ContentFragment`) is identified by the `android:name` attribute on the `<fragment>` element. Instead of `android:name`, you can use `class`, though most of the Android documentation has now switched over to `android:name`.

Android Studio users can drag a fragment out of the “Custom” section of the graphical layout editor tool palette, if desired, rather than setting up the `<fragment>` element directly in the XML. Eclipse users have a similar option in the “Layouts” section of the tool palette.

The Activity Class

`StaticFragmentsDemoActivity` — our new launcher activity — looks identical to the previous version, with the exception of the class name:

```
package com.commonware.android.sfrag;

import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class StaticFragmentsDemoActivity extends
    LifecycleLoggingActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        Intent other=new Intent(this, OtherActivity.class);

        other.putExtra(OtherActivity.EXTRA_MESSAGE,
            getString(R.string.other));
        startActivity(other);
    }
}
```

Since the `res/layout/main.xml` file has the `<fragment>` element, the fragment is simply loaded into position in the call to `setContentView()`.

The Fragment Lifecycle Methods

Fragments have lifecycle methods, just like activities do. In fact, they support most of the same lifecycle methods as activities:

- `onCreate()`
- `onStart()` (but not `onRestart()`)
- `onResume()`
- `onPause()`
- `onStop()`
- `onDestroy()`

By and large, the same rules apply for fragments as do for activities with respect to these lifecycle methods (e.g., `onDestroy()` may not be called).

In addition to those and the `onCreateView()` method we examined earlier in this chapter, there are four other lifecycle methods that you can elect to override if you so choose.

`onAttach()` will be called first, even before `onCreate()`, letting you know that your fragment has been attached to an activity. You are passed the `Activity` that will host your fragment.

`onViewCreated()` will be called after `onCreateView()`. This is particularly useful if you are inheriting the `onCreateView()` implementation but need to configure the resulting views, such as with a `ListFragment` and needing to set up an adapter.

`onActivityCreated()` will be called after `onCreate()` and `onCreateView()`, to indicate that the activity's `onCreate()` has completed. If there is something that you need to initialize in your fragment that depends upon the activity's `onCreate()` having completed its work, you can use `onActivityCreated()` for that initialization work.

`onDestroyView()` is called before `onDestroy()`. This is the counterpart to `onCreateView()` where you set up your UI. If there are things that you need to clean up specific to your UI, you might put that logic in `onDestroyView()`.

`onDetach()` is called after `onDestroy()`, to let you know that your fragment has been disassociated from its hosting activity.

Your First Dynamic Fragment

Static fragments are fairly simple, once you have the `Fragment` implementation: just add the `<fragment>` element to where you want to have the fragment appear in your activity's layout.

That simplicity, though, does come with some costs. We will review some of those limitations [in the next chapter](#).

Those limitations can be overcome by the use of dynamic fragments. Rather than indicating to Android that you wish to use a fragment by means of a <fragment> element in a layout, you will use a `FragmentManager` to add a fragment at runtime from your Java code.

With that in mind, take a look at the [Fragments/Dynamic](#) sample project.

This is the same project as the one for static fragments, except this time we will adjust `OtherActivity` to use a dynamic fragment, specifically a `ListFragment`.

The ListFragment Class

`ListFragment` serves the same role for fragments as `ListActivity` does for activities. It wraps up a `ListView` for convenient use. So, to have a more interesting `OtherActivity`, we start with an `OtherFragment` that is a `ListFragment`, designed to show our favorite 25 Latin words as seen in previous examples.

Just as a `ListActivity` does not need to call `setContentView()`, a `ListFragment` does not need to override `onCreateView()`. By default, the entire fragment will be comprised of a single `ListView`. And just as `ListActivity` has a `setListAdapter()` method to associate an `Adapter` with the `ListView`, so too does `ListFragment`:

```
package com.commonware.android.dfrag;

import android.app.Activity;
import android.app.ListFragment;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.AdapterView;

public class OtherFragment extends ListFragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };

    @Override
    public void onViewCreated(View view, Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);
    }
}
```

```
setListAdapter(new ArrayAdapter<String>(getActivity(),  
    android.R.layout.simple_list_item_1, items));
```

We call `setListAdapter()` in `onViewCreated()`, as we know that the `ListView` is now ready for use.

This class also overrides many fragment lifecycle methods, logging their results, akin to our other `Fragment` and `LifecycleLoggingActivity`.

The Activity Class

Now, `OtherActivity` no longer needs to load a layout — we have removed `res/layout/other.xml` from the project entirely. Instead, we will use a `FragmentManager` to add our fragment to the UI:

```
package com.commonware.android.dfrag;  
  
import android.os.Bundle;  
  
public class OtherActivity extends LifecycleLoggingActivity {  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
  
        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {  
            getFragmentManager().beginTransaction()  
                .add(android.R.id.content,  
                    new OtherFragment()).commit();  
        }  
    }  
}
```

To work with a `FragmentManager`, you need the `FragmentManager`. This object knows about all of the fragments that exist in your activity. If you are using the native API Level 11 edition of fragments, you can get your `FragmentManager` by calling `getFragmentManager()`. If you are using the Android Support package, you need to call `getSupportFragmentManager()` instead.

Given a `FragmentManager`, you can start a `FragmentManager` by calling `beginTransaction()`, which returns the `FragmentManager` object. `FragmentManager` operates on the builder pattern, so most methods on `FragmentManager` return the `FragmentManager` itself, so you can chain a series of method calls one after the next.

We call two methods on our `FragmentManager`: `add()` and `commit()`. The `add()` method, as you might guess, indicates that we want to add a fragment to the UI. We supply the actual fragment object, in this case by creating a new `OtherFragment`. We also need to indicate where in our layout we want this fragment to reside. Had we loaded a layout, we could drop this fragment in any desired container. In our case, since we did not load a layout, we supply `android.R.id.content` as the ID of the container to hold our fragment's `View`. Here, `android.R.id.content` identifies the container into which the results of `setContentView()` would go — it is a container supplied by `Activity` itself and serves as the top-most container for our content.

Just calling `add()` is insufficient. We then need to call `commit()` to make the transaction actually happen.

You might be wondering why we are trying to find a fragment in our `FragmentManager` before actually creating the fragment. We do that to help deal with configuration changes, and we will be exploring that further [in the next chapter](#).

Fragments and the Action Bar

Fragments can add items to the action bar by calling `setHasOptionsMenu(true)` from `onCreate()` (or any other early lifecycle method). This indicates to the activity that it needs to call `onCreateOptionsMenu()` and `onOptionsItemSelected()` on the fragment.

The [Fragments/ActionBarNative](#) sample application demonstrates this. This has the same functionality as does the `ActionBar/ActionBarDemoNative` sample from [the chapter on the action bar](#), just with the activity converted into a dynamic fragment.

In `onCreate()`, we call `setHasOptionsMenu(true)`, to indicate that we are interested in participating in the action bar:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
}
```

(we will discuss that `setRetainInstance(true)` call [in a later chapter](#))

That will trigger our fragment's `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods to be called at the appropriate time:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.add:
            addWord();

            return(true);

        case R.id.reset:
            initAdapter();

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

Here, we initialize our action bar from the `R.menu.actions` menu XML resource, including setting up our `EditText` widget, plus the logic to respond to the reset action overflow item.

Our activity does not need to do anything special to allow the fragment to contribute to the action bar — it just sets up the dynamic fragment:

```
package com.commonware.android.abf;

import android.app.Activity;
import android.os.Bundle;

public class ActionBarFragmentActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new ActionBarFragment()).commit();
        }
    }
}
```

Fragments Within Fragments: Just Say “Maybe”

Historically, one major limitation with fragments is that they could not contain other fragments. In most cases, this does not pose a major problem. However, there will be times when you might trip over this limitation, such as when using a `ViewPager`, as will be described in [a later chapter](#).

Android 4.2 — and the Android Support package — added support for nested fragments. Whereas an activity works with fragments via a `FragmentManager` obtained via `getFragmentManager()` or `getSupportFragmentManager()`, fragments can work with nested fragments via a call to `getChildFragmentManager()`.

However, Android 3.0 through 4.1 have a version of fragments that does not have `getChildFragmentManager()`. Hence, you have two options:

1. Use the Android Support package’s backport of fragments, until such time as you can drop support for Android 4.1 and earlier, or
2. Do not use nested fragments for the time being.

We will see how `getChildFragmentManager()` works in [the chapter on ViewPager](#).

Fragments and Multiple Activities

A fragment should handle functionality purely within the fragment itself. Anything outside the fragment should be the responsibility of the calling activity. For example, if the user taps on an item in a `ListFragment`, and the effects of that event might go beyond what is inside the `ListFragment` itself, the `ListFragment` should forward the event to the hosting activity, so it can perhaps perform additional steps (e.g., launch an activity, update another fragment hosted by the activity).

As we will see [in a later chapter](#), it is entirely possible — perhaps even likely — that some of our fragments will be hosted by multiple different activities. For example, we might have a fragment that is hosted in one case by an activity designed for larger screens (e.g., tablets) and in another case by an activity designed for smaller screens (e.g., phones).

In these cases, the fragment does not know at compile time which activity class will be hosting it at runtime. For those cases, you have two major options:

THE TACTICS OF FRAGMENTS

1. Have the activities implement a common interface, and have the fragment cast the result of calling `getActivity()` to that interface, so it can call methods on the hosting activity without knowing its exact implementation.
2. Have the activities supply a listener object, with a common interface, to the fragment via a setter, and have the fragment use that listener for raising events and so on.
3. Use an event bus, as we will explore [later in this book](#).

We will see much more on this subject when we get into large-screen strategies [in a later chapter](#).

Tutorial #9 - Starting Our Fragments

Much of the content of a digital book to be viewed in EmPubLite will be in the form of HTML and related assets (CSS, images, etc.). Hence, we will eventually need to render our content in a WebView widget, for best results with semi-arbitrary HTML content.

To do this, we will set up fragments for the bits of content:

- each chapter (or, in our case, HTML file containing chapters)
- other material, like our “help” and “about” pages

Right now, we will focus on just setting up some of the basic classes for these fragments — we will load them up with content and display them over the next few tutorials.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book’s GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Create a SimpleContentFragment

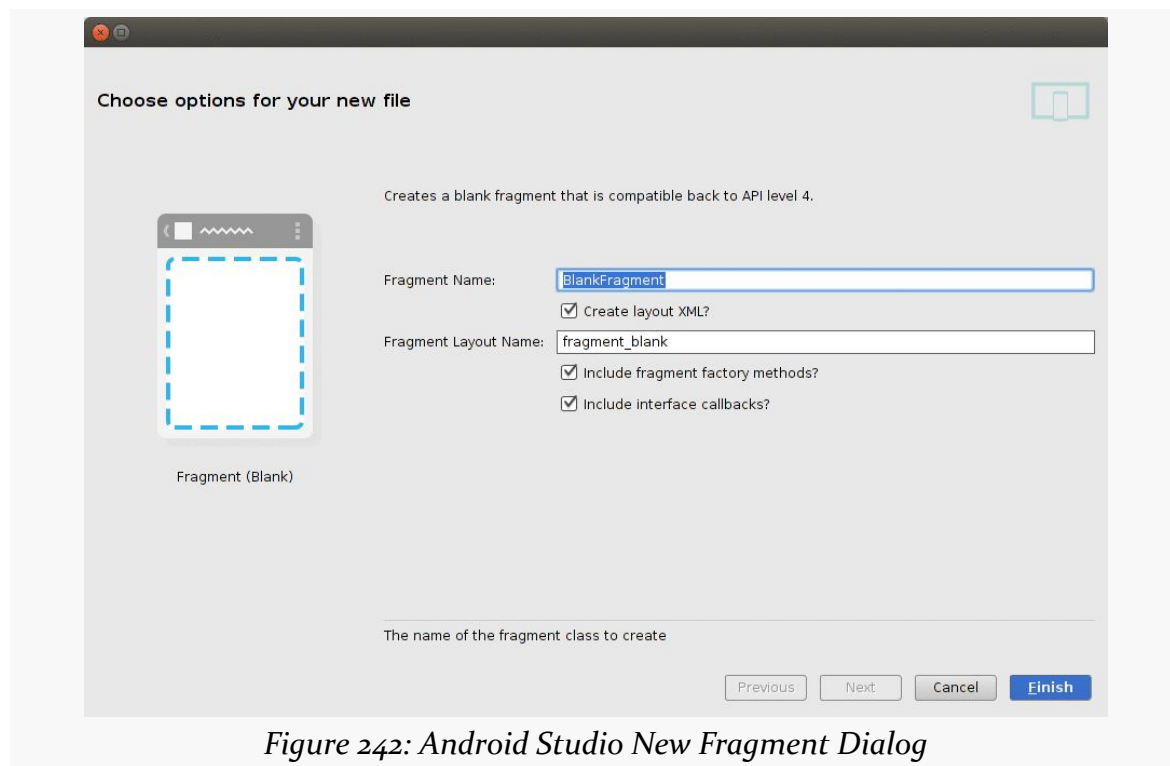

Android has a WebViewFragment for the native API Level 11+ implementation of fragments, designed to show some Web content in a WebView. In this step, we will create a subclass of WebViewFragment that adds in a bit of EmPubLite-specific business logic.

TUTORIAL #9 - STARTING OUR FRAGMENTS

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Fragment > “Fragment (Blank)”` from the context menu. That will bring up a new-fragment dialog:

Fill in `SimpleContentFragment` for the “Fragment Name” and uncheck all three checkboxes. Then, click `Finish` to create the fragment class.

Then, replace the contents of the fragment class with the following code:

```
package com.commonware.empublite;

import android.annotation.SuppressLint;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebViewFragment;
```

TUTORIAL #9 - STARTING OUR FRAGMENTS

```
public class SimpleContentFragment extends WebViewFragment {
    private static final String KEY_FILE = "file";

    protected static SimpleContentFragment newInstance(String file) {
        SimpleContentFragment f = new SimpleContentFragment();
        Bundle args = new Bundle();

        args.putString(KEY_FILE, file);
        f.setArguments(args);

        return (f);
    }

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setRetainInstance(true);
    }

    @SuppressWarnings("SetJavaScriptEnabled")
    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result =
            super.onCreateView(inflater, container, savedInstanceState);

        getWebView().getSettings().setJavaScriptEnabled(true);
        getWebView().getSettings().setSupportZoom(true);
        getWebView().getSettings().setBuiltInZoomControls(true);
        getWebView().loadUrl(getPage());

        return (result);
    }

    private String getPage() {
        return (getArguments().getString(KEY_FILE));
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

You can also delete the `hello_blank_fragment` string from `res/values/strings.xml`.

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in

SimpleContentFragment in the “Name” field. Then, click the “Browse...” button next to the “Superclass” field and find WebViewFragment to set as the superclass. Then, click “Finish” on the new-class dialog to create the SimpleContentFragment class.

Then, replace its contents with the code shown in the Android Studio instructions above.

Step #2: Examining SimpleContentFragment

SimpleContentFragment is simple, with a total of four methods:

- onCreate(), where we call setRetainInstance(true) — the utility of this will be examined in greater detail [in an upcoming chapter](#).
- onCreateView(), where we chain to the superclass (to have it create the WebView), then configure it to accept JavaScript and support zoom operations. We then have it load some content, retrieved in the form of a URL from a private getPage() method. Finally, we return what the superclass returned from onCreateView() — effectively, we are simply splicing in our own configuration logic.
- newInstance() static factory method. This method creates an instance of SimpleContentFragment, takes a passed-in String (pointing to the file to load), puts it in a Bundle identified as KEY_FILE, hands the Bundle to the fragment as its arguments, and returns the newly-created SimpleContentFragment.
- getPage(), where it returns a value out of the “arguments” Bundle supplied to the fragment — specifically the string identified as KEY_FILE.

This means that anyone wanting to use SimpleContentFragment should use the factory method, to provide the path to the content to load. We will see why we implemented SimpleContentFragment this way in [the next chapter](#).

In Our Next Episode...

... we will [set up horizontal swiping](#) of book chapters in our tutorial project.

Swiping with ViewPager

Android, over the years, has put increasing emphasis on UI design and having a fluid and consistent user experience (UX). While some mobile operating systems take “the stick” approach to UX (forcing you to abide by certain patterns or be forbidden to distribute your app), Android takes “the carrot” approach, offering widgets and containers that embody particular patterns that they espouse. The action bar, for example, grew out of this and is now the backbone of many Android activities.

Another example is the ViewPager, which allows the user to swipe horizontally to move between different portions of your content. However, ViewPager is not distributed as part of the firmware, but rather via the Android Support package. Hence, even though ViewPager is a relatively new widget, you can use it on Android 1.6 and up.

This chapter will focus on where you should apply a ViewPager and how to set one up.

Swiping Design Patterns

In 2012, Google released [Android design guidelines](#) as an adjunct to the existing developer documentation. This site outlines many aspects of UI and UX design for Android, from recommended sizing to maintaining platform fidelity instead of mimicking another mobile operating system.

They have [a page dedicated to “swipe views”](#), where they outline the scenario for using horizontal swiping: moving from peer to peer in sequence in a collection of content:

- Email messages in a folder or label

- Chapters in an ebook
- Tabs in a collection of tabs

The primary way to implement this pattern in Android is the `ViewPager`.

Pieces of a Pager

`AdapterView` classes, like `ListView`, work with `Adapter` objects, like `ArrayAdapter`. `ViewPager`, however, is not an `AdapterView`, despite adopting many of the patterns from `AdapterView`. `ViewPager`, therefore, does not work with an `Adapter`, but instead with a `PagerAdapter`, which has a slightly different API.

Android ships two `PagerAdapter` implementations in the Android Support package: `FragmentPagerAdapter` and `FragmentStatePagerAdapter`. The former is good for small numbers of fragments, where holding them all in memory at once will work. `FragmentStatePagerAdapter` is for cases where holding all possible fragments to be viewed in the `ViewPager` would be too much, where Android will discard fragments as needed and hold onto the (presumably smaller) states of those fragments instead.

Paging Fragments

The simplest way to use a `ViewPager` is to have it page fragments in and out of the screen based on user swipes.

To see this in action, this section will examine the [ViewPager/Fragments](#) sample project.

The project has a dependency on the Android Support package, in order to be able to use `ViewPager`. In Android Studio, this is a compile statement in the dependencies closure of `build.gradle`:

```
dependencies {  
    compile 'com.android.support:support-v13:21.0.3'  
}
```

In Eclipse, this is a bare JAR in the project's `libs/` directory.

The Activity Layout

The layout used by the activity just contains the ViewPager. Note that since ViewPager is not in the android.widget package, we need to fully-qualify the class name in the element:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</android.support.v4.view.ViewPager>
```

Note that ViewPager is not available for drag-and-drop in the IDE graphical designers, probably because it comes from the Android Support package and therefore is not available to all projects.

The Activity

As you see, the ViewPagerFragmentDemoActivity itself is blissfully small:

```
package com.commonware.android.pager;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.ViewPager;

public class ViewPagerFragmentDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        pager.setAdapter(new SampleAdapter(getFragmentManager()));
    }
}
```

All we do is load the layout, retrieve the ViewPager via findViewById(), and provide a SampleAdapter to the ViewPager via setAdapter().

The PagerAdapter

Our SampleAdapter inherits from FragmentPagerAdapter and implements two required callback methods:

- getCount(), to indicate how many pages will be in the ViewPager, and
- getItem(), which returns a Fragment for a particular position within the ViewPager (akin to getView() in a classic Adapter)

```
package com.commonware.android.pager;

import android.app.Fragment;
import android.app.FragmentManager;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    public SampleAdapter(FragmentManager mgr) {
        super(mgr);
    }

    @Override
    public int getCount() {
        return(10);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }
}
```

Here, we say that there will be 10 pages total, each of which will be an instance of an EditorFragment. In this case, rather than use the constructor for EditorFragment, we are using a newInstance() factory method. The rationale for that will be explained in the next section.

The Fragment

EditorFragment will host a full-screen EditText widget, for the user to enter in a chunk of prose, as is defined in the res/layout/editor.xml resource:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:inputType="textMultiLine"
    android:gravity="left|top"
/>
```

We want to pass the position number of the fragment within the ViewPager, simply to customize the hint displayed in the EditText before the user types in anything. With normal Java objects, you might pass this in via the constructor, but it is not a good idea to implement a constructor on a Fragment. Instead, the recipe is to create a static factory method (typically named `newInstance()`) that will create the Fragment and provide the parameters to it by updating the fragment's "arguments" (a Bundle):

```
static EditorFragment newInstance(int position) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
}
```

You might be wondering why we are bothering with this Bundle, instead of just using a regular data member. The arguments Bundle is part of our "saved instance state", for dealing with things like screen rotations — a concept we will get into [later in the book](#). For the moment, take it on faith that this is a good idea.

In `onCreateView()` we inflate our `R.layout.editor` resource, get the EditText from it, get our position from our arguments, format a hint containing the position (using a string resource), and setting the hint on the EditText:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);
    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(String.format(getString(R.string.hint), position + 1));

    return(result);
}
```

The Result

When initially launched, the application shows the first fragment:

SWIPING WITH VIEWPAGER

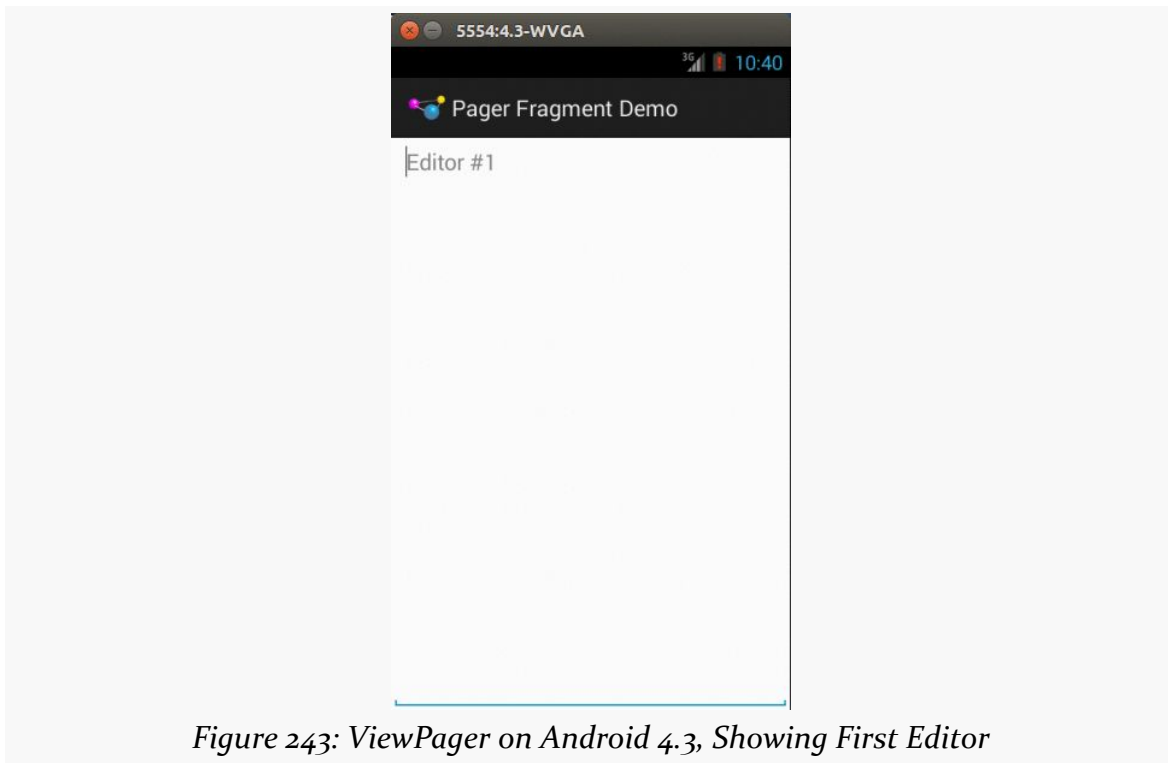

Figure 243: ViewPager on Android 4.3, Showing First Editor

However, you can horizontally swipe to get to the next fragment:

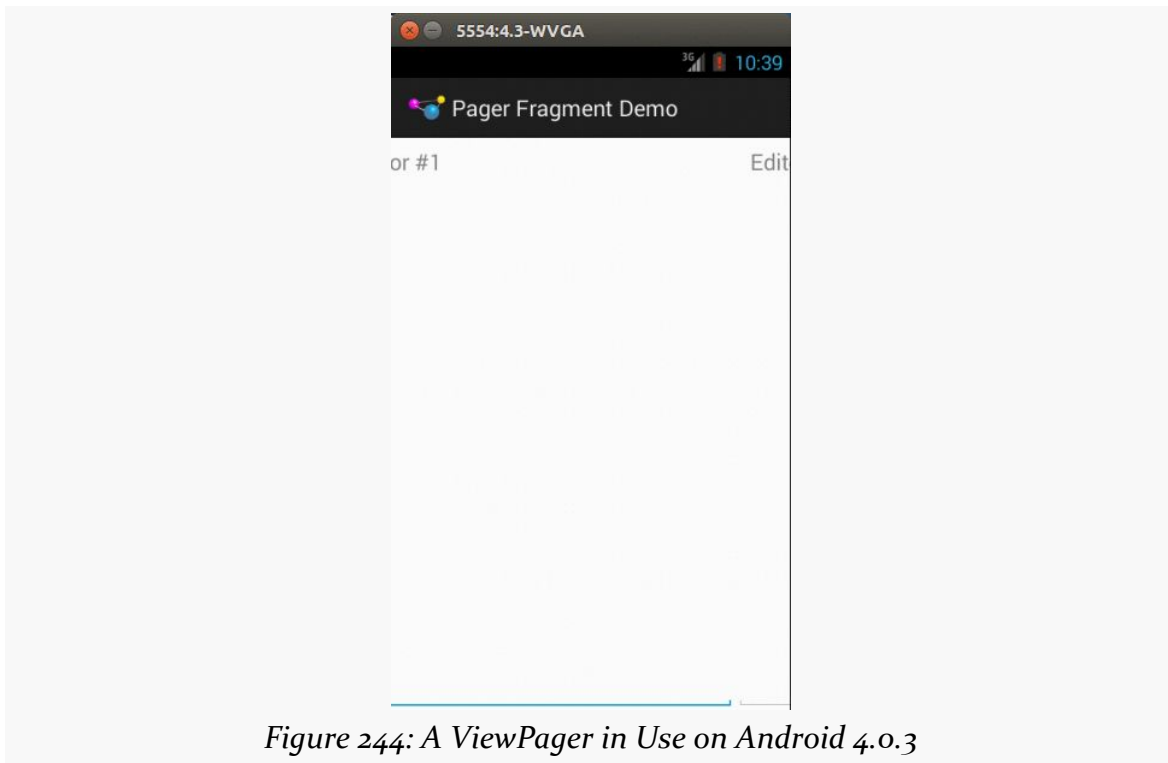

Figure 244: A ViewPager in Use on Android 4.0.3

Swiping works in both directions, so long as there is another page in your desired direction.

Paging Other Stuff

You do not have to use fragments inside a ViewPager. A regular PagerAdapter actually hands View objects to the ViewPager. The supplied fragment-based PagerAdapter implementations get the View from a fragment and use that, but you are welcome to create your own PagerAdapter that eschews fragments.

Hence, if you want ViewPager to page things other than fragments, the solution is to not use FragmentPagerAdapter or FragmentStatePagerAdapter, but instead create your own implementation of the PagerAdapter interface, one that avoids the use of fragments.

We will see an example of this [in a later chapter](#), where we also examine [how to have more than one page of the ViewPager be visible at a time](#).

Indicators

By itself, there is no visual indicator of where the user is within the set of pages contained in the ViewPager. In many instances, this will be perfectly fine, as the pages themselves will contain cues as to position. However, even in those cases, it may not be completely obvious to the user how many pages there are, which directions for swiping are active, etc.

Hence, you may wish to attach some other widget to the ViewPager that can help clue the user into where they are within “page space”.

PagerTitleStrip and PagerTabStrip

The primary built-in indicator options available to use are PagerTitleStrip and PagerTabStrip. As the name suggests, PagerTitleStrip is a strip that shows titles of your pages. PagerTabStrip is much the same, but the titles are formatted somewhat like tabs, and they are clickable (switching you to the clicked-upon page), whereas PagerTitleStrip is non-interactive.

To use either of these, you first must add it to your layout, inside your ViewPager, as shown in the `res/layout/main.xml` resource of the [ViewPager/Indicator](#) sample project, a clone of the ViewPager/Fragments project that adds a PagerTabStrip to our UI:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</android.support.v4.view.ViewPager>
```

Here, we set the `android:layout_gravity` of the PagerTabStrip to `top`, so it appears above the pages. You could similarly set it to `bottom` to have it appear below the pages.

Our SampleAdapter needs another method: getPageTitle(), which will return the title to display in the PagerTabStrip for a given position:

```
package com.commonware.android.pager2;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(10);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }

    @Override
    public String getPageTitle(int position) {
        return(EditorFragment.getTitle(ctxt, position));
    }
}
```

Here, we call a static getTitle() method on EditorFragment. That is a refactored bit of code from our former onCreateView() method, where we create the string for the hint — we will use the hint text as our page title:

```
package com.commonware.android.pager2;

import android.app.Fragment;
import android.content.Context;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private static final String KEY_POSITION="position";

    static EditorFragment newInstance(int position) {
```

SWIPING WITH VIEWPAGER

```
EditorFragment frag=new EditorFragment();
Bundle args=new Bundle();

args.putInt(KEY_POSITION, position);
frag.setArguments(args);

return(frag);
}

static String getTitle(Context ctxt, int position) {
    return(String.format(ctxt.getString(R.string.hint), position + 1));
}

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);
    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(getTitle(getActivity(), position));

    return(result);
}
}
```

Third-Party Indicators

If you want something else for your indicators, besides a strip of page titles, you might wish to check out the [ViewPagerIndicator library](#). This library contains a series of widgets that serve in the same role as PagerTitleStrip, with different looks. We will look at one such indicator, TabPageIndicator, [later in this book](#).

Visit the Trails!

There is [a chapter on advanced ViewPager techniques](#) that may interest you!

Tutorial #10 - Rigging Up a ViewPager

A ViewPager is a fairly slick way to present a digital book. You can have individual portions of the book be accessed by horizontal swiping, with the prose within a portion accessed by scrolling vertically. While not offering “page-at-a-time” models used by some book reader software, it is **much** simpler to set up.

So, that’s the approach we will use with EmPubLite. Which means, among other things, that we need to add a ViewPager to the app.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book’s GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Add a ViewPager to the Layout

Right now, the layout for EmPubLiteActivity just has a ProgressBar. We need to augment that to have our ViewPager as well, set up such that we can show either the ProgressBar (while we load the book) or the ViewPager as needed.

Since ViewPager is not available for drag-and-drop through the IDE graphical layout editors, even IDE users are going to have to dive into the layout XML this time.

Open up `res/layout/main.xml` and switch to the appropriate sub-tab to see the raw XML. As a child of the `<RelativeLayout>`, after the `<ProgressBar>`, add a `<android.support.v4.view.ViewPager>` element as follows:

TUTORIAL #10 - RIGGING UP A VIEWPAGER

```
<android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:visibility="gone" />
```

This adds the ViewPager, also having it fill the parent, but with the visibility initially set to gone, meaning that the user will not see it.

The entire layout should now resemble:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context=".EmPubLiteActivity">

    <ProgressBar
        android:id="@+id/progressBar1"
        style="?android:attr/progressBarStyleLarge"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true" />

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:visibility="gone" />

</RelativeLayout>
```

Step #2: Obtaining Our ViewPager

We will be referencing the ViewPager from a few places in the activity, so we may as well get a reference to it and hold onto it in a data member, for easy access.

Add a data member to EmPubLiteActivity:

```
private ViewPager pager=null;
```

You will also need to add an import for `android.support.v4.view.ViewPager` to get this to compile.

Then, in `onCreate()`, after the call to `setContentView(R.layout.main)`, use `findViewById()` to retrieve the ViewPager and store it in the pager data member:

```
pager=(ViewPager)findViewById(R.id.pager);
```

You may see a warning that pager is not used – do not worry, as we will be using it soon enough.

Step #3: Creating a ContentsAdapter

A ViewPager needs a PagerAdapter to populate its content, much like a ListView needs a ListAdapter. We cannot completely construct a PagerAdapter yet, as we still need to learn how to load up our book content from files. But, we can get part-way towards having a useful PagerAdapter now.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `ContentsAdapter` as the name and click OK to create the empty class.

Then, replace the generated `ContentsAdapter.java` file with the following content:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.support.v13.app.FragmentStatePagerAdapter;

public class ContentsAdapter extends FragmentStatePagerAdapter {
    public ContentsAdapter(Activity ctxt) {
        super(ctxt.getFragmentManager());
    }

    @Override
    public Fragment getItem(int arg0) {
        // TODO Auto-generated method stub
        return null;
    }

    @Override
    public int getCount() {
        // TODO Auto-generated method stub
        return 0;
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `ContentsAdapter` in the “Name” field. Then, click the “Browse...” button next to the “Superclass” field and find `FragmentStatePagerAdapter - android.support.v13.app` to set as the superclass. Note that there are two `FragmentStatePagerAdapter` implementations, and you want the one with `v13`, not `v4`, in the package name. Then, click “Finish” on the new-class dialog to create the `ContentsAdapter` class.

This will immediately show an error in the Eclipse editor, as `FragmentStatePagerAdapter` requires a public constructor, and we do not have one yet. So, add the following constructor implementation to the class:

```
public ContentsAdapter(Activity ctxt) {  
    super(ctxt.getFragmentManager());  
}
```

This simply chains to the superclass, supplying the requisite `FragmentManager` instance, culled from our parent activity. Note that you will need to add an import for `android.app.Activity` to the class.

Step #4: Setting Up the ViewPager

Let's add a few more lines to the bottom of `onCreate()` of `EmPubLiteActivity`, to set up `ContentsAdapter` and attach it to the `ViewPager`:

```
adapter=new ContentsAdapter(this);  
pager.setAdapter(adapter);  
findViewById(R.id.progressBar1).setVisibility(View.GONE);  
pager.setVisibility(View.VISIBLE);
```

This will require a new data member:

```
private ContentsAdapter adapter=null;
```

It will also require an import for `android.view.View`.

TUTORIAL #10 - RIGGING UP A VIEWPAGER

What we are doing is creating our `ContentsAdapter` instance, associating it with the `ViewPager`, and toggling the visibility of the `ProgressBar` (making it `GONE`) and the `ViewPager` (making it `VISIBLE`).

The net effect, if you run this modified version of the app, is that we no longer see the `ProgressBar`. Instead, we have a big blank area, taken up by our empty `ViewPager`:

Figure 246: EmPubLite, With Empty ViewPager

The `ViewPager` is empty simply because our `ContentsAdapter` returned 0 from `getCount()`, indicating that there are no pages to be displayed. The `ProgressBar` is no longer visible because we are immediately swapping in the `ViewPager`, but in the future, if it takes some time to get the `ViewPager` set up (e.g., disk I/O), we will see the `ProgressBar` briefly.

In Our Next Episode...

... we will [finish our “help” and “about” screens](#) in our tutorial project.

Resource Sets and Configurations

Devices sometimes change while users are using them, in ways that our application will care about:

- The user might rotate the screen from portrait to landscape, or vice versa
- The user might put the device in a car or desk dock, or remove it from such a dock
- The user might put the device in a “netbook dock” that adds a full QWERTY keyboard, or remove it from such a dock
- The user might switch to a different language via the Settings application, returning to our running application afterwards
- And so on

In all of these cases, it is likely that we will want to change what resources we use. For example, our layout for a portrait screen may be too tall to use in landscape mode, so we would want to substitute in some other layout.

This chapter will explore how to provide alternative resources for these different scenarios — called “configuration changes” — and will explain what happens to our activities when the user changes the configuration while we are in the foreground.

What’s a Configuration? And How Do They Change?

Different pieces of Android hardware can have different capabilities, such as:

- Different screen sizes
- Different screen densities (dots per inch)

- Different number and capabilities of cameras
- Different mix of radios (GSM? CDMA? GPS? Bluetooth? WiFi? NFC? something else?)
- And so on

Some of these, in the eyes of the core Android team, might drive the selection of resources, like layouts or drawables. Different screen sizes might drive the choice of layout. Different screen densities might drive the choice of drawable (using a higher-resolution image on a higher-density device). These are considered part of the device’s “configuration”.

Other differences — ones that do not drive the selection of resources — are not part of the device’s configuration but merely are “features” that some devices have and other devices do not. For example, cameras and Bluetooth and WiFi are features.

Some parts of a configuration will only vary based on different devices. A screen will not change density on the fly, for example. But some parts of a configuration can be changed during operation of the device, such as orientation (portrait vs. landscape) or language. When a configuration switches to something else, that is a “configuration change”, and Android provides special support for such events to help developers adjust their applications to match the new configuration.

Configurations and Resource Sets

One set of resources may not fit all situations where your application may be used. One obvious area comes with string resources and dealing with internationalization (I18N) and localization (L10N). Putting strings all in one language works fine — probably at least for the developer — but only covers one language.

That is not the only scenario where resources might need to differ, though. Here are others:

1. *Screen orientation*: is the screen in a portrait orientation? Landscape?
2. *Screen size*: is this something sized like a phone? A tablet? A television?
3. *Screen density*: how many dots per inch does the screen have? Will we need a higher-resolution edition of our icon so it does not appear too small?
4. *Keyboard*: what keyboard does the user have (QWERTY, numeric, neither), either now or as an option?
5. *Other input*: does the device have some other form of input, like a directional pad or click-wheel?

The way Android currently handles this is by having multiple resource directories, with the criteria for each embedded in their names.

Suppose, for example, you want to support strings in both English and Spanish. Normally, for a single-language setup, you would put your strings in a file named `res/values/strings.xml`. To support both English and Spanish, you could create two folders, `res/values-en/` and `res/values-es/`, where the value after the hyphen is the [ISO 639-1](#) two-letter code for the language you want. Your English-language strings would go in `res/values-en/strings.xml` and the Spanish ones in `res/values-es/strings.xml`. Android will choose the proper file based on the user's device settings.

However, the **better** approach is for you to consider some language to be your default, and put those strings in `res/values/strings.xml`. Then, create other resource directories for your translations (e.g., `res/values-es/strings.xml` for Spanish). Android will try to match a specific language set of resources; failing that, it will fall back to the default of `res/values/strings.xml`. This way, if your app winds up on a device with a language that you do not expect, you at least serve up strings in your chosen default language. Otherwise, if there is no such default, you will wind up with a `ResourceNotFoundException`, and your application will crash.

This, therefore, is the bedrock resource set strategy: have a complete set of resources in the default directory (e.g., `res/layout/`), and override those resources in other resource sets tied to specific configurations as needed (e.g., `res/layout-land/`).

Screen Size and Orientation

Perhaps the most important resource set qualifiers that we have not yet seen are the ones related to screen size and orientation. Here, “orientation” refers to how the device is being held: portrait or landscape.

Orientation is fairly easy, as you can just use `-port` or `-land` as resource set qualifiers to restrict resources in a directory to a specific orientation. The convention is to put landscape resources in a `-land` directory (e.g., `res/layout-land/`) and to put portrait resource in the default directory (e.g., `res/layout/`). However, this is merely a convention, and you are welcome to use `-port` if you prefer.

Screen size is a bit more complicated, simply because the available approaches have changed over the years.

The Original: Android-Defined Buckets

Way back in the beginning, with Android 1.0, all screen sizes were created equal... mostly because there was only one screen size, and that mostly because there was only one device.

Android 1.5, however, introduced three screen sizes and associated resource set qualifiers, with a fourth (-xlarge) added later:

- -small for screens at or under 3" in diagonal size
- -normal for screens between 3" and 5" in diagonal size
- -large for screens between 5" and 10" in diagonal size
- -xlarge for screens at or over 10" in diagonal size

As we will see, these resource set qualifiers establish lower bounds for when a directory's worth of resources will be used. So a `res/layout-normal/` directory will not be used for -small screens but would be used for -normal, -large, and -xlarge screens.

The Modern: Developer-Defined Buckets

The problem with the classic size buckets is that they were fairly inflexible. What if you think that so-called "phablets", like the Samsung Galaxy Note series, should have layouts more like phones, while larger tablets, such as the 8.9" Kindle Fire HD, should have layouts more like 10" tablets? That was not possible given the fixed buckets.

Android 3.2 gave us more control. We can have our own buckets for screen size, using the somewhat-confusing -swNNNdp resource set qualifier. Here, the NNN is replaced by you with a value, measured in dp, for the *shortest width* of the screen. "Shortest width" basically means the width of the screen when the device is held in portrait mode. Hence, rather than measuring based on diagonal screen size, as with the classic buckets, your custom buckets are based on the linear screen size of the shortest screen side.

For example, suppose that you wish to consider a dividing line between resources to be at the 7" point — 7" and smaller devices would get one set of layouts, while larger devices would get a different set of layouts. 7" tablets usually have a shortest width of around 3.5" to 3.75", given common aspect ratios. Since 1 dp is 1/160th of an inch, those shortest widths equate to 560–600 dp. Hence, you might set up a -sw600dp

resource set for your larger layouts, and put the smaller layouts in a default resource set.

Mashups: Width and Height Buckets

Using `-swNNNdp` does not address orientation, as the shortest width is the same regardless of whether the device is held in portrait or landscape. Hence, you would need to add `-swNNNdp-land` as a resource set for landscape resources for your chosen dividing line.

An alternative is to use `-wNNNdp` or `-hNNNdp`. These resource set qualifiers work much like `-swNNNdp`, particularly in terms of what NNN means. However, whereas `-swNNNdp` refers to the shortest width, `-wNNNdp` refers the *current* width, and `-hNNNdp` refers to the *current* height. Hence, these change with orientation changes.

About That API Level

`-swNNNdp`, `-wNNNdp`, and `-hNNNdp` were added in API Level 13. Hence, older devices will ignore any resource sets with those qualifiers.

In principle, this might seem like a big problem, for those developers still supporting older devices.

In practice, it is less of an issue than you might expect, simply because the *vast* majority of those older devices were phones, not tablets. The only Android 2.x tablets that sold in any significant quantity were three 7" models:

- the original Kindle Fire
- the original Barnes & Noble NOOK series
- the original Samsung Galaxy Tab

Of those, only the Galaxy Tab had the then-Android Market (now the Play Store). Hence, if you are only distributing via the Play Store, you might be in position to simply ignore pre-API Level 13 tablets. Use `-swNNNdp` to create your dividing line for larger devices, and the Galaxy Tab will simply use the layouts for your smaller devices.

If this concerns you, or you are also supporting the Kindle Fire and early NOOKs, you can use layout aliases to minimize code duplication. For example, suppose that you have a `res/layout/main.xml` that you wanted to have different versions for phones and tablets, and you want to use `-swNNNdp` for your dividing line as to where

the tablet layouts get used, but you also want to have the older tablets, like the Galaxy Tab, use the following recipe:

- Put your tablet-sized layouts in `res/layout/`, but with *different* filenames (e.g., `res/layout/main_to_be_used_for_tablets.xml`)
- In `res/values-swNNNdp/layouts.xml`, for your chosen value of `NNN`, put aliases (via `<item>` elements) for the original names (via the `name` attribute) pointing to the resources you want to use for `-swNNNdp` devices:

```
<resources>
  <item name="main" type="layout">@layout/main_to_be_used_for_tablets</item>
</resources>
```

- In `res/values-large/layouts.xml`, put those same aliases

Now, both older and newer devices, when referencing the same resource name, will get routed to the right layouts for their screen size.

Coping with Complexity

Where things start to get complicated is when you need to use multiple disparate criteria for your resources.

For example, suppose that you have drawable resources that are locale-dependent, such as a stop sign. You might want to have resource sets of drawables tied to language, so you can substitute in different images for different locales. However, you might also want to have those images vary by density, using higher-resolution images on higher-density devices, so the images all come out around the same physical size.

To do that, you would wind up with directories with multiple resource set qualifiers, such as:

- `res/drawable-ldpi/`
- `res/drawable-mdpi/`
- `res/drawable-hdpi/`
- `res/drawable-xhdpi/`
- `res/drawable-en-rUK-ldpi/`
- `res/drawable-en-rUK-mdpi/`
- `res/drawable-en-rUK-hdpi/`
- `res/drawable-en-rUK-xhdpi/`

- And so on

(with the default language being, say, US English, using a US stop sign)

Once you get into these sorts of situations, though, a few rules come into play, such as:

1. The configuration options (e.g., -en) have a particular order of precedence, and they must appear in the directory name in that order. The [Android documentation](#) outlines the specific order in which these options can appear. For the purposes of this example, screen size is more important than screen orientation, which is more important than screen density, which is more important than whether or not the device has a keyboard.
2. There can only be one value of each configuration option category per directory.
3. Options are case sensitive

For example, you might want to have different layouts based upon screen size and orientation. Since screen size is more important than orientation in the resource system, the screen size would appear in the directory name ahead of the orientation, such as:

- `res/layout-sw600dp-land/`
- `res/layout-sw600dp/`
- `res/layout-land/`
- `res/layout/`

Choosing The Right Resource

Given that you can have N different definitions of a resource, how does Android choose the one to use?

First, Android tosses out ones that are specifically invalid. So, for example, if the language of the device is -ru, Android will ignore resource sets that specify other languages (e.g., -zh). The exceptions to this are density qualifiers and screen size qualifiers — we will get to those exceptions later.

Then, Android chooses the resource set that has the desired resource and has *the most important distinct qualifier*. Here, by “most important”, we mean the one that appears left-most in the directory name, based upon the directory naming rules

[discussed above](#). And, by “distinct”, we mean where no other resource set has that qualifier.

If there is no specific resource set that matches, Android chooses the default set — the one with no suffixes on the directory name (e.g., `res/layout/`).

With those rules in mind, let’s look at some scenarios, to cover the base case plus the aforementioned exceptions.

Scenario #1: Something Simple

Let’s suppose that we have a `main.xml` file in:

- `res/layout-land/`
- `res/layout/`

When we call `setContentView(R.layout.main)`, Android will choose the `main.xml` in `res/layout-land/` if the device is in landscape mode. That particular resource set is valid in that case, and it has the most important distinct qualifier (`-land`). If the device is in portrait mode, though, the `res/layout-land/` resource set does not qualify, and so it is tossed out. That leaves us with `res/layout/`, so Android uses that `main.xml` version.

Scenario #2: Disparate Resource Set Categories

It is possible, though bizarre, for you to have a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land/`
- `res/layout/`

In this case, if the device’s locale is set to be English, Android will choose `res/layout-en/`, regardless of the orientation of the device. That is because `-en` is a more important resource set qualifier — “Language and region” appears higher in the “Table 2. Configuration qualifier names” from the Android documentation than does “Screen orientation” (for `-land`). If the device is not set for English, though, Android will toss out that resource set, at which point the decision-making process is the same as in Scenario #1 above.

Scenario #3: Multiple Qualifiers

Now let's envision a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land-v11/`
- `res/layout/`

You might think that `res/layout-land-v11/` would be the choice, as it is more specific, matching on two resource set qualifiers versus the one or none from the other resource sets.

(in fact, the author of this book thought this was the choice for many years)

In this case, though, language is more important than either screen orientation or Android API level, so the decision-making process is the similar to Scenario #2 above: Android chooses `res/layout-en/` for English-language devices, `res/layout-land-v11/` for landscape API Level 11+ devices, or `res/layout/` for everything else.

Scenario #4: Multiple Qualifiers, Revisited

Let's change the resource mix, so now we have a project with `main.xml` in:

- `res/layout-land-night/`
- `res/layout-land-v11/`
- `res/layout/`

Here, while `-land` is the most important resource set qualifier, it is not distinct — we have more than one resource set with `-land`. Hence, we need to check which is the next-most-important resource set qualifier. In this case, that is `-night`, as night mode is a more important category than is Android API level, and so Android will choose `res/layout-land-night/` if the device is in night mode. Otherwise, it will choose `res/layout-land-v11/` if the device is running API Level 11 or higher. If the device is not in night mode and is not running API Level 11 or higher, Android will go with `res/layout/`.

Scenario #5: Screen Density

Now, let's look at the first exception to the rules: screen density.

Android will *always* accept a resource set that contains a screen density, *even if it does not match the density of the device*. If there is an exact density match, of course, Android uses it. Otherwise, it will use what it feels is the next-best match, based upon how far off it is from the device's actual density and whether the other density is higher or lower than the device's actual density.

The reason for this is that for drawable resources, Android will downsample or upsample the image automatically, so the drawable will appear to be the right size, even though you did not provide an image in that specific density.

The catch is two-fold:

1. Android applies this logic to all resources, not just drawables, so even if there is no exact density match on, say, a layout, Android will still choose a resource from another density bucket for the layout
2. As a side-effect of the previous bullet, if you include a density resource set qualifier, Android will ignore any lower-priority resource set qualifiers (unless there are multiple directories with the same density resource set qualifier, in which case the lower-priority qualifiers serve as the “tiebreaker”)

So, now let's pretend that our project has `main.xml` in:

- `res/layout-mdpi/`
- `res/layout-nonav/`
- `res/layout/`

Android will choose `res/layout-mdpi/`, even for `-hdpi` devices that do not have a “non-touch navigation method”. While `-mdpi` does not match `-hdpi`, Android will still choose `-mdpi`. If we were dealing with drawables resources, Android would upsample the `-mdpi` image.

Scenario #6: Screen Sizes

If you have resource sets tied to screen size, Android will choose the one that is closest to the actual screen size yet smaller than the actual screen size. Resource sets for screen sizes larger than the actual screen size are ignored.

This works for `-swNNNdp`, `-wNNNdp`, and `-hNNNdp` for all devices. On `-large` or `-xlarge` devices, Android applies the same logic for the classic screen size qualifiers (`-small`, `-normal`, `-large`, `-xlarge`). However, Android does *not* apply this logic for `-small` or `-normal` devices — a `-normal` device will not load a `-small` resource.

Now let's pretend that our project has `main.xml` in:

- `res/layout-normal/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-normal/` if the device is not `-small`. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

Similarly, if we have:

- `res/layout-w320dp/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-w320dp/` for devices whose current screen width is 320dp or higher. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

API-Versioned Resources

As noted previously in this chapter, the `-vNNN` set of suffixes indicate that the resources in that directory are for the stated API level or higher. So, for example, `res/values-v21/` indicates that the resources in that directory should only be used on API Level 21 (Android 5.0) and higher. Devices running older versions of Android will ignore those resources.

This is a particularly important set of suffixes for dealing with major Android version changes. The look and feel of a stock Android app changed significantly at API Level 11 (Android 3.0) and API Level 21 (Android 5.0). You may find that you want to have different resources starting at those API level split points, so that your UI looks appropriately on all versions of Android that you are supporting.

Use Case: Themes by API Level

One big use case for this feature is having different themes by API level.

Even if your `minSdkVersion` is 11 or higher, you may want to have two different themes for your app:

- One, used from API Level 11–20, based on `Theme.Holo`
- Another, used from API Level 21 onwards, based on `Theme.Material`

Your rough alternative is to use [the appcompat-v7 backport](#) of the action bar and bits of the Material Design aesthetic. For highly stylized apps, or in cases where you are sure that you want Material Design on pre-Android 5.0 devices, appcompat-v7 is worth considering. But if you want to blend in better on each major native UI variant, you will want to support `Theme.Holo` on Android 3.x and 4.x and `Theme.Material` after that.

The hard work here is setting up your themes themselves, such as what was outlined back in [the chapter on the action bar](#). Having them both be available, depending upon device version, is merely a matter of putting the resources into the proper directories.

For example, take a look at the [ActionBar/VersionedColor](#) sample project. This is a “mashup” of the `HoloColor` and `MaterialColor` sample projects, where the determination of which theme to use is based on API level.

In the `res/values/` directory, we have a `styles.xml` file that is the same as the one in the `HoloColor` example, just with the filename standardized to `styles.xml`. It uses a custom theme (`Theme.Apptheme`) generated by the Action Bar Style Generator.

There is also a `res/values-v21/` directory, indicating values resources to be used on API Level 21 and higher. It has the theme originally seen in the `MaterialColor` example, where the style resource is renamed to `Theme.Apptheme`, to match the one defined in `res/values/`.

Then, with `<application>` referencing `Theme.Apptheme`, we get the right action bar on the right device.

Here, having the style resources names be the same is important, as we are referencing the name in the `<application>` element in the manifest. To be able to pull in the right one, we need them both to have the same name. However, resources that are referred to by only one of those themes, such as color and drawable resources, could go in a versioned directory or not, as you see fit. They *have* to go in versioned directories and *have* to have the same names if you want multiple editions where the API level chooses which edition to use.

For example, the `Theme.Material`-based theme defined in `res/values-v21/styles.xml` references three color resources. The file for those resources happens to

also be in `res/values-v21/` (`colors.xml`). However, since we are not looking to replace those colors based on API level, the `colors.xml` file could be placed in `res/values/` and work just as well. And, if we *did* want to have different colors by API level, we would need those colors defined in all relevant resource sets, such as both `res/values/` and `res/values-v21/`.

Default Change Behavior

When you call methods in the Android SDK that load a resource (e.g., the aforementioned `setContentView(R.layout.main)`), Android will walk through those resource sets, find the right resource for the given request, and use it.

But what happens if the configuration changes *after* we asked for the resource? For example, what if the user was holding their device in portrait mode, then rotates the screen to landscape? We would want a -land version of our layouts, if such versions exist. And, since we already requested the resources, Android has no good way of handing us revised resources on the fly... except by forcing us to re-request those resources.

So, this is what Android does, by default, to our foreground activity, when the configuration changes on the fly.

Destroy and Recreate the Activity

The biggest thing that Android does is destroy and recreate our activity. In other words:

- Android calls `onPause()`, `onStop()`, and `onDestroy()` on our original instance of the activity
- Android creates a brand new instance of the same activity class, using the same Intent that was used to create the original instance
- Android calls `onCreate()`, `onStart()`, and `onResume()` of the new activity instance
- The new activity appears on the screen

This may seem... invasive. You might not expect that Android would wipe out a perfectly good activity, just because the user flicked her wrist and rotated the screen of her phone. However, this is the only way Android has that guarantees that we will re-request all our resources.

Rebuild the Fragments

If your activity is using fragments, the new instance of the activity will contain the same fragments that the old instance of the activity does. This includes both static and dynamic fragments.

By default, Android destroys and recreates the fragments, just as it destroys and recreates the activities. However, as we will see, we do have an option to tell Android to retain certain dynamic fragment instances — for those, it will have the new instance use the same fragment instances as were used by the old activity, instead of creating new instances from scratch.

Recreate the Views

Regardless of whether or not Android recreates all of the fragments, it will call `onCreateView()` of all of the fragments (plus call `onDestroyView()` on the original set of fragments). In other words, Android recreates all of the widgets and containers, to pour them into the new activity instance.

Retain Some Widget State

Android will hold onto the “instance state” of some of the widgets we have in our activity and fragments. Mostly, it holds onto obviously user mutable state, such as:

- What has been typed into an `EditText`
- Whether a `CompoundButton`, like a `CheckBox` or `RadioButton`, is checked or not
- Etc.

Android will collect this information from the widgets of the old activity instance, carry that data forward to the new activity instance, and update the new set of widgets to have that same state.

State Saving Scenarios

When the user rotates the screen, or puts the device in a car dock, or changes the language of the device, your process is not terminated. Your foreground activity will be re-created by default — as will your widgets and fragments — but the process sticks around.

However, there are plenty of cases when your process will be terminated once you move into the background. That might be done automatically by Android or manually by the user.

Depending on *how* your process is terminated, there may be ways that the user can return to your app and expect that they will return to it just how they left it. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and Android terminates your process to free up memory for other apps. Sometime after that, the user brings up the recent-tasks list and taps on your app in that list. From the *user's* perspective, they should be returning to your app in the same state that they left it when they pressed HOME. However, if your process was terminated, by default you lost all that state.

Some of the techniques for dealing with a configuration change — those involving the “saved instance state Bundle” — will *also* help you handle the recent-tasks-list scenario. Other of the techniques — such as retaining a fragment — only help with handling configuration changes and will do nothing for you in terms of the recent-tasks-list scenario. The general rule of thumb, therefore, is to use the Bundle where you can, and use other techniques (e.g., retained fragments) where the Bundle is inappropriate or inadequate. We will see those techniques in the next section.

However, bear in mind that all of this state is designed for transient data, data that the user will not mind if they never see again. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and due to the user having busily used their device, you “*fall off*” the recent-tasks list, as that list will not extend indefinitely. In this case, if the user starts up your app again (e.g., via the home screen launcher icon), you will *not* get any state information back for use. Data that the user filled into the old app instance, where that data *must be remembered* and reused in any future run of your app, will need to be persisted yourself, in a database or other type of file.

With all of that in mind, let's examine our options for dealing with the transient state, with an emphasis on configuration changes.

Your Options for Configuration Changes

As noted, a configuration change is fairly invasive on your activity, replacing it outright with all new content (albeit with perhaps some information from the old activity's widgets carried forward into the new activity's widgets).

Hence, you have several possible approaches for handling configuration changes in any given activity.

Do Nothing

The easiest thing to do, of course, is to do nothing at all. If all your state is bound up in stuff Android handles automatically, you do not need to do anything more than the defaults.

For example, the ViewPager/Fragments demo from [the preceding chapter](#) works correctly “out of the box”. All of our “state” is tied up in EditText widgets, which Android handles automatically. So, we can type in stuff in a bunch of those widgets, rotate the screen (e.g., via <Ctrl>-<F11> in the emulator on a Windows or Linux PC), and our entered text is retained.

Alas, there are plenty of cases where the built-in behavior is either incomplete or simply incorrect, and we will need to do more work to make sure that our configuration changes are handled properly.

Retain Your Fragments

One approach for handling these sorts of configuration changes is to have Android retain a dynamic fragment.

Here, “retain” means that Android will keep the same fragment instance across the configuration change, detaching it from the original hosting activity and attaching it to a new hosting activity. Since it is the same fragment instance, anything contained inside that instance is itself retained and, therefore, is not lost when the activity is destroyed and recreated.

To see this in action, take a look at the [ConfigChange/Fragments](#) sample project.

The business logic for this demo (and for all the other demos in this chapter) is that we want to allow the user to pick a contact out of the roster of contacts found on their device or emulator. We will do that by having the user press a “Pick” button, at which time we will display an activity that will let the user pick the contact and return the result to us. Then, we will enable a “View” button, and let the user view the details of the selected contact. The key is that our selected contact needs to be retained across configuration changes — otherwise, the user will rotate the screen, and the activity will appear to forget about the chosen contact.

The activity itself just loads the dynamic fragment, following the recipe seen previously in this book:

```
package com.commonware.android.rotation.frag;

import android.app.Activity;
import android.os.Bundle;

public class RotationFragmentDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new RotationFragment()).commit();
        }
    }
}
```

The reason for checking for the fragment's existence should now be clearer. Since Android will automatically recreate (or retain) our fragments across configuration changes, we do not want to create a *second* copy of the same fragment when we already have an existing copy.

The fragment is going to use an `R.layout.main` layout resource, with two implementations. One, in `res/layout-land/`, will be used in landscape:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/pick"
        android:enabled="true"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/view"
        android:enabled="false"
    />
</LinearLayout>
```

The portrait edition, in `res/layout/`, is identical save for the orientation of the `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/pick"
        android:enabled="true"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/view"
        android:enabled="false"
    />
</LinearLayout>
```

Here is the complete implementation of `RotationFragment`:

```
package com.commonware.android.rotation.frag;

import android.app.Activity;
import android.app.Fragment;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.provider.ContactsContract;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RotationFragment extends Fragment implements
    View.OnClickListener {
    static final int PICK_REQUEST=1337;
    Uri contact=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        setRetainInstance(true);

        View result=inflater.inflate(R.layout.main, parent, false);

        result.findViewById(R.id.pick).setOnClickListener(this);
    }
}
```

```
View v=result.findViewById(R.id.view);

v.setOnClickListener(this);
v.setEnabled(contact != null);

return(result);
}

@Override
public void onActivityResult(int requestCode, int resultCode,
                             Intent data) {
    if (requestCode == PICK_REQUEST) {
        if (resultCode == Activity.RESULT_OK) {
            contact=data.getData();
            getView().findViewById(R.id.view).setEnabled(true);
        }
    }
}

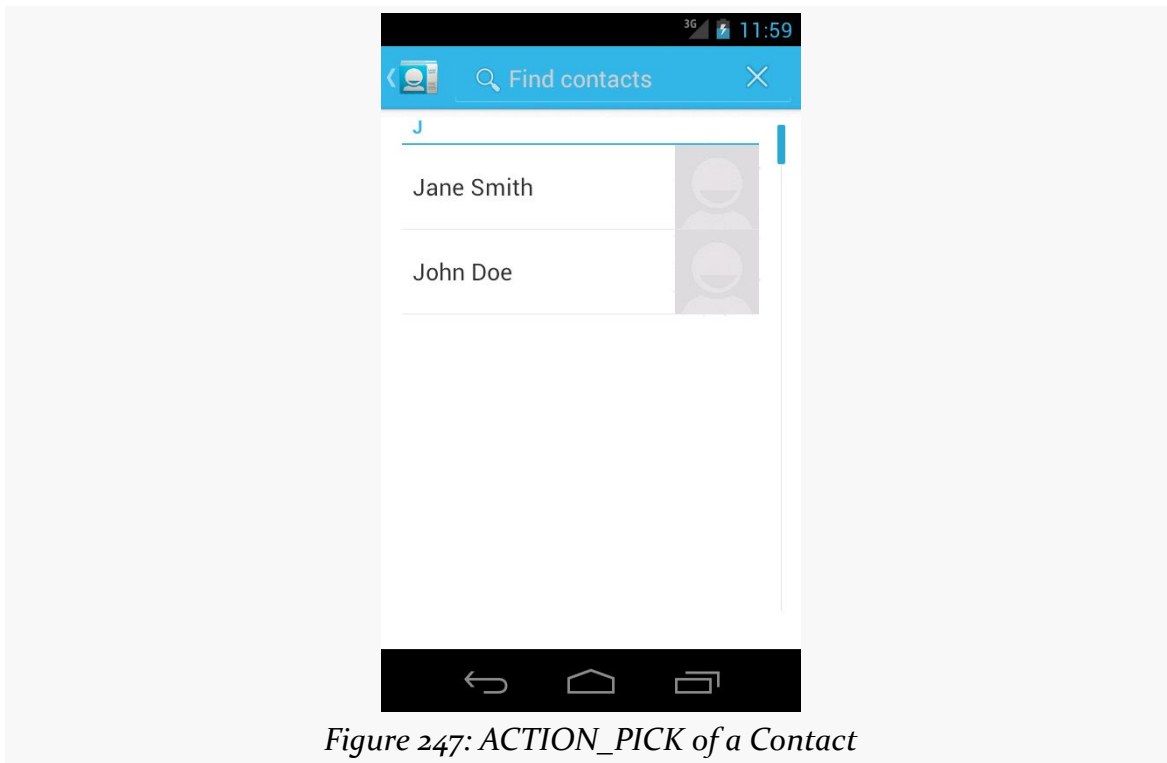

@Override
public void onClick(View v) {
    if (v.getId() == R.id.pick) {
        pickContact(v);
    }
    else {
        viewContact(v);
    }
}

public void pickContact(View v) {
    Intent i=
        new Intent(Intent.ACTION_PICK,
                   ContactsContract.Contacts.CONTENT_URI);

    startActivityResult(i, PICK_REQUEST);
}

public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
}
```

In `onCreateView()`, we hook up the “Pick” button to a `pickContact()` method. There, we call `startActivityResult()` with an `ACTION_PICK` Intent, indicating that we want to pick something from the `ContactsContract.Contacts.CONTENT_URI` collection of contacts. We will discuss `ContactsContract` in greater detail later in this book. For the moment, take it on faith that Android has such an `ACTION_PICK` activity, one that will display to the user the list of available contacts:

If the user picks a contact, control returns to our activity, with a call to `onActivityResult()`. `onActivityResult()` is passed:

- the unique ID we supplied to `startActivityForResult()`, to help identify this result from any others we might be receiving
- `RESULT_OK` if the user did pick a contact, or `RESULT_CANCELED` if the user abandoned the pick activity
- an `Intent` containing the result from the pick activity, which, in this case, will contain a `Uri` representing the selected contact, retrieved via `getData()`

We store that `Uri` in a data member, plus we enable the “View” button, which, when clicked, will bring up an `ACTION_VIEW` activity on the selected contact via its `Uri`:

Figure 248: ACTION_VIEW of a Contact

Up in `onCreateView()`, we called `setRetainInstance(true)`. This tells Android to keep this fragment instance across configuration changes. Hence, we can pick a contact in portrait mode, then rotate the screen (e.g., `<Ctrl>-<F11>` in the emulator on Windows or Linux), and view the contact in landscape mode. Even though the activity and the buttons were replaced as a result of the rotation, the fragment was not, and the fragment held onto the `Uri` of the selected contact.

Note that `setRetainInstance()` only works with dynamic fragments, not static fragments. Static fragments are always recreated when the activity is itself destroyed and recreated.

The benefit of this technique, over others, is that you can retain any sort of data you want: any data type, any size, etc. However, this approach does not save state that will be given back to you after your process had been terminated, such as when the user goes back to your app via the recent-tasks list.

Model Fragment

A variation on this theme is the “model fragment”. While fragments normally are focused on supplying portions of the UI to a user, that is not really a requirement. A

model fragment is one that simply uses `setRetainInstance(true)` to ensure that it sticks around as configurations change. This fragment then holds onto any model data that its host activity needs, so as that activity gets destroyed and recreated, the model data sticks around in the model fragment.

This is particularly useful for data that might not otherwise have a fragment home. For example, imagine an activity whose UI consists entirely of a `ViewPager`, (like the tutorial app). Even though that `ViewPager` might hold fragments, there will be many pages in most pagers. It may be simpler to add a separate, UI-less model fragment and have it hold the activity's data model for the `ViewPager`. This allows the activity to still be destroyed and recreated, and even allows the `ViewPager` to be destroyed and recreated, while still retaining the already-loaded data.

Google recommends using a model fragment instead of using `setRetainInstance(true)` with a regular fragment. The less the retained fragment holds, the less likely it is that you will hold something that you should not be holding, such as a string that needs to be reloaded from a string resource due to a possible locale change. That being said, if you are careful and make sure that all your data members are accounted for properly, using `setRetainInstance(true)` from any fragment can be made safe.

Add to the Bundle

If you want state to be maintained not only for configuration changes, but also for process terminations, you will want to use `onSaveInstanceState()` and `onRestoreInstanceState()`.

You can override `onSaveInstanceState()` in your activity. It is passed a `Bundle`, into which you can store data that should be maintained across the configuration change. The catch is that while `Bundle` looks a bit like it is a `HashMap`, it actually cannot hold arbitrary data types, which limits the sort of information you can retain via `onSaveInstanceState()`. `onSaveInstanceState()` is called around the time of `onPause()` and `onStop()`.

The widget state maintained automatically by Android is via the built-in implementation of `onSaveInstanceState()`. If you override it yourself, typically you will want to chain to the superclass to get this inherited behavior, in addition to putting things into the `Bundle` yourself.

That `Bundle` is passed back to you in two places:

- onCreate()
- onRestoreInstanceState()

Since onCreate() is called in many cases other than due to a configuration change, frequently the passed-in Bundle is null. onRestoreInstanceState(), on the other hand, is only called when there is a Bundle to be used.

To see how this works, take a look at the [ConfigChange/Bundle](#) sample project.

Here, RotationBundleDemo is an activity with all the same core business logic as was in our fragment in the preceding demo. Since the activity will be destroyed and recreated on a configuration change, we override onSaveInstanceState() and onRestoreInstanceState() to retain our contact, if one was selected prior to the configuration change:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    if (contact != null) {
        outState.putParcelable("contact", contact);
    }
}

@Override
protected void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    contact=state.getParcelable("contact");
    viewButton.setEnabled(contact != null);
}
```

Here, we use putParcelable() to put the Uri into the Bundle. Parcelable is an interface that you can implement on a Java class to allow instance of it to be put into a Bundle. Uri happens to implement Parcelable.

The downside of this approach is that not everything can go into a Bundle. A Bundle cannot hold arbitrary data types, so you cannot put a Socket into a Bundle, for example. Also, this Bundle needs to be fairly small, as it is passed across process boundaries, so you cannot put large objects (e.g., bitmaps) into the Bundle. For those cases, you will have to settle for the retained-fragment approach.

Fragments *and* a Bundle

Fragments also have an `onSaveInstanceState()` method that they can override. It works just like the Activity equivalent — you can store data in the supplied Bundle that will be supplied back to you later on. The biggest difference is that there is no `onRestoreInstanceState()` method — instead, you are handed the Bundle in other lifecycle methods:

- `onCreate()`
- `onCreateView()`
- `onViewCreated()`
- `onActivityCreated()`

We can see this in the [ConfigChange/FragmentBundle](#) sample project. This is effectively a mashup of the previous two samples: fragments, but using `onSaveInstanceState()` instead of `setRetainInstance(true)`.

Our `RotationFragment` now has an `onSaveInstanceState()` method that looks a lot like the one from the `ConfigChange/Bundle` sample's activity:

```
@Override
public void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    if (contact != null) {
        outState.putParcelable("contact", contact);
    }
}
```

Our `onCreateView()` method examines the passed-in Bundle, and if it is not null tries to obtain our contact from it:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                        Bundle state) {
    View result=inflater.inflate(R.layout.main, parent, false);

    result.findViewById(R.id.pick).setOnClickListener(this);

    View v=result.findViewById(R.id.view);

    v.setOnClickListener(this);

    if (state != null) {
        contact=(Uri)state.getParcelable("contact");
    }
}
```

```
v.setEnabled(contact != null);  
  
return(result);  
}
```

This does not allow our fragment to hold onto arbitrary data, the way `setRetainInstance(true)` does. However, as with `onSaveInstanceState()` at the activity level, there are scenarios that `onSaveInstanceState()` handles that retained fragments will not, such as terminating your process due to low memory, yet the user later uses BACK to return to what should have been your activity (and its fragments).

DIY

In a few cases, even a retained fragment is insufficient, because transferring and re-applying the state would be too complex or too slow. Or, in some cases, the hardware will get in the way, such as when trying to use the Camera for taking pictures — a concept we will cover later in this book.

If you are completely desperate, you can tell Android to *not* destroy and recreate the activity on a configuration change... though this has its own set of consequences. To do this:

- Put an `android:configChanges` entry in your `AndroidManifest.xml` file, listing the configuration changes you want to handle yourself versus allowing Android to handle for you
- Implement `onConfigurationChanged()` in your Activity, which will be called when one of the configuration changes you listed in `android:configChanges` occurs

Now, for any configuration change you want, you can bypass the whole activity-destruction process and simply get a callback letting you know of the change.

For example, take a look at the [ConfigChange/DIY](#) sample project.

In `AndroidManifest.xml`, we add the `android:configChanges` attribute to the `<activity>` element, indicating that we want to handle several configuration changes ourselves:

```
<activity  
    android:name="RotationDIYDemo"  
    android:configChanges="keyboardHidden|orientation|screenSize"  
    android:label="@string/app_name">
```

```
<intent-filter>
  <action android:name="android.intent.action.MAIN"/>

  <category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
</activity>
```

Many recipes for this will have you handle orientation and keyboardHidden. However, nowadays, you need to also handle screenSize (and, in theory, smallestScreenSize), if you have your android:targetSdkVersion set to 13 or higher. Note that this will require your build target (e.g., compileSdkVersion in Android Studio) to be set to 13 or higher.

Hence, for those particular configuration changes, Android will not destroy and recreate the activity, but instead will call onConfigurationChanged(). In the RotationDIYDemo implementation, this simply toggles the orientation of the LinearLayout to match the orientation of the device:

```
@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    LinearLayout container=(LinearLayout)findViewById(R.id.container);

    if (newConfig.orientation == Configuration.ORIENTATION_LANDSCAPE) {
        container.setOrientation(LinearLayout.HORIZONTAL);
    }
    else {
        container.setOrientation(LinearLayout.VERTICAL);
    }
}
```

Since the activity is not destroyed during a configuration change, we do not need to worry at all about the Uri of the selected contact — it is not going anywhere.

The problem with this implementation is twofold:

1. We are not handling all possible configuration changes. If the user, say, puts the device into a car dock, Android will destroy and recreate our activity, and we will lose our selected contact.
2. We might forget some resource that needs to be changed due to a configuration change. For example, if we start translating the strings used by the layouts, and we include locale in android:configChanges, we not only need to update the LinearLayout but also the captions of the Button widgets, since Android will not do that for us automatically.

It is these two problems that are why Google does not recommend the use of this technique unless absolutely necessary.

Also, bear in mind that this approach does not help at all for retaining state when your process is terminated and the user returns to your app via the recent-tasks list.

Blocking Rotations

No doubt that you have seen some Android applications that simply ignore any attempt to rotate the screen. Many games work this way, operating purely in landscape mode, regardless of how the device is positioned.

To do this, add `android:screenOrientation="sensorLandscape"`, or possibly `android:screenOrientation="sensorPortrait"`, to your manifest. The “sensor” portions of those names indicate that your app can work in regular or “reverse” versions of the orientation (e.g., “regular” landscape is the device rotated 90 degrees counter-clockwise from portrait, while “reverse” landscape is the device rotated 90 degrees clockwise from portrait). On API Level 18+, you could use `userLandscape` or `userPortrait` instead, as those will honor the user’s system-level choice of whether to lock screen rotation or not, defaulting to the behavior of `sensorLandscape` or `sensorPortrait` if the user has not locked screen rotation.

Ideally, you choose landscape, as some devices (e.g., Android TV) can only *be* landscape.

Also note that Android *still* treats this as a configuration change, despite the fact that there is no visible change to the user. Hence, you still need to use one of the aforementioned techniques to handle this configuration change, along with any others (e.g., dock events, locale changes).

And Now, a Word From the Android Project View

Earlier in the book, when introducing Android Studio, we saw [the Android project view](#).

One of the reasons why the Android project view was created was to help you manage resources, particularly across various resource sets.

For example, here is a screenshot of the same Android project, but this time with the values resources expanded in the tree:

RESOURCE SETS AND CONFIGURATIONS

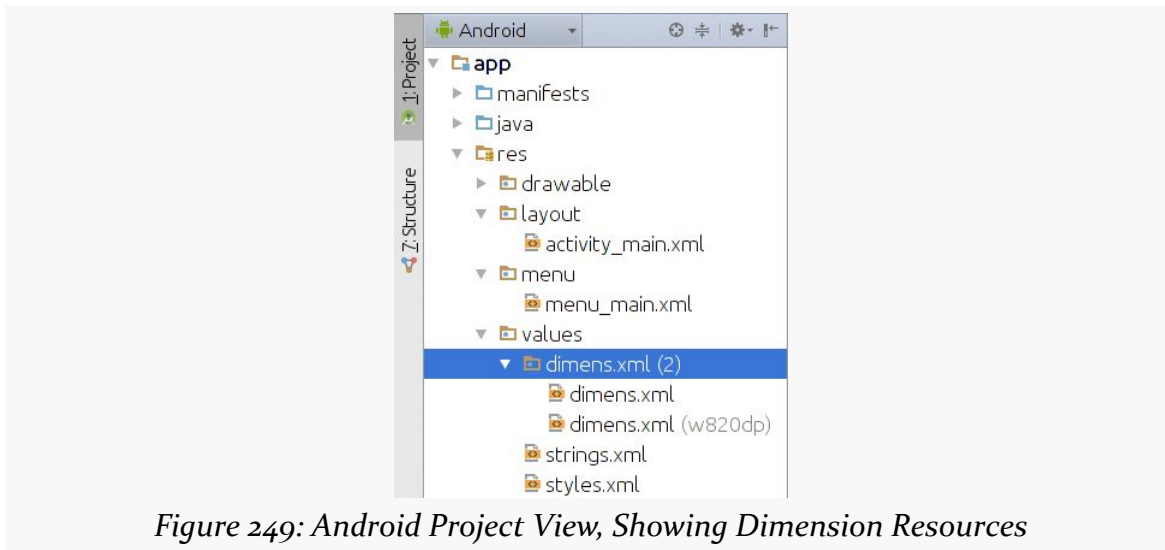

Figure 249: Android Project View, Showing Dimension Resources

What, from a tree standpoint, looks like `res/values/dimens.xml` in turn has two “children”, one with just the bare `dimens.xml` filename and one with a “(w820dp)” appended.

This reflects the fact that there are two versions of `dimens.xml`: one in `res/values/` and one in `res/values-w820dp/`:

RESOURCE SETS AND CONFIGURATIONS

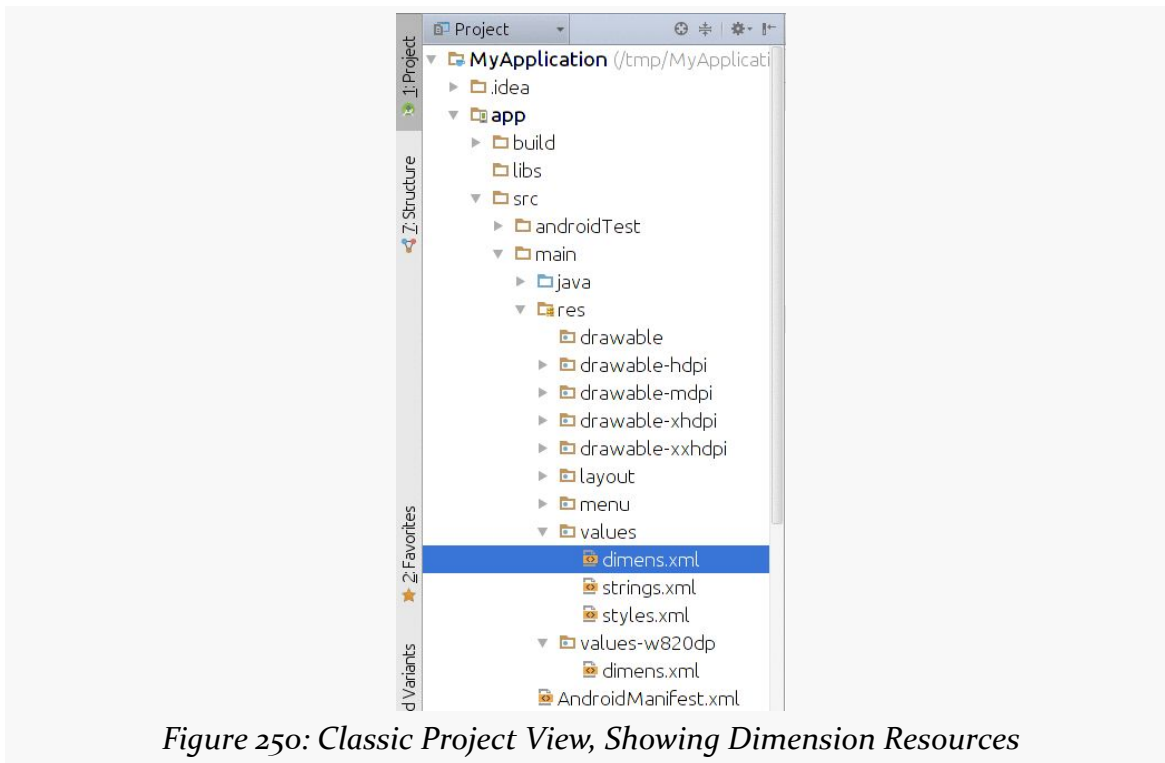

Figure 250: Classic Project View, Showing Dimension Resources

In the Android project view, resources are organized by resource, not by resource set. This can be useful for finding all files that need to be adjusted when you go to adjust one version of the resource, for example.

Material Design Basics

We have already been exposed to `Theme.Material` as part of this book, such as with the action bar.

Android 5.0+, combined with `Theme.Material`, give you a lot of capabilities tied to Google's Material Design aesthetic. In this chapter, we will cover some basic Material Design capabilities that will affect your `Theme.Material` app on Android 5.0+, starting with color.

Your App, in Technicolor!

Some developers want to change the colors used by their app to match some specific color or color palette. In some cases, the colors in question are tied to the app's branding. In other cases, the developer simply wants something different than the stock colors you get from something like `Theme.Holo` or `Theme.Holo.Light`.

Creating custom themes to apply colors to `Theme.Holo` and kin was enough of a pain that a [separate theme generator](#) was created for it, independent of the generator for custom action bar colors.

Affecting color changes in your `Theme.Material`-based Android app is vastly simplified — both for the action bar and the widgets — courtesy of `Theme.Material`'s tinting options.

Basic Tinting Options

In the chapter on the action bar, we saw how to set up [a custom theme](#) based on `Theme.Material` that had custom color tinting rules that affected the action bar:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

At that time, we focused on the effects that these tints had on the action bar itself. However, with `Theme.Material`, not only do the tints affect the action bar, but they affect the widgets themselves.

The [BasicMaterial](#) directory contains clones of some of the [basic widget samples](#) outlined earlier in this book, where each includes the custom theme demonstrated for the action bar.

In some cases, the custom tints are not normally visible, such as with a button:

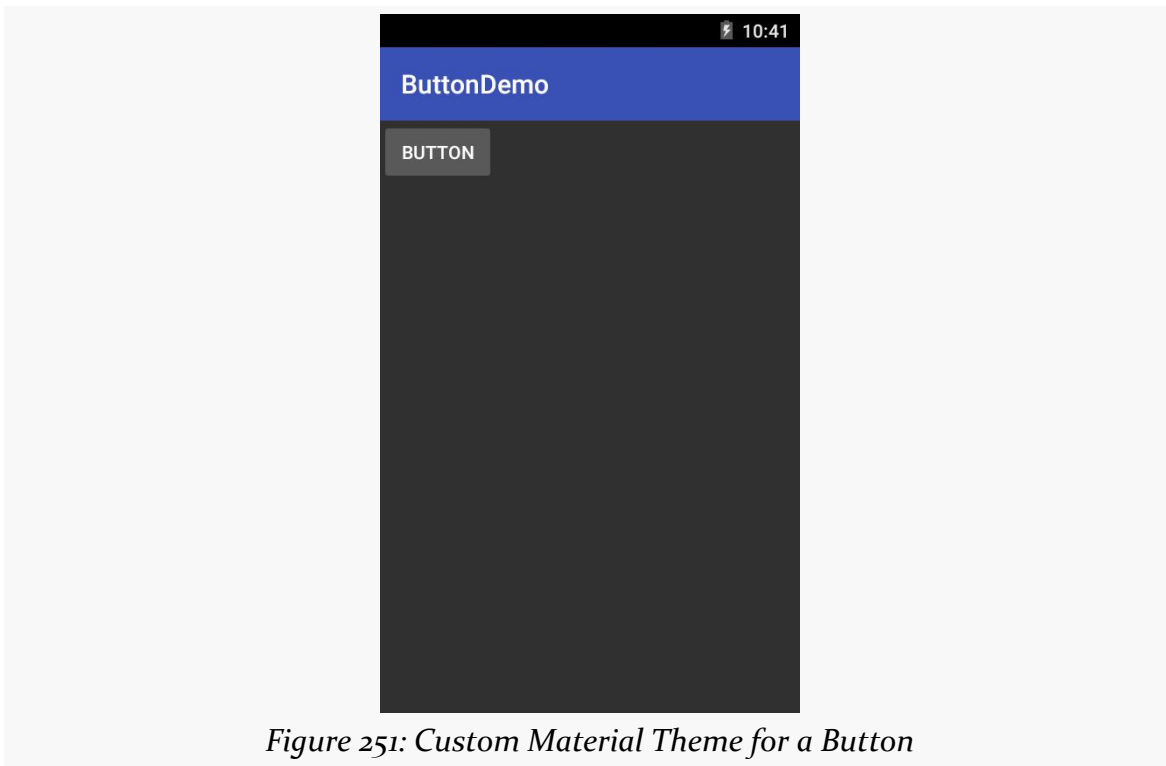

Figure 251: Custom Material Theme for a Button

However, when you tap the button, the animated “ripple” effect shown on the button will use your accent color.

In other cases, the accent color will show up in a more “steady state”, such as in a checked `CheckBox`:

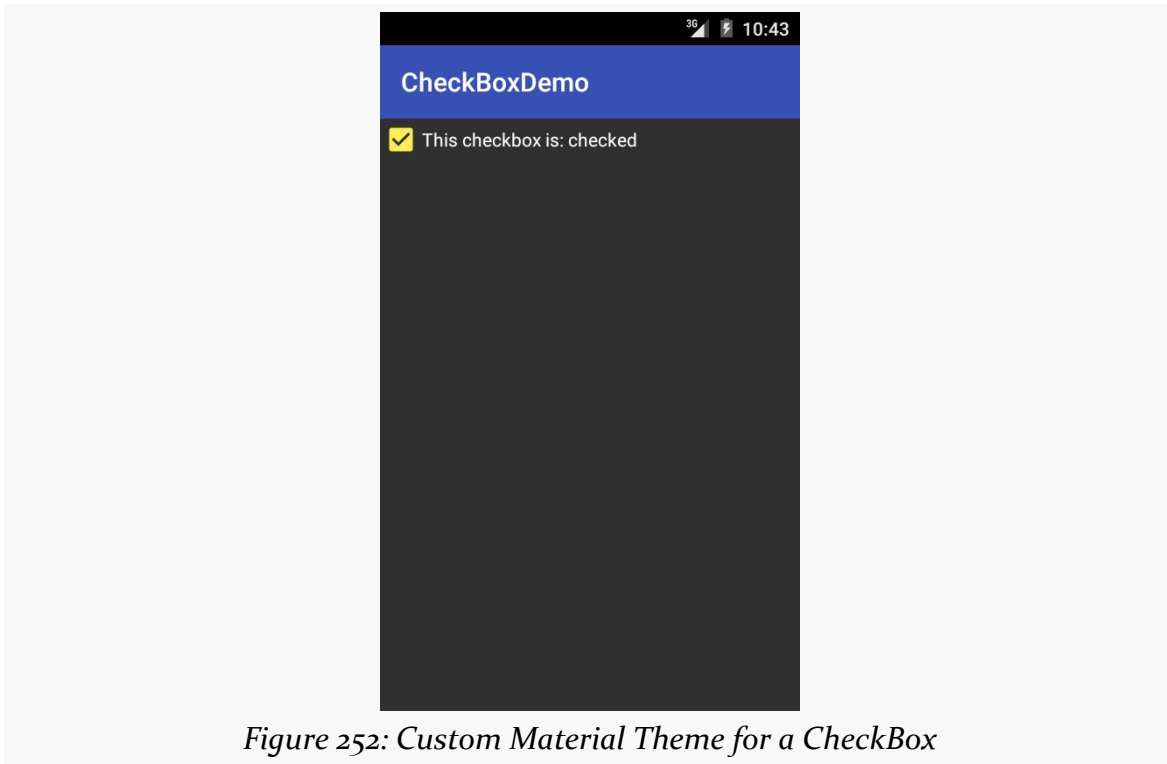

Figure 252: Custom Material Theme for a CheckBox

Similarly, your accent color shows up in things like:

- the “underbar” and drag-cursor in an `EditText`:

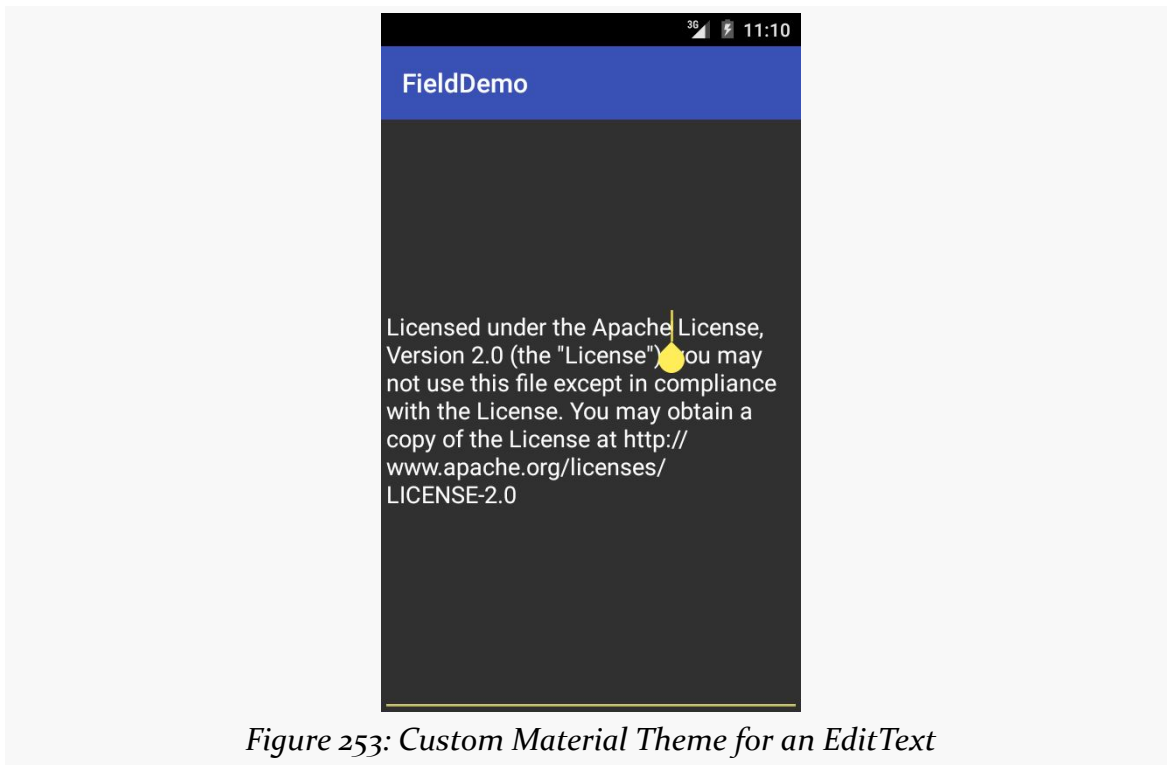

Figure 253: Custom Material Theme for an EditText

- the checked state (and ripple effect when toggling the state) of a `RadioButton`:

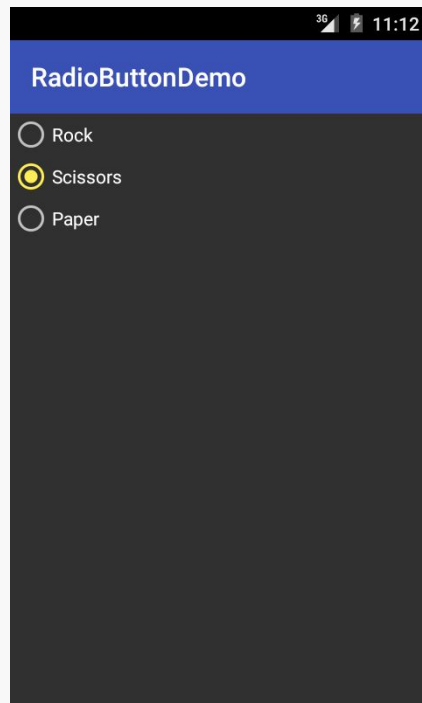

Figure 254: Custom Material Theme for a RadioButton

- the “checked” state of a Switch:

Figure 255: Custom Material Theme for a Switch

Similar effects can be seen in other widgets as well. Hence, your choice of tint values in your custom theme will affect the look of the widgets as well as of the action bar.

Official Google-Approved Colors

Of course, you are welcome to pick whatever colors you like for your theme.

Google has its opinion of what it thinks are good ideas.

As part of [the Material Design documentation](#), you will find [a “Color palette” page](#) that outlines possible colors to use.

[A Redditor](#) has also published [an Android color resource file](#) that contains all of the colors outlined in the Material Design guide.

There is also the [material palette site](#), which generates an color resource file based upon colors that you select from a large grid of color swatches.

Tinting the Status Bar

However, when our action bar is a color other than black, white, or shades in between, there can be a color clash with the black background of the status bar. To combat this, Android 5.0 allows you tint the status bar from your Java code. The general guidance is that if your action bar is using your primary color, the status bar should be tinted to the dark primary color.

To do this, as the first thing in your activity's `onCreate()` after chaining to `super.onCreate()` and before setting your content view, you will need to add a bit of code:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        Window window = getWindow();

        window.addFlags(WindowManager.LayoutParams.FLAG_DRAWS_SYSTEM_BAR_BACKGROUNDS);
        window.clearFlags(WindowManager.LayoutParams.FLAG_TRANSLUCENT_STATUS);
        window.setStatusBarColor(getResources().getColor(R.color.primary_dark));
    }

    initAdapter();
}
```

This code snippet assumes that your desired color is found in a color resource named `R.color.primary_dark`, which may need to be changed if you have the resource named differently. Or, if you really want to hard-code a hex color value here (e.g., `0x1a237e`), you can do that instead of looking up the color via a resource.

When run on hardware, you will see the tinted status bar:

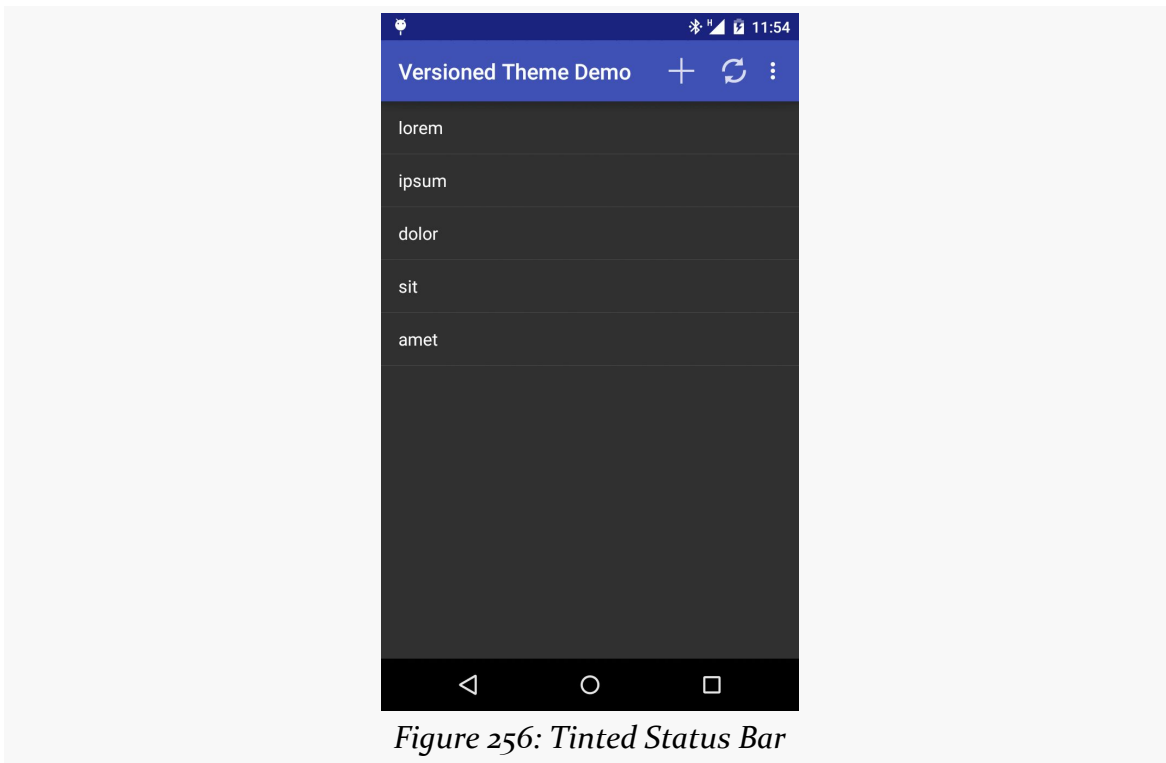

Figure 256: Tinted Status Bar

The Android SDK emulators do not exhibit this behavior at the present time.

Dealing with Threads

Users like snappy applications. Users do not like applications that feel sluggish.

The way to help your application feel snappy is to use the standard threading capabilities built into Android. This chapter will go through the issues involved with thread management in Android and will walk you through some of the options for keeping the user interface crisp and responsive.

The Main Application Thread

When you call `setText()` on a `TextView`, you probably think that the screen is updated with the text you supply, right then and there.

You would be mistaken.

Rather, everything that modifies the widget-based UI goes through a message queue. Calls to `setText()` do not update the screen — they just place a message on a queue telling the operating system to update the screen. The operating system pops these messages off of this queue and does what the messages require.

The queue is processed by one thread, variously called the “main application thread” and the “UI thread”. So long as that thread can keep processing messages, the screen will update, user input will be handled, and so on.

However, the main application thread is also used for nearly all callbacks into your activity. Your `onCreate()`, `onClick()`, `onListItemClick()`, and similar methods are all called on the main application thread. While your code is executing in these methods, Android is not processing messages on the queue, and so the screen does not update, user input is not handled, and so on.

This, of course, is bad. So bad, that if you take more than a few seconds to do work on the main application thread, Android may display the dreaded “Application Not Responding” dialog (ANR for short), and your activity may be killed off.

Nowadays, though, the bigger concern is jank.

“Jank”, as used in Android, refers to sluggish UI updates, particularly when something is animating. For example, you may have encountered some apps that when you scroll a `ListView` in the app, the `ListView` does not scroll smoothly. Rather, it scrolls jerkily, interleaving periods of rapid movement with periods where the animation is frozen. Most of the time, this is caused by the app’s author doing too much work on the main application thread.

Android 4.1 introduced “Project Butter”, which, among other things, established a baseline for “doing too much work on the main application thread”. We will “drop frames” if we take more than ~16ms per frame (60 frames per second), and dropped frames are the source of jank. Since we may be called many times during a frame, each of our callbacks needs to be very cheap, ideally below 1ms. We will get much more into the issue of jank [later in the book](#), but it is important to understand now that any significant delay in the execution of our code on the main application thread can have visible effects to the user.

Hence, you want to make sure that all of your work on the main application thread happens quickly. This means that anything slow should be done in a background thread, so as not to tie up the main application thread. This includes things like:

1. Internet access, such as sending data to a Web service or downloading an image
2. Significant file operations, since flash storage can be remarkably slow at times
3. Any sort of complex calculations

Fortunately, Android supports threads using the standard `Thread` class from Java, plus all of the wrappers and control structures you would expect, such as the `java.util.concurrent` class package.

However, there is one big limitation: you cannot modify the UI from a background thread. You can only modify the UI from the main application thread. If you call `setText()` on a `TextView` from a background thread, your application will crash, with an exception indicating that you are trying to modify the UI from a “non-UI thread” (i.e., a thread other than the main application thread).

This is a pain.

Getting to the Background

Hence, you need to get long-running work moved into background threads, but those threads need to do something to arrange to update the UI using the main application thread.

There are various facilities in Android for helping with this.

Some are high-level frameworks for addressing this issue for major functional areas. One example of this is the Loader framework for retrieving information from databases, and we will examine this [in a later chapter](#).

Sometimes, there are asynchronous options built into other Android operations. For example, when we discuss SharedPreferences [in a later chapter](#), we will see that we can persist changes to those preferences synchronously or asynchronously.

And, there are a handful of low-level solutions for solving this problem, ones that you can apply for your own custom business logic.

Asynching Feeling

One popular approach for handling this threading problem is to use AsyncTask. With AsyncTask, Android will handle all of the chores of coordinating separate work done on a background thread versus on the UI thread. Moreover, Android itself allocates and removes that background thread. And, it maintains a small work queue, further accentuating the “fire and forget” feel to AsyncTask.

The Theory

Theodore Levitt is quoted as saying, with respect to marketing: “People don’t want to buy a quarter-inch drill, they want a quarter-inch hole”. Hardware stores cannot sell holes, so they sell the next-best thing: devices (drills and drill bits) that make creating holes easy.

Similarly, many Android developers who have struggled with background thread management do not want background threads — they want work to be done off the UI thread, to avoid jank. And while Android cannot magically cause work to not

consume UI thread time, Android can offer things that make such background operations easier and more transparent. AsyncTask is one such example.

To use AsyncTask, you must:

1. Create a subclass of AsyncTask
2. Override one or more AsyncTask methods to accomplish the background work, plus whatever work associated with the task that needs to be done on the UI thread (e.g., update progress)
3. When needed, create an instance of the AsyncTask subclass and call `execute()` to have it begin doing its work

What you do *not* have to do is:

1. Create your own background thread
2. Terminate that background thread at an appropriate time
3. Call all sorts of methods to arrange for bits of processing to be done on the UI thread

AsyncTask, Generics, and Varargs

Creating a subclass of AsyncTask is not quite as easy as, say, implementing the Runnable interface. AsyncTask uses generics, and so you need to specify three data types:

1. The type of information that is needed to process the task (e.g., URLs to download)
2. The type of information that is passed within the task to indicate progress
3. The type of information that is passed when the task is completed to the post-task code

What makes this all the more confusing is that the first two data types are actually used as varargs, meaning that an array of these types is used within your AsyncTask subclass.

This should become clearer as we work our way towards an example.

The Stages of AsyncTask

There are four methods you can override in AsyncTask to accomplish your ends.

The one you must override, for the task class to be useful, is `doInBackground()`. This will be called by `AsyncTask` on a background thread. It can run as long as it needs to in order to accomplish whatever work needs to be done for this specific task. Note, though, that tasks are meant to be finite – using `AsyncTask` for an infinite loop is not recommended.

The `doInBackground()` method will receive, as parameters, a varargs array of the first of the three data types listed above — the data needed to process the task. So, if your task's mission is to download a collection of URLs, `doInBackground()` will receive those URLs to process.

The `doInBackground()` method must return a value of the third data type listed above — the result of the background work.

You may wish to override `onPreExecute()`. This method is called, from the UI thread, before the background thread executes `doInBackground()`. Here, you might initialize a `ProgressBar` or otherwise indicate that background work is commencing.

Also, you may wish to override `onPostExecute()`. This method is called, from the UI thread, after `doInBackground()` completes. It receives, as a parameter, the value returned by `doInBackground()` (e.g., success or failure flag). Here, you might dismiss the `ProgressBar` and make use of the work done in the background, such as updating the contents of a list.

In addition, you may wish to override `onProgressUpdate()`. If `doInBackground()` calls the task's `publishProgress()` method, the object(s) passed to that method are provided to `onProgressUpdate()`, but in the UI thread. That way, `onProgressUpdate()` can alert the user as to the progress that has been made on the background work. The `onProgressUpdate()` method will receive a varargs of the second data type from the above list — the data published by `doInBackground()` via `publishProgress()`.

A Quick Note About Toasts

In the sample app that follows, we use a `Toast` to let the user know some work has been completed.

A `Toast` is a transient message, meaning that it displays and disappears on its own without user interaction. Moreover, it does not take focus away from the currently-active `Activity`, so if the user is busy writing the next *Great Programming Guide*, they will not have keystrokes be “eaten” by the message.

Since a Toast is transient, you have no way of knowing if the user even notices it. You get no acknowledgment from them, nor does the message stick around for a long time to pester the user. Hence, the Toast is mostly for advisory messages, such as indicating a long-running background task is completed, the battery has dropped to a low-but-not-too-low level, etc.

Making a Toast is fairly easy. The Toast class offers a static `makeText()` method that accepts a String (or string resource ID) and returns a Toast instance. The `makeText()` method also needs the Activity (or other Context) plus a duration. The duration is expressed in the form of the `LENGTH_SHORT` or `LENGTH_LONG` constants to indicate, on a relative basis, how long the message should remain visible. Once your Toast is configured, call its `show()` method, and the message will be displayed.

A Sample Task

As mentioned earlier, implementing an AsyncTask is not quite as easy as implementing a Runnable. However, once you get past the generics and varargs, it is not too bad.

To see an AsyncTask in action, this section will examine the [Threads/AsyncTask](#) sample project.

The Fragment and its AsyncTask

We have a ListFragment, named AsyncDemoFragment:

```
package com.commonware.android.async;

import android.app.ListFragment;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.Toast;
import java.util.ArrayList;

public class AsyncDemoFragment extends ListFragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> model=null;
    private ArrayAdapter<String> adapter=null;
```

```
private AddStringTask task=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    if (model == null) {
        model=new ArrayList<String>();
        task=new AddStringTask();
        task.execute();
    }

    adapter=
        new ArrayAdapter<String>(getActivity(),
                                android.R.layout.simple_list_item_1,
                                model);
}

@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);
}

@Override
synchronized public void onDestroy() {
    if (task != null) {
        task.cancel(false);
    }

    super.onDestroy();
}

synchronized private void clearTask() {
    task=null;
}

class AddStringTask extends AsyncTask<Void, String, Void> {
    @Override
    protected Void doInBackground(Void... unused) {
        for (String item : items) {
            if (isCancelled())
                break;

            publishProgress(item);
            SystemClock.sleep(400);
        }

        return(null);
    }
}
```

```
@Override
protected void onProgressUpdate(String... item) {
    if (!isCancelled()) {
        adapter.add(item[0]);
    }
}

@Override
protected void onPostExecute(Void unused) {
    if (!isCancelled()) {
        Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
            .show();
    }

    clearTask();
}
}
```

This is another variation on the *lorem ipsum* list of words, used frequently throughout this book. This time, rather than simply hand the list of words to an `ArrayAdapter`, we simulate having to work to create these words in the background using `AddStringTask`, our `AsyncTask` implementation.

In `onCreate()`, we call `setRetainInstance(true)`, so Android will retain this fragment across configuration changes, such as a screen rotation. We then examine a model data member. If it is null, we know that this is the first time our fragment has been used, so we initialize it to be an `ArrayList` of `String` values, plus kick off our `AsyncTask` (the `AddStringTask` inner class, described below), saving the `AddStringTask` in a task data member. Then, in `onViewCreated()`, we set up the adapter and attach it to the `ListView`, also preventing the `ListView` scrollbars from fading away as is their norm.

In the declaration of `AddStringTask`, we use the generics to set up the specific types of data we are going to leverage. Specifically:

1. We do not need any configuration information in this case, so our first type is `Void`
2. We want to pass each string “generated” by our background task to `onProgressUpdate()`, so we can add it to our list, so our second type is `String`
3. We do not have any results, strictly speaking (beyond the updates), so our third type is `Void`

The `doInBackground()` method is invoked in a background thread. Hence, we can take as long as we like. In a production application, we would be, perhaps, iterating over a list of URLs and downloading each. Here, we iterate over our static list of *lorem ipsum* words, call `publishProgress()` for each, and then sleep 400 milliseconds to simulate real work being done. We also call `isCancelled()` on each pass, to see if our task has been cancelled, skipping the work if it has so we can clean up this background thread.

Since we elected to have no configuration information, we should not need parameters to `doInBackground()`. However, the contract with `AsyncTask` says we need to accept a varargs of the first data type, which is why our method parameter is `Void...`

Since we elected to have no results, we should not need to return anything. Again, though, the contract with `AsyncTask` says we have to return an object of the third data type. Since that data type is `Void`, our returned object is `null`.

The `onProgressUpdate()` method is called on the UI thread, and we want to do something to let the user know we are progressing on loading up these strings. In this case, we simply add the string to the `ArrayAdapter`, so it gets appended to the end of the list. However, we only do this if we have not already been canceled.

The `onProgressUpdate()` method receives a `String... varargs` because that is the second data type in our class declaration. Since we are only passing one string per call to `publishProgress()`, we only need to examine the first entry in the varargs array.

The `onPostExecute()` method is called on the UI thread, and we want to do something to indicate that the background work is complete. In a real system, there may be some `ProgressBar` to dismiss or some animation to stop. Here, we simply raise a `Toast` and set task to `null` (via a `clearTask()` method on the fragment), if our task has not been canceled (checked via another call to `isCancelled()`).

Since we elected to have no results, we should not need any parameters. The contract with `AsyncTask` says we have to accept a single value of the third data type. Since that data type is `Void`, our method parameter is `Void` unused.

To use `AddStringTask`, we simply create an instance and call `execute()` on it. That starts the chain of events eventually leading to the background thread doing its work.

If `AddStringTask` required configuration parameters, we would have not used `Void` as our first data type, and the constructor would accept zero or more parameters of the defined type. Those values would eventually be passed to `doInBackground()`.

Our fragment also has an `onDestroy()` method that calls `cancel()` on the `AsyncTask` if it is still outstanding (task is not `null`). This work of cancelling the task and checking to see if the task is cancelled exists for two reasons:

1. Efficiency, as we should skip any serious work that is not needed if our task itself is not needed
2. To avoid a crash if we attempt to raise a `Toast` on a destroyed activity, such as the user launching the activity, then pressing `BACK` before we complete the background work and display the `Toast`

The Activity and the Results

`AsyncDemo` is a `FragmentActivity` with the standard recipe for kicking off an instance of a dynamic fragment:

```
package com.commonware.android.async;

import android.app.Activity;
import android.os.Bundle;

public class AsyncDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new AsyncDemoFragment()).commit();
        }
    }
}
```

If you build, install, and run this project, you will see the list being populated in “real time” over a few seconds, followed by a `Toast` indicating completion.

Threads and Configuration Changes

One problem with the default destroy-and-create cycle that activities go through on a configuration change comes from background threads. If the activity has started some background work — through an `AsyncTask`, for example – and then the

activity is destroyed and re-created, somehow the `AsyncTask` needs to know about this. Otherwise, the `AsyncTask` might well send updates and final results to the *old* activity, with the new activity none the wiser. In fact, the new activity might start up the background work *again*, wasting resources.

That is why, in the sample above, we are retaining the fragment instance. The fragment instance holds onto its data model (in this case, the `ArrayList` of Latin words) and knows not to kick off a new `AsyncTask` just because the configuration changed. Moreover, we retain that data model, so the new `ListView` created due to the configuration change can work with a new adapter backed by the old data model, so we do not lose our existing set of Latin words.

We also have to be very careful not to try referring to the activity (via `getActivity()` on the fragment) from our background thread (`doInBackground()`). Because, suppose that during the middle of the `doInBackground()` processing, the user rotates the screen. The activity we work with will change on the fly, on the main application thread, independently of the work being done in the background. The activity returned by `getActivity()` may not be in a useful state for us while this configuration change is going on.

However, it is safe for us to use `getActivity()` from `onPostExecute()`, and even from `onProgressUpdate()`. For those callbacks, either the configuration change has not yet happened, or it has been completed — we will not be in the middle of the change.

Where Not to Use AsyncTask

`AsyncTask`, particularly in conjunction with a dynamic fragment, is a wonderful solution for most needs for a background thread.

The key word in that sentence is “most”.

`AsyncTask` manages a thread pool, from which it pulls the threads to be used by task instances. Thread pools assume that they will get their threads back after a reasonable period of time. Hence, `AsyncTask` is a poor choice when you do not know how long you need the thread (e.g., thread listening on a socket for a chat client, where you need the thread until the user exits the client).

About the AsyncTask Thread Pool

Moreover, the thread pool that `AsyncTask` manages has varied in size.

In Android 1.5, it was a single thread.

In Android 1.6, it was expanded to support many parallel threads, probably more than you will ever need.

In Android 3.2, it has shrunk back to a single thread, if your `android:targetSdkVersion` is set to 13 or higher. This was to address concerns about:

- Forking too many threads and starving the CPU
- Developers thinking that there is an ordering dependency between forked tasks, when with the parallel execution there is none

If you wish, starting with API Level 11, you can supply your own `Executor` (from the `java.util.concurrent` package) that has whatever thread pool you wish, so you can manage this more yourself. In addition to the serialized, one-at-a-time `Executor`, there is a built-in `Executor` that implements the old thread pool, that you can use rather than rolling your own.

If your `minSdkVersion` is 11 or higher, use `executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR)` if you specifically want to opt into a multi-thread thread pool. If your `minSdkVersion` is below 11, you will still want to do that... but only on API Level 11+ devices, falling back to `execute()` on the older devices. This static utility method handles this for you:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task,
                                     T... params) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);
    }
    else {
        task.execute(params);
    }
}
```

To use this, call `executeAsyncTask()`, passing in your `AsyncTask` instance and the parameters you would ordinarily have passed to `execute()`.

An explanation of what we are doing here, in terms of the `@TargetApi` annotation and such, will come [later in the book](#).

Also note that the number of threads in the multiple-thread thread pool has *also* changed over the years. Originally, that pool could climb to as many as 128 threads,

which was far too many. As of Android 4.4, [the thread pool will only grow to “the number of CPU cores * 2 + 1”](#), so on a dual-core device, the thread pool will cap at 5 threads. Further tasks will be queued, up to a maximum of 128 queued tasks.

Alternatives to AsyncTask

There are other ways of handling background threads without using AsyncTask:

- You can employ a Handler, which has a `handleMessage()` method that will process Message objects, dispatched from a background thread, on the main application thread
- You can supply a Runnable to be executed on the main application thread to `post()` on any View, or to `runOnUiThread()` on Activity
- You can supply a Runnable, plus a delay period in milliseconds, to `postDelayed()` on any View, to run the Runnable on the main application thread after *at least* that number of millisecond has elapsed

Of these, the Runnable options are the easiest to use.

These can also be used to allow the main application thread to postpone work, to be done *later* on the main application thread. For example, you can use `postDelayed()` to set up a lightweight polling “loop” within an activity, without needing the overhead of an extra thread, such as the one created by Timer and TimerTask. To see how this works, let’s take a peek at the [Threads/PostDelayed](#) sample project.

This project contains a single activity, named PostDelayedDemo:

```
package com.commonware.android.post;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.Toast;

public class PostDelayedDemo extends Activity implements Runnable {
    private static final int PERIOD=5000;
    private View root=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
        root=findViewById(android.R.id.content);
    }
}
```

```
@Override
public void onResume() {
    super.onResume();

    run();
}

@Override
public void onPause() {
    root.removeCallbacks(this);

    super.onPause();
}

@Override
public void run() {
    Toast.makeText(PostDelayedDemo.this, "Who-hoo!", Toast.LENGTH_SHORT)
        .show();
    root.postDelayed(this, PERIOD);
}
}
```

We want to display a Toast every five seconds. To do this, in `onCreate()`, we get our hands on the container for an activity's UI, known as `android.R.id.content`, via `findViewById()`. Then, in `onResume()`, we call a `run()` method on our activity, which displays the Toast and calls `postDelayed()` to schedule *itself* (as an implementation of `Runnable`) to be run again in `PERIOD` milliseconds. While our activity is in the foreground, the Toast will appear every `PERIOD` milliseconds as a result. Once something else comes to the foreground — such as by the user pressing BACK — our `onPause()` method is called, where we call `removeCallbacks()` to “undo” the `postDelayed()` call.

And Now, The Caveats

Background threads, while eminently possible using `AsyncTask` and kin, are not all happiness and warm puppies. Background threads not only add complexity, but they have real-world costs in terms of available memory, CPU, and battery life.

To that end, there is a wide range of scenarios you need to account for with your background thread, including:

1. The possibility that users will interact with your activity's UI while the background thread is chugging along. If the work that the background thread is doing is altered or invalidated by the user input, you will need to communicate this to the background thread. Android includes many classes

in the `java.util.concurrent` package that will help you communicate safely with your background thread.

2. The possibility that the process will be terminated while your work is still going on. This is why in many cases, rather than use an `AsyncTask` or a bare `Thread`, you will wind up using a `Service`, such as an `IntentService`. This will be explored in greater detail [later in this book](#).
3. The possibility that your user will get irritated if you chew up a lot of CPU time and battery life without giving any payback. Tactically, this means using `ProgressBar` or other means of letting the user know that something is happening. Strategically, this means you still need to be efficient at what you do — background threads are no panacea for sluggish or pointless code.
4. The possibility that you will encounter an error during background processing. For example, if you are gathering information off the Internet, the device might lose connectivity. Alerting the user of the problem via a `Notification` and shutting down the background thread may be your best option.

Event Buses

Event-driven programming has been around for nearly a quarter-century. Much of Android's UI model is event-driven, where we find out about these events via callbacks (e.g., `onCreate()` for the “start an activity” event) and registered listeners (e.g., `OnClickListener` for when the user taps on a widget).

However, originally, Android did not have a very fine-grained event or message bus implementation that we as developers could use. The `Intent` system works like a message bus, but it is aimed at inter-process communication (IPC) as much as in-process communication, and that comes with some costs.

However, over time, particularly starting in 2012, event buses started to pop up, and these are very useful for organizing communication within your Android application and across threads. Used properly, an event bus can eliminate the need for `AsyncTask` and the other solutions for communicating back to the main application thread, while simultaneously helping you logically decouple independent pieces of your code.

What Is an Event Bus?

Whether you consider it an “event bus” (or “message bus”), the “publisher/subscriber” (or “pub/sub”) pattern, or a subset of the “observer” pattern, the

programming model where components produce events that others consume for is reasonably common in modern software development.

An event bus is designed to decouple the sources of events from the consumers of those events. Or, [as one event bus author put it](#):

I want an easy, centralized way to notify code that's interested in specific types of events when those events occur without any direct coupling between the code the publishes an event and the code that receives it.

With the traditional Java listener or observer pattern implementation, the component producing an event needs direct access to consumers of that event. Sometimes, that list of consumers is limited to a single consumer, as with many event handlers associated with Android widgets (e.g., just one `OnClickListener`). But this source-holds-the-sinks coding pattern limits flexibility, as it requires explicit registration by consumers with producers of events, and it may not be that easy for the consumer to *reach* the producer. Furthermore, such direct connections are considered to be a relatively strong coupling between those components, and often times our objective is to have looser coupling.

An event bus provides a standard communications channel (or “bus”) that event producers and event consumers can hook into. Event producers merely need to hand the event to the bus; the bus will handle directing those events to relevant consumers. This reduces the coupling between the producers and consumers, sometimes even reducing the amount of code needed to source and sink these events.

OK, But Why Are We Bothering With This?

Later on, we are going to have components other than our activities. In particular, we will have [services](#), which are designed to run briefly in the background to perform some operation. Just as communications between activities tends to be loosely coupled, so too are communications between activities and services. An event bus is a great way for the service to let other pieces of the app know that certain work was done (e.g., “the download is complete, so update the UI”).

In the short term, we will use an event bus to have a [model fragment](#) let the app know that some data was loaded. In the tutorials, “some data” will be the book contents; in the sample app illustrated in this chapter, “some data” will be some Latin words.

Introducing greenrobot's EventBus

The event bus implementation that we will be using in the tutorials is [greenrobot's EventBus](#), an open source implementation based on the Guava project's event bus. With greenrobot's EventBus, it is fairly easy to send a message from one part of your app to another disparate part of your app.

To illustrate its use, take a look at the [EventBus/AsyncDemo](#) sample project. This is a reworking of a previous example that used an AsyncTask to pretend to download our list of Latin words, populating a ListView with those words as they arrive. This sample replaces the AsyncTask with a model fragment that will keep track of the words and a background thread that will “download” the words. We will use events raised by the model fragment to let the UI fragment know words as they arrive.

Defining Events

With greenrobot's EventBus, the “events” are objects of arbitrary classes that you define. Each different class represents a different type of event, and you can define as many different event classes as you wish. Those classes do not need to inherit from any special base class, or implement some special interface, or have any magic annotations. They are just classes.

You may wish to put data members, constructors, and accessor methods on the event classes, for any data you wish to pass around specific to the event itself. A SearchEvent, for example, might include the search query string as part of the event object.

In our case, we have a WordReadyEvent that contains the new word:

```
package com.commonware.android.eventbus;

class WordReadyEvent {
    private String word;

    WordReadyEvent(String word) {
        this.word=word;
    }

    String getWord() {
        return(word);
    }
}
```

Posting Events

To post an event, all you need to do is obtain an instance of an EventBus – typically via the `getDefault()` method on EventBus — and call `post()` on it, passing in the event to be delivered to any interested party within your app.

With that in mind, let's look at the `ModelFragment` that will be loading in our words:

```
package com.commonware.android.eventbus;

import android.app.Fragment;
import android.os.Bundle;
import android.os.SystemClock;
import java.util.ArrayList;
import de.greenrobot.event.EventBus;

public class ModelFragment extends Fragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> model=new ArrayList<String>();
    private boolean isStarted=false;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);

        if (!isStarted) {
            isStarted=true;
            new LoadWordsThread().start();
        }
    }

    public ArrayList<String> getModel() {
        return(new ArrayList<String>(model));
    }

    class LoadWordsThread extends Thread {
        @Override
        public void run() {
            for (String item : items) {
                if (!isInterrupted()) {
                    model.add(item);
                    EventBus.getDefault().post(new WordReadyEvent(item));
                    SystemClock.sleep(400);
                }
            }
        }
    }
}
```

```
}  
}
```

This fragment has no UI — it exists solely to manage a data model on behalf of the rest of the hosting activity. Hence, there is no `onCreateView()` or any other UI logic directly in this fragment.

In `onCreate()`, we call `setRetainInstance(true)`, so that if the user rotates the screen or otherwise triggers a configuration change, our model fragment will survive the change and be attached to the new activity instance. Then, if we have not already started the `LoadWordsThread`, we do so. `LoadWordsThread` iterates over our list of words, sleeps for 400ms to simulate doing real work, adds each word to an `ArrayList` of words that it manages... and calls `post()` to raise a `WordReadyEvent` to let something else know that the model has changed.

Receiving Events

To receive posted events, you need to do three things:

1. Call `register()` on the `EventBus` to tell it that you have an object that wants to receive events
2. Call `unregister()` on the `EventBus` to tell it to stop delivering events to a previously-registered object
3. Implement `onEventMainThread()`, or other `onEvent()` method flavors, to indicate the type of event you want to receive (and to actually process those events)

This sample app has an `AsyncDemoFragment` that performs those three steps:

```
package com.commonware.android.eventbus;  
  
import android.app.Activity;  
import android.app.ListFragment;  
import android.os.Bundle;  
import android.view.View;  
import android.widget.AdapterView;  
import java.util.ArrayList;  
import de.greenrobot.event.EventBus;  
  
public class AsyncDemoFragment extends ListFragment {  
    private ArrayAdapter<String> adapter=null;  
    private ArrayList<String> model=null;  
  
    @Override  
    public void onViewCreated(View view, Bundle savedInstanceState) {
```

```
adapter=
    new ArrayAdapter<String>(getActivity(),
                            android.R.layout.simple_list_item_1,
                            model);

getListView().setScrollbarFadingEnabled(false);
setListAdapter(adapter);
}

@Override
public void onAttach(Activity activity) {
    super.onAttach(activity);

    EventBus.getDefault().register(this);
}

@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
}

public void onEventMainThread(WordReadyEvent event) {
    adapter.add(event.getWord());
}

public void setModel(ArrayList<String> model) {
    this.model=model;
}
}
```

The fragment starts by overriding `onViewCreated()`, where we create an `ArrayAdapter` and use that to populate the `ListView`.

The `onAttach()` and `onDetach()` methods are where we indicate to the `EventBus` that this fragment object wants to receive relevant posted events. `onAttach()` calls `register()`; `onDetach()` calls `unregister()`.

The `onEventMainThread()` method, via its parameter, indicates that we are interested in `WordReadyEvents` as they are raised. Our `onEventMainThread()` method will be called for each `WordReadyEvent` passed to `post()` on the `EventBus`. As the method name suggests, `onEventMainThread()` is called on the main application thread, so it is safe for us to update our UI. `greenrobot's EventBus` is responsible for getting this event to the main application thread — note that we are posting the event from the `LoadWordsThread`, which is a background thread.

In `onEventMainThread()`, we get the newly-added word, which we can add to our `ArrayAdapter`. `add()` on `ArrayAdapter` appends the word to the end of the list and

informs the attached `ListView` that the data changed, so the `ListView` can redraw itself.

What is not obvious, though, from the code in this class is how we are getting the model that we are using in `onViewCreated()`. `AsyncDemoFragment` has its own `ArrayList` of words, set via the `setModel()` method. Our `ArrayAdapter` is wrapped around this model. But the master copy of the words is being held by the `ModelFragment`. If the `ModelFragment` has the model, and the `AsyncDemoFragment` needs the model, how are the two being connected?

The Activity

That is handled by our hosting activity, as it sets up these two fragments:

```
package com.commonware.android.eventbus;

import android.app.Activity;
import android.os.Bundle;

public class AsyncDemo extends Activity {
    private static final String MODEL_TAG="model";
    private ModelFragment mFrag=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        mFrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL_TAG);

        if (mFrag == null) {
            mFrag=new ModelFragment();

            getFragmentManager().beginTransaction().add(mFrag, MODEL_TAG)
                .commit();
        }

        AsyncDemoFragment demo=
            (AsyncDemoFragment)getFragmentManager().findFragmentById(android.R.id.content);

        if (demo == null) {
            demo=new AsyncDemoFragment();
            getFragmentManager().beginTransaction()
                .add(android.R.id.content, demo).commit();
        }

        demo.setModel(mFrag.getModel());
    }
}
```

```
}  
}
```

In `onCreate()`, we first see if we already have an instance of our model fragment, held by the `FragmentManager` under a `MODEL_TAG` tag. If not, we create an instance of the `ModelFragment` and add it to the `FragmentManager`, under that tag, via a `FragmentTransaction`.

We then see if we already have an instance of our `AsyncDemoFragment`. If not, we create one and add it to the `FragmentManager`, pouring its UI into `android.R.id.content`, via another `FragmentTransaction`.

Then, we connect the two, calling `getModel()` on the `ModelFragment` and handing the result to `setModel()` on the `AsyncDemoFragment`.

When our activity is newly launched, neither fragment exists. Both fragments are created, and the `AsyncDemoFragment` gets its model array from the `ModelFragment`. That array is initially empty. As the `ModelFragment` adds elements to the array, it posts the `WordReadyEvent`, which triggers the `AsyncDemoFragment` to tell the `ArrayAdapter` and `ListView` that the model data changed.

If we undergo a configuration change, the `ModelFragment` is retained, but the `AsyncDemoFragment` is not. Hence, the activity will always be creating an `AsyncDemoFragment`. But the model we give to the `AsyncDemoFragment` may already have words in it, and those words will appear immediately when the `ArrayAdapter` is wrapped around the model. If the `LoadWordsThread` is still running, the new `AsyncDemoFragment` will pick up any new `WordReadyEvents` that are raised, triggering it to update the `ListView` as before.

Visit the Trails!

We will cover much more about jank, and how to detect and diagnose it, [in a later chapter](#).

There are many more features in the greenrobot `EventBus` implementation. We will see some of those, plus other event bus implementations, in a later chapter on [event bus alternatives](#).

Requesting Permissions

In the late 1990's, a wave of viruses spread through the Internet, delivered via email, using contact information culled from Microsoft Outlook. A virus would simply email copies of itself to each of the Outlook contacts that had an email address. This was possible because, at the time, Outlook did not take any steps to protect data from programs using the Outlook API, since that API was designed for ordinary developers, not virus authors.

Nowadays, many applications that hold onto contact data secure that data by requiring that a user explicitly grant rights for other programs to access the contact information. Those rights could be granted on a case-by-case basis or all at once at install time.

Android is no different, in that it requires permissions for applications to read or write contact data. Android's permission system is useful well beyond contact data, and for content providers and services beyond those supplied by the Android framework.

You, as an Android developer, will frequently need to ensure your applications have the appropriate permissions to do what you want to do with other applications' data. This chapter covers this topic.

You may also elect to require permissions for other applications to use your data or services, if you make those available to other Android components. This will be discussed [later in this book](#).

Mother, May I?

Requesting the use of other applications' data or services requires the `uses-permission` element to be added to your `AndroidManifest.xml` file. Your manifest may have zero or more `uses-permission` elements, all as direct children of the root manifest element.

The `uses-permission` element takes a single attribute, `android:name`, which is the name of the permission your application requires:

```
<uses-permission android:name="android.permission.ACCESS_LOCATION" />
```

The stock system permissions all begin with `android.permission` and are listed in the Android SDK documentation for `Manifest.permission`. Third-party applications may have their own permissions, which hopefully they have documented for you. Here are some of the permissions we will see in this book:

1. `INTERNET`, if your application wishes to access the Internet through any means, from raw Java sockets through the `WebView` widget
2. `WRITE_EXTERNAL_STORAGE`, for writing data to external storage
3. `ACCESS_COARSE_LOCATION` and `ACCESS_FINE_LOCATION`, for determining where the device is
4. `CALL_PHONE`, to allow the application to place phone calls directly, without user intervention

Permissions are confirmed at the time the application is installed — the user will be prompted to confirm it is OK for your application to do what the permission calls for.

REQUESTING PERMISSIONS

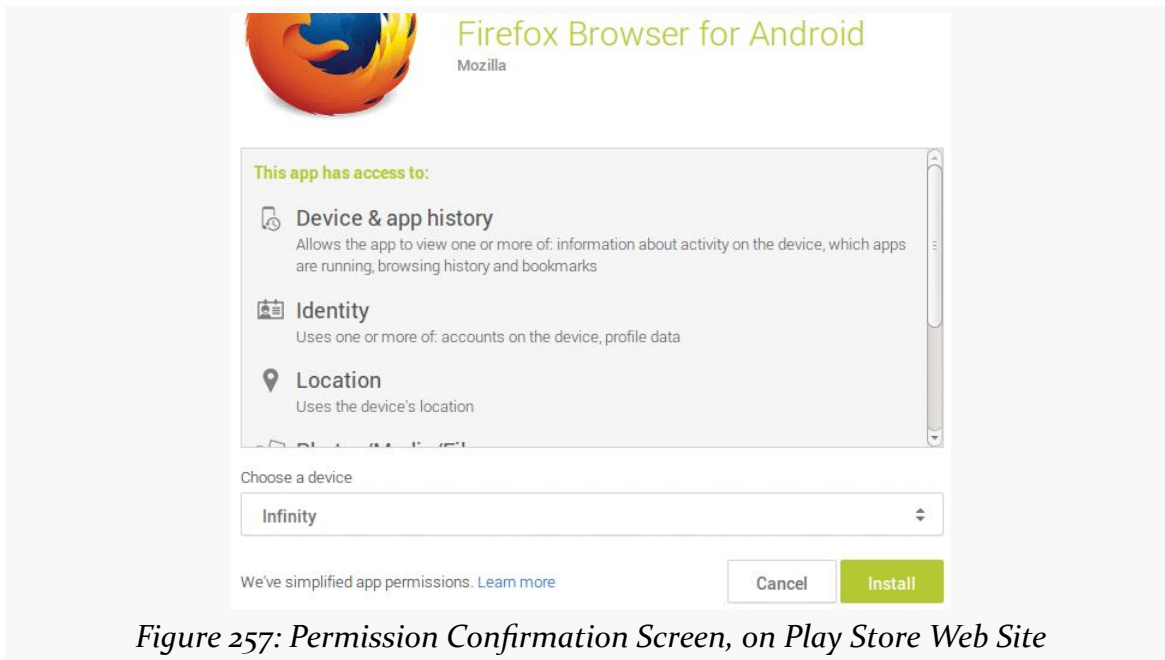

Figure 257: Permission Confirmation Screen, on Play Store Web Site

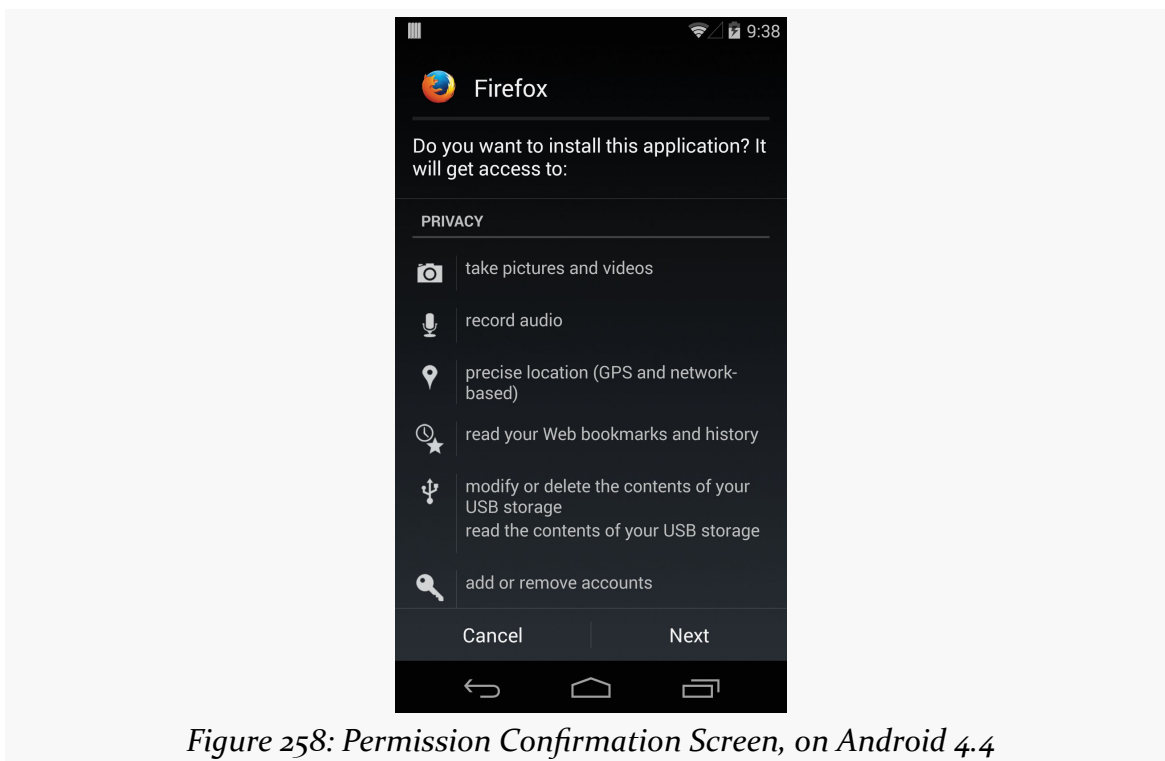

Figure 258: Permission Confirmation Screen, on Android 4.4

Hence, it is important for you to ask for as few permissions as possible and to justify those you ask for, so users do not elect to skip installing your application because

you ask for too many unnecessary permissions. Note that users are not asked to confirm permissions when loading an application via USB, such as during development.

If you do not have the desired permission and try to do something that needs it, you should get a `SecurityException` informing you of the missing permission. Note that you will only fail on a permission check if you forgot to ask for the permission — it is impossible for your application to be running and *not* have been granted your requested permissions, at least on conventional versions of Android. So-called “ROM mods” might allow users to revoke already-granted permissions.

New Permissions in Old Applications

Sometimes, Android introduces new permissions that govern behavior that formerly did not require permissions. `WRITE_EXTERNAL_STORAGE` is one example – originally, applications could write to external storage without any permission at all. Android 1.6 introduced `WRITE_EXTERNAL_STORAGE`, required before you can write to external storage. However, applications that were written before Android 1.6 could not possibly request that permission, since it did not exist at the time. Breaking those applications would seem to be a harsh price for progress.

What Android does is “grandfather” in certain permissions for applications supporting earlier SDK versions.

In particular, if you have `<uses-sdk android:minSdkVersion="3">` in your manifest, saying that you support Android 1.5, your application will automatically request `WRITE_EXTERNAL_STORAGE` and `READ_PHONE_STATE`, even if you do not explicitly request those permissions. People installing your application on an Android 1.5 device will see these requests.

Eventually, when you drop support for the older version (e.g., switch to `<uses-sdk android:minSdkVersion="4">`), Android will no longer automatically request those permissions. Hence, if your code really *does* need those permissions, you will need to ask for them yourself.

Permissions: Up Front Or Not At All

The permission system in Android is not especially flexible. Notably, you have to ask for all permissions you might ever need up front, and the user has to agree to all of them or abandon the installation of your app.

This means:

1. You cannot create optional permissions, ones the user could say “no, thanks” to, that your application could react to dynamically
2. You cannot request new permissions after installation, so even if a permission is only needed for some lightly-used feature, you have to ask for it anyway

Hence, it is important as you come up with the feature list for your app that you keep permissions in mind. Every additional permission that you request is a filter that will cost you some portion of your prospective audience. Certain combinations — such as `INTERNET` and `READ_CONTACTS` — will have a stronger effect, as users fear what the combination can do. You will need to decide for yourself if the additional users you will get from having the feature will be worth the cost of requiring the permissions the feature needs to operate.

Signature Permissions

Some permissions listed in the SDK you can request but will not get. These permissions, such as `BRICK`, require your application to be signed by the same signing key as is used to sign the firmware. We will discuss these signing keys and how they work [in a later chapter](#).

Some permissions, like `REBOOT`, require that your application either be signed with the firmware’s signing key *or* that your application be “installed on the system partition” (which normally means that the app is distributed pre-installed on the device).

Unfortunately, the Android developer documentation does not tell you the requirements for any given permission. To find out, you will need to examine [the platform’s `AndroidManifest.xml` file](#) and find your permission in there. For example, here is one edition’s definition of the `BRICK` and `REBOOT` permissions:

```
<!-- Required to be able to disable the device (very dangerous!). -->
<permission android:name="android.permission.BRICK"
    android:label="@string/permlab_brick"
    android:description="@string/permdesc_brick"
    android:protectionLevel="signature" />

<!-- Required to be able to reboot the device. -->
<permission android:name="android.permission.REBOOT"
    android:label="@string/permlab_reboot"
```

```
android:description="@string/permdesc_reboot"  
android:protectionLevel="signature|system" />
```

The BRICK permission has an `android:protectionLevel` of `signature`, meaning the app requesting the permission must have the same signing key as does the firmware. Instead, the REBOOT permission has `signature|system`, meaning that the app could just be installed on the system partition in order to hold this permission. Here, the pipe operator is a logical OR, meaning that the app must either be signed by the firmware's signing key (`signature`) or installed on the system partition (`system`).

Requiring Permissions

The XML elements shown from Android's own manifest are `<permission>` elements. These define new permissions to the system.

You can use `<permission>` elements to define your own custom permissions for use with your own apps. This would be important if you are planning on allowing third-party applications to integrate with yours and possibly retrieve data that you are storing. The user probably should “get a vote” on whether that data sharing is allowed. To do that, you could define a permission and declare that one or more of your components (e.g., activities) are protected by that permission. Only third parties that request the permission via `<uses-permission>` will be able to use those components.

We will get into this scenario in greater detail [in a later chapter](#).

Assets, Files, and Data Parsing

Android offers a few structured ways to store data, notably [SharedPreferences](#) and [local SQLite databases](#). And, of course, you are welcome to store your data “in the cloud” by using an [Internet-based service](#). We will get to all of those topics shortly.

Beyond that, though, Android allows you to work with plain old ordinary files, either ones baked into your app (“assets”) or ones on so-called internal or external storage.

To make those files work — and to consume data off of the Internet — you will likely need to employ a parser. Android ships with several choices for XML and JSON parsing, in addition to [third-party libraries](#) you can attempt to use.

This chapter focuses on assets, files, and parsers.

Packaging Files with Your App

Let’s suppose you have some static data you want to ship with the application, such as a list of words for a spell-checker. Somehow, you need to bundle that data with the application, in a way you can get at it from Java code later on, or possibly in a way you can pass to another component (e.g., `WebView` for bundled HTML files).

There are three main options here: raw resources, XML resources, and assets.

Raw Resources

One way to deploy a file like a spell-check catalog is to put the file in the `res/raw` directory, so it gets put in the Android application .apk file as part of the packaging process as a raw resource.

To access this file, you need to get yourself a `Resources` object. From an activity, that is as simple as calling `getResources()`. A `Resources` object offers `openRawResource()` to get an `InputStream` on the file you specify. Rather than a path, `openRawResource()` expects an integer identifier for the file as packaged. This works just like accessing widgets via `findViewById()` – if you put a file named `words.xml` in `res/raw`, the identifier is accessible in Java as `R.raw.words`.

Since you can only get an `InputStream`, you have no means of modifying this file. Hence, it is really only useful for static reference data. Moreover, since it is unchanging until the user installs an updated version of your application package, either the reference data has to be valid for the foreseeable future, or you will need to provide some means of updating the data. The simplest way to handle that is to use the reference data to bootstrap some other modifiable form of storage (e.g., a database), but this makes for two copies of the data in storage. An alternative is to keep the reference data as-is but keep modifications in a file or database, and merge them together when you need a complete picture of the information. For example, if your application ships a file of URLs, you could have a second file that tracks URLs added by the user or reference URLs that were deleted by the user.

XML Resources

If, however, your file is in an XML format, you are better served not putting it in `res/raw/`, but rather in `res/xml/`. This is a directory for XML resources – resources known to be in XML format, but without any assumptions about what that XML represents.

To access that XML, you once again get a `Resources` object by calling `getResources()` on your `Activity` or other `Context`. Then, call `getXml()` on the `Resources` object, supplying the ID value of your XML resource (e.g., `R.xml.words`). This will return an `XmlResourceParser`, which implements the `XmlPullParser` interface. We will discuss how to use this parser, and the performance advantage of using XML resources, [later in this chapter](#).

As with raw resources, XML resources are read-only at runtime.

Assets

Your third option is to package the data in the form of an asset. You can create an `assets/` directory at the root of your project directory, then place whatever files you want in there. Those are accessible at runtime by calling `getAssets()` on your

Activity or other Context, then calling `open()` with the path to the file (e.g., `assets/foo/index.html` would be retrieved via `open("foo/index.html")`). As with raw resources, this returns an `InputStream` on the file's contents. And, as with all types of resources, assets are read-only at runtime.

One benefit of using assets over raw resources is the `file:///android_asset/` Uri prefix. You can use this to load an asset into a `WebView`. For example, for an asset located in `assets/foo/index.html` within your project, calling `loadUrl("file:///android_asset/foo/index.html")` will load that HTML into the `WebView`.

Note that assets are compressed when the APK is packaged. Unfortunately, on Android 1.x/2.x, this compression mechanism has a 1MB file size limit. If you wish to package an asset that is bigger than 1MB, you either need to give it a file extension that will not be compressed (e.g., `.mp3`) or actually store a ZIP file of the asset (to avoid the automatic compression) and decompress it yourself at runtime, using the standard `java.util.zip` classes. This restriction was lifted with Android 3.0, and so if your `minSdkVersion` is 11 or higher, this will not be an issue for you.

Files and Android

On the whole, Android just uses normal Java file I/O for local files. You will use the same `File` and `InputStream` and `OutputStream` and other classes that you have used time and again in your prior Java development work.

What is distinctive in Android is *where* you read and write. Akin to writing a Java Web app, you do not have read and write access to arbitrary locations. Instead, there are only a handful of directories to which you have any access, particularly when running on production hardware.

Internal vs. External

Internal storage refers to your application's portion of the on-board, always-available flash storage. External storage refers to storage space that can be mounted by the user as a drive in Windows (or, possibly with some difficulty, as a volume in OS X or Linux).

Historically (i.e., Android 1.x/2.x), internal storage was very limited in space. That is far less of a problem on 3.0 and higher.

Similarly, external storage is not always available on Android 1.x and 2.x – if it is mounted as a drive or volume on a host desktop or notebook, your app will not have access to external storage. We will examine this limitation in a bit more detail [later in this chapter](#). This is not usually a problem on Android 3.0+.

Standard vs. Cache

On both internal and external storage, you have the option of saving files as a cache, or on a more permanent basis. Files located in a cache directory may be deleted by the OS or third-party apps to free up storage space for the user. Files located outside of cache will remain unless manually deleted.

Yours vs. Somebody Else's

Internal storage is on a per-application basis. Files you write to in your own internal storage cannot be read or written to by other applications... normally. Users who “root” their phones can run apps with superuser privileges and be able to access your internal storage. Most users do not root their phones, and so only your app will be able to access your internal storage files.

Files on external storage, though, are visible to all applications and the user. Anyone can read anything stored there, and any application that requests to can write or delete anything it wants.

Working with Internal Storage

You have a few options for manipulating the contents of your app's portion of internal storage.

One possibility is to use `openFileInput()` and `openFileOutput()` on your Activity or other Context to get an `InputStream` and `OutputStream`, respectively. However, these methods do not accept file paths (e.g., `path/to/file.txt`), just simple filenames.

If you want to have a bit more flexibility, `getFilesDir()` and `getCacheDir()` return a `File` object pointing to the roots of your files and cache locations on internal storage, respectively. Given the `File`, you can create files and subdirectories as you see fit.

To see how this works, take a peek at the [Files/ReadWrite](#) sample project.

This application implements an `EditorFragment`, containing a full-screen `EditText`, hosted by a `FilesDemoActivity` as a static fragment. There is a `CheckBox` in the action bar to toggle between using internal and external storage:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/location"
        android:actionLayout="@layout/action_location"
        android:showAsAction="always">
    </item>
    <item
        android:id="@+id/save"
        android:icon="@android:drawable/ic_menu_save"
        android:showAsAction="always|withText"
        android:title="@string/save">
    </item>
    <item
        android:id="@+id/saveBackground"
        android:icon="@android:drawable/ic_menu_save"
        android:showAsAction="never"
        android:title="@string/saveBackground">
    </item>

</menu>
```

We get at that `CheckBox` in `onCreateOptionsMenu()` of `EditorFragment`, storing it in a data member of the fragment:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);
    external=(CheckBox)menu.findItem(R.id.location).getActionView();
}
```

When they go to work with the file (e.g., press a Save toolbar button), we use a `getTarget()` method to return a `File` object pointing at the file to be manipulated. In the case where the `CheckBox` is unchecked — meaning we are to use internal storage — `getTarget()` uses `getFilesDir()`:

```
private File getTarget() {
    File root=null;

    if (external != null && external.isChecked()) {
        root=getActivity().getExternalFilesDir(null);
    }
    else {
        root=getActivity().getFilesDir();
    }
}
```

```
return(new File(root, FILENAME));  
}
```

Note that the `CheckBox` may not yet exist, depending on the timing of `onCreateOptionsMenu()` and `onResume()`. That timing varies a bit by Android version.

Methods like `load()` then load that `File` by using standard Java file I/O:

```
private String load(File target) throws IOException {  
    String result="";  
  
    try {  
        InputStream in=new FileInputStream(target);  
  
        if (in != null) {  
            try {  
                InputStreamReader tmp=new InputStreamReader(in);  
                BufferedReader reader=new BufferedReader(tmp);  
                String str;  
                StringBuilder buf=new StringBuilder();  
  
                while ((str=reader.readLine()) != null) {  
                    buf.append(str);  
                    buf.append("\n");  
                }  
  
                result=buf.toString();  
            }  
            finally {  
                in.close();  
            }  
        }  
    }  
    catch (java.io.FileNotFoundException e) {  
        // that's OK, we probably haven't created it yet  
    }  
  
    return(result);  
}
```

The files stored in internal storage are accessible only to your application, by default. Other applications on the device have no rights to read, let alone write, to this space. However, bear in mind that some users “root” their Android phones, gaining superuser access. These users will be able to read and write whatever files they wish. As a result, please consider application-local files to be secure against malware but not necessarily secure against interested users.

Working with External Storage

On most Android 1.x devices and some early Android 2.x devices, external storage came in the form of a micro SD card or the equivalent. On the remaining Android 2.x devices, external storage was part of the on-board flash, but housed in a separate partition from the internal storage. On most Android 3.0+ devices, external storage is now simply a special directory in the partition that holds internal storage.

Devices will have at least 1GB of external storage free when they ship to the user. That being said, many devices have much more than that, but the available size at any point could be smaller than 1GB, depending on how much data the user has stored.

Where to Write

If you have files that are tied to your application that are simply too big to risk putting in internal storage, or if the user should be able to download the files off their device at will, you can use `getExternalFilesDir()`, available on any activity or other Context. This will give you a File object pointing to an automatically-created directory on external storage, unique for your application. While not secure against other applications, it does have one big advantage: when your application is uninstalled, these files are automatically deleted, just like the ones in the application-local file area. This method was added in API Level 8. This method takes one parameter — typically `null` — that indicates a particular type of file you are trying to save (or, later, load).

For example, the aforementioned `getTarget()` method of `EditorFragment` uses `getExternalFilesDir()` if the user has checked the `CheckBox` in the action bar:

```
private File getTarget() {
    File root=null;

    if (external != null && external.isChecked()) {
        root=getActivity().getExternalFilesDir(null);
    }
    else {
        root=getActivity().getFilesDir();
    }

    return(new File(root, FILENAME));
}
```

There is also `getExternalCacheDir()`, which returns a `File` pointing at a directory that contains files that you would like to have, but if Android or a third-party app clears the cache, your app will continue to function normally.

Android 4.4 (API Level 19) added two new methods, `getExternalCacheDirs()` and `getExternalFileDirs()`, the plural versions of the classic methods. These return an array of `File` objects, representing one *or more* places where your app can work with external storage. The first element in the array will be the same `File` object returned by the singular versions of the methods (e.g., `getExternalFilesDir()`). The other elements in the array, if any, will represent app-specific directories on alternative external storage locations, like removable cards. The Android Support package has a `ContextCompat` class containing static versions of `getExternalCacheDirs()` and `getExternalFileDirs()`, so you can use the same code on API Level 4 and above, though the backport will only ever return one directory in the array.

If you have files that belong more to the user than to your app — pictures taken by the camera, downloaded MP3 files, etc. — a better solution is to use `getExternalStoragePublicDirectory()`, available on the `Environment` class. This will give you a `File` object pointing to a directory set aside for a certain type of file, based on the type you pass into `getExternalStoragePublicDirectory()`. For example, you can ask for `DIRECTORY_MOVIES`, `DIRECTORY_MUSIC`, or `DIRECTORY_PICTURES` for storing MP4, MP3, or JPEG files, respectively. These files will be left behind when your application is uninstalled. This method was also added in API Level 8.

You will also find a `getExternalStorageDirectory()` method on `Environment`, pointing to the root of the external storage. This is no longer the preferred approach — the methods described above help keep the user's files better organized. However, if you are supporting older Android devices, you may need to use `getExternalStorageDirectory()`, simply because the newer options may not be available to you.

Relevant Permissions

On all relevant Android versions prior to Android 4.4 (API Level 19), if you want to write to external storage, you need to hold the `WRITE_EXTERNAL_STORAGE` permission. And, on those versions, you do not need a permission to read from external storage.

On Android 4.4 and up, the rules are a bit different:

- To read or write in the directory trees rooted at `getExternalFilesDir()` and `getExternalCacheDir()`, you do not need a permission
- To write to anywhere else on external storage, you need `WRITE_EXTERNAL_STORAGE`
- To read from anywhere else on external storage, you need either `WRITE_EXTERNAL_STORAGE` (if you already have that) or `READ_EXTERNAL_STORAGE` (if not)

Hence, so long as your `android:minSdkVersion` is less than 19, you need to take the most conservative approach:

- If you are writing *anywhere* on external storage, request the `WRITE_EXTERNAL_STORAGE` permission
- If you are only reading, but from *anywhere* on external storage, request the `READ_EXTERNAL_STORAGE` permission

Note that you might get paths to external storage locations from third-party apps, typically in the form of a `Uri`. If you are handling `Uri` values from third-party apps, you should request `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE`, in case the third-party app hands you a `Uri` pointing to external storage.

For example, here is the sample app's manifest, complete with the `<uses-permission>` element for `WRITE_EXTERNAL_STORAGE`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.frw"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"
        android:xlargeScreens="true"/>

    <uses-permission
        android:name="android.permission.WRITE_EXTERNAL_STORAGE"
        android:maxSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
```

```
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar"
    android:uiOptions="splitActionBarWhenNarrow">
    <activity
        android:name=".FilesDemoActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

Note the use of `android:maxSdkVersion`. This tells Android to only request this permission up to the stated API level. After that, ignore the request. This sample uses `getExternalFilesDir()` and therefore does not need `WRITE_EXTERNAL_STORAGE` on API Level 19+ devices. Users who install this app on such devices will not be prompted for this permission, while users who install this app on older devices will.

When to Write

Also, external storage may be tied up by the user having mounted it as a USB storage device. You can use `getExternalStorageState()` (a static method on `Environment`) to determine if external storage is presently available or not. On Android 3.0 and higher, this should be much less of an issue, as they changed how the external storage is used by the host PC — originally, this used USB Mass Storage Mode (think thumb drives) and now uses the USB Media Transfer Protocol (think MP3 players). With MTP, both the Android device and the PC it is connected to can have access to the files simultaneously; Mass Storage Mode would only allow the host PC to have access to the files if external storage is mounted.

Nowadays, you can use `getStorageState()` on the `Environment` class (or `getStorageState()` on the `EnvironmentCompat` class from the Android Support package) to find out the state of external storage, for the particular `File` passed as a parameter.

Letting the User See Your Files

The switch to MTP has one side-effect for Android developers: files you write to external storage may not be automatically visible to the user. At the time of this writing, the only files that will show up on the user's PC will be ones that have been indexed by the `MediaStore`. While the `MediaStore` is typically thought of as only

indexing “media” (images, audio files, video files, etc.), it was given the added role in Android 3.0 of maintaining an index of *all* files for the purposes of MTP.

Your file that you place on external storage will not be indexed automatically simply by creating it and writing to it. Eventually, it will be indexed, though it may be quite some time for an automatic indexing pass to take place.

To force Android to index your file, you can use `scanFile()` on `MediaScannerConnection`:

```
String[] paths={pathToYourNewFileOnExternalStorage};  
MediaScannerConnection.scanFile(this, paths, null, null);
```

The third parameter to `scanFile()` is an array of MIME types, to line up with the array of paths in the second parameter. If your file is some form of media, and you know the MIME type, supplying that will ensure that your media will be visible as appropriate to the right apps (e.g., images in the Gallery app). Otherwise, Android will try to infer a MIME type from the file extension.

Limits on External Storage Open Files

Many Android devices will have a per-process limit of 1024 open files, on any sort of storage. This is usually not a problem for developers.

On some devices — including probably all that are running Android 4.2 and higher — there is a *global* limit of 1024 open files on external storage. In other words, all running apps combined can only open 1024 files simultaneously on external storage.

This means that it is important for you to minimize how many open files on external storage you have at a time. Having a few open files is perfectly reasonable; having a few hundred open files is not.

Multiple User Accounts

On Android 4.1 and earlier, each Android device was assumed to be used by just one person.

On Android 4.2 and higher, though, it is possible for a tablet owner to set up multiple user accounts. Each user gets their own section of internal and external storage for files, databases, `SharedPreferences`, and so forth. From your standpoint,

it is as if the users are really on different devices, even though in reality it is all the same hardware.

However, this means that paths to internal and external storage now may vary by user. Hence, it is *very important* for you to use the appropriate methods, outlined in this chapter, for finding locations on internal storage (e.g., `getFilesDir()`) and external storage (e.g., `getExternalFilesDir()`).

Some blog posts, Stack Overflow answers, and the like will show the use of hard-coded paths for these locations (e.g., `/sdcard` or `/mnt/sdcard` for the root of external storage). Hard-coding such paths was never a good idea. And, as of Android 4.2, those paths are simply wrong and will not work.

On Android 4.2+, for the original user of the device, internal storage will wind up in the same location as before, but external storage will use a different path. For the second and subsequent users defined on the device, both internal and external storage will reside in different paths. The various methods, like `getFilesDir()`, will handle this transparently for you.

Note that, at the time of this writing, multiple accounts are not available on the emulators, only on actual tablets. Phones usually will not have multiple-account support, under the premise that tablets are more likely to be shared than are phones.

Linux Filesystems: You Sync, You Win

Android is built atop a Linux kernel and uses Linux filesystems for holding its files. Classically, Android used YAFFS (Yet Another Flash File System), optimized for use on low-power devices for storing data to flash memory.

YAFFS has one big problem: only one process can write to the filesystem at a time. For those of you into filesystems, rather than offering file-level locking, YAFFS has partition-level locking. This can become a bit of a bottleneck, particularly as Android devices grow in power and start wanting to do more things at the same time like their desktop and notebook brethren.

Android 3.0 switched to ext4, another Linux filesystem aimed more at desktops/notebooks. Your applications will not directly perceive the difference. However, ext4 does a fair bit of buffering, and it can cause problems for applications that do not take this buffering into account. Linux application developers ran headlong into this

in 2008–2009, when ext4 started to become popular. Android developers will need to think about it now... for your own file storage.

If you are using SQLite or SharedPreferences, you do not need to worry about this problem. Android (and SQLite, in the case of SQLite) handle all the buffering issues for you. If, however, you write your own files, you may wish to contemplate an extra step as you flush your data to disk. Specifically, you need to trigger a Linux system call known as `fsync()`, which tells the filesystem to ensure all buffers are written to disk.

If you are using `java.io.RandomAccessFile` in a synchronous mode, this step is handled for you as well, so you will not need to worry about it. However, Java developers tend to use `FileOutputStream`, which does not trigger an `fsync()`, even when you call `close()` on the stream. Instead, you call `getFD().sync()` on the `FileOutputStream` to trigger the `fsync()`. Note that this may be time-consuming, and so disk writes should be done off the main application thread wherever practical, such as via an `AsyncTask`.

This is why, in `EditorFragment`, our `save()` implementation looks like this:

```
private void save(String text, File target) throws IOException {
    FileOutputStream fos=new FileOutputStream(target);
    OutputStreamWriter out=new OutputStreamWriter(fos);

    out.write(text);
    out.flush();
    fos.getFD().sync();
    out.close();
}
```

StrictMode: Avoiding Janky Code

Users are more likely to like your application if, to them, it feels responsive. Here, by “responsive”, we mean that it reacts swiftly and accurately to user operations, like taps and swipes.

Conversely, users are less likely to be happy with you if they perceive that your UI is “janky” — sluggish to respond to their requests. For example, maybe your lists do not scroll as smoothly as they would like, or tapping a button does not yield the immediate results they seek.

While threads and `AsyncTask` and the like can help, it may not always be obvious where you should be applying them. A full-scale performance analysis, using

[Traceview](#) or similar Android tools, is certainly possible. However, there are a few standard sorts of things that developers do, sometimes quite by accident, on the main application thread that will tend to cause sluggishness:

1. Flash I/O, both for internal and external storage
2. Network I/O

However, even here, it may not be obvious that you are performing these operations on the main application thread. This is particularly true when the operations are really being done by Android's code that you are simply calling.

That is where `StrictMode` comes in. Its mission is to help you determine when you are doing things on the main application thread that might cause a janky user experience.

`StrictMode` works on a set of policies. There are presently two categories of policies: VM policies and thread policies. The former represent bad coding practices that pertain to your entire application, notably leaking SQLite Cursor objects and kin. The latter represent things that are bad when performed on the main application thread, notably flash I/O and network I/O.

Each policy dictates what `StrictMode` should watch for (e.g., flash reads are OK but flash writes are not) and how `StrictMode` should react when you violate the rules, such as:

1. Log a message to LogCat
2. Display a dialog
3. Crash your application (seriously!)

The simplest thing to do is call the static `enableDefaults()` method on `StrictMode` from `onCreate()` of your first activity. This will set up normal operation, reporting all violations by simply logging to LogCat. However, you can set your own custom policies via Builder objects if you so choose.

However, do not use `StrictMode` in production code. It is designed for use when you are building, testing, and debugging your application. It is not designed to be used in the field.

In `FilesDemoActivity`, in addition to loading `R.layout.main` with our `EditorFragment` statically defined, we configure `StrictMode`, if and only if we are

building a debug version of the app and are on a version of Android that supports StrictMode:

```
package com.commonware.android.frw;

import android.app.Activity;
import android.os.Build;
import android.os.Bundle;
import android.os.StrictMode;

public class FilesDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        if (BuildConfig.DEBUG
            && Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
            StrictMode.setThreadPolicy(buildPolicy());
        }
    }

    private StrictMode.ThreadPolicy buildPolicy() {
        return(new StrictMode.ThreadPolicy.Builder().detectAll()
            .penaltyLog().build());
    }
}
```

Here, we are asking to flag all faults (`detectAll()`), logging any violations to LogCat (`penaltyLog()`).

`BuildConfig.DEBUG` is a flag that indicates if we are on a debug build or not. The `BuildConfig` class is code-generated alongside the `R` class, in whatever Java package we declared in the `<manifest>` element of our manifest.

If we press the “Save” action bar item, instead of going to the menu and using “Save in Background”, we will do disk I/O on the main application thread and generate StrictMode violations as a result:

```
D/StrictMode(1902): StrictMode policy violation; ~duration=1 ms:
android.os.StrictMode$StrictModeDiskWriteViolation: policy=31 violation=1
D/StrictMode(1902):   at
android.os.StrictMode$AndroidBlockGuardPolicy.onWriteToDisk(StrictMode.java:1097)
D/StrictMode(1902):   at libcore.io.BlockGuardOs.fsync(BlockGuardOs.java:96)
D/StrictMode(1902):   at java.io.FileDescriptor.sync(FileDescriptor.java:74)
D/StrictMode(1902):   at
com.commonware.android.frw.EditorFragment.save(EditorFragment.java:111)
...
```

While wordy, and logged only at debug severity, this is enough to point out where in your code the violation occurred — in our case, in `onOptionsItemSelected()` of `EditorFragment`.

Note that `StrictMode` will also report leaked open files. For example, if you create a `FileOutputStream` on a `File` and fail to `close()` it later, when the `FileOutputStream` (and related objects) are garbage-collected, `StrictMode` will report to you the fact that you failed to close the stream. This is very useful to help you make sure that you are not leaking open files that may contribute to [exhausting the 1,024 open file limit on external storage](#).

XML Parsing Options

Android supports a fairly standard implementation of the Java DOM and SAX APIs. If you have existing experience with these, or if you have code that already leverages them, feel free to use them.

Android also bakes in the `XmlPullParser` from [the xmlpull.org site](#). Like SAX, the `XmlPullParser` is an event-driven interface, compared to the DOM that builds up a complete data structure and hands you that result. Unlike SAX, which relies on a listener and callback methods, the `XmlPullParser` has you pull events off a queue, ignoring those you do not need and dispatching the rest as you see fit to the rest of your code.

The primary reason the `XmlPullParser` was put into Android was for XML-encoded resources. While you write plain-text XML during development, what is packaged in your APK file is a so-called “binary XML” format, where angle brackets and quotation marks and such are replaced by bitfields. This helps compression a bit, but mostly this conversion is done to speed up parsing. Android’s XML resource parser can parse this “binary XML” approximately ten times faster than it can parse the equivalent plain-text XML. Hence, anything you put in an XML resource (`res/xml/`) will be parsed similarly quickly.

For plain-text XML content, the `XmlPullParser` is roughly equivalent, speed-wise, to SAX. All else being equal, lean towards SAX, simply because more developers will be familiar with it from classic Java development. However, if you really like the `XmlPullParser` interface, feel free to use it.

You are welcome to try a third-party XML parser JAR, but bear in mind [that there may be issues when trying to get it working in Android](#).

JSON Parsing Options

Android has bundled the `org.json` classes into the SDK since the beginning, for use in parsing JSON. These classes have a DOM-style interface: you hand `JSONObject` a hunk of JSON, and it gives you an in-memory representation of the completely parsed result. This is handy but, like the DOM, a bit of a performance hog.

API Level 11 added `JSONReader`, based on Google's GSON parser, as a "streaming" parser alternative. `JSONReader` is much more reminiscent of the `XmlPullParser`, in that you pull events out of the "reader" and process them. This can have significant performance advantages, particularly in terms of memory consumption, if you do not need the entire JSON data structure. However, this is only available on API Level 11 and higher.

Because `JSONReader` is a bit "late to the party", there has been extensive work on getting other JSON parsers working on Android. [Google's GSON](#) is popular, as is [Jackson](#). Jackson offers a few APIs, and the streaming API reportedly works very nicely on Android with top-notch performance.

Visit the Trails!

In addition to this chapter, you can learn more about accessing multimedia files [via the MediaStore](#) and learn more about [the impacts of multiple user accounts on tablets](#).

Tutorial #11 - Adding Simple Content

Now that we have seen how to work with assets, we can start putting them to use, by defining some “help” and “about” HTML files and displaying them in their respective activities.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book’s GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Adding Some Content

Your project may already have an `assets/` folder. If not, create one:

- In Android Studio, right-click over the main sourceset directory, choose New > Directory from the context menu, fill in the name `assets` in the dialog, and click OK
- In Eclipse, right-click over the project in the Package Explorer, choose New > Folder from the context menu, fill in the name `assets` in the dialog, and click Finish

In `assets/`, create a `misc/` sub-folder, by right-clicking over the `assets/` folder and choosing to add a new directory named `misc` (e.g., New > Directory from the Android Studio context menu).

In `assets/misc/`, create two files, `about.html` and `help.html`:

- In Android Studio, right-click over the assets/misc/ folder in the project explorer, choose New > File from the context menu, fill in the desired filename in the dialog, and click OK
- Eclipse users can create files by right-clicking over the folder, choosing New > File from the context menu, supplying the name of the file, and clicking “Finish”.

The actual HTML content of these two files does not matter, so long as you can tell them apart when looking at them. If you prefer, you can download sample [about.html](#) and [help.html](#) files from the application’s GitHub repository, via the links.

Eclipse users should note that the default behavior of double-clicking on an HTML file in the IDE is to open it in some Eclipse-supplied internal browser. This is not especially useful. If you right-click over the file and choose Open With > Text Editor, from that point forward that specific file will be opened in an editor pane you can use to add or edit the HTML you want to have.

Step #2: Using SimpleContentFragment

Now, open up SimpleContentActivity and replace the stub implementation that we have now with the following Java:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {
    public static final String EXTRA_FILE="file";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            String file=getIntent().getStringExtra(EXTRA_FILE);
            Fragment f=SimpleContentFragment.newInstance(file);

            getFragmentManager().beginTransaction()
                .add(android.R.id.content, f).commit();
        }
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

In `onCreate()`, we follow the standard recipe for defining our fragment if (and only if) we were started new, rather than restarted after a configuration change, by seeing if the fragment already exists. If we do need to add the fragment, we retrieve a string extra from the Intent used to launch us (identified as `EXTRA_FILE`), create an instance of `SimpleContentFragment` using that value from the extra, and execute a `FragmentManager` to add the `SimpleContentFragment` to our UI.

Step #3: Launching Our Activities, For Real This Time

Now, what remains is to actually supply that `EXTRA_FILE` value, which we are not doing presently when we start up `SimpleContentActivity` from `EmPubLiteActivity`.

Modify `onOptionsItemSelected()` of `EmPubLiteActivity` to look like this:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case android.R.id.home:
            return(true);

        case R.id.about:
            Intent i=new Intent(this, SimpleContentActivity.class);

            i.putExtra(SimpleContentActivity.EXTRA_FILE,
                "file:///android_asset/misc/about.html");
            startActivity(i);

            return(true);

        case R.id.help:
            i=new Intent(this, SimpleContentActivity.class);

            i.putExtra(SimpleContentActivity.EXTRA_FILE,
                "file:///android_asset/misc/help.html");
            startActivity(i);

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

TUTORIAL #11 - ADDING SIMPLE CONTENT

You are adding the two `putExtra()` calls in the `R.id.about` and `R.id.help` branches of the switch statement. In both cases, we are using a quasi-URL with the prefix `file:///android_asset/`. This points to the root of our project's `assets/` folder. `WebView` knows how to interpret these URLs, to load files out of our assets directly.

Now, if you run the application and choose “Help” from the action bar overflow, you will see your help content on-screen:

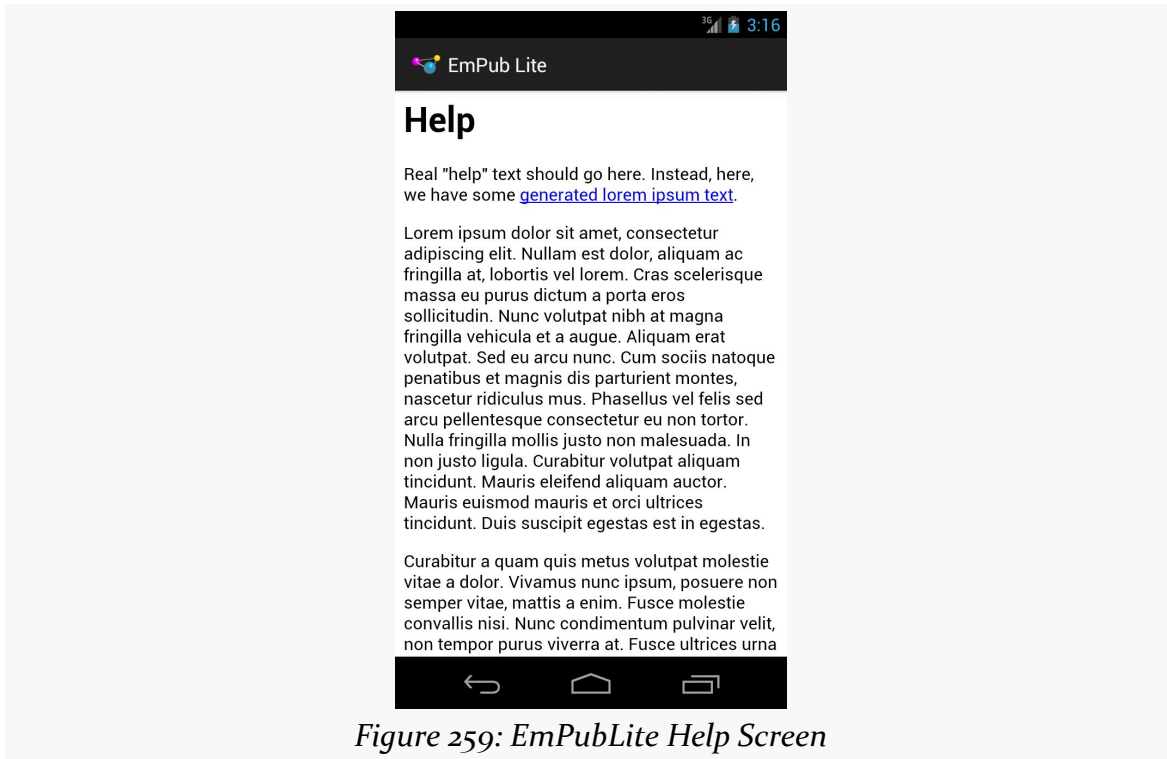

Figure 259: EmPubLite Help Screen

Pressing BACK and choosing “About” from the action bar overflow will bring up your about content:

TUTORIAL #11 - ADDING SIMPLE CONTENT

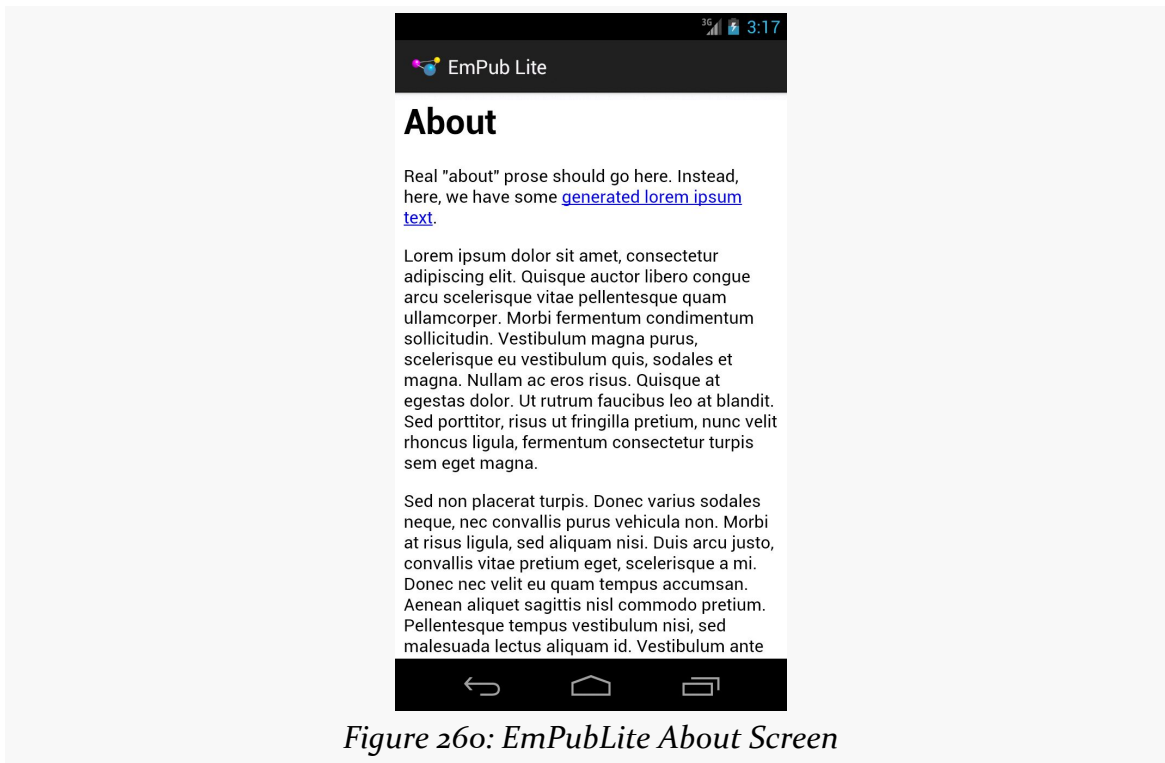

Figure 26o: EmPubLite About Screen

In Our Next Episode...

... we will [display the actual content of our book](#) in our tutorial project.

Tutorial #12 - Displaying the Book

At this point, you are probably wondering when we are *ever* going to have our digital book reader let us read a digital book.

Now, in this tutorial, your patience will be rewarded.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Note that starting in this tutorial, it is assumed that you know how to add `import` statements as needed as we refer to new classes in existing code, and so the required imports are not always going to be specified.

Step #1: Adding a Book

First, we need a book. Expecting you to write a book as part of this tutorial would seem to be a bit excessive. So, instead, we will use an already-written book: [The War of the Worlds](#), by H. G. Wells, as distributed by [Project Gutenberg](#).

EDITOR'S NOTE: We realize that this choice of book may be seen as offensive by Martians, as it depicts them as warlike invaders with limited immune systems. Please understand that this book is a classic of Western literature and reflects the attitude of the times. If you have any concerns about this material, please contact us at martians-so-do-not-exist@commonsware.com.

Download <http://misc.commonsware.com/WarOfTheWorlds.zip> and unpack its contents (a book/ directory of files) into your assets/ folder of your project. IDE users can drag this book/ directory into the project and drop it in assets/ to copy the files to the proper location. You should wind up with assets/book/ and files inside of there.

In that directory, you will find some HTML and CSS files with the prose of the book, plus a contents.json file with metadata. We will examine this metadata in greater detail in the next section.

Step #2: Creating a ModelFragment

This sample project will use [the “model fragment” pattern](#) to hold onto the data about the book to be viewed. The “model fragment” pattern works well for cases where:

- the data is only needed by one activity, not several components, and
- we want to hold onto the data during a configuration change (e.g., screen rotation), so that we do not have to perform some work again to obtain the data

Something has to load that BookContents, ideally in the background, since reading an asset and parsing the JSON will take time. Also, something has to hold onto that BookContents, so it can be used from EmPubLiteActivity and the various chapter fragments in the ViewPager.

To that end, we will create a new class, cunningly named ModelFragment.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the com.commonsware.empublite package in your java/ directory and choose New > Java Class from the context menu. Fill in ModelFragment as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonsware.empublite;
```

```
import android.app.Fragment;

public class ModelFragment extends Fragment {

}
```

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `ModelFragment` in the “Name” field. Then, click the “Browse...” button next to the “Superclass” field and find `android.app.Fragment` to set as the superclass. Then, click “Finish” on the new-class dialog to create the `ModelFragment` class.

Step #3: Defining Our Model

That `contents.json` file contains a bit of metadata about the contents of the book: the book’s title and a roster of its “chapters”:

```
{
  "title": "The War of the Worlds",
  "chapters": [
    {
      "file": "0.htm",
      "title": "Book One: Chapters 1-9"
    },
    {
      "file": "1.htm",
      "title": "Book One: Chapters 10-14"
    },
    {
      "file": "2.htm",
      "title": "Book One: Chapters 14-17"
    },
    {
      "file": "3.htm",
      "title": "Book Two: Chapters 1-7"
    },
    {
      "file": "4.htm",
      "title": "Book Two: Chapters 7-10"
    },
    {
      "file": "5.htm",
      "title": "Project Gutenberg"
    }
  ]
}
```

TUTORIAL #12 - DISPLAYING THE BOOK

In the case of this book from Project Gutenberg, the `assets/book/` directory contains six HTML files which EmPubLite will consider as “chapters”, even though each of those HTML files contains multiple chapters from the source material. You are welcome to reorganize that HTML if you wish, updating `contents.json` to match.

We need to load `contents.json` into memory, so EmPubLite knows how many chapters to display and where those chapters can be found. We will pour `contents.json` into a `BookContents` model object, leveraging the GSON library that we added to our project [in an earlier tutorial](#).

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookContents` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

import java.util.List;

public class BookContents {
    String title;
    List<BookContents.Chapter> chapters;

    int getChapterCount() {
        return(chapters.size());
    }

    String getChapterFile(int position) {
        return(chapters.get(position).file);
    }

    String getTitle() {
        return(title);
    }

    static class Chapter {
        String file;
        String title;
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `BookContents` in the “Name” field. Leave the “Superclass” field alone, as `BookContents` has no explicit superclass. Then, click “Finish” on the new-class dialog to create the `BookContents` class.

Then, with `BookContents` open in the editor, paste in the class definition shown in the Android Studio instructions above.

Step #4: Examining Our Model

`BookContents` is a GSON interpretation of the JSON structure of `contents.json`. `BookContents` holds onto the `title` and `chapters`, with the latter being a `List` of `BookContents.Chapter` objects, each of which holds onto its `file` and `title`.

`BookContents` also supplies three accessor methods:

- `getChapterCount()` to identify the number of chapters (i.e., the size of the `chapters` array in the JSON)
- `getChapterFile()`, to return the relative path within `assets/book/` that represents our “chapter” of HTML
- `getTitle()` to retrieve the book title out of the object

Step #5: Defining Our Event

We will want to load the JSON and create the `BookContents` on a background thread, as we will be performing enough I/O and parsing that we might make our UI a bit sluggish if we do the work on the main application thread. However, we need to let the UI layer (`EmPubLiteActivity` and its `ViewPager`) know when the book is loaded, so it can be poured into the user interface.

We could use an `AsyncTask` for that, notifying the activity in `onPostExecute()`. However, we will need more flexible inter-component communication over time, things that cannot be handled by a simple `AsyncTask`. Hence, we will start using the

TUTORIAL #12 - DISPLAYING THE BOOK

event bus pattern here, employing greenrobot's EventBus library that we added to our project [in a previous tutorial](#).

With EventBus, we create our own event classes. The one event that we have up front is one to indicate that our book metadata has been loaded and is ready for use, in the form of a BookContents object. Hence, in this step of the tutorial, we will define a BookLoadedEvent that will be posted when the book is loaded. And, we will have the event hold onto the BookContents, to lightly simplify populating the UI later on.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the com.commonware.empublite package in your java/ directory and choose New > Java Class from the context menu. Fill in BookLoadedEvent as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

public class BookLoadedEvent {
    private BookContents contents=null;

    public BookLoadedEvent(BookContents contents) {
        this.contents=contents;
    }

    public BookContents getBook() {
        return(contents);
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Eclipse

Right click over the com.commonware.empublite package in the src/ folder of your project, and choose New > Class from the context menu. Fill in BookLoadedEvent in the "Name" field. Leave the "Superclass" field alone, as BookLoadedEvent has no

explicit superclass. Then, click “Finish” on the new-class dialog to create the BookLoadedEvent class.

Then, with BookLoadedEvent open in the editor, paste in the class definition shown in the Android Studio instructions above.

Step #6: Loading Our Model

Now, we need to actually arrange to load the book on a background thread and post our newly-created BookLoadedEvent. This is one of the key jobs of our ModelFragment: to manage the loading of our activity’s model, using background threads.

With that in mind, replace our stub ModelFragment implementation with the following:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.os.Process;
import android.util.Log;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import com.google.gson.Gson;
import de.greenrobot.event.EventBus;

public class ModelFragment extends Fragment {
    private BookContents contents=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);
    }

    @Override
    public void onAttach(Activity host) {
        super.onAttach(host);

        if (contents == null) {
            new LoadThread(host.getAssets()).start();
        }
    }
}
```

```
}

public BookContents getBook() {
    return(contents);
}

private class LoadThread extends Thread {
    private AssetManager assets=null;

    LoadThread(AssetManager assets) {
        super();

        this.assets=assets;
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
        Gson gson=new Gson();

        try {
            InputStream is=assets.open("book/contents.json");
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(is));

            contents=gson.fromJson(reader, BookContents.class);
            EventBus.getDefault().post(new BookLoadedEvent(contents));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

In `onCreate()`, we call `setRetainInstance(true)`, to tell the framework to keep this fragment despite a configuration change, just passing it to the new activity created as a result of that configuration change.

In `onAttach()`, if we do not already have our `BookContents` object, we fork a `LoadThread` to populate it, and we cannot readily get at an `AssetManager` until we are attached to the hosting activity. This is why we are not forking `LoadThread` in `onCreate()`.

`LoadThread` takes the `AssetManager` as a parameter, stashing it in a data member in the `LoadThread` constructor. The constructor also calls `setThreadPriority()` to drop

the thread's priority to that of a background thread. This reduces how much we compete with the main application thread for CPU time.

Then, in the `run()` method that is called on the background thread, we read in the JSON using GSON to create the `BookContents` instance. GSON automatically deserializes our JSON into the `BookContents` and `BookContents.Chapter` instances, given that we are telling the `fromJson()` method that it is to be loading an instance of a `BookContents` object. Finally, we `post()` a `BookLoadedEvent` to the default `EventBus`.

The `open()` method on `AssetManager` could throw an `IOException`. Normally, this indicates a development-time bug (e.g., we failed to actually set up the `book/contents.json` file), which is why we log the message to `LogCat`. A production-grade book reader should also `post()` an `EventBus` event to allow the UI layer to let the user know that we could not load the book. As it stands, the book reader will remain stuck on the `ProgressBar` forever in case of this sort of problem. Augmenting the tutorial in this way is left as an exercise for the reader.

Note that the `LoadThread` implementation has a pair of references to `Process`. In this case, this is `android.os.Process`, not `java.lang.Process`. Since `java.lang.Process` is automatically imported, if you fail to import `android.os.Process`, you will see errors about how `THREAD_PRIORITY_BACKGROUND` and `setThreadPriority()` are not defined. Since we are not using `java.lang.Process` in this class, having the import to `android.os.Process` (as shown in the code listing above) resolves this conflict.

Step #7: Registering for Events

Right now, our `BookLoadedEvent` will be posted... and ignored, as nothing in the application is set up to watch for such events. Our `EmPubLiteActivity` needs to know about these events, and the first step to accomplishing that is to have it register for events in general with the `EventBus`.

Add the following two methods to `EmPubLiteActivity`:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);
}

@Override
public void onPause() {
    EventBus.getDefault().unregister(this);
}
```

```
super.onPause();  
}
```

These simply register the activity with the EventBus while it is in the foreground.

Step #8: Adapting the Content

Before we can use the BookContents, we need to update ContentsAdapter to display the prose on the screen.

First, add a BookContents data member to ContentsAdapter:

```
private BookContents contents=null;
```

Then, add the BookContents parameter to the constructor, assigning it to the new data member:

```
public ContentsAdapter(Activity ctxt, BookContents contents) {  
    super(ctxt.getFragmentManager());  
  
    this.contents=contents;  
}
```

Next, update getCount() to use the getChapterCount() of our BookContents:

```
@Override  
public int getCount() {  
    return(contents.getChapterCount());  
}
```

Finally, modify getItem() to retrieve the relative path for a given chapter from the BookContents and create a SimpleContentFragment on the complete file:///android_asset path to the file in question:

```
@Override  
public Fragment getItem(int position) {  
    String path=contents.getChapterFile(position);  
  
    return(SimpleContentFragment.newInstance("file:///android_asset/book/"  
        + path));  
}
```

Note that you may need to change the parameter name in the getItem() declaration to be position, as it may be another value (e.g., arg0).

Step #9: Showing the Content When Loaded

Now, we can actually add the logic to display the book once it is loaded.

Create a `setupPager()` method on `EmPubLiteActivity` as follows:

```
private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);
    findViewById(R.id.progressBar1).setVisibility(View.GONE);
    pager.setVisibility(View.VISIBLE);
}
```

The contents of this method are almost identical to four lines in `onCreate()` – we have just moved them to a separate method. Remove those duplicate lines from `onCreate()`, so you have:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
}
```

Then, add the following `onEventMainThread()` method to `EmPubLiteActivity`:

```
public void onEventMainThread(BookLoadedEvent event) {
    setupPager(event.getBook());
}
```

This tells `EventBus` that if a `BookLoadedEvent` is posted, we are interested in it, and it should be delivered to our `onEventMainThread()` method on the main application thread.

Step #10: Attaching our ModelFragment

We also need to add some code to set up the `ModelFragment` — it will not magically appear on its own. So, the first time we create an `EmPubLiteActivity`, we want to create our `ModelFragment`. To do that, define a static data member named `MODEL` in `EmPubLiteActivity`:

```
private static final String MODEL="model";
```

TUTORIAL #12 - DISPLAYING THE BOOK

Then, add an `onResume()` method in `EmPubLiteActivity` to see if we already have the fragment before creating one:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        ModelFragment mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            getFragmentManager().beginTransaction()
                .add(new ModelFragment(), MODEL).commit();
        }
        else if (mfrag.getBook() != null) {
            setupPager(mfrag.getBook());
        }
    }
}
```

If you run the result in a device or emulator, you will see the book content appear:

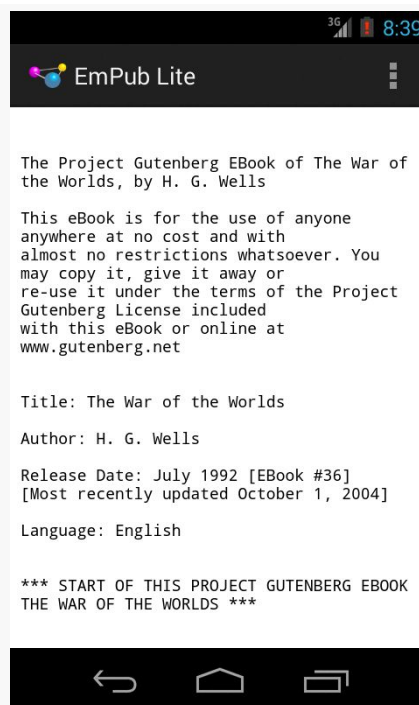

Figure 261: EmPubLite, With Content

Swiping left and right will take you to the other portions of the book.

Step #11: Showing the Content After a Configuration Change

While you can see the book contents now, if you try rotating the screen, the book contents will not appear. That is because the `ModelFragment` has already loaded the contents (so the `BookLoadedEvent` has passed), but we have no logic in `EmPubLiteActivity` to populate the book by other means.

To do that, simply add an `else` clause to the `if` in `onResume()`, to get the book contents over to `setupPager()` if they are ready:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        ModelFragment mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            getFragmentManager().beginTransaction()
                .add(new ModelFragment(), MODEL).commit();
        }
        else if (mfrag.getBook() != null) {
            setupPager(mfrag.getBook());
        }
    }
}
```

Now, if you run the sample and rotate the screen (e.g., `Ctrl-F11` on the Windows/Linux emulator), the book will appear in either case.

NOTE: Bugs in the Android 4.4 and Android 5.0 emulators prevent the app from finding out about the rotation event, and so nothing rotates. Please use an Android 4.3 or earlier emulator, or an actual Android device, for testing this.

Step #12: Going Home, Again

We can now take advantage of the icon in the action bar (a.k.a., the “app icon”), using it to bring us back to the first chapter. While the first chapter in our book is

not very distinctive compared to the other chapters, you might have a table of contents or a cover or something as the first “chapter”.

The big thing that you need to do to support this is add one line to our `android.R.id.home` portion of the `switch()` in `onOptionsItemSelected()`, telling the `ViewPager` to go back to the first page:

```
case android.R.id.home:
    pager.setCurrentItem(0, false);
    return(true);
```

You also need to teach the action bar to support taps on this “app icon”, by adding this line to the bottom of your `onCreate()` of `EmPubLiteActivity`:

```
getActionBar().setHomeButtonEnabled(true);
```

If you run this on a device or emulator, swipe to some later chapter, then tap the icon in the upper-left corner, you will be returned to the first chapter.

Step #13: Setting Up StrictMode

Since we are now starting to do disk I/O, particularly aiming to have it done on background threads, it would be a good idea to configure `StrictMode`, so it will complain if we fail in our quest and accidentally do this I/O on the main application thread.

Add the following method to `EmPubLiteActivity`:

```
private void setupStrictMode() {
    StrictMode.ThreadPolicy.Builder builder=
        new StrictMode.ThreadPolicy.Builder().detectNetwork();

    if (BuildConfig.DEBUG) {
        builder.penaltyDeath();
    }
    else {
        builder.penaltyLog();
    }

    StrictMode.setThreadPolicy(builder.build());
}
```

Here, we create a `StrictMode.ThreadPolicy.Builder`, configured to detect network I/O on the main application thread. If we are in a `DEBUG` build, we will crash the app; otherwise, we will simply log the stack trace to `LogCat`.

TUTORIAL #12 - DISPLAYING THE BOOK

You might wonder why we are not checking for disk I/O, since the opening paragraph of this section suggested that is what we would be doing. Ideally, we would have `detectDiskReads()` and `detectDiskWrites()` calls in here as well to enable those checks. Unfortunately, Google engineers do not check the framework code for these sorts of violations, leading to some bugs that we as app developers cannot resolve. As a result, for the purposes of this tutorial, we will not check for those problems.

Then, just after `super.onCreate()` in the `onCreate()` in `EmPubLiteActivity`, add in a call to the new `setupStrictMode()` method. This will give you an `onCreate()` method that looks like:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setupStrictMode();

    setContentView(R.layout.main);
    pager=(ViewPager)findViewById(R.id.pager);

    getActionBar().setHomeButtonEnabled(true);
}
```

If you set up an emulator running Android 5.0, please switch to an emulator running Android 4.3 or older. Android 5.0 has [a bug](#) which causes a `StrictMode` violation when we use our `WebViewFragment`.

Otherwise, if you run the app, nothing unusual should happen, which is good.

In Our Next Episode...

... we will allow the user to [manipulate some preferences](#) in our tutorial project.

Using Preferences

Android has many different ways for you to store data for long-term use by your activity. The simplest ones to use are `SharedPreferences` and simple files.

Android allows activities and applications to keep preferences, in the form of key/value pairs (akin to a `Map`), that will hang around between invocations of an activity. As the name suggests, the primary purpose is for you to store user-specified configuration details, such as the last feed the user looked at in your feed reader, or what sort order to use by default on a list, or whatever. Of course, you can store in the preferences whatever you like, so long as it is keyed by a `String` and has a primitive value (`boolean`, `String`, etc.)

Preferences can either be for a single activity or shared among all activities in an application. Other components, such as services, also can work with shared preferences.

Getting What You Want

To get access to the preferences, you have three APIs to choose from:

- `getPreferences()` from within your Activity, to access activity-specific preferences
- `getSharedPreferences()` from within your Activity (or other application Context), to access application-level preferences
- `getDefaultSharedPreferences()`, on `PreferenceManager`, to get the shared preferences that work in concert with Android's overall preference framework

The first two take a security mode parameter. The right answer here is `MODE_PRIVATE`, so no other applications can access the file. The `getSharedPreferences()` method also takes a name of a set of preferences; `getPreferences()` effectively calls `getSharedPreferences()` with the activity's class name as the preference set name. The `getDefaultSharedPreferences()` method takes the `Context` for the preferences (e.g., your `Activity`).

All of those methods return an instance of `SharedPreferences`, which offers a series of getters to access named preferences, returning a suitably-typed result (e.g., `getBoolean()` to return a boolean preference). The getters also take a default value, which is returned if there is no preference set under the specified key.

Unless you have a good reason to do otherwise, you are best served using the third option above — `getDefaultSharedPreferences()` — as that will give you the `SharedPreferences` object that works with a `PreferenceActivity` by default, as will be described [later in this chapter](#).

Stating Your Preference

Given the appropriate `SharedPreferences` object, you can use `edit()` to get an “editor” for the preferences. This object has a set of setters that mirror the getters on the parent `SharedPreferences` object. It also has:

1. `remove()` to get rid of a single named preference
2. `clear()` to get rid of all preferences
3. `apply()` or `commit()` to persist your changes made via the editor

The last one is important — if you modify preferences via the editor and fail to save the changes, those changes will evaporate once the editor goes out of scope. `commit()` is a blocking call, while `apply()` works asynchronously. Ideally, use `apply()` where possible, though it was only added in Android 2.3, so it may not be available to you if you are aiming to support earlier versions of Android than that.

Conversely, since the preferences object supports live changes, if one part of your application (say, an activity) modifies shared preferences, another part of your application (say, a service) will have access to the changed value immediately.

Introducing PreferenceActivity

You could roll your own activity to collect preferences from the user. On the whole, this is a bad idea. Instead, use preference XML resources and a PreferenceActivity.

Why?

One of the common complaints about Android developers is that they lack discipline, not following any standards or conventions inherent in the platform. For other operating systems, the device manufacturer might prevent you from distributing apps that violate their human interface guidelines. With Android, that is not the case — but this is not a blanket permission to do whatever you want. Where there is a standard or convention, please follow it, so that users will feel more comfortable with your app and their device.

Using a PreferenceActivity for collecting preferences is one such convention.

The linchpin to the preferences framework and PreferenceActivity is yet another set of XML data structures. You can describe your application's preferences in XML files stored in your project's `res/xml/` directory. Given that, Android can present a pleasant UI for manipulating those preferences, which are then stored in the `SharedPreferences` you get back from `getDefaultSharedPreferences()`.

To see how all of this works, take a look at the [Prefs/FragmentsBC](#) sample project.

What We Are Aiming For

This project's main activity hosts a `TableLayout`, into which we will load the values of five preferences:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/checkbox"/>

        <TextView
            android:id="@+id/checkbox"
            style="@style/value"/>

    </TableRow>

</TableLayout>
```

```
</TableRow>

<TableRow>

    <TextView
        style="@style/label"
        android:text="@string/ringtone"/>

    <TextView
        android:id="@+id/ringtone"
        style="@style/value"/>
</TableRow>

<TableRow>

    <TextView
        style="@style/label"
        android:text="@string/checkbox2"/>

    <TextView
        android:id="@+id/checkbox2"
        style="@style/value"/>
</TableRow>

<TableRow>

    <TextView
        style="@style/label"
        android:text="@string/text"/>

    <TextView
        android:id="@+id/text"
        style="@style/value"/>
</TableRow>

<TableRow>

    <TextView
        style="@style/label"
        android:text="@string/list"/>

    <TextView
        android:id="@+id/list"
        style="@style/value"/>
</TableRow>
</TableLayout>
```

The above layout is used by `PreferenceContentsFragment`, which populates the right-hand column of `TextView` widgets at runtime in `onResume()`, pulling the values from the default `SharedPreferences` for our application:

USING PREFERENCES

```
package com.commonware.android.preffragsbc;

import android.app.Fragment;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;

public class PreferenceContentsFragment extends Fragment {
    private TextView checkbox=null;
    private TextView ringtone=null;
    private TextView checkbox2=null;
    private TextView text=null;
    private TextView list=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.content, parent, false);

        checkbox=(TextView)result.findViewById(R.id.checkbox);
        ringtone=(TextView)result.findViewById(R.id.ringtone);
        checkbox2=(TextView)result.findViewById(R.id.checkbox2);
        text=(TextView)result.findViewById(R.id.text);
        list=(TextView)result.findViewById(R.id.list);

        return(result);
    }

    @Override
    public void onResume() {
        super.onResume();

        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(getActivity());

        checkbox.setText(Boolean.valueOf(prefs.getBoolean("checkbox",
false)).toString());
        ringtone.setText(prefs.getString("ringtone", "<unset>"));
        checkbox2.setText(Boolean.valueOf(prefs.getBoolean("checkbox2",
false)).toString());
        text.setText(prefs.getString("text", "<unset>"));
        list.setText(prefs.getString("list", "<unset>"));
    }
}
```

The main activity, `FragmentsDemo`, simply loads `res/layout/main.xml`, which contains a `<fragment>` element pointing at `PreferenceContentsFragment`. It also defines an options menu, which we will examine later in this section.

USING PREFERENCES

The result is an activity showing the default values of the preferences when it is first run, since we have not set any values yet:

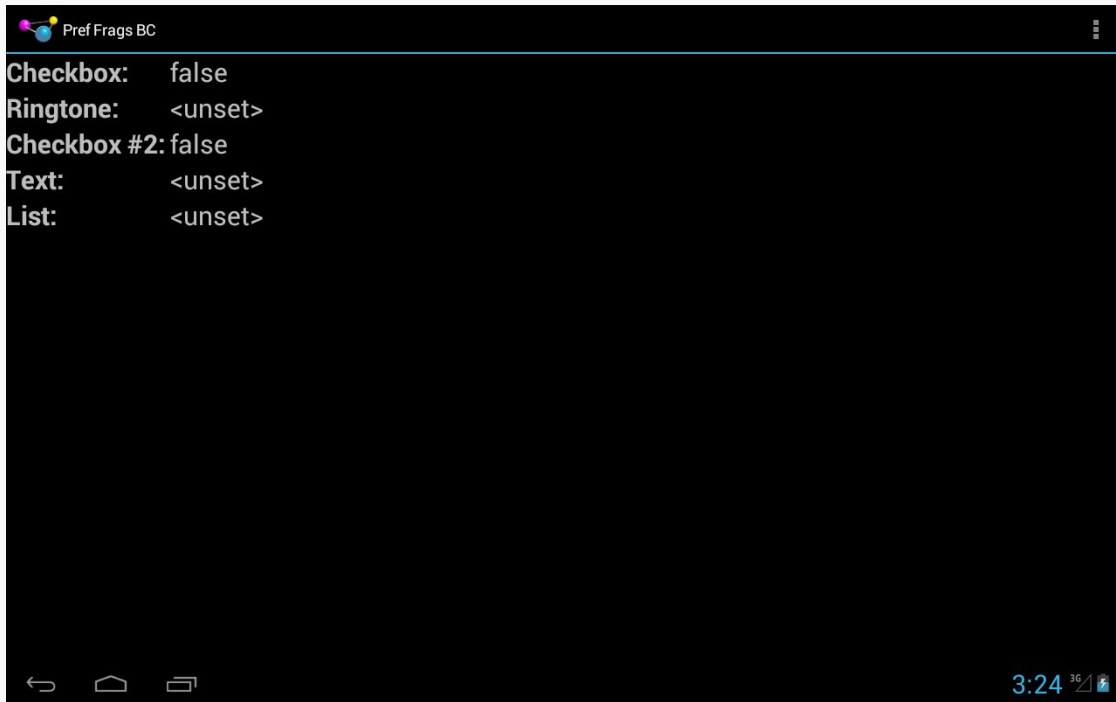

Figure 262: Activity Showing Preference Values

We will also have two flavors of a `PreferenceActivity`, to collect the preferences from the user. Those preferences will be divided into two “preference headers”, following the two-pane preference UI adopted with Android 3.0:

USING PREFERENCES

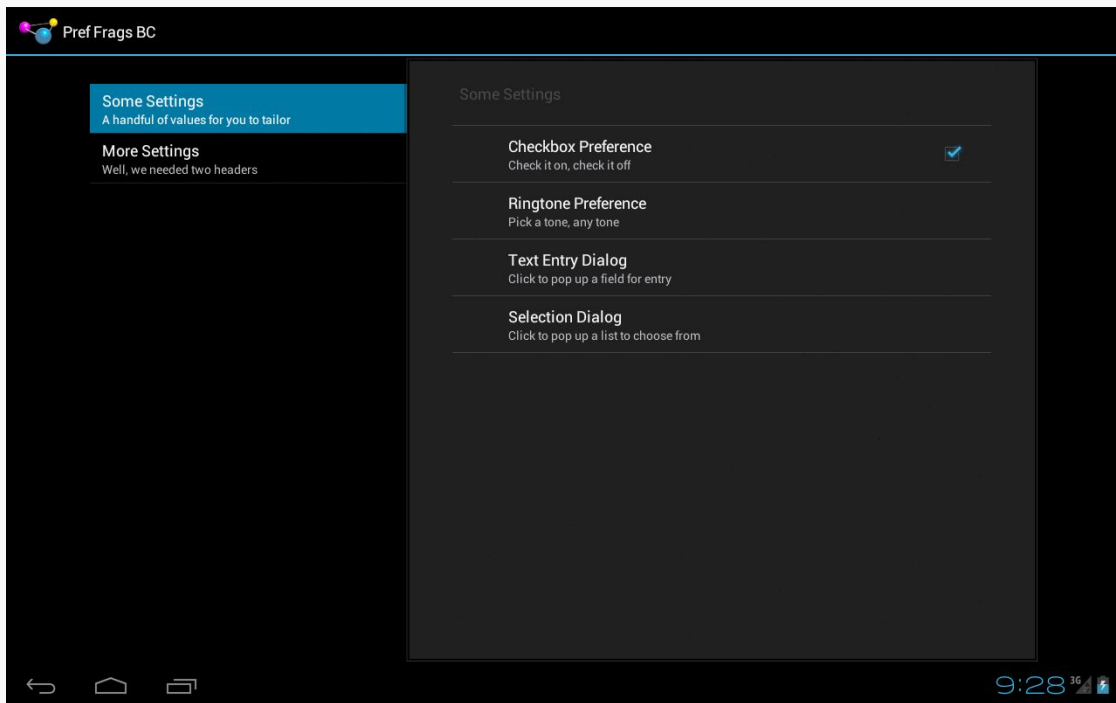

Figure 263: Android 4.0 PreferenceActivity, on Tablet

On a phone-sized screen, those panes become two separate screens, the first showing the list of headers:

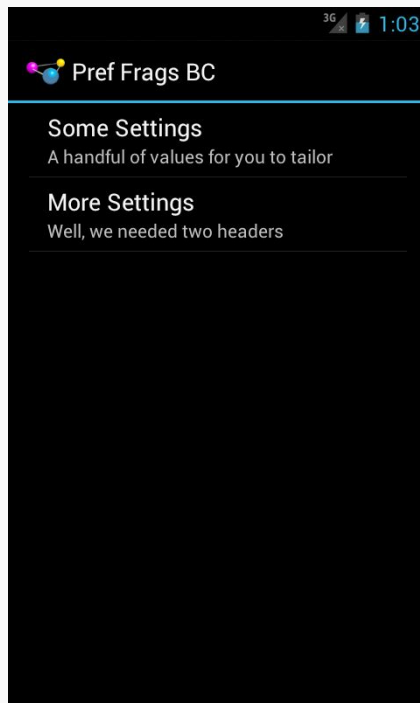

Figure 264: Android 4.0 PreferenceActivity, on Phone

and the second showing the contents of a specific header:

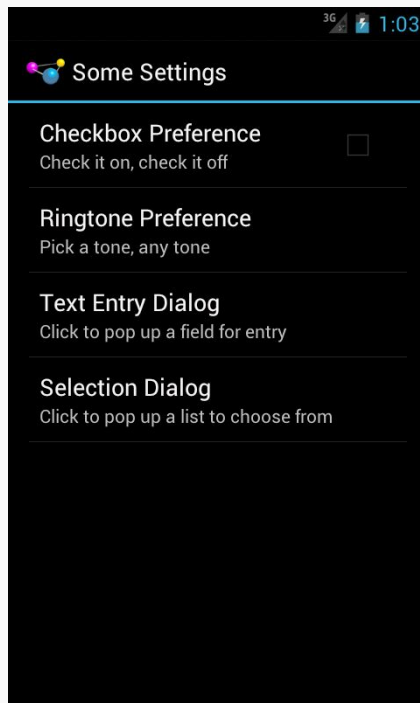

Figure 265: Android 4.0 PreferenceActivity, on Phone, Showing Second Preference Header

Defining Your Preferences

First, you need to tell Android what preferences you are trying to collect from the user.

To do this, you will need to add a `res/xml/` directory to your project, if one does not already exist. Then, for each preference header, you will want an XML file in `res/xml/` to contain the definition of the preferences you want to appear in that header.

The root element of this XML file will be `<PreferenceScreen>`, and it will contain child elements, one per preference.

For example, here is the second preference header's preferences, from `res/xml/preference2.xml`:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
    <CheckBoxPreference
        android:key="checkbox2"
        android:summary="@string/pref5summary"
```

```
    android:title="@string/pref5title"/>
</PreferenceScreen>
```

There is a single `<CheckBoxPreference>` element inside the `<PreferenceScreen>`, allowing the user to toggle a boolean value via a `CheckBox` widget.

Each preference element has two attributes at minimum:

1. `android:key`, which is the key you use to look up the value in the `SharedPreferences` object via methods like `getInt()`
2. `android:title`, which is a few words identifying this preference to the user

You may also wish to consider having `android:summary`, which is a short sentence explaining what the user is to supply for this preference

We will examine more preference elements [later in this chapter](#).

Defining Your Preference Headers

There is another XML resource you will need to define, one containing details about your preference headers. In this sample project, that is found in `res/xml/preference_headers.xml`:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
    <header
        android:fragment="com.commonware.android.preffrgsbc.EditPreferences$First"
        android:summary="@string/header1summary"
        android:title="@string/header1title">
    </header>
    <header
        android:fragment="com.commonware.android.preffrgsbc.EditPreferences$Second"
        android:summary="@string/header2summary"
        android:title="@string/header2title">
    </header>
</preference-headers>
```

Here, your root element is `<preference-headers>`, containing a series of `<header>` elements. Each `<header>` contains at least three attributes:

1. `android:fragment`, which identifies the Java class implementing the `PreferenceFragment` to use for this header, as is described in the next section

2. `android:title`, which is a few words identifying this header to the user

Once again, you may wish to also include `android:summary`, which is a short sentence explaining what the user will find inside of this header.

You can, if you wish, include one or more `<extra>` child elements inside the `<header>` element. These values will be put into the “arguments” `Bundle` that your `PreferenceFragment` can retrieve via `getArguments()`.

Creating Your PreferenceFragments

Preference XML, on API Level 11 and higher, is loaded by an implementation of `PreferenceFragment`. The mission of `PreferenceFragment` is to call `addPreferencesFromResource()` in `onCreate()`, supplying the resource ID of the preference XML to load for a particular preference header (e.g., `R.xml.preferences2`).

There are two ways you can go about doing this. One is to create a dedicated `PreferenceFragment` subclass per preference header. The other is to create a single reusable `PreferenceFragment` implementation that can load up the preference XML for any preference header.

This sample app takes the former approach. Our `PreferenceActivity` implementation — named `EditPreferences` — has a pair of static inner classes representing the preference fragments:

```
public static class First extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        addPreferencesFromResource(R.xml.preferences);
    }
}

public static class Second extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        addPreferencesFromResource(R.xml.preferences2);
    }
}
```

Each of those `PreferenceFragment` implementations has an `onCreate()` method that calls `addPreferencesFromResource()` for its specific preferences.

We will illustrate the other approach, of creating a reusable PreferenceFragment, later in this chapter.

Creating Your PreferenceActivity

Our PreferenceActivity subclass is named EditPreferences, which contains little more than the two fragments shown above:

```
package com.commonware.android.preffragsbc;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        if (First.class.getName().equals(fragmentName)
            || Second.class.getName().equals(fragmentName)) {
            return(true);
        }

        return(false);
    }

    public static class First extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences);
        }
    }

    public static class Second extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences2);
        }
    }
}
```

`onBuildHeaders()` is where we supply the preference headers, via a call to `loadHeadersFromResource()`.

We also need to have an `isValidFragment()` method, that will return `true` if the supplied fragment name is one we should be showing in this `PreferenceActivity`, `false` otherwise. This will only be called on Android 4.4+. However, we need to set up the project build target (e.g., `compileSdkVersion` in Android Studio, `Project > Preferences > Android` in Eclipse) to API Level 19 or higher. Failing to have this method will cause your app to crash on Android 4.4+ devices, when the user tries to bring up one of your `PreferenceFragments`.

Types of Preferences

There are a variety of subclasses of `Preference` in the Android SDK for use with `PreferenceActivity`. This section will outline the major ones as of Android 4.4. [Later in the book](#) we will examine how to create your own custom `Preference` classes.

CheckBoxPreference and SwitchPreference

The sample application shown above has a pair of `CheckBoxPreference` elements, one per preference XML file. A `CheckBoxPreference` is an “inline” preference, in that the widget the user interacts with (in this case, a `CheckBox`) is part of the preference screen itself, rather than contained in a separate dialog.

`SwitchPreference` is functionally equivalent to `CheckBoxPreference`, insofar as both collect boolean values from the user. The difference is that `SwitchPreference` uses a `Switch` widget that the user slides left and right to toggle between “on” and “off” states. Also note that `SwitchPreference` was added in API Level 14 and therefore will not be available to older Android versions.

EditTextPreference

`EditTextPreference`, when tapped by the user, pops up a dialog that contains an `EditText` widget. You can configure this widget via attributes on the `<EditTextPreference>` element — in addition to standard preference attributes like `android:key`, you can include any attribute understood by `EditText`, such as `android:inputType`.

The value stored in the `SharedPreferences` is a string.

RingtonePreference

RingtonePreference pops up a dialog with a list of ringtones installed on the device or emulator. However, note that the Android emulator does not come with any ringtones at the present time.

In addition to the standard preference attributes, you can include `android:showDefault`, indicating that the list should contain a “Default ringtone” option. If the user chooses this ringtone, they are effectively choosing the same ringtone that they have set up for incoming phone calls.

You can also use `android:showSilent`, which allows the user to choose a “Silence” pseudo-ringtone, to indicate not to play any ringtone.

For example, `res/xml/preferences.xml` from the sample project contains a RingtonePreference:

```
<RingtonePreference
    android:key="ringtone"
    android:showDefault="true"
    android:showSilent="true"
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>
```

The value stored in the SharedPreferences is a string, specifically the string representation of a Uri pointing to a ContentProvider that can serve up the ringtone for playback. The use of ContentProvider will be covered [in a later chapter](#), and playing back media like ringtones will be covered [in another later chapter](#).

ListPreference and MultiSelectListPreference

Visually, a ListPreference looks just like RingtonePreference, except that you control what goes into the list. You do this by specifying a pair of string-array resources in your preference XML.

String resources hold individual strings; string array resources hold a collection of strings. Typically, you will find string array resources in `res/values/arrays.xml` and related resource sets for translation. The `<string-array>` element has the `name` attribute to identify the resource, along with child `<item>` elements for the individual strings in the array.

For example, the sample application profiled in this chapter has a pair of string array resources in `res/values/arrays.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="cities">
    <item>Philadelphia</item>
    <item>Pittsburgh</item>
    <item>Allentown/Bethlehem</item>
    <item>Erie</item>
    <item>Reading</item>
    <item>Scranton</item>
    <item>Lancaster</item>
    <item>Altoona</item>
    <item>Harrisburg</item>
  </string-array>
  <string-array name="airport_codes">
    <item>PHL</item>
    <item>PIT</item>
    <item>ABE</item>
    <item>ERI</item>
    <item>RDG</item>
    <item>AVP</item>
    <item>LNS</item>
    <item>A00</item>
    <item>MDT</item>
  </string-array>
</resources>
```

One of these (`cities`) will be the values the user sees in the list, and is associated with our preference via the `android:entries` attribute. The other (`airport_codes`) will be the *corresponding* values stored in the `SharedPreferences` as a string, and is associated with our preference via the `android:entryValues` attribute:

```
<ListPreference
  android:dialogTitle="@string/listdialogtitle"
  android:entries="@array/cities"
  android:entryValues="@array/airport_codes"
  android:key="list"
  android:summary="@string/pref4summary"
  android:title="@string/pref4title"/>
```

We also use `android:dialogTitle` to provide the caption for the dialog:

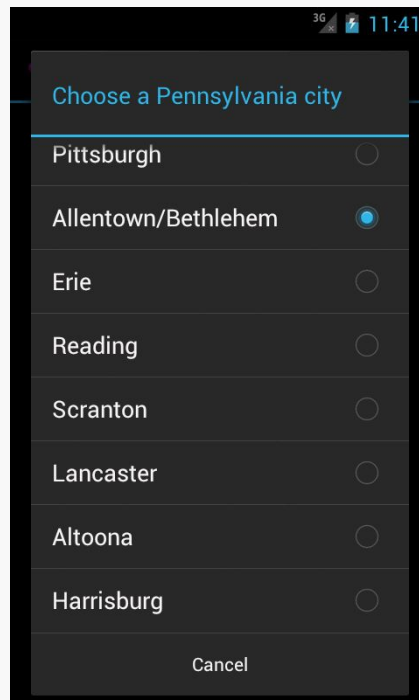

Figure 266: ListPreference on Android 4.0.3

When the user chooses a value (e.g., “Allentown/Bethlehem”), the corresponding value out of the other string array resource is stored in the SharedPreferences (e.g., “ABE”).

MultiSelectListPreference works much the same way, except:

- The list contains checkboxes, not radio buttons
- The user can check multiple items
- The result is stored in a “string set” in the SharedPreferences, retrieved via `getStringSet()`
- It is only available on API Level 11 and higher

Intents for Headers or Preferences

If you have the need to collect some preferences that are beyond what the standard preferences can handle, you have some choices.

One is to create a custom Preference. Extending `DialogPreference` to create your own Preference implementation is not especially hard. However, it does constrain you to something that can fit in a dialog.

Another option is to specify an `<intent>` element as a child of a `<header>` element. When the user taps on this header, your specified Intent is used with `startActivity()`, giving you a gateway to your own activity for collecting things that are beyond what the preference UI can handle. For example, you could have the following `<header>`:

```
<header android:icon="@drawable/something"
        android:title="Fancy Stuff"
        android:summary="Click here to transcend your
plane of existence">
  <intent android:action="com.commonware.android.MY_CUSTOM_ACTION" />
</header>
```

Then, so long as you have an activity with an `<intent-filter>` specifying your desired action (`com.commonware.android.MY_CUSTOM_ACTION`), that activity will get control when the user taps on the associated header.

Conditional Headers

The two-tier, headers-and-preferences approach is fine and helps to organize large rosters of preferences. However, it does tend to steer developers in the direction of displaying headers *all of the time*. For many apps, that is rather pointless, because there are too few preferences to collect to warrant having more than one header.

One alternative approach is to use the headers on larger devices, but skip them on smaller devices. That way, the user does not have to tap past a single-item `ListFragment` just to get to the actual preferences to adjust.

This is a wee bit tricky to implement. However, you have two options for how to accomplish it.

(The author would like to thank Richard Le Mesurier, whose question on this topic spurred the development of this section and its samples)

Option #1: Do Not Define the Headers

The basic plan in the first approach is to have smarts in `onBuildHeaders()` to handle this. `onBuildHeaders()` is the callback that Android invokes on our

USING PREFERENCES

`PreferenceActivity` to let us define the headers to use in the master-detail pattern. If we want to have headers, we would supply them here; if we want to skip the headers, we would instead fall back to the classic (and, admittedly, deprecated) `addPreferencesFromResource()` method to load up some preference XML.

There is an `isMultiPane()` method on `PreferenceActivity`, starting with API Level 11, that will tell you if the activity will render with two fragments (master+detail) or not. In principle, this would be ideal to use. Unfortunately, it does not seem to be designed to be called from `onBuildHeaders()`. Similarly, `addPreferencesFromResource()` does not seem to be callable from `onBuildHeaders()`. Both are due to timing: `onBuildHeaders()` is called in the middle of the `PreferenceActivity` `onCreate()` processing.

So, we have to do some fancy footwork.

By examining [the source code to PreferenceActivity](#), you will see that the logic that drives the single-pane vs. dual-pane UI decision boils down to:

```
onIsHidingHeaders() || !onIsMultiPane()
```

If that expression returns true, we are in single-pane mode; otherwise, we are in dual-pane mode. `onIsHidingHeaders()` will normally return false, while `onIsMultiPane()` will return either true or false based upon screen size.

So, we can leverage this information in a `PreferenceActivity` to conditionally load our headers, as seen in the `EditPreferences` class in the [Prefs/SingleHeader](#) sample project:

```
package com.commonware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    private boolean needResource=false;

    @SuppressWarnings("deprecation")
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (needResource) {
            addPreferencesFromResource(R.xml.preferences);
        }
    }
}
```

```
@Override
public void onBuildHeaders(List<Header> target) {
    if (onIsHidingHeaders() || !onIsMultiPane()) {
        needResource=true;
    }
    else {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }
}

@Override
protected boolean isValidFragment(String fragmentName) {
    return (StockPreferenceFragment.class.getName().equals(fragmentName));
}
}
```

Here, if we are in dual-pane mode, `onBuildHeaders()` populates the headers as normal. If, though, we are in single-pane mode, we skip that step and make note that we need to do some more work in `onCreate()`.

Then, in `onCreate()`, if we did not load our headers we use the classic `addPreferencesFromResource()` method.

The net result is that on Android 3.0+ tablets, we get the dual-pane, master-detail look with our one header, but on smaller devices (regardless of version), we roll straight to the preferences themselves.

Note that this sample application uses a single `PreferenceFragment` implementation, named `StockPreferenceFragment`:

```
package com.commonware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceFragment;

public class StockPreferenceFragment extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        int res=
            getActivity().getResources()
                .getIdentifier(getArguments().getString("resource"),
                    "xml",
                    getActivity().getPackageName());

        addPreferencesFromResource(res);
    }
}
```

USING PREFERENCES

StockPreferenceFragment does what it is supposed to: call `addPreferencesFromResource()` in `onCreate()` with the resource ID of the preferences to load. However, rather than hard-coding a resource ID, as we normally would, we look it up at runtime.

The `<extra>` elements in our preference header XML supply the name of the preference XML to be loaded:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
    <header
        android:fragment="com.commonware.android.pref1header.StockPreferenceFragment"
        android:summary="@string/header1summary"
        android:title="@string/header1title">
        <extra
            android:name="resource"
            android:value="preferences"/>
        </header>
</preference-headers>
```

We get that name via the arguments Bundle (`getArguments().getString("resource")`).

To look up a resource ID at runtime, we can use the `Resources` object, available from our activity via a call to `getResources()`. `Resources` has a method, `getIdentifier()`, that will return a resource ID given three pieces of information:

1. The base name of the resource (in our case, the value retrieved from the `<extra>` element)
2. The type of the resource (e.g., "xml")
3. The package holding the resource (in our case, our own package, retrieved from our activity via `getPackageName()`)

Note that `getIdentifier()` uses reflection to find this value, and so there is some overhead in the process. Do not use `getIdentifier()` in a long loop – cache the value instead.

The net is that `StockPreferenceFragment` loads the preference XML described in the `<extra>` element, so we do not need to create separate `PreferenceFragment` implementations per preference header.

Option #2: Go Directly to the Fragment

The advantage of the above approach is that it works with Android's own logic of whether to display the master-detail fragments or just one at a time. However, that logic — the fact that `onIsHidingHeaders() || !onIsMultiPane()` determines the look of the activity — is not documented, and therefore may change in future Android releases.

Another option is to launch your `PreferenceActivity` in such a way that tells Android to skip showing the headers. This approach is better documented and therefore perhaps more stable. This can also be used in cases where you do want headers sometimes, but at other times you want to route the user to a specific `PreferenceFragment`. The downside is that this technique only works on API Level 11+.

To see how this works, take a look at the [Prefs/SingleHeader2](#) sample project.

Our `EditPreferences` class is the same implementation as in the original sample for this chapter, except that we only load up the single XML resource's worth of preferences:

```
package com.commonware.android.pref1header;

import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        return (StockPreferenceFragment.class.getName().equals(fragmentName));
    }
}
```

However, there is a change in our main activity (`FragmentsDemo`). Before, when the user chose the “Settings” action bar overflow item, we would just call `startActivity()` to bring up `EditPreferences`. Now, we delegate that work to an `editPrefs()` method on `FragmentsDemo`, which will have the smarts to control *how* we bring up the `EditPreferences` activity:

USING PREFERENCES

```
private void editPrefs() {
    Intent i=new Intent(this, EditPreferences.class);

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT,
               StockPreferenceFragment.class.getName());

    Bundle b=new Bundle();

    b.putString("resource", "preferences");

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT_ARGUMENTS, b);

    startActivity(i);
}
```

Here, we will add two extras to our Intent:

- EXTRA_SHOW_FRAGMENT, set to the fully-qualified class name of the PreferenceFragment to be displayed, here obtained by calling getName() on the Class object for StockPreferenceFragment
- EXTRA_SHOW_FRAGMENT_ARGUMENTS, set to a Bundle containing the same values that would ordinarily be loaded from the <extra> elements in the preference header XML resource (in our case, the name of the preference XML resource to load)

Those extras will be automatically handled by PreferenceActivity (on API Level 11+) and will have the effect of directly taking the user to our one-and-only fragment, bypassing the headers.

Tutorial #13 - Using Some Preferences

Now that we have the core reading functionality working, we can start to add other features for the user.

One common thing in Android applications is to collect preferences from the user, tailoring the way the app behaves. In the case of EmPubLite, we will initially track two preferences:

- Whether the user wants to return to the book on the same chapter (page in the ViewPager) that they were on when they last were reading the book
- Whether the user wants us to keep the screen on, so they do not have to keep tapping the screen to prevent Android's automatic sleep mode from kicking in

In this tutorial, we will collect and use these two preferences.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Defining the Preference XML Files

We need two XML files to define what preferences we wish to collect. One will define the preference headers (the left column of the two-pane tablet preference UI).

TUTORIAL #13 - USING SOME PREFERENCES

The other will define the preferences that we wish to collect for the one header we will define.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Add six new `<string>` elements to `res/values/strings.xml`:

```
<string name="prefdesc">Settings for use of EmPubLite</string>
<string name="preftitle">Display and Navigation</string>
<string name="lastpositiontitle">Save Last Position</string>
<string name="lastpositionsummary">Save the last chapter you were viewing and
open up on that chapter when re-opening the app</string>
<string name="keepscreenon_summary">Keep the screen powered on while the reader
is in the foreground</string>
<string name="keepscreenon_title">Keep Screen On</string>
```

Right click over `res/` in your project, and choose `New > "Android resource directory"` from the context menu. Change the "Resource type" drop-down to be "xml", then click OK to create the directory.

Then, right-click over your new `res/xml/` directory and choose `New > "XML resource file"` from the context menu. Fill in `preference_headers.xml` in the "New XML Resource File" dialog, then click OK to create the file. It will open up into an XML editor, into which you can paste the following content:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
    <header
        android:fragment="com.commonware.empublite.Preferences$Display"
        android:summary="@string/prefdesc"
        android:title="@string/preftitle">
        <extra
            android:name="resource"
            android:value="pref_display"/>
        </header>
</preference-headers>
```

Repeat the above steps to create a `res/xml/pref_display.xml` file, with the following content:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:empub="http://schemas.android.com/apk/res-auto">
```

```
<CheckBoxPreference
    android:defaultValue="false"
    android:key="saveLastPosition"
    android:summary="@string/lastpositionsummary"
    android:title="@string/lastpositiontitle"/>
<CheckBoxPreference
    android:defaultValue="false"
    android:key="keepScreenOn"
    android:summary="@string/keepscreenon_summary"
    android:title="@string/keepscreenon_title"/>
</PreferenceScreen>
```

Eclipse

Double-click on the `res/values/strings.xml` file in your Package Explorer. Use the “Add...” button to define a new string resource, with a name of `prefdesc` and a value of `Settings` for use of `EmPubLite`. Then, use the “Add...” button again to define another string resource, with a name of `preftitle` and a value of `Display` and `Navigation`. Repeat the process with four more string resources:

- `lastpositionsummary` = Save the last chapter you were viewing and open up on that chapter when re-opening the app
- `lastpositiontitle` = Save Last Position
- `keepscreenon_summary` = Keep the screen powered on while the reader is in the foreground
- `keepscreenon_title` = Keep Screen On

Right-click over the `res/` folder, and choose `New > Folder` from the context menu. Fill in `xml` as the folder name, then click “Finish” to create the folder.

Right-click over the `xml/` folder, and choose `New > File` from the context menu. Fill in `preference_headers.xml` as the name and `preference-headers` as the root element, then click “Finish” to create the file. Switch to the `preference_headers.xml` sub-tab of the newly-opened editor and paste in the following:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
    <header
        android:fragment="com.commonware.empublite.Preferences$Display"
        android:summary="@string/prefdesc"
        android:title="@string/preftitle">
        <extra
            android:name="resource"
            android:value="pref_display"/>
        </header>
```

```
</preference-headers>
```

You will get an error from Eclipse complaining that `com.commonsware.empublite.Preferences$Display` is not recognized — we will correct that problem later in this tutorial.

Then, right-click over the `xml` folder, and choose `New > File` from the context menu. Fill in `pref_display.xml` as the name, leaving the root element alone, then click “Finish” to create the file. Switch to the `pref_display.xml` sub-tab of the newly-opened editor and paste in the following:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:empub="http://schemas.android.com/apk/res-auto">

    <CheckBoxPreference
        android:defaultValue="false"
        android:key="saveLastPosition"
        android:summary="@string/lastpositionsummary"
        android:title="@string/lastpositiontitle"/>
    <CheckBoxPreference
        android:defaultValue="false"
        android:key="keepScreenOn"
        android:summary="@string/keepscreenon_summary"
        android:title="@string/keepscreenon_title"/>

</PreferenceScreen>
```

Note that while the code listing may show the root element wrapping onto a second line, it really should be all on one line.

Step #2: Creating Our PreferenceActivity

We now need an implementation of `PreferenceActivity`, named `Preferences`, to load our preference XML, using a static inner class implementation of a `PreferenceFragment`, named `Display`.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `Preferences` as the name and click `OK` to create the empty class.

In the `Preferences` class that is created, replace the current implementation with the following:

```
package com.commonware.empublite;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class Preferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        if (Display.class.getName().equals(fragmentName)) {
            return(true);
        }

        return(false);
    }

    public static class Display extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.pref_display);
        }
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Then, open up `AndroidManifest.xml` and add the following `<activity>` element inside the `<application>` element:

```
<activity android:name="Preferences"></activity>
```

Eclipse

Right-click over the EmPubLite project in the Package Explorer, then choose New > Other from the context menu. In the list of possible things to add to your project, choose “Android Activity” and click Next. In the list of templates, choose “Empty Activity” and click Next.

In the last page of the new-activity wizard, fill in:

- Preferences in the “Activity Name” field
- pleasedeleteme for the “Layout Name”
- pleasedeletemetoo for the “Title”

Leave the rest of the wizard at its defaults, then click on Finish.

In the Preferences class that is created, replace the current implementation with the source shown in the Android Studio instructions above.

You can also delete the `/res/layout/pleasedeleteme.xml` file, by right-clicking over it and choosing “Delete...” from the context menu.

Finally, open up `res/values/strings.xml` and delete the `title_activity_simple_content` that the wizard added, which we are no longer using. At this point, you can save your changes to this file (e.g., `<Ctrl>-<S>`).

Step #3: Adding To Our Action Bar

Of course, having this activity does us no good if we cannot start it up, so we need to add another hook to our action bar configuration for that.

First, copy the `13_extra_actions_settings` icons from the Action Bar Icons/ `holo_dark/` directory from the “Action Bar Icon Pack” into your project. In the `13_extra_actions_settings` directory, you will see versions of this icon in various densities. Copy those icon files into their corresponding directories in your project. You can do this by dragging the file from your development desktop OS into the project explorer window and dropping it into the proper directory.

Add the following XML element to `res/menu/options.xml` as the first child of the `<menu>` root element:

```
<item
    android:id="@+id/settings"
    android:icon="@drawable/ic_action_settings"
    android:showAsAction="never"
    android:title="@string/settings">
</item>
```

You will also need to add a settings string resource, with a value of Settings:

```
<string name="settings">Settings</string>
```

Step #4: Launching the PreferenceActivity

The only thing yet needed to allow the user to get to the preferences is to add another case to the switch() statement in onOptionsItemSelected() of EmPubLiteActivity:

```
case R.id.settings:
    startActivity(new Intent(this, Preferences.class));

    return(true);
```

Now, if you run this in an emulator or device, you will see the new option in the action bar overflow:

TUTORIAL #13 - USING SOME PREFERENCES

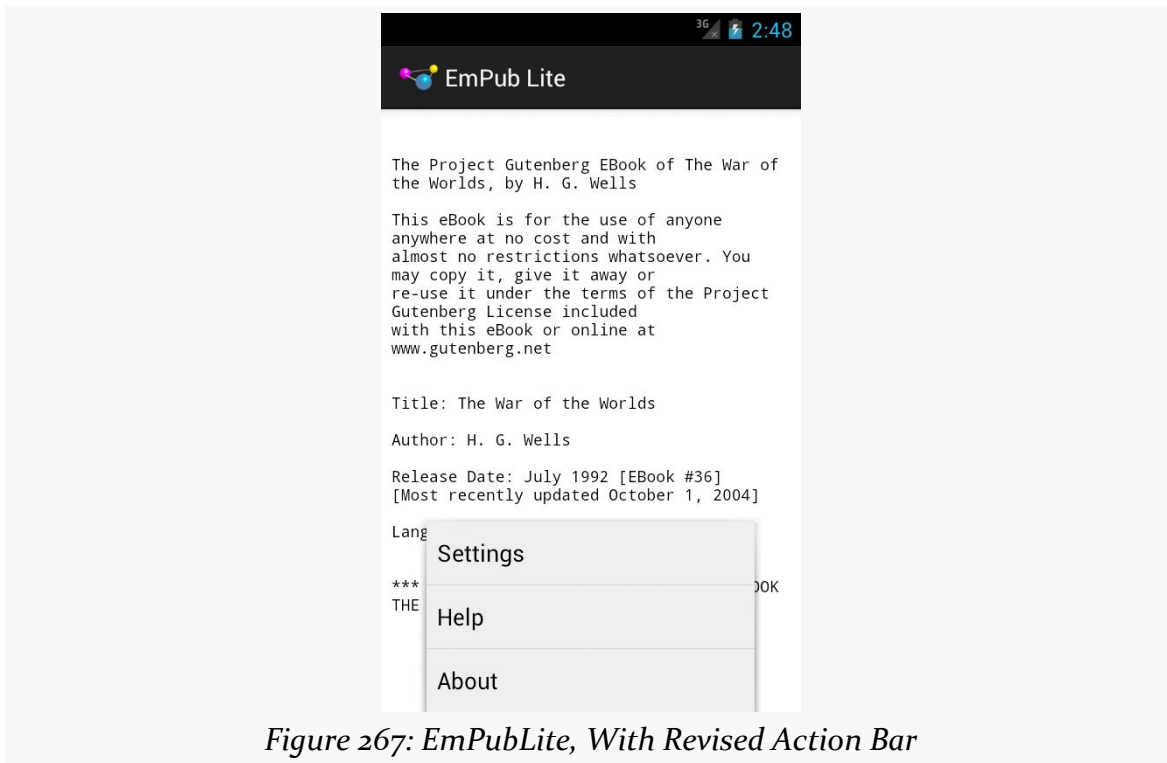

Figure 267: EmPubLite, With Revised Action Bar

Choosing the “Settings” option brings up the list of preference headings:

TUTORIAL #13 - USING SOME PREFERENCES

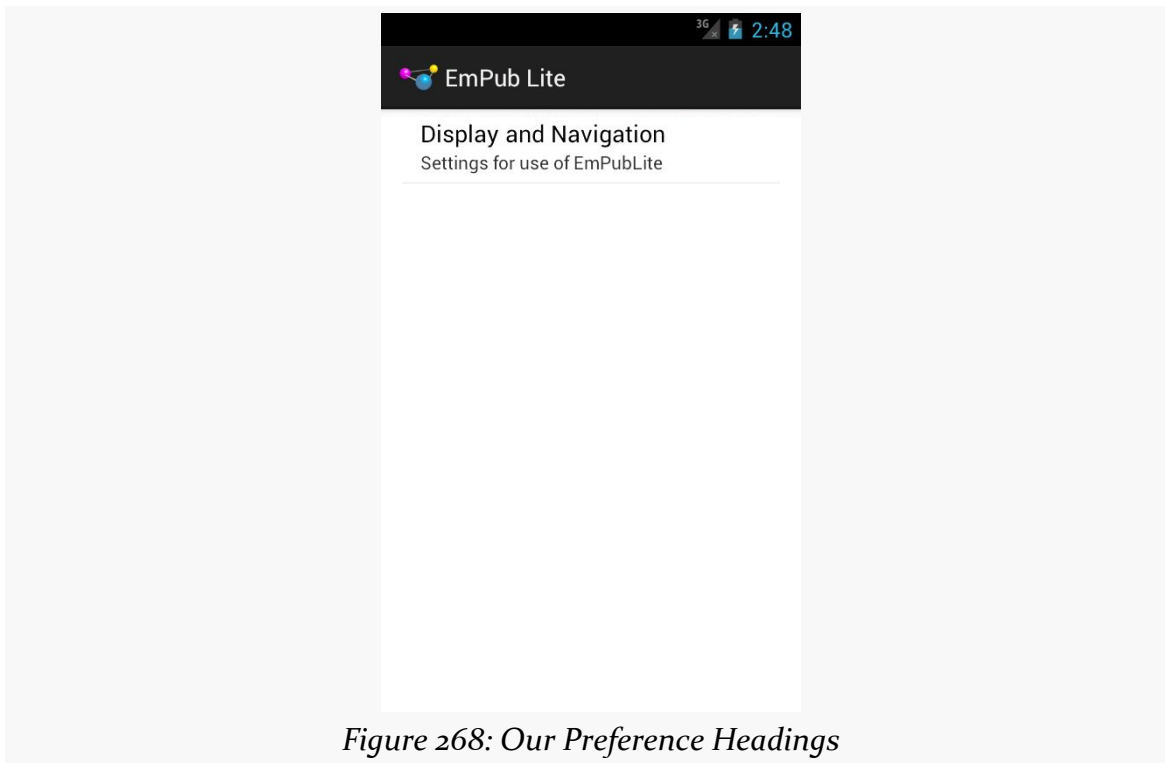

Figure 268: Our Preference Headings

Tapping on the “Display and Navigation” heading brings up our two preferences:

TUTORIAL #13 - USING SOME PREFERENCES

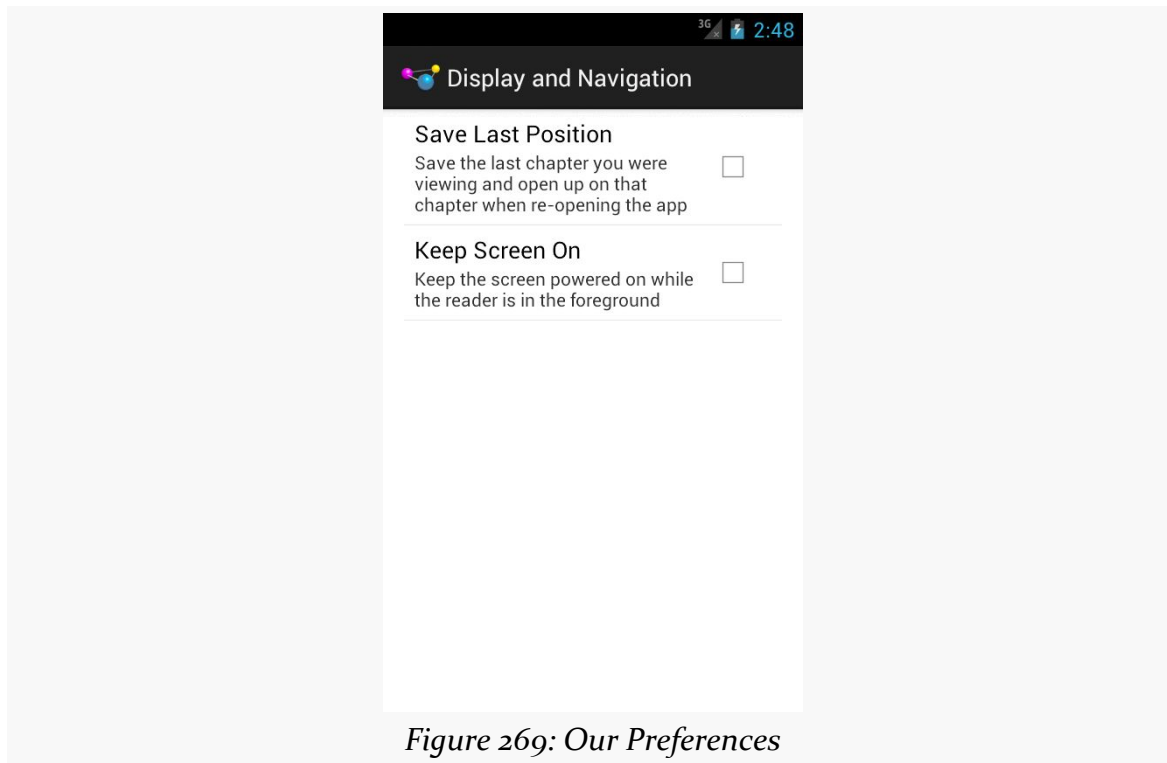

Figure 269: Our Preferences

On a tablet, we see the headings and the selected headings' worth of preferences at the same time:

TUTORIAL #13 - USING SOME PREFERENCES

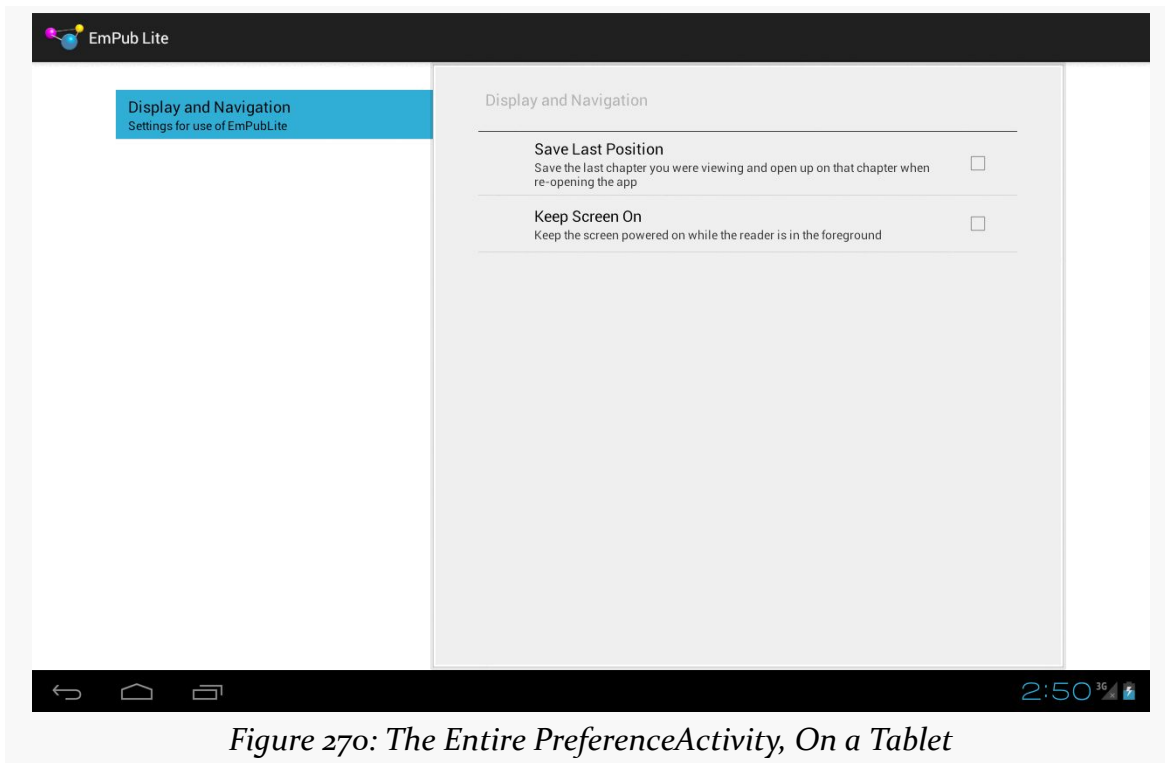

Figure 270: The Entire PreferenceActivity, On a Tablet

Step #5: Loading the Preferences

Now, we need to actually arrange to load the preferences on a background thread. As noted, this will be handled by our `ModelFragment`, much as it handles the loading of the book contents.

First, add a private data member named `prefs`, of type `SharedPreferences`, to `ModelFragment`:

```
private SharedPreferences prefs=null;
```

Then, add a `getPrefs()` method to `ModelFragment` that returns the `prefs` value:

```
public SharedPreferences getPrefs() {  
    return(prefs);  
}
```

Next, revise `LoadThread` to:

- Replace the `assets` data member with a `ctxt` data member of type `Context`

TUTORIAL #13 - USING SOME PREFERENCES

- Take in a Context in the constructor, instead of an AssetManager (this way, even if for some strange reason our original activity is destroyed and recreated while we are loading the preferences, we will not be leaking the original activity)
- Save the application context (from `getApplicationContext()` on Context) in a data member, instead of an AssetManager
- Call `getAssets()` on that Context in `run()`, instead of using the former AssetManager
- Also retrieve the SharedPreferences in `run()`

```
private class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
        super();

        this.ctxt=ctxt(getApplicationContext());
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
        prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);

        Gson gson=new Gson();

        try {
            InputStream is=ctxt.getAssets().open("book/contents.json");
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(is));

            contents=gson.fromJson(reader, BookContents.class);
            EventBus.getDefault().post(new BookLoadedEvent(contents));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

This has our LoadThread load both the SharedPreferences and the BookContents, and do so in a known order (SharedPreferences first).

You will need to modify `onAttach()` to just pass in the Activity to the LoadThread constructor:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);
```

TUTORIAL #13 - USING SOME PREFERENCES

```
        if (contents == null) {  
            new LoadThread(host).start();  
        }  
    }  
}
```

The resulting ModelFragment should look like:

```
package com.commonware.empublite;  
  
import android.app.Activity;  
import android.app.Fragment;  
import android.content.Context;  
import android.content.SharedPreferences;  
import android.os.Bundle;  
import android.os.Process;  
import android.preference.PreferenceManager;  
import android.util.Log;  
import java.io.BufferedReader;  
import java.io.IOException;  
import java.io.InputStream;  
import java.io.InputStreamReader;  
import com.google.gson.Gson;  
import de.greenrobot.event.EventBus;  
  
public class ModelFragment extends Fragment {  
    private BookContents contents=null;  
    private SharedPreferences prefs=null;  
  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
  
        setRetainInstance(true);  
    }  
  
    @Override  
    public void onAttach(Activity host) {  
        super.onAttach(host);  
  
        if (contents == null) {  
            new LoadThread(host).start();  
        }  
    }  
  
    public BookContents getBook() {  
        return(contents);  
    }  
  
    public SharedPreferences getPrefs() {  
        return(prefs);  
    }  
}
```

```
private class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
        super();

        this.ctxt=ctxt.getApplicationContext();
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
        prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);

        Gson gson=new Gson();

        try {
            InputStream is=ctxt.getAssets().open("book/contents.json");
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(is));

            contents=gson.fromJson(reader, BookContents.class);
            EventBus.getDefault().post(new BookLoadedEvent(contents));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

Step #6: Saving the Last-Read Position

One preference is to restore our current page in the ViewPager when the user later re-opens the app. To make that work, we need to start saving the current page as the user leaves the app. And, we may as well use our freshly-minted SharedPreferences to store this value.

We need a key under which we will store this value in the SharedPreferences, so add a new static data member to EmPubLiteActivity:

```
private static final String PREF_LAST_POSITION="lastPosition";
```

We are also going to need access to our ModelFragment from outside of onCreate() in EmPubLiteActivity. Add a ModelFragment data member named mfrag:

```
private ModelFragment mfrag=null;
```

TUTORIAL #13 - USING SOME PREFERENCES

Then, modify `onResume()` to refer to the `mfrag` data member, replacing the former `mfrag` local variable:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (adapter==null) {
        mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            mfrag=new ModelFragment();
            getFragmentManager().beginTransaction().add(mfrag, MODEL).commit();
        }
        else if (mfrag.getBook() != null) {
            setupPager(mfrag.getBook());
        }
    }
}
```

Next, update `onPause()` on `EmPubLiteActivity` to track the page of the `ViewPager` that the user is on at the point in time when `onPause()` is called:

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    if (mfrag.getPrefs() != null) {
        int position=pager.getCurrentItem();

        mfrag.getPrefs().edit().putInt(PREF_LAST_POSITION, position)
            .apply();
    }

    super.onPause();
}
```

Here, we check to see that we have the `SharedPreferences` loaded — odds are that we do, but we cannot be certain. If we do have access to the `SharedPreferences`, we find out the current position within the `ViewPager` via `getCurrentItem()` (e.g., 0 for the first page). We then obtain a `SharedPreferences.Editor` and use it to save this position value in the `SharedPreferences`, keyed as `PREF_LAST_POSITION`, using `apply()` to persist the changes.

Step #7: Restoring the Last-Read Position

Now that we are saving this position data, we can start to use it.

Our preference XML has our key to the “Save Last Position” preference, but we need it in Java code as well, so add another static data member to `EmPubLiteActivity`:

```
private static final String PREF_SAVE_LAST_POSITION="saveLastPosition";
```

Add the following lines to the end of `setupPager()` in `EmPubLiteActivity`:

```
SharedPreferences prefs=mfrag.getPrefs();

if (prefs != null) {
    if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
        pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
    }
}
```

Here, we check to see if the user has enabled having us restore the last-saved position (defaulting to `false`). If the user has, we retrieve the last-saved position (defaulting to 0, or the first page), and call `setCurrentItem()` on the `ViewPager` to shift to that particular page.

If you run this in a device or emulator, check the “Save Last Position” preference checkbox, flip ahead a couple of chapters, exit the app via the BACK button, and go back into the app, you will see that you are taken back to the chapter you were last reading.

Step #9: Keeping the Screen On

Our other preference is whether or not the screen should stay on, without user input, while we are reading the book. The bare-bones implementation of this requires just two lines of additional code.

First, we need to define another static data member on `EmPubLiteActivity`, this time with the key for our keep-screen-on preference:

```
private static final String PREF_KEEP_SCREEN_ON="keepScreenOn";
```

Then, add one more line to `setupPager()` in `EmPubLiteActivity`, inside of the `if` block:

TUTORIAL #13 - USING SOME PREFERENCES

```
pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
```

This will give you:

```
private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);
    findViewById(R.id.progressBar1).setVisibility(View.GONE);
    pager.setVisibility(View.VISIBLE);

    SharedPreferences prefs=mfrag.getPrefs();
    if (prefs != null) {
        if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
            pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
        }

        pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
    }
}
```

setKeepScreenOn(), called on any View, will keep the screen lit and active without continuous user input, so long as that View is on the screen.

This approach is somewhat limited, in that we are only setting this during the call to setupPager(). If the user changes the preference value, that change would only take effect when the activity was restarted (e.g., user rotates the screen, user exits the app via BACK and returns later).

The simplest way for us to have this take more immediate effect is to realize that EmPubLiteActivity will be paused and stopped when the Preferences activity is on the screen, and will be started and resumed when the user is done adjusting preferences. So, we can simply augment onResume() to also update the screen-on setting:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (adapter==null) {
        mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            mfrag=new ModelFragment();
            getFragmentManager().beginTransaction().add(mfrag, MODEL).commit();
        }
        else if (mfrag.getBook() != null) {
```

```
        setupPager(mfrag.getBook());
    }

    if (mfrag.getPrefs() != null) {
        pager.setKeepScreenOn(mfrag.getPrefs()
            .getBoolean(PREF_KEEP_SCREEN_ON, false));
    }
}
```

Of course, we may not *have* the `SharedPreferences` yet, when the app is first starting up, so we avoid making any changes in that case.

If you run this on a device (note: *not* an emulator), you can play with this preference and see the changes in the screen's behavior.

In Our Next Episode...

... we will allow the user to [write, save, and delete notes](#) for the currently-viewed chapter, using a database.

SQLite Databases

Besides `SharedPreferences` and your own file structures, the third primary means of persisting data locally on Android is via SQLite. For many applications, SQLite is the app's backbone, whether it is used directly or via some third-party wrapper.

This chapter will focus on how you can directly work with SQLite to store relational data.

Introducing SQLite

[SQLite](#) is a very popular embedded database, as it combines a clean SQL interface with a very small memory footprint and decent speed. Moreover, it is public domain, so everyone can use it. Lots of firms (Adobe, Apple, Google, Symbian) and open source projects (Mozilla, PHP, Python) all ship products with SQLite.

For Android, SQLite is “baked into” the Android runtime, so every Android application can create SQLite databases. Since SQLite uses a SQL interface, it is fairly straightforward to use for people with experience in other SQL-based databases. However, its native API is not JDBC, and JDBC might be too much overhead for a memory-limited device like a phone, anyway. Hence, Android programmers have a different API to learn — the good news being is that it is not that difficult.

This chapter will cover the basics of SQLite use in the context of working on Android. It by no means is a thorough coverage of SQLite as a whole. If you want to learn more about SQLite, the [SQLite Web site](#) may help.

Thinking About Schemas

SQLite is a typical relational database, containing tables (themselves consisting of rows and columns), indexes, and so on. Your application will need its own set of tables and so forth for holding whatever data you wish to hold. This structure is generally referred to as a “schema”.

It is likely that your schema will need to change over time. You might add new tables or columns in support of new features. Or, you might significantly reorganize your data structure and wind up dropping some tables while moving the data into new ones.

As a result, when you ship an update to your application to your users, not only will your Java code change, but the *expectations* of that Java code will change as well, with respect to what your database schema will look like. Version 1 of your app will use your original schema, but by the time you ship, say, version 5 of the app, you might need an adjusted schema.

Android has facilities to assist you with handling changing database schemas, mostly centered around the `SQLiteOpenHelper` class.

Start with a Helper

`SQLiteOpenHelper` is designed to consolidate your code related to two very common problems:

1. What happens the very first time when your app is run on a device after it is installed? At this point, we do not yet have a database, and so you will need to create your tables, indexes, starter data, and so on.
2. What happens the very first time when an upgraded version of your app is run on a device, where the upgraded version is expecting a newer database schema? Your database will still be on the old schema from the older edition of the app. You will need to have a chance to alter the database schema to match the needs of the rest of your app.

`SQLiteOpenHelper` wraps up the logic to create and upgrade a database, per your specifications, as needed by your application. You will need to create a custom subclass of `SQLiteOpenHelper`, implementing three methods at minimum:

1. The constructor, chaining upward to the SQLiteOpenHelper constructor. This takes the Context (e.g., an Activity), the name of the database, an optional cursor factory (typically, just pass null), and an integer representing the version of the database schema you are using (typically start at 1 and increment from there).
2. onCreate(), called when there is no database and your app needs one, which passes you a SQLiteDatabase object, pointing at a newly-created database, that you use to populate with tables and initial data, as appropriate.
3. onUpgrade(), called when the schema version you are seeking does not match the schema version of the database, which passes you a SQLiteDatabase object and the old and new version numbers, so you can figure out how best to convert the database from the old schema to the new one.

To see how all this SQLite stuff works in practice, we will examine the [Database/ConstantsROWID](#) sample application. This application pulls a bunch of gravitational constants from the SensorManager class, puts them in a database table, displays them in a ListFragment, and allows the user to add new ones via the action bar.

First, we need a SQLiteOpenHelper subclass, here named DatabaseHelper.

The DatabaseHelper constructor chains to the superclass and supplies the name of the database (held in a DATABASE_NAME static data member) and the version number of our database schema (held in SCHEMA):

```
public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    private static final int SCHEMA=1;
    static final String TITLE="title";
    static final String VALUE="value";
    static final String TABLE="constants";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, SCHEMA);
    }
}
```

We also need an onCreate() method, which will be called and passed a SQLiteDatabase object when a database needs to be newly created. Below you will see the DatabaseHelper implementation of onCreate(), though we will get into how it is using the SQLiteDatabase object more later in this chapter:

```
@Override
public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");
}
```

```
ContentValues cv=new ContentValues();

cv.put(TITLE, "Gravity, Death Star I");
cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Earth");
cv.put(VALUE, SensorManager.GRAVITY_EARTH);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Jupiter");
cv.put(VALUE, SensorManager.GRAVITY_JUPITER);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Mars");
cv.put(VALUE, SensorManager.GRAVITY_MARS);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Mercury");
cv.put(VALUE, SensorManager.GRAVITY_MERCURY);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Moon");
cv.put(VALUE, SensorManager.GRAVITY_MOON);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Neptune");
cv.put(VALUE, SensorManager.GRAVITY_NEPTUNE);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Pluto");
cv.put(VALUE, SensorManager.GRAVITY_PLUTO);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Saturn");
cv.put(VALUE, SensorManager.GRAVITY_SATURN);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Sun");
cv.put(VALUE, SensorManager.GRAVITY_SUN);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, The Island");
cv.put(VALUE, SensorManager.GRAVITY_THE_ISLAND);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Uranus");
cv.put(VALUE, SensorManager.GRAVITY_URANUS);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Venus");
cv.put(VALUE, SensorManager.GRAVITY_VENUS);
```

```
db.insert(TABLE, TITLE, cv);  
}
```

Suffice it to say for the moment that it is creating a constants table and inserting several rows into it, all wrapped in a transaction.

We also need `onUpgrade()`... even though it should never be called right now:

```
@Override  
public void onUpgrade(SQLiteDatabase db, int oldVersion,  
                      int newVersion) {  
    throw new RuntimeException("How did we get here?");  
}
```

After all, right now, we only have one version of our schema (1) and therefore will have no need to upgrade. If, in the future, we change `SCHEMA` to a higher value (e.g., 2), and we upgrade our app on a device that had previously been run with our earlier schema, *then* we will be called with `onUpgrade()`. We are passed the old and new schema versions, so we know what needs to be upgraded.

Bear in mind that users do not necessarily have to take on each of your application updates, and so you might find that a user skipped a schema version:

- You release an app on Monday, with schema version 1
- A user installs your app on Tuesday and runs it, creating a database via `onCreate()`
- You release an upgraded app on Wednesday, with schema version 2
- You release yet another upgrade on Thursday, with schema version 3
- The user installs your upgrade, now needing a schema version 3 database instead of the version 1 presently on the device, triggering a call to `onUpgrade()`

There are two other methods you can elect to override in your `SQLiteOpenHelper`, if you feel the need:

- You can override `onOpen()`, to get control when somebody opens this database. Usually, this is not required.
- Android 3.0 introduced `onDowngrade()`, which will be called if the code requests an older schema than what is in the database presently. This is the converse of `onUpgrade()` — if your version numbers differ, one of these two methods will be invoked. Since normally you are moving forward with updates, you can usually skip `onDowngrade()`.

Employing Your Helper

To use your SQLiteOpenHelper subclass, create and hold onto an instance of it. Then, when you need a SQLiteDatabase object to do queries or data modifications, ask your SQLiteOpenHelper to `getReadableDatabase()` or `getWritableDatabase()`, depending upon whether or not you will be changing its contents.

For example, the ConstantsFragment from the sample app creates a DatabaseHelper instance in `onViewCreated()` and holds onto it in a data member:

```
db=new DatabaseHelper(getActivity());
```

When you are done with the database (e.g., your activity is being closed), simply call `close()` on your SQLiteOpenHelper to release your connection, as ConstantsFragment does (among other things) in `onDestroy()`:

```
@Override
public void onDestroy() {
    super.onDestroy();

    ((CursorAdapter)getListAdapter()).getCursor().close();
    db.close();
}
```

Where to Hold a Helper

For trivial apps, like the one profiled in this chapter, holding a SQLiteOpenHelper in a data member of your one-and-only activity is fine.

If, however, you have multiple components — such as multiple activities — all needing to use the database, you are much better served having a *singleton instance* of your SQLiteOpenHelper, compared to having each activity have its own instance.

The reason is threading.

You really should do your database I/O on background threads. Opening a database is cheap, but working with it (queries, inserts, etc.) is not. The SQLiteDatabase object managed by SQLiteOpenHelper is thread-safe... so long as all threads are using the same instance.

For singleton objects that depend upon a Context, like SQLiteOpenHelper, rather than create the object using a garden-variety Context like an Activity, you really should create it with an Application. There is a singleton instance of a Context, in

the form of the `Application` subclass, created in your process moments after it is started. You can retrieve this singleton by calling `getApplicationContext()` on any other `Context`. The advantage of using `Application` is memory leaks: if you put a `SQLiteOpenHelper` in a singleton, and use, say, an `Activity` to create it, then the `Activity` might not be able to be garbage-collected, because the `SQLiteOpenHelper` keeps a strong reference to it. Since `Application` is itself a singleton (and, hence, is “pre-leaked”, so to speak), the risks of a memory leak diminish significantly.

So, instead of:

```
db=new DatabaseHelper(getActivity());
```

in a fragment, with `db` as a data member, you might have:

```
db=new DatabaseHelper(getActivity().getApplicationContext());
```

with `db` as a static data member, shared by multiple activities or other components.

Getting Data Out

One popular thing to do with a database is to get data out of it. Android has a few ways you can execute a query on a `SQLiteDatabase` (from your `SQLiteOpenHelper`), along with some classes, like `CursorAdapter`, to help you use the results you get back.

Your Query Options

In most cases, your simplest option for executing a query is to call `rawQuery()` on the `SQLiteDatabase`. This takes two parameters:

- A SQL `SELECT` statement (or anything else that returns a result set), optionally with `?` characters in the `WHERE` clause (or `ORDER BY` or similar clauses) representing parameters to be bound at runtime
- An optional `String` array of the parameters to be used to replace the `?` characters in the query

If you do not use the `?` position parameter syntax in your query, you are welcome to pass `null` as the second parameter to `rawQuery()`.

The nice thing about `rawQuery()` is that any valid SQL syntax works, so long as it returns a result set. You are welcome to use joins, sub-selects, and so on without issue.

There are two other query options — `query()` and `SQLiteQueryBuilder`. These both build up a SQL `SELECT` statement from its component parts (e.g., name of the table to query, `WHERE` clause and positional parameters). These are more cumbersome to use, particularly with complex `SELECT` statements. Mostly, they would be used in cases where, for one reason or another, you do not know the precise query at compile time and find it easier to use these facilities to construct the query from parts at runtime. Some developers will do this to avoid duplicating values, by defining constants for things like table names and column names.

For example, `ConstantsFragment` has a private inner class named `BaseTask` which has `doQuery()` method that uses `query()`:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    @Override
    public void onPostExecute(Cursor result) {
        ((CursorAdapter)getListAdapter()).changeCursor(result);
    }

    protected Cursor doQuery() {
        Cursor result=
            db
                .getReadableDatabase()
                .query(DatabaseHelper.TABLE,
                    new String[] {"ROWID AS _id",
                                   DatabaseHelper.TITLE,
                                   DatabaseHelper.VALUE},
                    null, null, null, null, DatabaseHelper.TITLE);

        result.getCount();

        return(result);
    }
}
```

Do not concatenate your own `WHERE` clause, though. Let the `?` positional parameters handle that for you, as the work they do to escape your apostrophes, quotation marks, and the like also helps to defend against SQL injection attacks. In this particular case, we do not have a `WHERE` clause.

If that `ROWID AS _id` piece looks a bit odd, we will see why that is in the query a bit later in this chapter.

What Is a Cursor?

All three of these give you a Cursor when you are done. In Android, a Cursor represents the entire result set of the query — all the rows and all the columns that the query returned. In this respect, it is reminiscent of a “client-side cursor” from toolkits like ODBC, JDBC, etc.

(if the Cursor result set is over 1MB, it actually only holds a “window” on the data, and the story gets really really complicated...)

As such, a Cursor can be quite the memory hog. Please `close()` the Cursor when you are done with it, to free up the heap space it consumes and make that memory available to the rest of your application.

Using the Cursor Manually

With the Cursor, you can:

1. Find out how many rows are in the result set via `getCount()`
2. Iterate over the rows via `moveToFirst()`, `moveToNext()`, and `isAfterLast()`
3. Find out the names of the columns via `getColumnNames()`, convert those into column numbers via `getColumnIndex()`, and get values for the current row for a given column via methods like `getString()`, `getInt()`, etc.

For example, here we iterate over a fictitious `widgets` table’s rows:

```
Cursor result=
    db.rawQuery("SELECT _id, name, inventory FROM widgets", null);

while (result.moveToNext()) {
    int id=result.getInt(0);
    String name=result.getString(1);
    int inventory=result.getInt(2);

    // do something useful with these
}

result.close();
```

Introducing CursorAdapter

Another way to use a Cursor is to wrap it in a CursorAdapter. Just as ArrayAdapter adapts arrays, CursorAdapter adapts Cursor objects, making their data available to an AdapterView like a ListView.

The easiest way to set one of these up is to use SimpleCursorAdapter, which extends CursorAdapter and provides some boilerplate logic for taking values out of columns and putting them into row View objects for a ListView (or other AdapterView). The sample app does just that:

```
SimpleCursorAdapter adapter=
    new SimpleCursorAdapter(getActivity(), R.layout.row,
        current, new String[] {
            DatabaseHelper.TITLE,
            DatabaseHelper.VALUE },
        new int[] { R.id.title, R.id.value },
        0);

setListAdapter(adapter);
```

Here, we are telling SimpleCursorAdapter to take rows out of a Cursor named constantsCursor, turning each into an inflated R.layout.row ViewGroup, in this case, a RelativeLayout holding a pair of TextView widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentLeft="true"
        android:textSize="20sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentRight="true"
        android:textSize="20sp"
        android:textStyle="bold"/>

</RelativeLayout>
```

For each row in the Cursor, the columns named `title` and `value` (represented by `TITLE` and `VALUE` constants on `DatabaseHelper`) are to be poured into their respective `TextView` widgets (`R.id.title` and `R.id.value`).

Note, though, that if you are going to use `CursorAdapter` or its subclasses (like `SimpleCursorAdapter`), your result set of your query *must* contain an integer column named `_id` that is unique for the result set. This “id” value is then supplied to methods like `onListItemClick()`, to identify what item the user clicked upon in the `AdapterView`. Note that this requirement is on the result set in the `Cursor`, so if you have a suitable column in a table that is not named `_id`, you can rename it in your query (e.g., `SELECT key AS _id, ...`).

However, if you want, you can use the built-in `ROWID`

Quoting [the SQLite documentation](#):

In SQLite, every row of every table has an 64-bit signed integer `ROWID`. The `ROWID` for each row is unique among all rows in the same table. You can access the `ROWID` of an SQLite table using one the special column names `ROWID`, `_ROWID_`, or `OID`... If a table contains a column of type `INTEGER PRIMARY KEY`, then that column becomes an alias for the `ROWID`. You can then access the `ROWID` using any of four different names, the original three names described above or the name given to the `INTEGER PRIMARY KEY` column. All these names are aliases for one another and work equally well in any context.

With that in mind, if you want to query SQLite and use the results in a `CursorAdapter`, but you do not have your own `INTEGER PRIMARY KEY` column, you can just include `ROWID` in your query, renaming it to `_id` to satisfy `CursorAdapter`.

That is why we have the `ROWID AS _id` in the `doQuery()` method: to satisfy this `_id` requirement of `CursorAdapter`.

Also note that you cannot `close()` the `Cursor` used by a `CursorAdapter` until you no longer need the `CursorAdapter`. That is why we do not close the `Cursor` until `onDestroy()` of the fragment:

```
@Override
public void onDestroy() {
    super.onDestroy();

    ((CursorAdapter)getListAdapter()).getCursor().close();
}
```

```
db.close();  
}
```

We retrieve the Cursor from the CursorAdapter, which we get by calling getListAdapter() on the fragment.

Getting Data Out, Asynchronously

Ideally, queries are done on a background thread, as they may take some time.

One approach for doing that is to use an AsyncTask. In the sample application, ConstantsFragment kicks off a LoadCursorTask in onCreateView() (shown above). LoadCursorTask extends the BaseTask class mentioned previously, where the doQuery() method resides. LoadCursorTask is responsible for doing the query (via the doQuery() method shown above) and putting the results in the ListView inside the fragment (using the SimpleCursorAdapter shown above):

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {  
    @Override  
    public void onPostExecute(Cursor result) {  
        ((CursorAdapter)getListAdapter()).changeCursor(result);  
    }  
  
    protected Cursor doQuery() {  
        Cursor result=  
            db  
                .getReadableDatabase()  
                .query(DatabaseHelper.TABLE,  
                    new String[] {"ROWID AS _id",  
                                DatabaseHelper.TITLE,  
                                DatabaseHelper.VALUE},  
                    null, null, null, null, DatabaseHelper.TITLE);  
  
        result.getCount();  
  
        return(result);  
    }  
}  
  
private class LoadCursorTask extends BaseTask<Void> {  
    @Override  
    protected Cursor doInBackground(Void... params) {  
        return(doQuery());  
    }  
}
```

We execute the actual query in doInBackground() and call getCount() on the Cursor, to force it to actually perform the query — query() returns the Cursor, but

the query is not actually executed until we do something that needs the result set. This also holds true for `rawQuery()`, which is why we need to make sure to “touch” the `Cursor` while we are on the background thread.

`onPostExecute()` then uses `changeCursor()` to replace the `Cursor` in the `SimpleCursorAdapter` with the results. Since our `SimpleCursorAdapter` was created with a null `Cursor`, `changeCursor()` just slides in the new `Cursor`, telling the `ListView` that the data changed. This causes our `ListView` to be populated.

This way, the UI will not be frozen while the query is being executed, yet we only update the UI from the main application thread.

Also note that the first time we try using the `SQLiteOpenHelper` is in our background thread. `SQLiteOpenHelper` will not try creating our database (e.g., for a new app install) until we call `getReadableDatabase()` or `getWritableDatabase()`. Hence, `onCreate()` (or, later, `onUpgrade()`) of our `SQLiteOpenHelper` will wind up being called on the background thread as well, meaning that the time spent creating (or upgrading) the database also does not freeze the UI.

The Rest of the CRUD

To get data out of a database, it is generally useful to put data into it in the first place. The sample app starts by loading in data when the database is created (in `onCreate()` of `DatabaseHelper`), plus has an action bar item to allow the user to add other constants as needed.

In this section, we will examine in further detail how we manipulate the database, for both the write aspects of CRUD (create-read-update-delete) and for data definition language (DDL) operations (creating tables, creating indexes, etc.).

The Primary Option: `execSQL()`

For creating your tables and indexes, you will need to call `execSQL()` on your `SQLiteDatabase`, providing the DDL statement you wish to apply against the database. Barring a database error, this method returns nothing.

So, for example, you can call `execSQL()` to create the constants table, as shown in the `DatabaseHelper` `onCreate()` method:

```
db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");
```

This will create a table, named `constants`, with two data columns: `title` (text) and `value` (a float, or “real” in SQLite terms).

Most likely, you will create tables and indexes when you first create the database, or possibly when the database needs upgrading to accommodate a new release of your application. If you do not change your table schemas, you might never drop your tables or indexes, but if you do, just use `execSQL()` to invoke `DROP INDEX` and `DROP TABLE` statements as needed.

Alternative Options

For inserts, updates, and deletes of data, you have two choices. You can always use `execSQL()`, just like you did for creating the tables. The `execSQL()` method works for any SQL that does not return results, so it can handle `INSERT`, `UPDATE`, `DELETE`, etc. just fine.

Your alternative is to use the `insert()`, `update()`, and `delete()` methods on the `SQLiteDatabase` object, which eliminate much of the SQL syntax required to do basic operations.

For example, here we `insert()` a new row into our `constants` table, again from `onCreate()` of `DatabaseHelper`:

```
ContentValues cv=new ContentValues();  
  
cv.put(TITLE, "Gravity, Death Star I");  
cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);  
db.insert(TABLE, TITLE, cv);
```

These methods make use of `ContentValues` objects, which implement a Map-esque interface, albeit one that has additional methods for working with SQLite types. For example, in addition to `get()` to retrieve a value by its key, you have `getAsInteger()`, `getAsString()`, and so forth.

The `insert()` method takes the name of the table, the name of one column as the “null column hack”, and a `ContentValues` with the initial values you want put into this row. The “null column hack” is for the case where the `ContentValues` instance is empty — the column named as the “null column hack” will be explicitly assigned the value `NULL` in the SQL `INSERT` statement generated by `insert()`. This is required due to a quirk in SQLite’s support for the SQL `INSERT` statement.

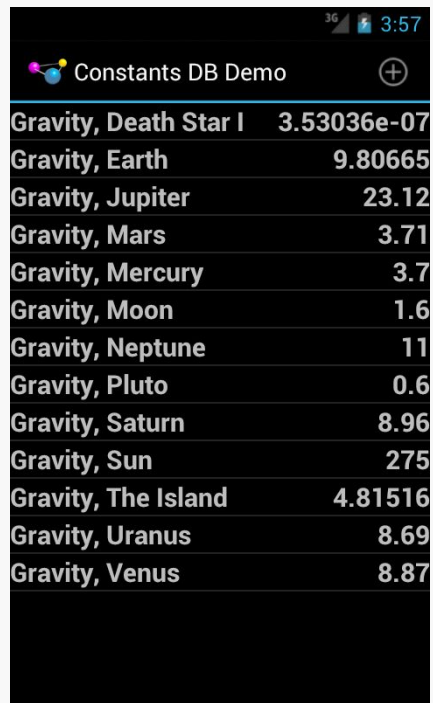

The `update()` method takes the name of the table, a `ContentValues` representing the columns and replacement values to use, an optional `WHERE` clause, and an optional list of parameters to fill into the `WHERE` clause, to replace any embedded question marks (?). Since `update()` only replaces columns with fixed values, versus ones computed based on other information, you may need to use `execSQL()` to accomplish some ends. The `WHERE` clause and parameter list works akin to the positional SQL parameters you may be used to from other SQL APIs.

The `delete()` method works akin to `update()`, taking the name of the table, the optional `WHERE` clause, and the corresponding parameters to fill into the `WHERE` clause.

Asynchronous CRUD and UI Updates

Just as querying a database should be done on a background thread, so should modifying a database. This is why it is important to make the first time you request a `SQLiteDatabase` from a `SQLiteOpenHelper` be on a background thread, in case `onCreate()` or `onUpgrade()` are needed.

The same thing holds true if you need to update the database during normal operation of your app. For example, the sample application has an “add” action bar item in the upper-right corner of the screen:

The screenshot shows a mobile application titled "Constants DB Demo". It displays a list of gravity values for various celestial bodies. The list is as follows:

Gravity, Death Star I	3.53036e-07
Gravity, Earth	9.80665
Gravity, Jupiter	23.12
Gravity, Mars	3.71
Gravity, Mercury	3.7
Gravity, Moon	1.6
Gravity, Neptune	11
Gravity, Pluto	0.6
Gravity, Saturn	8.96
Gravity, Sun	275
Gravity, The Island	4.81516
Gravity, Uranus	8.69
Gravity, Venus	8.87

Figure 271: The ConstantsBrowser Sample

Clicking on that brings up a dialog — a technique we will discuss later in this book:

Figure 272: The ConstantsBrowser Sample, Add Constant Dialog

If the user fills in a constant and clicks the “OK” button, we need to insert a new record in the database. That is handled via an `InsertTask`:

```
private class InsertTask extends AsyncTask<ContentValues> {  
    @Override  
    protected Cursor doInBackground(ContentValues... values) {  
        db.getWritableDatabase().insert(DatabaseHelper.TABLE,  
                                         DatabaseHelper.TITLE, values[0]);  
  
        return(doQuery());  
    }  
}
```

The `InsertTask` is supplied a `ContentValues` object with our title and value, just as we used in `onCreate()` of `DatabaseHelper`. In `doInBackground()`, we get a writable database from `DatabaseHelper` and perform the `insert()` call, so the database I/O does not tie up the main application thread.

However, in `doInBackground()`, we *also* call `doQuery()` again. This retrieves a fresh `Cursor` with the new roster of constants... including the one we just inserted. As with `LoadCursorTask`, we execute `doQuery()` in `doInBackground()` to keep the database I/O off the main application thread. This triggers the same `onPostExecute()` as

before, inherited from `BaseTask`, which uses `changeCursor()` to replace any existing results with the new results.

Setting Transaction Bounds

By default, each SQL statement executes in its own transaction — this is fairly typical behavior for a SQL database, and SQLite is no exception.

There are two reasons why you might want to have your own transaction bounds, larger than a single statement:

1. The classic “we have a series of operations that need to succeed or fail as a whole” rationale, for maintaining data integrity
2. Performance, as each database transaction involves disk I/O, and one large transaction will be much faster than lots of little transactions

The basic recipe for your own transactions is:

```
try {
    db.beginTransaction();

    // several SQL statements in here

    db.setTransactionSuccessful();
}
finally {
    db.endTransaction();
}
```

`beginTransaction()` marks the fact that you want a transaction.
`setTransactionSuccessful()` indicates that you want the transaction to commit. However, the actual COMMIT or ROLLBACK does not occur until `endTransaction()`. In the normal case, `setTransactionSuccessful()` does get called, and `endTransaction()` performs a COMMIT. If, however, one of your SQL statements fails (e.g., violates a foreign key constraint), the `setTransactionSuccessful()` call is skipped, so `endTransaction()` will do a ROLLBACK.

You might wonder why we did not bother with a transaction in `onCreate()` method of `DatabaseHelper`, given the latter reason. That is because `onCreate()` is called within a transaction set up by `SQLiteOpenHelper` itself, so you do not need your own.

Hey, What About Hibernate?

Those of you with significant Java backgrounds outside of Android are probably pounding your head against your desk right about now. Outside of a few conveniences like `SQLiteOpenHelper` and `CursorAdapter`, Android's approach to database I/O feels a bit like classic JDBC. Java developers, having experienced the pain of raw JDBC, created various wrappers around it, the most prominent of which is an ORM (object-relational mapper) called Hibernate.

Alas, Hibernate is designed for servers, not mobile devices. It is a little bit heavyweight, and it is designed for use with JDBC, not Android's SQLite classes.

Android did not include any sort of ORM in the beginning for two main reasons:

1. To keep the firmware size as small as possible, as smaller firmware can lead to less-expensive devices
2. To eliminate the ORM overhead (e.g., reflection), which would have been too much for early Android versions on early Android devices

The Android ecosystem has come up with alternatives, such as [ORMLite](#) and [greenDAO](#). So, if you are used to using an ORM, you may want to investigate these sorts of solutions — they just are not built into Android itself.

Visit the Trails!

If you are interested in exposing your database contents to a third-party application, you may wish to read up on [ContentProvider](#).

The trails also have chapters on [encrypted databases using SQLCipher](#) and [shipping pre-packaged databases with your app](#).

Tutorial #14 - Saving Notes

It would be nice if the user could add some personal notes to the chapter that she is reading, whether that serves as commentary, points to be researched, complaints about the author's hair (or lack thereof), or whatever.

So, in this chapter, we will add a new fragment and new activity to allow the user to add notes per chapter, via a large `EditText` widget. Those notes will be stored in a SQLite database.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Adding a DatabaseHelper

The first step for working with SQLite is to add an implementation of `SQLiteOpenHelper`, which we will do here, named `DatabaseHelper`.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `DatabaseHelper` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

import android.content.Context;
import android.database.sqlite.SQLiteDatabase;
import android.database.sqlite.SQLiteOpenHelper;

public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="empublite.db";
    private static final int SCHEMA_VERSION=1;
    private static DatabaseHelper singleton=null;

    synchronized static DatabaseHelper getInstance(Context ctxt) {
        if (singleton == null) {
            singleton=new DatabaseHelper(ctxt.getApplicationContext());
        }

        return(singleton);
    }

    private DatabaseHelper(Context ctxt) {
        super(ctxt, DATABASE_NAME, null, SCHEMA_VERSION);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        db.execSQL("CREATE TABLE notes (position INTEGER PRIMARY KEY, prose TEXT);");
    }

    @Override
    public void onUpgrade(SQLiteDatabase db, int oldVersion,
        int newVersion) {
        throw new RuntimeException("This should not be called");
    }
}
```

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `DatabaseHelper` in the “Name” field. Click the “Browse...” button next to the “Superclass” field and find

SQLiteOpenHelper to set as the superclass. Then, click “Finish” on the new-class dialog to create the DatabaseHelper class.

Then, with DatabaseHelper open in the editor, paste in the class definition shown in the Android Studio instructions above.

Step #2: Examining DatabaseHelper

Our initial version of DatabaseHelper has a few things:

- It has the constructor, supplying to the superclass the name of the database file (DATABASE_NAME) and the revision number of our schema (SCHEMA_VERSION). Note that the constructor is private, as we are using the singleton pattern, so only DatabaseHelper should be able to create DatabaseHelper instances.
- It has the onCreate() method, invoked the first time we run the app on a device or emulator, to let us populate the database. Here, we use execSQL() to define a notes with a position column (indicating our chapter) and a prose column (what the user types in as the note).
- It has the onUpgrade() method, needed because SQLiteOpenHelper is abstract, so our app will not compile without an implementation. Until we revise our schema, though, this method should never be called, so we raise a RuntimeException in the off chance that it is called unexpectedly.
- It has a static DatabaseHelper singleton instance and a getInstance() method to lazy-initialize it.

As noted in [the chapter on databases](#), it is important to ensure that all threads are accessing the same SQLiteDatabase object, for thread safety. That usually means you hold onto a single SQLiteOpenHelper object. And, in our case, we might want to get at this database from more than one activity. Hence, we go with the singleton approach, so everyone works with the same DatabaseHelper instance.

Step #3: Creating a NoteFragment

Having a database is nice and all, but we need to work on the UI to allow users to enter notes. To do that, we will start with a NoteFragment.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteFragment` as the name and click OK to create the empty class.

Next, replace the contents of that class with the following:

```
package com.commonware.empublite;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class NoteFragment extends Fragment {
    private static final String KEY_POSITION="position";
    private EditText editor=null;

    static NoteFragment newInstance(int position) {
        NoteFragment frag=new NoteFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_POSITION, position);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.editor, container, false);

        editor=(EditText)result.findViewById(R.id.editor);

        return(result);
    }

    private int getPosition() {
        return(getArguments().getInt(KEY_POSITION, -1));
    }
}
```

You will have a couple of warnings, for things in this code that we are setting up (editor and position) that are not yet used, but we will take care of that in later steps of the tutorial.

TUTORIAL #14 - SAVING NOTES

Then, right-click over the `res/` directory and choose `New > XML > Layout XML File` from the context menu. This brings up the New Layout XML File dialog:

Figure 273: Android Studio New Layout XML File Dialog

Fill in `editor` as the “Layout File Name”, leave the rest of the dialog alone, and click the “Finish” button.

In the Design tab of the graphical layout editor for `res/layout/editor.xml`, drag a “Multiline Text” widget from the palette into the preview area. In the properties pane, change the `android:layout_width` and `android:layout_height` each to be `match_parent`, change the ID to `editor`, and change the gravity (*not* the layout gravity) to be both top and left:

TUTORIAL #14 - SAVING NOTES

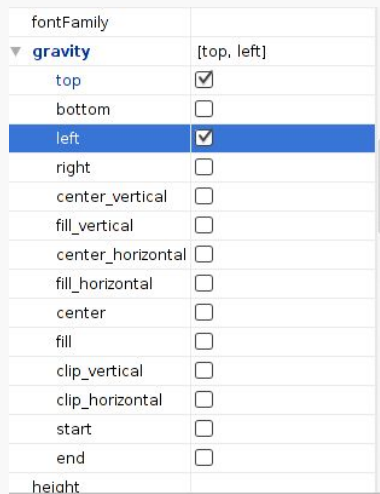

Figure 274: Android Studio Layout Editor Properties Pane, Showing Gravity Options

Next, in the properties pane, click on the “hint” entry, then click the “...” button to the right of it. This will open up a string resource picker dialog:

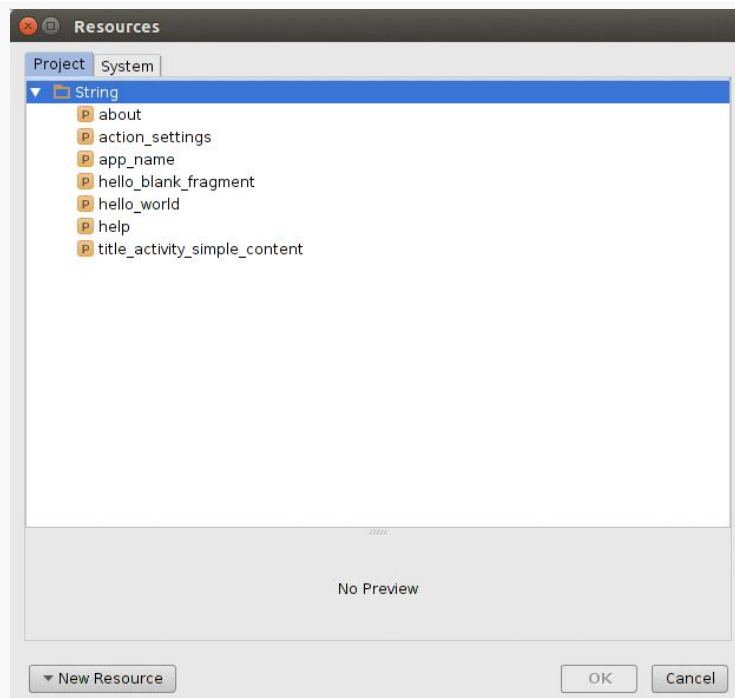

Figure 275: Android Studio String Resource Picker Dialog

TUTORIAL #14 - SAVING NOTES

Towards the bottom, click the “New Resource” drop-down and choose “New String Value...” from it, to bring up the string resource editor dialog:

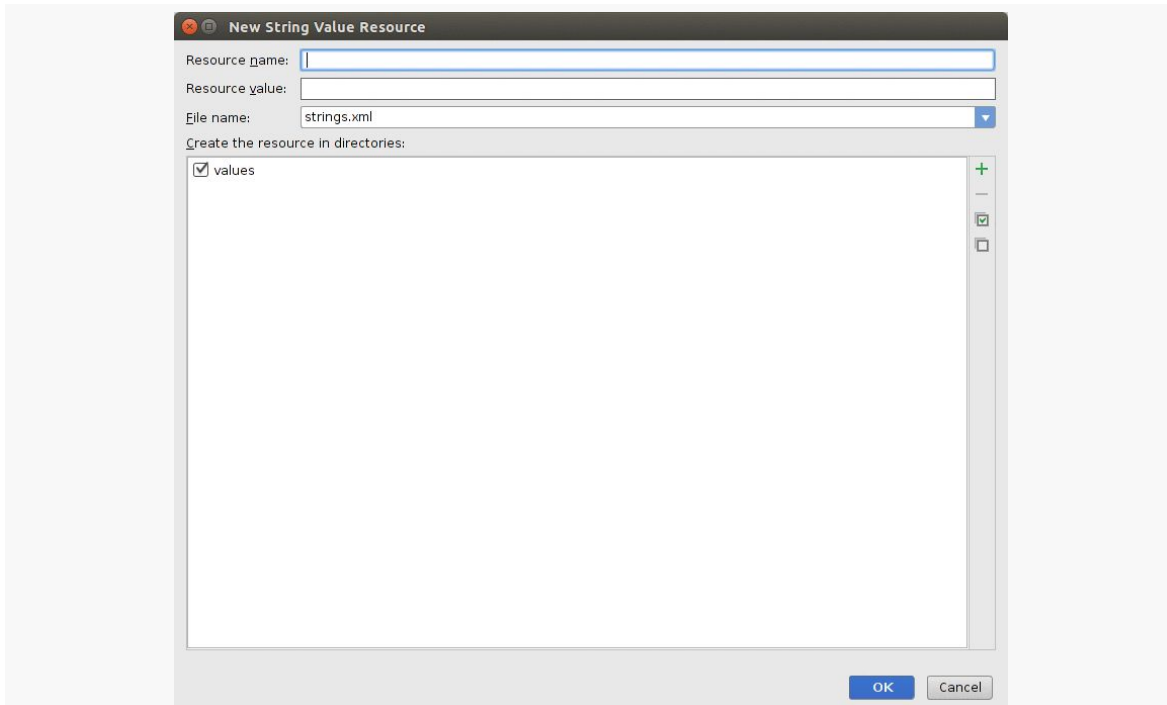

Figure 276: Android Studio New String Resource Dialog

Fill in a resource name of `hint` and a value of `Enter notes here`. Leave the rest of the dialog alone, and click OK.

Eclipse

Right click over the `res/layout/` directory in your project, and choose `New > Other` from the context menu. Choose “Android XML Layout File” from the first page of the new-file wizard, then click “Next”. In the second page of the wizard, give the file a name of `editor.xml` and choose `LinearLayout` as being the root element. Then, click “Finish” to generate the file.

Next, in the Graphical Layout sub-tab of the Eclipse layout editor, click on the “Text Fields” section of the tool palette, and drag a “Multiline Text” widget into the layout. Give it an ID of `@+id/editor`. Change the “Layout height” and “Layout width” to be `match_parent`. Add or change the Gravity to be `top|left`. Finally, add or change the Hint to be a new string resource (named `hint`) with a value of `Enter notes here`.

Then, right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `NoteFragment` in the “Name” field. Click the “Browse...” button next to the “Superclass” field and find `Fragment - (android.app)` to set as the superclass. Then, click “Finish” on the new-class dialog to create the `NoteFragment` class.

Then, with `NoteFragment` open in the editor, paste in the class definition seen in the Android Studio instructions above. As is noted there, you will have a couple of warnings, for things in this code that we are setting up (editor and position) that are not yet used, but we will take care of that in later steps of the tutorial.

Step #4: Examining NoteFragment

Our `NoteFragment` is fairly straightforward and is reminiscent of the `SimpleContentFragment` we created in [Tutorial #11](#).

`NoteFragment` has a `newInstance()` static factory method. This method creates an instance of `NoteFragment`, takes a passed-in `int` (identifying the chapter for which we are creating a note), puts it in a `Bundle` identified as `KEY_POSITION`, hands the `Bundle` to the fragment as its arguments, and returns the newly-created `NoteFragment`.

In `onCreateView()`, we inflate the `R.layout.editor` resource that we defined and get our hands on our `EditText` widget for later use.

Step #5: Creating the NoteActivity

Having a fragment without displaying it is fairly pointless, so we need something to load a `NoteFragment`. Particularly for phones, the simplest answer is to create a `NoteActivity` for that, paralleling the relationship between `SimpleContentFragment` and `SimpleContentActivity`.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteActivity` as the name and click OK to create the empty class.

In the `NoteActivity` class that is created, replace the current implementation with the following:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity {
    public static final String EXTRA_POSITION="position";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

            if (position >= 0) {
                Fragment f=NoteFragment.newInstance(position);

                getFragmentManager().beginTransaction()
                    .add(android.R.id.content, f).commit();
            }
        }
    }
}
```

Then, open up `AndroidManifest.xml` and add the following `<activity>` element inside the `<application>` element:

```
<activity android:name="NoteActivity"></activity>
```

Eclipse

Right-click over the `EmPubLite` project in the `Package Explorer`, then choose `New > Other` from the context menu. In the list of possible things to add to your project, choose “Android Activity” and click Next. In the list of templates, choose “Empty Activity” and click Next.

In the last page of the new-activity wizard, fill in:

- `NoteActivity` in the “Activity Name” field
- `pleasedeleteme` for the “Layout Name”
- `pleasedeletemetoo` for the “Title”

Leave the rest of the wizard at its defaults, then click on Finish.

In the `NoteActivity` class that is created, replace the current implementation with the source shown in the Android Studio instructions above.

You can also delete the `/res/layout/pleasedeleteme.xml` file, by right-clicking over it and choosing “Delete...” from the context menu.

Finally, open up `res/values/strings.xml` and delete the `title_activity_simple_content` that the wizard added, which we are no longer using. At this point, you can save your changes to this file (e.g., `<Ctrl>-<S>`).

Step #6: Examining `NoteActivity`

As you can see, this is a fairly trivial activity. In `onCreate()`, if we are being created anew, we execute a `FragmentManager` to add a `NoteFragment` to our activity, pouring it into the full screen (`android.R.id.content`). Here, `android.R.id.content` identifies the container into which the results of `setContentView()` would go — it is a container supplied by Activity itself and serves as the top-most container for our content.

However, we expect that we will be passed an `Intent` extra with the position (`EXTRA_POSITION`), which we pass along to the `NoteFragment` factory method.

Step #7: Add Notes to the Action Bar

Of course, none of this is useful if we do not give the user a way to get to the `NoteActivity`. Specifically, we can add a `notes` entry to our `res/menu/options.xml` resource, to have a new toolbar button appear on our main activity’s action bar.

First, copy the `01_core_edit` icons from the `Action Bar Icons/holo_dark/` directory from the “Action Bar Icon Pack” into your project. In the `01_core_edit` directory, you will see versions of this icon in various densities. Copy those icon files into their corresponding directories in your project. You can do this by dragging the

TUTORIAL #14 - SAVING NOTES

file from your development desktop OS into the project explorer window and dropping it into the proper directory.

Then, modify `res/menu/options.xml` to look like:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/notes"
        android:icon="@drawable/ic_action_edit"
        android:showAsAction="ifRoom|withText"
        android:title="@string/notes">
    </item>
    <item
        android:id="@+id/settings"
        android:icon="@drawable/ic_action_settings"
        android:showAsAction="never"
        android:title="@string/settings">
    </item>
    <item
        android:id="@+id/help"
        android:icon="@drawable/ic_action_help"
        android:title="@string/help">
    </item>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        android:title="@string/about">
    </item>

</menu>
```

Either IDE can handle this via editing the XML. Eclipse users also can add this via the structured editor for `res/menu/options.xml`, following the instructions used for other action bar items.

Note that this menu definition requires a new string resource, named `notes`, with a value like `Notes`.

Then, in `EmPubLiteActivity`, add the following case to the switch statement in `onOptionsItemSelected()`:

```
case R.id.notes:
    i=new Intent(this, NoteActivity.class);
    i.putExtra(NoteActivity.EXTRA_POSITION, pager.getCurrentItem());
    startActivity(i);

    return(true);
```

Note that depending on where you place this, you will need to remove one existing declaration of `Intent i` from one of the case blocks, whichever comes second.

Here, we get the currently-viewed position from the `ViewPager` and pass that as the `EXTRA_POSITION` extra to `NoteActivity`.

Step #8: Defining a `NoteLoadedEvent`

We will want to load notes from the database on a background thread. Hence, we can apply the same basic approach as we used with `ModelFragment`, posting an event on the greenrobot `EventBus` when the load is completed, to deliver the results to the `NoteFragment`. This step will create a `NoteLoadedEvent` to handle this case.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteLoadedEvent` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

class NoteLoadedEvent {
    int position;
    String prose;

    NoteLoadedEvent(int position, String prose) {
        this.position=position;
        this.prose=prose;
    }

    int getPosition() {
        return(position);
    }

    String getProse() {
        return(prose);
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `NoteLoadedEvent` in the "Name" field. Leave the "Superclass" field alone, as `NoteLoadedEvent` has no explicit superclass. Then, click "Finish" on the new-class dialog to create the `NoteLoadedEvent` class.

Then, with `NoteLoadedEvent` open in the editor, paste in the class definition shown in the Android Studio instructions above.

Step #9: Loading a Note from the Database

Next, we need to add code somewhere that will actually query the database (on a background thread) to load the note for a given `ViewPager` position. One common pattern is to put this sort of database-access logic on your `SQLiteOpenHelper` subclass, so all of your database-specific code resides in one place. That is the approach we will take here, adding a `loadNote()` method that will fork a thread, query the database, and post a `NoteLoadedEvent` as a result.

Edit your `DatabaseHelper` to add its own `LoadThread` inner class, reminiscent of the one from `ModelFragment`:

```
private class LoadThread extends Thread {
    private int position=-1;

    LoadThread(int position) {
        super();

        this.position=position;
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
        String[] args= { String.valueOf(position) };
        Cursor c=
            getReadableDatabase().rawQuery("SELECT prose FROM notes WHERE position
= ?",
                                           args);

        if (c.getCount() > 0) {
            c.moveToFirst();
        }
    }
}
```

```
        EventBus.getDefault().post(new NoteLoadedEvent(position,
                                                         c.getString(0)));
    }

    c.close();
}
}
```

Here, we use `rawQuery()` to retrieve the note based upon a supplied position. If there is no such note, our `Cursor` will have no rows, and we are done. If, however, we did get results back on the query, we then post a `NoteLoadedEvent` with the position and the prose (the text from the database).

You will need to add an import manually to `android.os.Process`, to be able to resolve the `setThreadPriority()` method and its parameter.

Also, add a `loadNote()` method to `DatabaseHelper` that forks this `LoadThread`:

```
void loadNote(int position) {
    new LoadThread(position).start();
}
```

Step #10: Loading the Note Into the Fragment

Now that we can query the database and get back a note (if any), we can tie that into the `NoteFragment` to load the note for the fragment's position when the fragment is opened. We will not only need to call `loadNote()` on the `DatabaseHelper`, but also be able to respond to the `NoteLoadedEvent` when it arrives.

Add the following `onResume()` method to `NoteFragment`:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (TextUtils.isEmpty(editor.getText())) {
        DatabaseHelper db=DatabaseHelper.getInstance(getActivity());

        db.loadNote(getPosition());
    }
}
```

Here, we register for the `EventBus`. Then, if we do not have any text in the `EditText` widget, we call `loadNote()` on our singleton instance of the `DatabaseHelper`, passing

in the position that our fragment is managing. The reason for checking to see if the `EditText` is empty is to handle configuration changes. This fragment is not a retained fragment, and so it will be destroyed and re-created. The default `onSaveInstanceState()` logic of `EditText` will retain our note, though, so we do not want to re-load it from the database. This approach is not optimal, in that we will wind up calling `loadNote()` in cases where we could know that there is no note. That optimization is complex enough to not make it worthwhile for a set of book tutorials, though it is something you might wish to explore in a commercial-grade application.

Next, add the corresponding `onPause()` to `NoteFragment`, to unregister from the `EventBus`:

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

Finally, add an `onEventMainThread(NoteLoadedEvent)` method to `NoteFragment`, so we receive the `NoteLoadedEvent` on the main application thread:

```
public void onEventMainThread(NoteLoadedEvent event) {
    if (event.getPosition() == getPosition()) {
        editor.setText(event.getProse());
    }
}
```

Here, we confirm that the event is for our fragment's position, as it is conceivable that this event is for some other note, though that is rather unlikely given how the user would view notes. That being said, if the note is for our position, we populate the `EditText` with the note prose.

Step #11: Updating the Database

Of course, loading notes from a database is all fine and well... except that we do not have any notes *in* the database. We really should fix that.

Add an `UpdateThread` inner class to `DatabaseHelper`:

```
private class UpdateThread extends Thread {
    private int position=-1;
    private String prose=null;
```

```
UpdateThread(int position, String prose) {
    super();

    this.position=position;
    this.prose=prose;
    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
}

@Override
public void run() {
    String[] args= { String.valueOf(position), prose };

    getWritableDatabase().execSQL("INSERT OR REPLACE INTO notes (position,
prose) VALUES (?, ?)",
                                args);
}
}
```

Here, we use `execSQL()` to execute an `INSERT OR REPLACE` SQL statement. As the name suggests, this will insert a new row if there is no match on our primary key (position). Otherwise, it will update the other columns if there is a match.

Note that we do not post an event here. We could, if there was something in the app that needed to know when a note was updated.

Also, add an `updateNote()` method to `DatabaseHelper` that forks this `UpdateThread`:

```
void updateNote(int position, String prose) {
    new UpdateThread(position, prose).start();
}
```

Step #12: Saving the Note

Somewhere, we need to call `updateNote()`. A classic “desktop” approach would be to have a “save” action bar item in the `NoteFragment`, which the user would need to click upon to save the note. However, this does not deal with the interrupt-driven nature of phones all that well. For example, the user might start typing in a note, then wind up taking a phone call. If our process is terminated, depending upon how the user tries getting back into our app, we might not have the note from our saved instance state.

A better approach, in many cases, is to save data in `onPause()` or `onStop()`, when the activity moves into the background. If there is a chance that the user might not want the partially-entered information, you could save it in a “side” area, such as a

TUTORIAL #14 - SAVING NOTES

temporary file, and deal with it when the user returns to your app. Or, you could just update the real data store... which is what we will do here.

Edit the `onPause()` method in `NoteFragment` to look like the following:

```
@Override
public void onPause() {
    DatabaseHelper.getInstance(getActivity())
        .updateNote(getPosition(),
            editor.getText().toString());

    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

Here, we update the note. This is a bit inefficient, as we update the database even if the user did not change the text of the note, or even if the note is empty. That represents another optimization that a production-grade app might wish to pursue but is skipped here in the interests of simplicity.

If you build and run the app on a device or emulator, you will see the new “notes” toolbar button in the action bar:

TUTORIAL #14 - SAVING NOTES

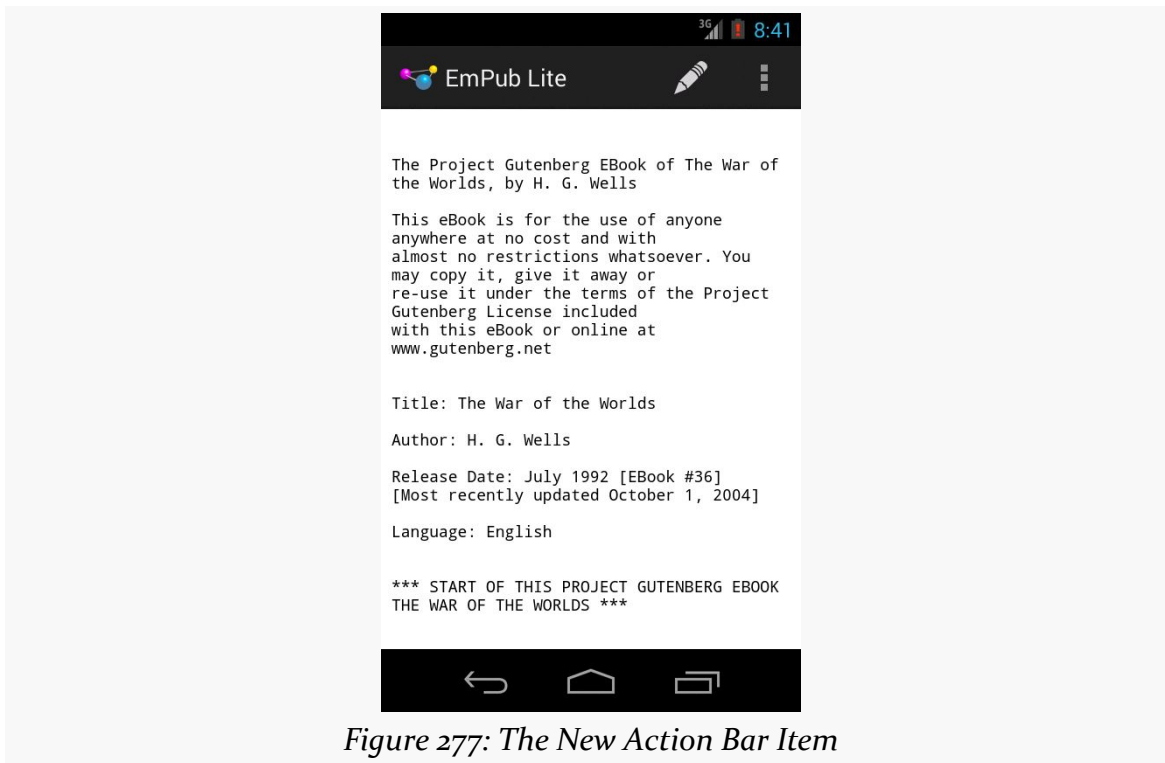

Figure 277: The New Action Bar Item

Tapping that will bring up the notes for whatever ViewPager position that you are on. Entering in some notes and pressing BACK to exit the activity will save those notes, which you will see again if you tap the action bar toolbar button again. If you change the notes, pressing BACK will save the changed notes in the database, to be viewed again later when you go back into the notes for that ViewPager position.

Step #13: Adding a Delete Action Bar Item

The only problem with this solution is that the notes never leave. While the user could manually delete everything in the EditText, it would be nice to make that perhaps a bit simpler. In this step, we will add an action bar item that will clear the EditText for the user.

First, copy the 01_core_discard icons from the Action Bar Icons/holo_dark/ directory from the “Action Bar Icon Pack” into your project. In the 01_core_discard directory, you will see versions of this icon in various densities. Copy those icon files into their corresponding directories in your project. You can do this by dragging the file from your development desktop OS into the project explorer window and dropping it into the proper directory.

TUTORIAL #14 - SAVING NOTES

Create a new resource, `res/menu/notes.xml`, to configure the action bar for the activity hosting our `NoteFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/delete"
        android:icon="@drawable/ic_action_discard"
        android:showAsAction="ifRoom|withText"
        android:title="@string/delete">
    </item>
</menu>
```

This simply defines a single action bar item, with an ID of `delete`.

To do this, Android Studio users can right-click over the `res/menu/` directory and choose `New > "Menu resource file"` from the context menu. Fill in `notes.xml` in the "New Menu Resource File" dialog and click OK. Paste in the XML shown above into that file.

Eclipse users can right-click over the `res/menu/` directory and choose `New > File` from the context menu, filling in `notes.xml` as the file name. Then, switch over to the "notes.xml" sub-tab and paste in the XML shown above into that file.

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#). Note that you will also need to add a new string resource, named `delete`, with a value of `Delete`.

To let Android know that our `NoteFragment` wishes to participate in the action bar, we need to call `setHasOptionsMenu(true)` at some point. Add an `onCreate()` method to `NoteFragment` to handle this when the fragment is created:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
}
```

That will trigger a call to `onCreateOptionsMenu()`, which we will need to add to `NoteFragment`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);
}
```

```
super.onCreateOptionsMenu(menu, inflater);  
}
```

This just inflates our new resource for use in the options menu.

If the user taps on that toolbar button, `onOptionsItemSelected()` will be called, so we will need to add that as well to `NoteFragment`:

```
@Override  
public boolean onOptionsItemSelected(MenuItem item) {  
    if (item.getItemId() == R.id.delete) {  
        editor.setText(null);  
  
        return(true);  
    }  
  
    return(super.onOptionsItemSelected(item));  
}
```

Here, if the user tapped on our delete action bar item, we clear the `EditText` widget.

Step #14: Closing the NoteFragment When Deleted

However, tapping on that action bar item keeps the `NoteFragment` on the screen. It might be nice to automatically return to the book instead. However, the `NoteFragment` itself does not know how to do that, as something else (in this case, `NoteActivity`) put the `NoteFragment` on the screen. Hence, we need to pass the request to close the `NoteFragment` along to the proper party.

We could use another event object and our `EventBus`. In this case, we will demonstrate another approach: using the contract pattern to alert the hosting activity that the notes should be closed.

Define an *inner interface* in the `NoteFragment`, named `Contract`, as follows:

```
public interface Contract {  
    void closeNotes();  
}
```

You might put those lines immediately after the `public class NoteFragment...` line, before the declaration of any of the data members or methods, for example.

TUTORIAL #14 - SAVING NOTES

Then, add a private `getContract()` method, that casts the hosting Activity to the `Contract` interface:

```
private Contract getContract() {  
    return((Contract) getActivity());  
}
```

What we are doing here is enforcing that the activity that hosts our `NoteFragment` must implement the `NoteFragment.Contract` interface.

Then, add a call to `closeNotes()` on the `Contract` to our logic in `onOptionsItemSelected()`:

```
@Override  
public boolean onOptionsItemSelected(MenuItem item) {  
    if (item.getItemId() == R.id.delete) {  
        editor.setText(null);  
        getContract().closeNotes();  
  
        return(true);  
    }  
  
    return(super.onOptionsItemSelected(item));  
}
```

Now, when the user clicks on the delete action bar item, we clear the `EditText` and ask the hosting activity to get rid of us. Along the way, our `onPause()` will be called, causing us to clear the content of the prose column in our database row as well.

At this point, `NoteFragment` should resemble:

```
package com.commonware.empublite;  
  
import android.app.Fragment;  
import android.os.Bundle;  
import android.text.TextUtils;  
import android.view.LayoutInflater;  
import android.view.Menu;  
import android.view.MenuInflater;  
import android.view.MenuItem;  
import android.view.View;  
import android.view.ViewGroup;  
import android.widget.EditText;  
import de.greenrobot.event.EventBus;  
  
public class NoteFragment extends Fragment {  
    public interface Contract {  
        void closeNotes();  
    }  
}
```

TUTORIAL #14 - SAVING NOTES

```
private static final String KEY_POSITION="position";
private EditText editor=null;

static NoteFragment newInstance(int position) {
    NoteFragment frag=new NoteFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
}

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
}

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    return(result);
}

@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (TextUtils.isEmpty(editor.getText())) {
        DatabaseHelper db=DatabaseHelper.getInstance(getActivity());

        db.loadNote(getPosition());
    }
}

@Override
public void onPause() {
    DatabaseHelper.getInstance(getActivity())
        .updateNote(getPosition(),
                    editor.getText().toString());

    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

TUTORIAL #14 - SAVING NOTES

```
}

@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.delete) {
        editor.setText(null);
        getContract().closeNotes();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}

public void onEventMainThread(NoteLoadedEvent event) {
    if (event.getPosition() == getPosition()) {
        editor.setText(event.getProse());
    }
}

private int getPosition() {
    return(getArguments().getInt(KEY_POSITION, -1));
}

private Contract getContract() {
    return((Contract) getActivity());
}
}
```

NoteActivity now must implement NoteFragment.Contract and implement closeNotes(). Modify NoteActivity to look like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity implements
    NoteFragment.Contract {
    public static final String EXTRA_POSITION="position";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

TUTORIAL #14 - SAVING NOTES

```
if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
    int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

    if (position >= 0) {
        Fragment f=NoteFragment.newInstance(position);

        getFragmentManager().beginTransaction()
            .add(android.R.id.content, f).commit();
    }
}

public void closeNotes() {
    finish();
}
```

This adds the implements keyword and the closeNotes() implementation, which just finishes the NoteActivity, returning control to the EmPubLiteActivity.

If you run this in a device or emulator, and you go into the notes, you will see our delete toolbar button:

Figure 278: The New Action Bar Item

Tapping that toolbar button will clear the note and close the activity, returning you to the book.

In Our Next Episode...

... we will allow the user to [share a chapter's notes](#) with somebody else.

Internet Access

The expectation is that most, if not all, Android devices will have built-in Internet access. That could be WiFi, cellular data services (EDGE, 3G, etc.), or possibly something else entirely. Regardless, most people — or at least those with a data plan or WiFi access — will be able to get to the Internet from their Android phone.

Not surprisingly, the Android platform gives developers a wide range of ways to make use of this Internet access. Some offer high-level access, such as the integrated WebKit browser component (WebView) we saw in an [earlier chapter](#). If you want, you can drop all the way down to using raw sockets. Or, in between, you can leverage APIs — both on-device and from 3rd-party JARs — that give you access to specific protocols: HTTP, XMPP, SMTP, and so on.

The emphasis of this book is on the higher-level forms of access: the [WebKit component](#) and Internet-access APIs, as busy coders should be trying to reuse existing components versus rolling one's own on-the-wire protocol wherever possible.

DIY HTTP

In many cases, your only viable option for accessing some Web service or other HTTP-based resource is to do the request yourself. The Google-endorsed API for doing this nowadays in Android is to use the classic `java.net` classes for HTTP operation, centered around `HttpURLConnection`. There is quite a bit of material on this already published, as these classes have been in Java for a long time. The focus here is in showing how this works in an Android context.

Note, however, that you may find it easier to use some HTTP client libraries that handle various aspects of the Internet access for you, as will be described [later in this chapter](#).

A Sample Usage of HttpURLConnection

This chapter walks through several implementations of a Stack Overflow client application. The app has a single activity, with a single `ListFragment`. The app will load the latest block of Stack Overflow questions tagged with `android`, using the Stack Exchange public API. Those questions will be shown in the list, and tapping on a question will bring up the Web page for that question in the user's default Web browser.

All implementations of the app have the same core UI logic. What differs is in how each handles the Internet access. In this section, we will take a look at the [Internet/HURL](#) sample project, which uses `HttpURLConnection` to retrieve the questions from the Stack Exchange Web service API.

Asking Permission

To do anything with the Internet (or a local network) from your app, you need to hold the `INTERNET` permission. This includes cases where you use things like `WebView` — if your *process* needs network access, you need the `INTERNET` permission.

Hence, the manifest for our sample project contains the requisite `<uses-permission>` declaration:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

Creating Your Data Model

The Stack Exchange Web service API returns JSON in response to various queries. Hence, we need to create Java classes that mirror that JSON structure. In particular, many of the examples will be using Google's `Gson` to populate those data models automatically based upon its parsing of the JSON that we receive from the Web service.

In our case, we are going to use a specific endpoint of the Stack Exchange API, referred to as `/questions` after the distinguishing portion of the path. The

documentation for this endpoint can be found in [the Stack Exchange API documentation](#).

We will examine the URL for the endpoint a bit later in this section.

The results we get for issuing a GET request for the URL is a JSON structure (here showing a single question, to keep the listing short):

```
{

NOTE: Some of the longer URLs will word-wrap in the book, but they are on a single line in the actual JSON. Honest.

We get back a JSON object, where our questions are found under the name of `items`. `items` is a JSON array of JSON objects, where each JSON object represents a single question, with fields like `title` and `link`. The question JSON object has an embedded `owner` JSON object with additional information.

We do not necessarily need all of this information. In fact, for this first version of the sample, all we really need are the title and link of each entry in the items array.

The key is that, by default, the data members in our Java data model must *exactly* match the JSON keys for the JSON objects.

So, we have an Item class, representing the information from an individual entry in the items array:

```
package com.commonware.android.hurl;

public class Item {
    String title;
    String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

The toString() implementation is there so we can toss our Item array into an ArrayAdapter without needing to write a getView() method to pull the title out manually.

However, our Web service does not return the items array directly. items is the key in a JSON object that is the actual JSON returned by Stack Exchange. So, we need another Java class that contains the data members we need from that outer JSON object, here named SOQuestions (for lack of a better idea for a name...):

```
package com.commonware.android.hurl;

import java.util.List;

public class SOQuestions {
    List<Item> items;
}
```

Having an items data member that is a List of Item tells GSON that we are expecting the JSON object to be used for SOQuestions to have a JSON array, named items, where each element in that array should get mapped to Item objects.

A Thread for Loading

We need to do the network I/O on a background thread, so we do not tie up the main application thread. To that end, the sample app has a `LoadThread` that loads our questions:

```
package com.commonware.android.hurl;

import android.util.Log;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.net.HttpURLConnection;
import java.net.URL;
import com.google.gson.Gson;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
    static final String SO_URL=
        "https://api.stackexchange.com/2.1/questions?"
        + "order=desc&sort=creation&site=stackoverflow&tagged=android";

    @Override
    public void run() {
        try {
            HttpURLConnection c=
                (HttpURLConnection)new URL(SO_URL).openConnection();

            try {
                InputStream in=c.getInputStream();
                BufferedReader reader=
                    new BufferedReader(new InputStreamReader(in));
                SOQuestions questions=
                    new Gson().fromJson(reader, SOQuestions.class);

                reader.close();

                EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
            }
            catch (IOException e) {
                Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
            }
            finally {
                c.disconnect();
            }
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

LoadThread:

- Creates an `URLConnection` by creating a URL for our Stack Exchange API endpoint and opening a connection
- Creates a `BufferedReader` wrapped around the `InputStream` from the HTTP connection
- Parses the JSON we get back from that HTTP request via a `Gson` instance, loading the data into an instance of our `SOQuestions`
- Close the `BufferedReader` (and the `InputStream` by extension)
- Post a `QuestionsLoadedEvent` to greenrobot's `EventBus`, to let somebody know that our questions exist
- Log messages to `LogCat` in case of errors

`QuestionsLoadedEvent` is a simple wrapper around an `SOQuestions` instance, serving as an event class for use with `EventBus`:

```
package com.commonware.android.hurl;

public class QuestionsLoadedEvent {
    final SOQuestions questions;

    QuestionsLoadedEvent(SOQuestions questions) {
        this.questions=questions;
    }
}
```

A Fragment for Questions

The sample app has a `QuestionsFragment` that should display these loaded questions:

```
package com.commonware.android.hurl;

import android.app.ListFragment;
import android.os.Bundle;
import android.text.Html;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;
import java.util.List;
import de.greenrobot.event.EventBus;

public class QuestionsFragment extends ListFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);

setRetainInstance(true);
new LoadThread().start();
}

@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);
}

@Override
public void onPause() {
    EventBus.getDefault().unregister(this);
    super.onPause();
}

@Override
public void onItemClick(ListView l, View v, int position, long id) {
    Item item=((ItemsAdapter)getListAdapter()).getItem(position);

    EventBus.getDefault().post(new QuestionClickedEvent(item));
}

public void onEventMainThread(QuestionsLoadedEvent event) {
    setListAdapter(new ItemsAdapter(event.questions.items));
}

class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(getActivity(), android.R.layout.simple_list_item_1, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView title=(TextView)row.findViewById(android.R.id.text1);

        title.setText(Html.fromHtml(getItem(position).title));

        return(row);
    }
}
```

In `onCreate()`, we mark that this fragment should be retained and fork the `LoadThread`. Hence, once we have our questions, our retained fragment will hold onto that model data for us, and we avoid duplicating the `LoadThread` if a configuration change occurs sometime after our fragment was initially created.

In `onResume()` and `onPause()`, we register and unregister from the `EventBus`. Our `onEventMainThread()` method will be called when the `QuestionsLoadedEvent` is raised by `LoadThread`, and there we hold onto the loaded questions and populate the `ListView`. We use an `ItemsAdapter`, which knows how to render an `Item` as a simple `ListView` row showing the question title. The `ItemsAdapter` uses `Html.fromHtml()` to populate the `ListView` rows, not because Stack Overflow hands back titles with HTML tags, but because Stack Overflow hands back titles with HTML *entity references*, and `Html.fromHtml()` should handle many of those.

And, in `onListItemClick()`, we find the `Item` associated with the row that the user clicked upon, then raise a `QuestionClickedEvent` to let somebody know that the user clicked on that row. The `QuestionClickedEvent` class is a simple wrapper around an `Item` to serve as an event class for use with `EventBus`:

```
package com.commonware.android.hurl;

public class QuestionClickedEvent {
    final Item item;

    QuestionClickedEvent(Item item) {
        this.item=item;
    }
}
```

An Activity for Orchestration

`MainActivity` sets up the fragment in `onCreate()`, registers and unregisters for the event bus in `onResume()` and `onPause()`, and handles the click events in `onEventMainThread()`:

```
package com.commonware.android.hurl;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import de.greenrobot.event.EventBus;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new QuestionsFragment()).commit();
        }
    }
}
```

```
    }  
}  
  
@Override  
public void onResume() {  
    super.onResume();  
    EventBus.getDefault().register(this);  
}  
  
@Override  
public void onPause() {  
    EventBus.getDefault().unregister(this);  
    super.onPause();  
}  
  
public void onEventMainThread(QuestionClickedEvent event) {  
    startActivity(new Intent(Intent.ACTION_VIEW,  
                             Uri.parse(event.item.link)));  
}  
}
```

Hence, MainActivity is serving in an orchestration role. QuestionsFragment is a local controller, handling direct events raised by its widgets (a ListView). MainActivity is responsible for handling events that transcend an individual fragment — in this case, it starts a browser to view the clicked-upon question.

The result is a simple ListView showing questions:

What Android Brings to the Table

Google has augmented `HttpURLConnection` to do more stuff to help developers. Notably:

- It automatically uses GZip compression on requests, adding the appropriate HTTP header and automatically decompressing any compressed responses (added in Android 2.3)
- It uses [Server Name Indication](#) to help work with several HTTPS hosts sharing a single IP address
- API Level 13 (Android 4.0) added an `HttpResponseBodyCache` implementation of the `java.net.ResponseCache` base class, that can be installed to offer transparent caching of your HTTP requests.

Also, courtesy of some third-party code (OkHttp) that we will discuss shortly, `HttpURLConnection` also supports [the SPDY protocol](#) for accelerating Web content distribution over SSL as of Android 4.4.

Testing with StrictMode

StrictMode, mentioned in [the chapter on files](#), can also report on performing network I/O on the main application thread. More importantly, on Android 4.0 and higher, the emulator will, by default, crash your app if you try to perform network I/O on the main application thread.

Hence, it is generally a good idea to test your app, either using StrictMode yourself or using a suitable emulator, to make sure that you are not performing network I/O on the main application thread.

What About HttpClient?

Android also contains a mostly-complete copy of version 4.0.2beta of the [Apache HttpClient library](#). Many developers use this, as they prefer the richer API offered by this library over the somewhat more clunky approach used by `java.net`. And, truth be told, this was the more stable option prior to Android 2.3.

There are a few reasons why this is no longer recommended, for Android 2.3 and beyond:

- The core Android team is better able to add capabilities to the `java.net` implementation while maintaining backwards compatibility, because its API is more narrow.
- The problems previously experienced on Android with the `java.net` implementation have largely been fixed.
- The Apache HttpClient project continuously evolves its API. This means that Android will continue to fall further and further behind the latest-and-greatest from Apache, as Android insists on maintaining the best possible backwards compatibility and therefore cannot take on newer-but-different HttpClient versions.

That being said, you are welcome to use HttpClient if you are not concerned about these limitations.

HTTP via DownloadManager

If your objective is to download some large file, you may be better served by using the DownloadManager added to Android 2.3, as it handles a lot of low-level complexities for you. For example, if you start a download on WiFi, and the user

leaves the building and the device fails over to some form of mobile data, you need to reconnect to the server and either start the download again or use some content negotiation to pick up from where you left off. `DownloadManager` handles that.

However, `DownloadManager` is dependent upon some broadcast Intent objects, a technique we have not discussed yet, so we will delay covering `DownloadManager` until [later in the book](#).

Using Third-Party JARs

To some extent, the best answer is to not write the code yourself, but rather use some existing JAR that handles both the Internet I/O and any required data parsing. This is commonplace when accessing public Web services — either because the firm behind the Web service has released a JAR, or because somebody in the community has released a JAR for that Web service.

Examples include:

- Using [JTwitter](#) to access Twitter's API
- Using [Amazon's JAR](#) to access various AWS APIs, including S3, SimpleDB, and SQS
- Using the [Dropbox SDK](#) for accessing DropBox folders and files

However, beyond the [classic potential JAR problems](#), you may encounter another when it comes to using JARs for accessing Internet services: versioning. For example:

- JTwitter bundles the `org.json` classes in its JAR, which will be superseded by Android's own copy, and if the JTwitter version of the classes have a different API, JTwitter could crash.
- Libraries dependent upon `HttpClient` might be dependent upon a version with a different API (e.g., 4.1.1) than is in Android (4.0.2 beta).

Try to find JARs that have been tested on Android and are clearly supported as such by their author. Lacking that, try to find JARs that are open source, so you can tweak their implementation if needed to add Android support.

[Later in this chapter](#), we will review another class of third-party JARs, ones that are more general-purpose than things like JTwitter, but still offer to simplify HTTP processing.

SSL

Of course, if you are thinking about HTTP, you really should be thinking about HTTPS — SSL-encrypted HTTP operations.

Normally, SSL “just works”, by using an `https://` URL. Hence, typically, there is little that you need to do to enable simple encryption.

However, there are other aspects of SSL to consider, including:

- What if the server is not using an SSL certificate that Android will honor, such as a self-signed certificate?
- What about man-in-the-middle attacks, hacked certificate authorities, and the like?

The trails contain [a chapter dedicated to SSL](#) that you are encouraged to read, so that this chapter does not get crazy-long.

Using HTTP Client Libraries

Often times, writing Internet access code is a pain in various body parts.

Not surprisingly, there are a variety of third-party libraries designed to assist with this. Some are designed to provide access to a specific API, such as the ones mentioned earlier in this chapter. However, others are more general-purpose, designed to make writing HTTP operations a bit easier, by handling things like:

- Retries (e.g., device failed over from WiFi to mobile data mid-transaction)
- Threading (e.g., handling doing the Internet work on a background thread for you)
- Data parsing and marshaling, for well-known formats (e.g., JSON)

In this section, we will look at four libraries that exemplify this approach: OkHttp, Retrofit, Picasso, and Ion. Later, we will see other libraries that you might wish to investigate, including Google’s own Volley HTTP client API.

OkHttp

[OkHttp](#) uses a modified clone of the standard `URLConnection` to offer many performance improvements. Most notable is its support for [SPDY](#), a Google

sponsored enhanced version of HTTP, going beyond classic HTTP “keep-alive” support to allow for many requests and responses to be delivered over the same socket connection. Many Google APIs are served by SPDY-capable servers, and SPDY support is available for others to use as well.

Beyond that, OkHttp wraps up common HTTP performance-improvement patterns, such as GZIP compression, response caching, and connection pooling. It also is more aware of “real world” connection issues, like mis-configured proxy servers and the like.

OkHttp supports both `URLConnection`- and `HttpClient`-compatible APIs. To accommodate this, OkHttp is broken up into three JARs:

- One for OkHttp’s core (`okhttp-X.Y.Z.jar`)
- One for the `URLConnection` API (`okhttp-URLConnection-X.Y.Z.jar`)
- One for the `HttpClient` API (`okhttp-apache-X.Y.Z.jar`)

Android Studio users can add a dependency on either `com.squareup.okhttp:okhttp-URLConnection:...` or `com.squareup.okhttp:okhttp-apache:...`, for some version denoted by `...`. This will automatically pull down the OkHttp core code as well.

You will need to choose which of those you want. Going with the core JAR plus one of the API JARs means that your existing code that uses the classic APIs will require very little in the way of change. For example, to use the `URLConnection` API, given the requisite two JARs, is mostly a matter of creating an instance of `OkHttpClient` and using its `open()` method to open a connection to a URL. `open()` will return an `URLConnection`, which you use the same as you would normally, except that OkHttp’s implementation adds the aforementioned features.

However, you are still stuck with the `URLConnection` or `HttpClient` APIs, handling things like request generation and response processing yourself. Square’s other two HTTP client libraries — Retrofit and Picasso — layer atop of OkHttp to help address usability issues for specific scenarios. And OkHttp 2.0 added a new native API that is designed to be simpler and cleaner than either `URLConnection` or `HttpClient`.

Note that OkHttp is used as the standard implementation of `URLConnection` in Android 4.4 and higher — this is where Android’s SPDY support comes from.

Retrofit

Many times, when working with HTTP requests, our needs are fairly simple: just retrieve some JSON (or other structured data, such as XML) from some Web service, or perhaps upload some JSON to that Web service.

[Retrofit](#) is designed to simplify this, by handling the data parsing and marshaling for us, along with the HTTP operations and (optionally) background threading. We are left with a fairly natural-looking Java API to send/receive Java objects to/from the Web service. Retrofit accomplishes this through the cunning use of annotations, reflection, and, where available, OkHttp itself.

To demonstrate Retrofit, let's review the [HTTP/Retrofit](#) sample project. This project is a clone of the preceding one, this time using Retrofit for retrieving and parsing our Stack Overflow questions.

Note that Stack Overflow happens to use JSON as its data format, which works nicely with Retrofit, as JSON is its default data format. However, you can supply your own conversion logic, to convert data to/from other formats, such as XML or [Protocol Buffers](#).

Downloading and Installing Retrofit

Retrofit is available as a small JAR from the aforementioned [Retrofit Web site](#). By default, it uses [Google's Gson](#) for its JSON parsing, so you will need to download that JAR as well. If you also have OkHttp in your project, Retrofit will automatically use it, falling back to standard Android HTTP APIs if OkHttp is unavailable.

The combination of these JARs totals around 600KB, mostly coming from Gson and OkHttp. For most apps, this will not be a major issue, but if APK size is important to you, you need to keep in mind the footprint that these JARs consume.

Creating Your Service Interface

The first thing we need is to tell Retrofit more about where our JSON is coming from. To do this, we need to create a Java interface with some specific Retrofit-supplied annotations, documenting:

- the HTTP operations that we wish to perform
- the path (and, if needed, query parameters) to apply an HTTP operation to

- the per-request data to configure the HTTP operation, such as the dynamic portions of the path for a REST-style API, or additional query parameters to attach to the URL
- what object should be used for pouring the HTTP response into

For example, let's take a look at `StackOverflowInterface`, our interface for making a query of Stack Exchange's API to get questions from Stack Overflow:

```
package com.commonware.android.retrofit;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    void questions(@Query("tagged") String tags, Callback<SOQuestions> cb);
}
```

Each method in the interface should have an annotation identifying the HTTP operation to perform, such as `@GET` or `@POST`. The parameter to the annotation is the path for the request and any fixed query parameters. In our case, we are using the path documented by Stack Exchange for retrieving questions (`/2.1/questions`), plus some fixed query parameters:

- `order` for whether the results should be ascending (`asc`) or descending (`desc`)
- `sort` to indicate how the questions should be sorted, such as `creation` to sort by time when the question was posted
- `site` to indicate what Stack Exchange site we are querying (e.g., `stackoverflow`)

The method name can be whatever you want.

If you have additional query parameters that vary dynamically, you can use the `@Query` annotation on `String` parameters to have them be added to the end of the URL. In our case, the `tagged` query parameter will be added with whatever the `tags` parameter is to our `questions()` method.

Similarly, you can use `{name}` placeholders for path segments, and replace those at runtime via `@Path`-annotated parameters to the method.

To get results back, and indicate the data type for those results, you have two choices:

1. Have the method return the data type you wish, in which case when we eventually call this method, the HTTP operation will be performed synchronously, blocking our method call
2. Pass a `Callback` parameter, declared with the desired data type (e.g., `SOQuestions`), in which case when we eventually call this method, the HTTP operation will be performed on a background thread, with the results delivered to us asynchronously via a custom `Callback` implementation that we will supply

In this case, we are electing to let `Retrofit` handle the threading for us, so we supply a `Callback` and have the method return `void`.

Curiously, we will never create an implementation of the `StackOverflowInterface` ourselves. Instead, `Retrofit` generates one for us, with code that implements our requested behaviors.

Creating the `RestAdapter`

To use this generated `StackOverflowInterface`, and to actually perform these operations, we need to create an instance of a `RestAdapter`. Usually, you will do this via a `RestAdapter.Builder`, to configure what you want done.

The biggest thing you will provide to `RestAdapter.Builder` is the server tied to these HTTP operations. Calling `setEndpoint()` allows you to specify the scheme, host, and port to be attached to the rest of the URL, coming from your interface. For example, we need to make our requests of the `https://api.stackexchange.com` server, so we have:

```
RestAdapter restAdapter=  
    new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")  
                              .build();
```

Other methods on `RestAdapter.Builder` include:

- `setConverter()`, if your payloads are not in JSON format, but something else
- `setExecutors()`, to provide `Executor` objects (e.g., instances of `ThreadPoolExecutor`) to be used for requests and callbacks
- `setLog()` and `setDebug()` for controlling log output

When you are done configuring the `RestAdapter.Builder`, call `build()` to get the resulting `RestAdapter`.

Making Requests

Given a configured `RestAdapter`, you can retrieve an implementation of your API interface by calling the `create()` method:

```
StackOverflowInterface so=
    restAdapter.create(StackOverflowInterface.class);
```

You can then use the resulting interface-typed object no differently than you would any other Java object, despite the fact that you never wrote an implementation of that interface yourself.

In our case, we can call the `questions()` method, supplying the tag (or tags) from which we wish to receive recent questions:

```
so.questions("android", this);
```

The second parameter to `questions()` is an implementation of `Callback`, to receive asynchronous results from our HTTP GET request. `Callback` requires two methods, `success()` and `failure()`. `success()` takes two parameters: the data type you indicated in the interface (e.g., `SOQuestions`) representing the parsed results of the HTTP request, and a `Response` object containing other information from the HTTP response, such as headers:

```
@Override
public void success(SOQuestions questions, Response response) {
    setListAdapter(new ItemsAdapter(questions.items));
}
```

Here, we update our `ListView` with an `ItemsAdapter` based upon the received questions.

`failure()` takes a single parameter, an instance of `RetrofitError`, which is an `Exception` providing details of something that went wrong in the HTTP request (e.g., authorization was denied). You can handle that no differently than you might other exceptions from elsewhere in your app, to let the user know that something went wrong. In this case, we take the crude-but-easy approach of showing a `Toast` and logging the details to `LogCat`:

```
@Override
public void failure(RetrofitError exception) {
    Toast.makeText(getActivity(), exception.getMessage(),
        Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
        "Exception from Retrofit request to StackOverflow", exception);
}
```

Picasso

Sometimes, what you want to download is not JSON, or XML, or any sort of structured data.

Sometimes, it is an image.

For example, Stack Overflow users have avatars. In our sample app, it might be nice to display the avatar of the user who asked the question.

[Picasso](#) is a library from Square that is designed to help with asynchronously loading images, whether those images come from HTTP requests, local files, a ContentProvider, etc. In addition to doing the loading asynchronously, Picasso simplifies many operations on those images, such as:

- Caching the results in memory (or optionally on disk for HTTP requests)
- Displaying placeholder images while the real images are being loaded, and displaying error images if there was a problem in loading the image (e.g., invalid URL)
- Transforming the image, such as resizing or cropping it to fit a certain amount of space
- Loading the images directly into an `ImageView` of your choice, even handling cases where that `ImageView` is recycled (e.g., part of a row in a `ListView`, where the user scrolled while an image for that `ImageView` was still loading, and now *another* image is destined for that same `ImageView` when the row was recycled)

The [HTTP/Picasso](#) sample application extends the Retrofit one to download the avatar image of the person asking the question, displaying it in the `ListView` along with the question title.

Downloading and Installing Picasso

Picasso can be downloaded as a small JAR from [the aforementioned Web site](#). It requires OkHttp 1.6.0+, both the core JAR and the OkHttp HttpURLConnection JAR. Android Studio users can just add a dependency for `com.squareup.picasso:picasso:...` for some version denoted by `...`, and it will pull down all other dependencies needed by Picasso.

Updating the Model

Our original data model did not include information about the owner. Hence, we need to augment our data model, so Retrofit pulls that information out of the Stack Exchange JSON and makes it available to us.

To that end, we now have an `Owner` class, holding onto the one piece of information we need about the owner: the URL to the avatar (a.k.a., “profile image”):

```
package com.commonware.android.picasso;

import com.google.gson.annotations.SerializedName;

public class Owner {
    @SerializedName("profile_image") String profileImage;
}
```

The JSON key for this in the Stack Exchange API is `profile_image`, and underscores are not the conventional way of separating words in a Java data member. Java samples usually use “camelCase” instead. The default behavior of Retrofit would require us to name our data member `profile_image` to match the JSON.

However, under the covers, Retrofit is using Google’s Gson to do the mapping from JSON to objects. Gson supports a `@SerializedName` annotation, to indicate the JSON key to use for this data member. This allows us to give the data member the more natural name of `profileImage`, by using `@SerializedName("profile_image")` to teach Gson how to populate it properly.

(The author would like to thank Alec Holmes for his assistance with the Gson support)

Our `Item` class now has an `Owner`, named `owner`, since the owner data is in the owner key of an item’s JSON object:

```
package com.commonware.android.picasso;

public class Item {
    String title;
    Owner owner;
    String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

Those two changes are sufficient for Retrofit to give us our URL to be able to download the image.

Requesting the Images

Using Picasso is extremely simple, as it offers a fluent interface that allows us to set up a request in a single Java statement.

The statement begins with a call to the static `with()` method on the `Picasso` class, where we supply a `Context` (such as our activity) for Picasso to use. The statement *ends* with a call to `into()`, indicating the `ImageView` into which Picasso should load an image. In between those calls, we can chain other calls, as `with()` and most other methods on a `Picasso` object return the `Picasso` object itself.

So, we can do something like:

```
Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);
```

Here, we:

- Indicate that we want to `load()` an image found at a certain URL, identified by the `profileImage` data member of the `Owner` inside an `Item` referred to as `item`
- Say that we want to `fit()` the image to our target `ImageView`
- Specify that the image should be resized using `centerCrop()` rules, to center the image within the desired size (if it is smaller on one or both axes) and to crop the image (if it is larger on one or both axes)

- Indicate that we want to put a certain drawable resource as the `placeholder()` image to show in the `ImageView` while the loading is going on in the background
- State that we want to show a certain drawable resource in the `ImageView` in case of an `error()` when the image was being loaded

And that's it. Picasso will go off, download the image, and pour it into the `ImageView` when it is ready (and resized).

The Rest of the Story

That bit of Picasso code is in a new `getView()` method on our `ItemsAdapter`:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    Item item=getItem(position);
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    TextView title=(TextView)row.findViewById(R.id.title);

    title.setText(Html.fromHtml(getItem(position).title));

    return(row);
}
```

We have created our own row layout (`res/layout/row.xml`), consisting of an `ImageView` and a `TextView`. We have `ArrayAdapter` inflate or recycle our row, retrieve the `Item` for this row, retrieve the `ImageView` out of the row, use Picasso to start loading the real image, fill in the HTML-entity-aware text into the `TextView`, and then return our updated row. By the time we return the row, Picasso will have already loaded the placeholder image, which is what the user will initially see, while we download the real image.

The result is that we now have icons next to each of our question titles:

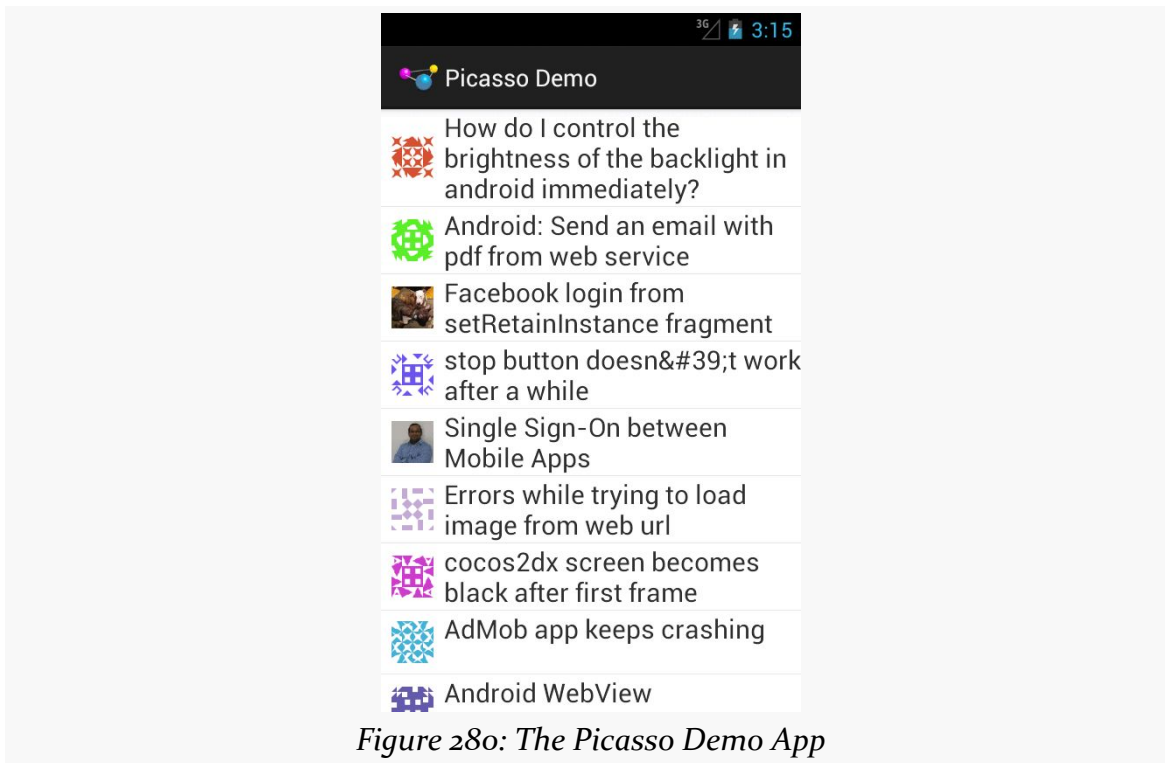

Figure 280: The Picasso Demo App

Ion

One complaint regarding the combination of Retrofit and Picasso is that you need two libraries. Picasso knows images, but cannot perform non-image HTTP requests, and Retrofit knows REST but not images.

[Ion](#) is a library that covers both, so let's see how it can be used, via the [HTTP/Ion](#) sample application. This is a port of the Retrofit/Picasso sample app, replacing those libraries with Ion.

Getting the Questions

In the revised QuestionsFragment, in onCreateView(), we use Ion to retrieve the questions as a JsonObject:

```
@Override
public View onCreateView(LayoutInflater inflater,
                          ViewGroup container,
                          Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container, savedInstanceState);
```

```
setRetainInstance(true);

Ion.with(getActivity(),
    "https://api.stackexchange.com/2.1/questions?"
    + "order=desc&sort=creation&site=stackoverflow&"
    + "tagged=android").asJsonObject().setCallback(this);

return(result);
```

Ion, like Picasso, uses a fluent, builder-style interface. The static `with()` method on the Ion class takes a Context and the URL (or Uri) of the data to be retrieved. We then cascade onto the return value:

- a call to `asJsonObject()`, indicating that we want Ion to convert the JSON into a Gson `JsonObject`
- a call to `setCallback()`, indicating where the `JsonObject` should be delivered

The `setCallback()` call takes a `FutureCallback` as a parameter; we implement that interface on the `QuestionsFragment` itself. That, in turn requires that we implement `onCompleted()`:

```
@Override
public void onCompleted(Exception e, JsonObject json) {
    if (e != null) {
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception from Retrofit request to StackOverflow", e);
    }

    if (json != null) {
        JSONArray items=json.getAsJSONArray("items");
        ArrayList<JsonObject> normalized=new ArrayList<JsonObject>();

        for (int i=0; i < items.size(); i++) {
            normalized.add(items.get(i).getAsJsonObject());
        }

        setListAdapter(new ItemsAdapter(normalized));
    }
}
```

We are passed an `Exception` if there was a problem, or the `JsonObject` if we did indeed receive results. If we have an `Exception`, we show the message via a `Toast` and log it to `LogCat`. If we have a `JsonObject`, we convert the `JSONArray` of items into an `ArrayList` of `JsonObjects`, so that we can use `ArrayAdapter` (which

understands `java.util.List` but not `JSONArray`, as the Gson authors did not implement the `List` interface on `JSONArray`).

Getting the Avatars

That means that `ItemsAdapter` is now an `ArrayAdapter` of `JsonObject`, rather than an `ArrayAdapter` of a custom `Item` class. Our `getView()` method therefore must also be updated, both to grab the title and avatar URL from the `JsonObject` representing a question, and to use `Ion` to retrieve the avatar image:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    JsonObject item=getItem(position);
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    Ion.with(icon)
        .placeholder(R.drawable.owner_placeholder)
        .resize(size, size)
        .centerCrop()
        .error(R.drawable.owner_error)
        .load(item.getAsJsonObject("owner").get("profile_image")
            .getAsString());

    TextView title=(TextView)row.findViewById(R.id.title);

    title.setText(Html.fromHtml(item.get("title").getAsString()));

    return(row);
}
```

With Gson, `get()` on a `JsonObject` returns a `JsonElement`, which in turn can be coerced into various data types, such as using `getAsString()` to coerce it into a `String`. For example, we use that when populating the `TextView` with the question's title.

To retrieve the avatar and populate the `ImageView` with it, we use `Ion` much in the same fashion as we used `Picasso`. We use a different version of the static `with()` method, one that takes our `ImageView` as a parameter. The rest of the fluent API is similar to `Picasso`'s:

- `placeholder()` and `error()` indicate drawables to use when the image is loading or if an HTTP error was encountered, respectively
- `resize()` and `centerCrop()` allow us to crop the image to the desired size

- `load()` supplies the URL from which to retrieve the image, here obtained by driving down into Gson data structures to get the `profile_image` URL of the owner of this question

Visually, the result is the same as the Picasso example.

Other Candidate Libraries

There are plenty of other libraries that similarly try to help simplify Android HTTP operations, including:

- [android-async-http](#)
- [android-json-rpc](#)
- [Android-Universal-Image-Loader](#)
- [basic-http-client](#)
- [http-request](#)
- [ImageLoader](#)
- [OpenS](#)
- [Smart Image View](#)

and countless others.

Hey, What About Volley?

At the Google I/O 2013 conference, there was [a session](#) about Volley, an HTTP client library created by Google and used by internal apps, such as the Play Store. Volley can be thought of as a superset of Retrofit plus Picasso, minus Picasso's non-HTTP image loading facilities.

On the plus side, Volley is such a superset and therefore a single code base can be used to replace multiple libraries. Also, given Volley's use by Google, one imagines that this code has been applied to the widest range of possible devices.

However, Volley is distributed as just [a dump of source code](#). There is no packaging of the code into a JAR. There is no documentation beyond that I/O video and [a training module](#). There is no support mechanism, except perhaps via ad-hoc social media inquiries and general support sites (e.g., [Stack Overflow](#)).

If you are a fairly expert developer, and wish to experiment with Volley, there are plenty of others with a similar interest, and perhaps the community will build up its own knowledge base and be able to support Volley users. Otherwise, you may be

better served sticking with libraries that have more packaging, documentation, and support structures.

Visit the Trails

As noted earlier, there is a [chapter on SSL](#) that you should read, if you run into trouble using SSL in Android or want to improve your security further than you get with just stock SSL handling.

There is also a [chapter on miscellaneous network capabilities](#) – the coverage of DownloadManager can be found there.

Intents, Intent Filters

We have seen Intent objects briefly, in our discussion of [having multiple activities in our application](#). However, we really did not dive into too much of the details about those Intent objects, and they can be used in other ways besides starting up an activity. In this chapter, we will examine Intent and their filters.

What's Your Intent?

When Sir Tim Berners-Lee cooked up the Hypertext Transfer Protocol — HTTP — he set up a system of verbs plus addresses in the form of URLs. The address indicated a resource, such as a Web page, graphic, or server-side program. The verb indicated what should be done: GET to retrieve it, POST to send form data to it for processing, etc.

An Intent is similar, in that it represents an action plus context. There are more actions and more components to the context with Intent than there are with HTTP verbs and resources, but the concept is still the same.

Just as a Web browser knows how to process a verb+URL pair, Android knows how to find activities or other application logic that will handle a given Intent.

Pieces of Intents

The two most important pieces of an Intent are the action and what Android refers to as the “data”. These are almost exactly analogous to HTTP verbs and URLs — the action is the verb, and the “data” is a `Uri`, such as `http://commonsware.com` representing an HTTP URL to some balding guy's Web site. Actions are constants, such as `ACTION_VIEW` (to bring up a viewer for the resource) or `ACTION_EDIT` (to edit the resource).

If you were to create an Intent combining ACTION_VIEW with a content Uri of `http://commonsware.com`, and pass that Intent to Android via `startActivity()`, Android would know to find and open an activity capable of viewing that resource.

There are other criteria you can place inside an Intent, besides the action and “data” Uri, such as:

1. Categories. Your “main” activity will be in the LAUNCHER category, indicating it should show up on the launcher menu. Other activities will probably be in the DEFAULT category, though other categories exist and are used on occasion.
2. A MIME type, indicating the type of resource you want to operate on.
3. A component, which is to say, the class of the activity that is supposed to receive this Intent.
4. “Extras”, which is a Bundle of other information you want to pass along to the receiver with the Intent, that the recipient might want to take advantage of. What pieces of information a given recipient can use is up to the recipient and (hopefully) is well-documented.

You will find rosters of the standard actions, categories, and extras in the Android SDK documentation for the Intent class.

Intent Routing

As noted above, if you specify the target component in your Intent, Android has no doubt where the Intent is supposed to be routed to — it will launch the named activity. This might be OK if the target recipient (e.g., the activity to be started) is in your application. It definitely is not recommended for invoking functionality in other applications. Component names, by and large, are considered private to the application and are subject to change. Actions, Uri templates, and MIME types are the preferred ways of identifying capabilities you wish third-party code to supply.

If you do not specify the target component, then Android has to figure out what recipients are eligible to receive the Intent. For example, Android will take the Intent you supply to `startActivity()` and find the activities that might support it. Note the use of the plural “activities”, as a broadly-written intent might well resolve to several activities. That is the... ummm... intent (pardon the pun), as you will see [later in this chapter](#). This routing approach is referred to as implicit routing.

Basically, there are three rules, all of which must be true for a given activity to be eligible for a given Intent:

- The activity must support the specified action
- The activity must support the stated MIME type (if supplied)
- The activity must support all of the categories named in the Intent

The upshot is that you want to make your Intent specific enough to find the right recipient, and no more specific than that.

This will become clearer as we work through some examples throughout this chapter.

Stating Your Intent(ions)

All Android components that wish to be started via an Intent must declare Intent filters, so Android knows which intents should go to that component. A common approach for this is to add one or more `<intent-filter>` elements to your `AndroidManifest.xml` file, inside the element for the component that should respond to the Intent.

For example, all of the sample projects in this book have an `<intent-filter>` on an `<activity>` that looks like this:

```
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
```

Here, we declare that this activity:

1. Is the main activity for this application
2. It is in the LAUNCHER category, meaning it gets an icon in anything that thinks of itself as a “launcher”, such as the home screen

You are welcome to have more than one action or more than one category in your Intent filters. That indicates that the associated component (e.g., activity) handles multiple different sorts of Intent patterns.

Responding to Implicit Intents

We saw in the chapter on multiple activities how one activity can start another via an explicit Intent, identifying the particular activity to be started:

```
startActivity(new Intent(this, OtherActivity.class));
```

In that case, OtherActivity does not need an <intent-filter> in the manifest. It will automatically respond when somebody explicitly identifies it as the desired activity.

However, what if you want to respond to an implicit Intent, one that focuses on an action string and other values? Then you *will* need an <intent-filter> in the manifest.

For example, take a look at the [Intents/FauxSender](#) sample project.

Here, we have an activity, FauxSender, set up to respond to an ACTION_SEND Intent, specifically for content that has the MIME type of text/plain:

```
<activity
    android:name="FauxSender"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.NoDisplay">
    <intent-filter android:label="@string/app_name">
        <action android:name="android.intent.action.SEND"/>

        <data android:mimeType="text/plain"/>

        <category android:name="android.intent.category.DEFAULT"/>
    </intent-filter>
</activity>
```

The call to startActivity() will always add the DEFAULT category if no other category is specified, which is why our <intent-filter> also filters on that category.

Hence, if somebody on the system calls startActivity() on an ACTION_SEND Intent with a MIME type of text/plain, our FauxSender activity might get control. We will explain the use of the term “might” in the next section.

The [documentation for ACTION_SEND](#) indicates that a standard extra on the Intent is EXTRA_TEXT, representing the text to be sent. There might also be an EXTRA_SUBJECT, representing a subject line, if the “send” operation might have such a concept, such as an email client.

FauxSender can retrieve those extras and make use of them:

```
package com.commonware.android.fsender;

import android.app.Activity;
```

```
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);

        if (TextUtils.isEmpty(msg)) {
            msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);
        }

        if (TextUtils.isEmpty(msg)) {
            Toast.makeText(this, R.string.no_message_supplied,
                Toast.LENGTH_LONG).show();
        }
        else {
            Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
        }

        finish();
    }
}
```

Here, we use `TextUtils.isEmpty()` to detect if an extra is either null or has an empty string as its value. If `EXTRA_TEXT` is supplied, we show it in a Toast. Otherwise, we use `EXTRA_SUBJECT` if it is supplied, and if that is also missing, we show a stock message from a string resource.

The activity then immediately calls `finish()` from `onCreate()` to get rid of itself. That, coupled with `android:theme="@android:style/Theme.NoDisplay"` in the `<activity>` element, means that the activity will have no user interface, beyond the Toast. If run from the launcher, you will still see the launcher behind the Toast:

Figure 281: FauxSender, Showing EXTRA_TEXT

Requesting Implicit Intents

To send something via ACTION_SEND, you first set up the Intent, containing whatever information you want to send in EXTRA_TEXT, such as this code from the FauxSenderTest activity:

```
Intent i=new Intent(Intent.ACTION_SEND);  
i.setType("text/plain");  
i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);  
i.putExtra(Intent.EXTRA_TEXT, theMessage);
```

(where theMessage is a passed-in parameter to the method containing this code fragment)

If we call startActivity() on this Intent directly, there are three possible outcomes, described in the following sections.

Zero Matches

It is possible, though unlikely, that there are no activities at all on the device that will be able to handle this Intent. In that case, we crash with an `ActivityNotFoundException`. This is a `RuntimeException`, which is why we do not have to keep wrapping all our `startActivity()` calls in try/catch blocks. However, if we might start something that does not exist, we really should catch that exception... or avoid the call in the first place. Detecting up front whether there will be any matches for our activity is a topic that will be discussed later in this book.

Note that the odds of an `ActivityNotFoundException` climb substantially on Android 4.3+ tablets, when a restricted profile is in use, as will be discussed [later in this book](#).

One Match

It is possible that there will be exactly one matching activity. In that case, the activity in question starts up and takes over the foreground. This is what we see with the explicit Intent.

Many Matches, Default Behavior

It is possible that there will be more than one matching activity. In that case, by default, the user will be presented with a so-called “chooser” dialog box:

Figure 282: Chooser Dialog

The user can tap on any item in the list to have that particular activity be the one to process this event. And, if the user clicks on “Always”, and we invoke the same basic Intent again (same action, same MIME type, same categories, same Uri scheme), whatever the user chooses *now* will be used again automatically, bypassing the chooser. The “Always” button in the chooser dialog sets the default activity for handling the particular Intent structure that triggered the chooser.

The Chooser Override

For many Intent patterns, the notion of the user choosing a default makes perfect sense. For example, if the user installs another Web browser, until they set a default activity, every time they go to view a Web page, they will be presented with a chooser, to choose among the installed browsers. This can get annoying quickly.

However, ACTION_SEND is one of those cases where a default activity is usually inappropriate. Just because the user on Monday chose to send something via Bluetooth and accidentally clicked “Always” does not mean that every day thereafter, they *always* want *every* ACTION_SEND to go via Bluetooth, instead of Gmail or Email or Facebook or Twitter or any other ACTION_SEND-capable apps they may have installed.

INTENTS, INTENT FILTERS

You can elect to force a chooser to display, regardless of whether the user has set a default activity or not. To do this, instead of calling `startActivity()` on the Intent directly, you wrap the Intent in another Intent returned by the `createChooser()` static method on Intent itself:

```
void sendIt(String theMessage) {
    Intent i=new Intent(Intent.ACTION_SEND);

    i.setType("text/plain");
    i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);
    i.putExtra(Intent.EXTRA_TEXT, theMessage);

    startActivity(Intent.createChooser(i,
                                     getString(R.string.share_title)));
}
```

The second parameter to `createChooser()` is a message to appear at the top of the dialog box:

Figure 283: Your Tailored Chooser Dialog

Notice the lack of the “Always” button — not only must the user make a choice now, but also they cannot make a default choice for the future, either.

ShareActionProvider

Above, we saw how you can bring up a chooser when using `startActivity()` on an implicit Intent action, such as `ACTION_SEND`.

There is another option, if you are using the action bar: `ShareActionProvider`. Designed for use with `ACTION_SEND`, `ShareActionProvider` supplies a drop-down menu in the action bar to let the user invoke some implementation of an Intent that you configure and supply.

To see how you can add a `ShareActionProvider` to your activity or fragment, let us take a look at the [ActionBar/ShareNative](#) sample project.

Our activity — `MainActivity` — will utilize the action bar. Its action bar items are contained in a `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/share"
        android:actionProviderClass="android.widget.ShareActionProvider"
        android:showAsAction="ifRoom"/>

</menu>
```

In addition to specifying an ID and indicating that the item should always be shown in the action bar, we also include the `android:actionProviderClass` attribute. This points to a concrete implementation of the `ActionProvider` abstract base class, which is responsible for rendering the action bar item. In our case, we are using `ShareActionProvider`.

Our activity UI is simply a large `EditText` widget:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="left|top"
    android:inputType="textMultiLine"/>
```

We load that layout in `onCreate()` of `MainActivity`, along with initializing an Intent to be used when we employ the `ShareActionProvider`:

INTENTS, INTENT FILTERS

```
package com.commonware.android.sap;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.view.Menu;
import android.widget.EditText;
import android.widget.ShareActionProvider;
import android.widget.Toast;

public class MainActivity extends Activity implements
    ShareActionProvider.OnShareTargetSelectedListener, TextWatcher {
    private ShareActionProvider share=null;
    private Intent shareIntent=new Intent(Intent.ACTION_SEND);
    private EditText editor=null;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.activity_main);

        shareIntent.setType("text/plain");
        editor=(EditText)findViewById(R.id.editor);
        editor.addTextChangedListener(this);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        share=
            (ShareActionProvider)menu.findItem(R.id.share)
                                   .getActionProvider();
        share.setOnShareTargetSelectedListener(this);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onShareTargetSelected(ShareActionProvider source,
                                       Intent intent) {
        Toast.makeText(this, intent.getComponent().toString(),
                      Toast.LENGTH_LONG).show();

        return(false);
    }

    @Override
    public void afterTextChanged(Editable s) {
        shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());
        share.setShareIntent(shareIntent);
    }
}
```

```
@Override
public void beforeTextChanged(CharSequence s, int start, int count,
                             int after) {
    // ignored
}

@Override
public void onTextChanged(CharSequence s, int start, int before,
                          int count) {
    // ignored
}
}
```

We also register the activity itself to be a `TextWatcher`, to find out when the user types something into the `EditText` widget.

`onCreateOptionsMenu()` is where we configure the `ShareActionProvider`, which we obtain by calling `findItem()` on our `Menu` to get the item associated with the provider, then calling `getActionProvider()` on the supplied `MenuItem`. Specifically:

- We supply an `Intent` — configured with the action, MIME type, etc. that we wish to invoke — to `setShareIntent()`
- We supply `MainActivity` itself, as an implementation of `OnShareTargetSelectedListener`, via `setOnShareTargetSelectedListener()`

In the `afterTextChanged()` method needed by the `TextWatcher` interface, we update the `EXTRA_TEXT` extra in the `Intent` to be the current contents of the `EditText`. This way, as the user types, we keep the `Intent` “fresh” with respect to what should be shared. Many consumers of a `ShareActionProvider` will have less dynamic contents, in which case you can just set up the `Intent` up front before you register it with the `ShareActionProvider`.

If the user chooses an item from the `ShareActionProvider`, we are notified via a call to our `onShareTargetSelected()` method. Registering as the `OnShareTargetSelectedListener` is optional — Android will automatically start the selected activity without our involvement. `onShareTargetSelected()` is there if you wish to know the means of sharing that the user chose. In our case, we just flash a `Toast` to indicate that the callback worked.

Broadcasts and Broadcast Receivers

One channel of the Intent message bus is used to start activities. A second channel of the Intent message bus is used to send broadcasts. As the name suggests, a broadcast Intent is one that — by default — is published to any and all applications on the device that wish to tune in.

Sending a Simple Broadcast

The simplest way to send a broadcast Intent is to create the Intent you want, then call `sendBroadcast()`.

That's it.

At that point, Android will scan through everything set up to tune into a broadcast matching your Intent, typically filtering just on the action string. Anyone set up to receive this broadcast will, indeed, receive it, using a `BroadcastReceiver`.

Receiving a Broadcast: In an Activity

To receive such a broadcast in an activity (or a fragment), you will need to do four things.

First, you will need to create an instance of your own subclass of `BroadcastReceiver`. The only method you need to (or should) implement is `onReceive()`, which will be passed the Intent that was broadcast, along with a Context object that, in this case, you will typically ignore.

Second, you will need to create an instance of an `IntentFilter` object, describing the sorts of broadcasts you want to receive. Most of these filters are set up to watch for a single broadcast `Intent` action, in which case the simple constructor suffices:

```
new IntentFilter(Intent.ACTION_CAMERA_BUTTON)
```

Third, you will need to call `registerReceiver()`, typically from `onResume()` of your activity or fragment, supplying your `BroadcastReceiver` and your `IntentFilter`.

Fourth, you will need to call `unregisterReceiver()`, typically from `onPause()` of your activity or fragment, supplying the same `BroadcastReceiver` instance you provided to `registerReceiver()`.

In between the calls to `registerReceiver()` and `unregisterReceiver()`, you will receive any broadcasts matching the `IntentFilter`.

The biggest downside to this approach is that some activity has to register the receiver. Sometimes, you want to receive broadcasts even when there is no activity around. To do that, you will need to use a different technique: registering the receiver in the manifest.

Receiving a Broadcast: Via the Manifest

You can also tell Android about broadcasts you wish to receive by adding a `<receiver>` element to your manifest, identifying the class that implements your `BroadcastReceiver` (via the `android:name` attribute), plus an `<intent-filter>` that describes the broadcast(s) you wish to receive:

```
<receiver android:name=".OnBootReceiver">
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED"/>
  </intent-filter>
</receiver>
```

The good news is that this `BroadcastReceiver` will be available for broadcasts occurring at any time. There is no assumption that you have an activity already running that called `registerReceiver()`.

The bad news is that the instance of the `BroadcastReceiver` used by Android to process a broadcast will live for only so long as it takes to execute the `onReceive()` method. At that point, the `BroadcastReceiver` is discarded. Hence, it is not safe for a manifest-registered `BroadcastReceiver` to do anything that needs to run after

`onReceive()` itself completes, such as forking a thread. After all, Android may well terminate the process within milliseconds, if there is no other running component in the process.

More bad news: `onReceive()` is called on the main application thread — the same main application thread that handles the UI of all of your activities. And, you are subject to the same limitations as are your activity lifecycle methods and anything else called on the main application thread:

- Any time spent in `onReceive()` will freeze your UI, if you happen to have a foreground activity
- If you spend too long in `onReceive()`, Android will terminate your `BroadcastReceiver` without waiting for `onReceive()` to complete

This makes using a manifest-registered `BroadcastReceiver` a bit tricky. If the work to be done is very quick, just implement it in `onReceive()`. Otherwise, you will probably need to pair this `BroadcastReceiver` with a component known as an `IntentService`, which we will examine [in the next chapter](#).

The Stopped State

On Android 3.1 and higher, when your app is first installed on the device, it is in a “stopped” state. This has nothing to do with `onStop()` of any activity. While in the stopped state, your manifest-registered `BroadcastReceivers` will not receive any broadcasts.

Getting Out of the Stopped State

To get out of the stopped state, something on the app (that itself is not in the stopped state) must use an explicit `Intent` to invoke one of your components.

The most common way this happens is for the user to tap on a launcher icon associated with your launcher activity. Under the covers, the home screen’s launcher will create an explicit `Intent`, identifying your activity, and use that with `startActivity()`. This moves you out of the stopped state.

Getting Into the Stopped State

As noted above, you start off in the stopped state. Once you are moved out of the stopped state, via the explicit Intent, you will remain out of the stopped state until one of two things happens:

1. The user uninstalls your app
2. The user “force-stops” your app

The latter normally occurs when the user clicks the “Force Stop” button on your app’s screen in the Settings app (Settings > Apps). There is some evidence that some device manufacturers have tied their own device’s task manager to do a “force stop” when the user removes a task — this was not a particularly wise choice on the part of those manufacturers.

Note that a reboot does *not* move you back into the stopped state. You remain in the normal state through a reboot.

Example System Broadcasts

There are many, many broadcasts sent out by Android itself, which you can tune into if you see fit. Many, but not all, of these are documented on the Intent class. The values in the “Constants” table that have “Broadcast Action” leading off their description are action strings used for system broadcasts. There are other such broadcast actions scattered around the SDK, though, so do not assume that they are all documented on Intent.

The following sections will examine two of these broadcasts, to see how the BroadcastReceiver works in action.

At Boot Time

A popular request is to have code get control when the device is powered on. This is doable but somewhat dangerous, in that too many on-boot requests slow down the device startup and may make things sluggish for the user.

In order to be notified when the device has completed its system boot process, you will need to request the `RECEIVE_BOOT_COMPLETED` permission. Without this, even if you arrange to receive the boot broadcast Intent, it will not be dispatched to your receiver.

As the Android documentation describes it:

Though holding this permission does not have any security implications, it can have a negative impact on the user experience by increasing the amount of time it takes the system to start and allowing applications to have themselves running without the user being aware of them. As such, you must explicitly declare your use of this facility to make that visible to the user.

We also need to register our BroadcastReceiver in the manifest — by the time an activity would call `registerReceiver()`, the boot will have long since occurred.

For example, let us examine the [Intents/OnBoot](#) sample project.

In our manifest, we request the needed permission and register our BroadcastReceiver, along with an activity:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sysevents.boot"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="false"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <receiver android:name=".OnBootReceiver">
            <intent-filter>
                <action android:name="android.intent.action.BOOT_COMPLETED"/>
            </intent-filter>
        </receiver>

        <activity
            android:name="BootstrapActivity"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>
</application>

</manifest>
```

OnBootReceiver simply logs a message to LogCat:

```
package com.commonware.android.sysevents.boot;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.util.Log;

public class OnBootReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Log.d(getClass().getSimpleName(), "Hi, Mom!");
    }
}
```

To test this on Android 3.0 and earlier, simply install the application and reboot the device — you will see the message appear in LogCat.

However, on Android 3.1 and higher, the user must first manually launch some activity before any manifest-registered BroadcastReceiver objects will be used, as noted above in [the section covering the stopped state](#). Hence, if you were to just install the application and reboot the device, nothing would happen. The little BootstrapActivity is merely there for the user to launch, so that the ACTION_BOOT_COMPLETED BroadcastReceiver will start working.

On Battery State Changes

One theme with system events is to use them to help make your users happier by reducing your impacts on the device while the device is not in a great state. Most applications are impacted by battery life. Dead batteries run no apps. Hence, knowing the battery level may be important for your app.

There is an ACTION_BATTERY_CHANGED Intent that gets broadcast as the battery status changes, both in terms of charge (e.g., 80% charged) and charging (e.g., the device is now plugged into AC power). You simply need to register to receive this Intent when it is broadcast, then take appropriate steps.

BROADCASTS AND BROADCAST RECEIVERS

One of the limitations of ACTION_BATTERY_CHANGED is that you have to use `registerReceiver()` to set up a `BroadcastReceiver` to get this Intent when broadcast. You cannot use a manifest-declared receiver. There are separate ACTION_BATTERY_LOW and ACTION_BATTERY_OK broadcasts that you *can* receive from a manifest-registered receiver, but they are broadcast far less frequently, only when the battery level falls below or rises above some undocumented “low” threshold.

To demonstrate ACTION_BATTERY_CHANGED, take a peek at the [Intents/OnBattery](#) sample project.

In there, you will find a `res/layout/batt.xml` resource containing a `ProgressBar`, a `TextView`, and an `ImageView`, to serve as a battery monitor:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <ProgressBar
        android:id="@+id/bar"
        style="?android:attr/progressBarStyleHorizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <TextView
            android:id="@+id/level"
            android:layout_width="0px"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:textSize="16pt"/>

        <ImageView
            android:id="@+id/status"
            android:layout_width="0px"
            android:layout_height="wrap_content"
            android:layout_weight="1"/>
    </LinearLayout>
</LinearLayout>
```

This layout is used by a `BatteryFragment`, which registers to receive the ACTION_BATTERY_CHANGED Intent in `onResume()` and unregisters in `onPause()`:

BROADCASTS AND BROADCAST RECEIVERS

```
package com.commonware.android.battmon;

import android.app.Fragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.BatteryManager;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.ProgressBar;
import android.widget.TextView;

public class BatteryFragment extends Fragment {
    private ProgressBar bar=null;
    private ImageView status=null;
    private TextView level=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.batt, parent, false);

        bar=(ProgressBar)result.findViewById(R.id.bar);
        status=(ImageView)result.findViewById(R.id.status);
        level=(TextView)result.findViewById(R.id.level);

        return(result);
    }

    @Override
    public void onResume() {
        super.onResume();

        IntentFilter f=new IntentFilter(Intent.ACTION_BATTERY_CHANGED);

        getActivity().registerReceiver(onBattery, f);
    }

    @Override
    public void onPause() {
        getActivity().unregisterReceiver(onBattery);

        super.onPause();
    }

    BroadcastReceiver onBattery=new BroadcastReceiver() {
        public void onReceive(Context context, Intent intent) {
            int pct=
                100 * intent.getIntExtra(BatteryManager.EXTRA_LEVEL, 1)
                / intent.getIntExtra(BatteryManager.EXTRA_SCALE, 1);
```

```
bar.setProgress(pct);
level.setText(String.valueOf(pct));

switch (intent.getIntExtra(BatteryManager.EXTRA_STATUS, -1)) {
    case BatteryManager.BATTERY_STATUS_CHARGING:
        status.setImageResource(R.drawable.charging);
        break;

    case BatteryManager.BATTERY_STATUS_FULL:
        int plugged=
            intent.getIntExtra(BatteryManager.EXTRA_PLUGGED, -1);

        if (plugged == BatteryManager.BATTERY_PLUGGED_AC
            || plugged == BatteryManager.BATTERY_PLUGGED_USB) {
            status.setImageResource(R.drawable.full);
        }
        else {
            status.setImageResource(R.drawable.unplugged);
        }
        break;

    default:
        status.setImageResource(R.drawable.unplugged);
        break;
}
};
}
```

The key to ACTION_BATTERY_CHANGED is in the “extras”. Many extras are packaged in the Intent, to describe the current state of the battery, such as the following constants defined on the BatteryManager class:

- EXTRA_HEALTH, which should generally be BATTERY_HEALTH_GOOD
- EXTRA_LEVEL, which is the proportion of battery life remaining as an integer, specified on the scale described by the EXTRA_SCALE value
- EXTRA_PLUGGED, which will indicate if the device is plugged into AC power (BATTERY_PLUGGED_AC) or USB power (BATTERY_PLUGGED_USB)
- EXTRA_SCALE, which indicates the maximum possible value of level (e.g., 100, indicating that level is a percentage of charge remaining)
- EXTRA_STATUS, which will tell you if the battery is charging (BATTERY_STATUS_CHARGING), full (BATTERY_STATUS_FULL), or discharging (BATTERY_STATUS_DISCHARGING)
- EXTRA_TECHNOLOGY, which indicates what sort of battery is installed (e.g., "Li-Ion")
- EXTRA_TEMPERATURE, which tells you how warm the battery is, in tenths of a degree Celsius (e.g., 213 is 21.3 degrees Celsius)

BROADCASTS AND BROADCAST RECEIVERS

- EXTRA_VOLTAGE, indicating the current voltage being delivered by the battery, in millivolts

In the case of BatteryFragment, when we receive an ACTION_BATTERY_CHANGED Intent, we do three things:

1. We compute the percentage of battery life remaining, by dividing the level by the scale
2. We update the ProgressBar and TextView to display the battery life as a percentage
3. We display an icon, with the icon selection depending on whether we are charging (status is BATTERY_STATUS_CHARGING), full but on the charger (status is BATTERY_STATUS_FULL and plugged is BATTERY_PLUGGED_AC or BATTERY_PLUGGED_USB), or are not plugged in

If you plug this into a device, it will show you the device's charge level:

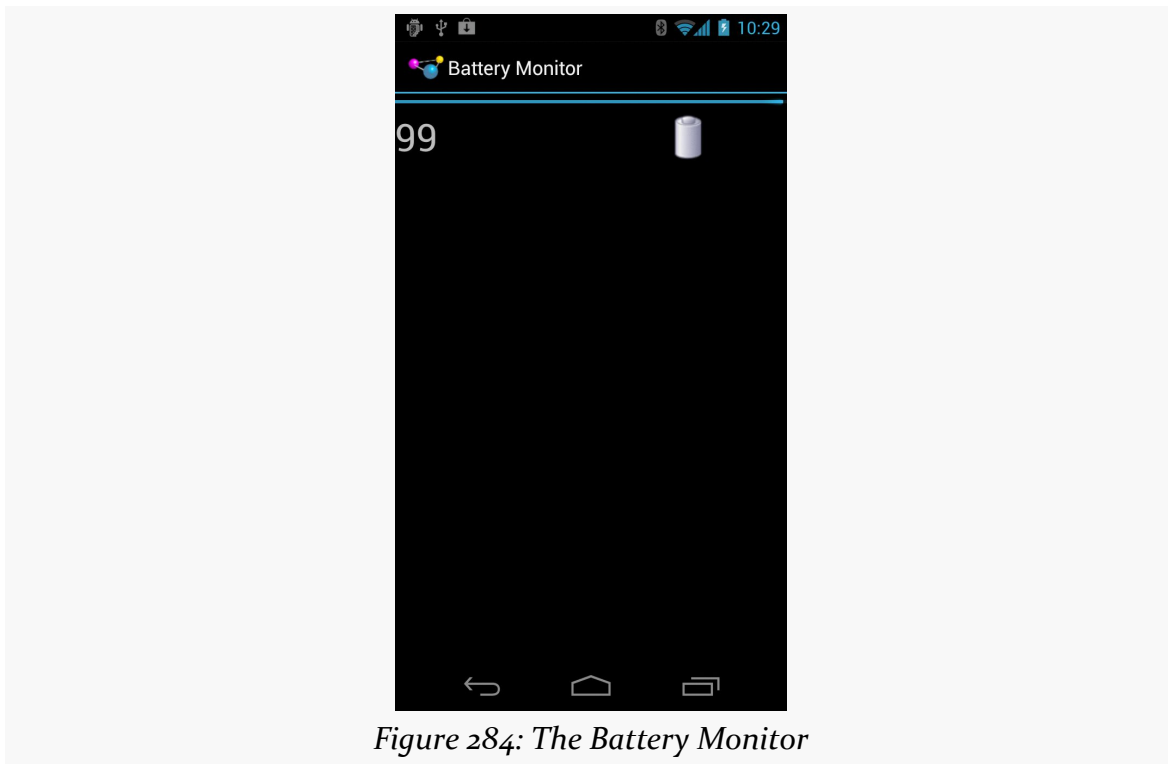

Figure 284: The Battery Monitor

Sticky Broadcasts and the Battery

NOTE: Sticky broadcasts are deprecated in Android 5.0, and the documentation hints that they may be abandoned entirely in the future.

Android has a notion of “sticky broadcast Intents”. Normally, a broadcast Intent will be delivered to interested parties and then discarded. A sticky broadcast Intent is delivered to interested parties and retained until the next matching Intent is broadcast. Applications can call `registerReceiver()` with an `IntentFilter` that matches the sticky broadcast, but with a null `BroadcastReceiver`, and get the sticky Intent back as a result of the `registerReceiver()` call.

This may sound confusing. Let’s look at this in the context of the battery.

Earlier in this section, you saw how to register for `ACTION_BATTERY_CHANGED` to get information about the battery delivered to you. You can also, though, get the latest battery information without registering a receiver. Just create an `IntentFilter` to match `ACTION_BATTERY_CHANGED` (as shown above) and call `registerReceiver()` with that filter and a null `BroadcastReceiver`. The Intent you get back from `registerReceiver()` is the last `ACTION_BATTERY_CHANGED` Intent that was broadcast, with the same extras. Hence, you can use this to get the current (or near-current) battery status, rather than having to bother registering an actual `BroadcastReceiver`.

This is why the sample app shows its results immediately — it was given the last-broadcast edition of the `ACTION_BATTERY_CHANGED` broadcast once we called `registerReceiver()`.

Battery and the Emulator

Your emulator does not really have a battery. If you run this sample application on an emulator, you will see, by default, that your device has 50% fake charge remaining and that it is being charged. However, it is charged infinitely slowly, as it will not climb past 50%... at least, not without help.

NOTE: At the time of this writing, the Linux emulator does not properly emulate the battery at all, showing 0% battery charge and not responding to the `telnet` commands described below. In theory, [this issue](#) will track progress on resolving this bug.

While the emulator will only show fixed battery characteristics, you can change what those values are, through the highly advanced user interface known as `telnet`.

You may have noticed that your emulator title bar consists of the name of your AVD plus a number, frequently 5554. That number is not merely some engineer's favorite number. It is also an open port, on your emulator, to which you can `telnet` into, on localhost (127.0.0.1) on your development machine.

There are many commands you can issue to the emulator by means of `telnet`. To change the battery level, use `power capacity NN`, where NN is the percentage of battery life remaining that you wish the emulator to return. If you do that while you have an `ACTION_BATTERY_CHANGED` `BroadcastReceiver` registered, the receiver will receive a broadcast `Intent`, informing you of the change.

You can also experiment with some of the other power subcommands (e.g., `power ac on` or `power ac off`), or other commands (e.g., `geo`, to send simulated GPS fixes, just as you can do from DDMS).

Battery Data on Android 5.0+

As noted earlier, Android 5.0 deprecates sticky broadcasts. The existing broadcasts still work, though. And, even if someday Android gets rid of sticky broadcasts entirely, broadcasts like `ACTION_BATTERY_CHANGED` most likely will *still* work, albeit just as a regular broadcast.

To get current battery information on Android 5.0 and higher, `BatteryManager` offers `getIntProperty()` and `getLongProperty()`, where the keys for the “properties” are `BATTERY_PROPERTY_*` constants defined on `BatteryManager`, such as `BATTERY_PROPERTY_CAPACITY` to determine the percentage of remaining battery capacity.

The Order of Things

Another variation on the broadcast `Intent` is the ordered broadcast.

Normally, if you broadcast an `Intent`, and there are 10 registered `BroadcastReceivers` that match that `Intent`, all 10 will receive the broadcast, in indeterminate order, and possibly in parallel (particularly on multi-core devices).

With an ordered broadcast, the behavior shifts a bit:

- Only one `BroadcastReceiver` at a time will receive the broadcast
- The order in which the `BroadcastReceivers` receive the broadcast is (somewhat) controlled by their developers
- A `BroadcastReceiver` can “abort” the broadcast, preventing other receivers in the chain from receiving it

Sending an ordered broadcast is merely a matter of calling `sendOrderedBroadcast()`.

Receiving an ordered broadcast, at its core, is identical to receiving a regular broadcast: you write a `BroadcastReceiver` and register it via the `manifest` or `registerReceiver()`. However, you have two additional options when registering that `BroadcastReceiver`.

First, you can specify a priority, either via `setPriority()` on the `IntentFilter` or `android:priority` on the `<intent-filter>` element. The priority is a positive integer, with higher numbers indicating higher priority. Higher-priority receivers will get the broadcast sooner than will lower-priority receivers.

Second, your `BroadcastReceiver` can call `abortBroadcast()` to consume the event, preventing any lower-priority receivers from even seeing the broadcast.

Keeping It Local

A broadcast `Intent`, by default and nearly by definition, is broadcast. Anything on the device could have a receiver “tuned in” to listen for such broadcasts. While you can use `setPackage()` on `Intent` to restrict the distribution, the broadcast still goes through the standard broadcast mechanism, which involves transferring the `Intent` to an OS process, which then does the actual broadcasting. Hence, a broadcast `Intent` has some overhead.

Yet, there are times when using broadcasts within an app is handy, but it would be nice to avoid the overhead. To help with this the core Android team added `LocalBroadcastManager` to the Android Support package, to provide an in-process way of doing broadcasts with the standard `Intent`, `IntentFilter`, and `BroadcastReceiver` classes, yet with less overhead.

`LocalBroadcastManager` is supplied by both the `android-support-v4.jar` and `android-support-v13.jar` libraries. Generally speaking, if your

android:minSdkVersion is less than 13, you probably should choose android-support-v4.jar.

The only real difference, from a coding standpoint, in using LocalBroadcastManager is that you call `registerReceiver()`, `unregisterReceiver()`, and `sendBroadcast()` on an instance of `LocalBroadcastManager`, instead of on an instance of `Context`. You get the `LocalBroadcastManager` singleton for your process via a static `getInstance()` method on `LocalBroadcastManager` itself.

We will see `LocalBroadcastManager` in use in one of the samples in [the services chapter](#).

Visit the Trails!

We examine `LocalBroadcastManager` in more detail, along with other event bus alternatives, [later in the book](#).

Tutorial #15 - Sharing Your Notes

Perhaps you would like to get your notes off of our book reader app and into someplace else, or perhaps you would like to share them with somebody else. Either way, we can do that using an `ACTION_SEND` operation, to allow the user to choose how to “send” the notes, such as sending them by email or uploading them to some third-party note service.

To make this work, we will add a `ShareActionProvider` to our action bar on the `NoteFragment`.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book’s GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Adding a `ShareActionProvider`

First, we need to allow the user to indicate that they want to “share” the note displayed in the current `NoteFragment`. By putting an action bar item on the activity where the `NoteFragment` is displayed, we do not need to worry about letting the user choose which note to send — we simply send whichever note they happen to be viewing or editing.

By using a `ShareActionProvider`, the action item will handle most of the work for allowing the user to choose where to send the note to. We only need to provide an `Intent` that identifies what is to be shared.

Modify `res/menu/notes.xml` to add in the new share toolbar button:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/share"
        android:actionProviderClass="android.widget.ShareActionProvider"
        android:showAsAction="ifRoom"
        android:title="@string/share"/>
    <item
        android:id="@+id/delete"
        android:icon="@drawable/ic_action_discard"
        android:showAsAction="ifRoom|withText"
        android:title="@string/delete">
    </item>
</menu>
```

Note that this menu definition requires a new string resource, named `share`, with a value like `Share`.

Step #2: Sharing the Note

Now, we need to configure the `ShareActionProvider`, in particular supplying it with a continuously-updated `Intent`, based upon what the user has typed into the `EditText`.

Add a `ShareActionProvider` data member to `NoteFragment`, named `share`, along with an `Intent` data member named `shareIntent` configured to use `ACTION_SEND` of a MIME type of `text/plain`:

```
private ShareActionProvider share=null;
private Intent shareIntent=
    new Intent(Intent.ACTION_SEND).setType("text/plain");
```

Then, in `onCreateView()`, tell the `EditText` to let us know when the user changes the text, via `addTextChangedListener()`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);
    editor.addTextChangedListener(this);
```

TUTORIAL #15 - SHARING YOUR NOTES

```
        return(result);  
    }
```

This will fail to compile, as our NoteFragment is not implementing the TextWatcher interface. So, modify the NoteFragment class declaration to include the TextWatcher interface:

```
public class NoteFragment extends Fragment implements TextWatcher {
```

That, in turn, will require us to implement three methods:

1. afterTextChanged()
2. beforeTextChanged()
3. onTextChanged()

In our case, we care about afterTextChanged(). So, add the following three methods to NoteFragment:

```
@Override  
public void afterTextChanged(Editable s) {  
    shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());  
}  
  
@Override  
public void beforeTextChanged(CharSequence s, int start, int count,  
                             int after) {  
    // ignored  
}  
  
@Override  
public void onTextChanged(CharSequence s, int start, int before,  
                          int count) {  
    // ignored  
}
```

Here, we update the shareIntent with the latest text to be shared, storing it in EXTRA_TEXT, per the instructions in the Android developer documentation for working with ACTION_SEND.

However, we have not initialized share yet. We can do that in onCreateOptionsMenu(), adding a call to findItem() to find our R.id.share menu item, then calling getActionProvider() to get the ShareActionProvider out of the menu item:

```
@Override  
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {  
    inflater.inflate(R.menu.notes, menu);
```

```
share=
    (ShareActionProvider)menu.findItem(R.id.share)
                                .getActionProvider();
share.setShareIntent(shareIntent);

super.onCreateOptionsMenu(menu, inflater);
}
```

Here, we also attach the `shareIntent` to the `ShareActionProvider`, so when it comes time to share the text, the `ShareActionProvider` knows how to do that.

Step #3: Testing the Result

If you run this on a device and navigate to a filled-in note, you will see the new action bar item:

Figure 285: ShareActionProvider in NoteFragment

If you tap on it, you will get a roster of possible ways to share the text:

TUTORIAL #15 - SHARING YOUR NOTES

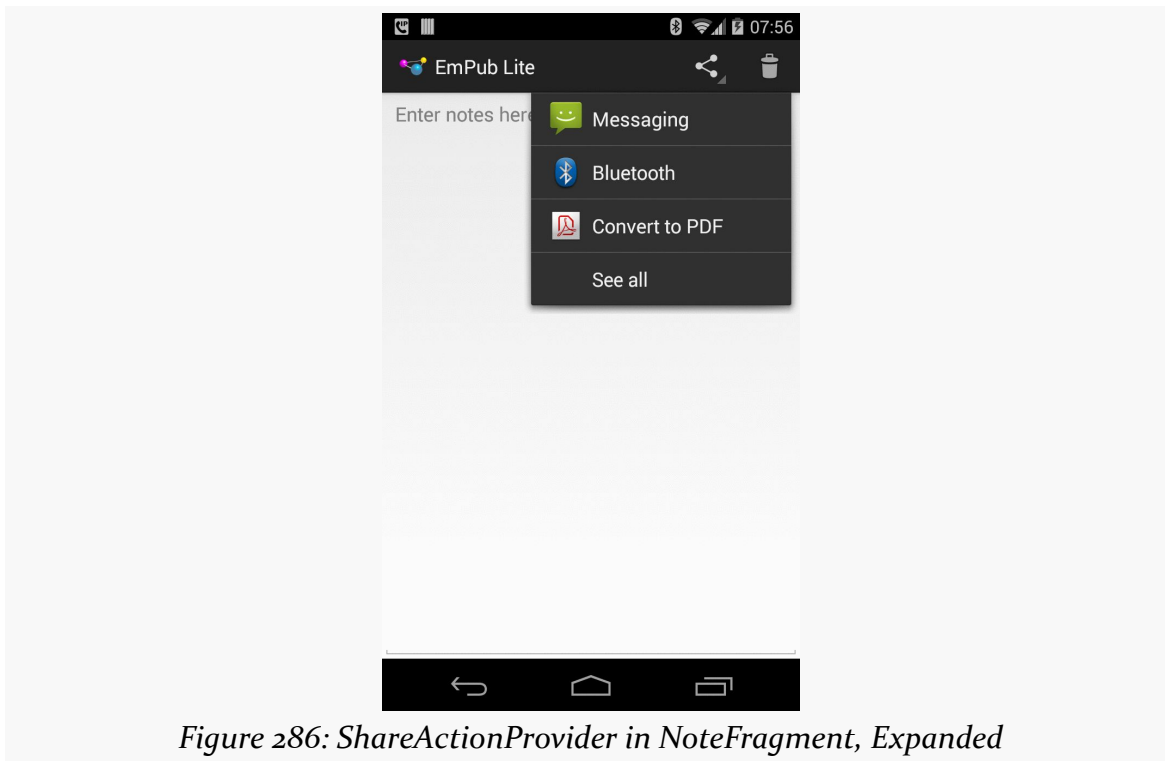

Figure 286: ShareActionProvider in NoteFragment, Expanded

The exact options you see will vary based on your device or emulator, and what apps are installed on it that know how to share plain text.

Unfortunately, your emulator may have nothing that can handle this Intent. If that is the case, you will crash with an `ActivityNotFoundException`. To get past this, if you enter <http://goo.gl/w113e> in your emulator's browser, that should allow you to download and install a copy of the APK from the [Intents/FauxSender](#) sample project that we covered [earlier in this book](#). When the download is complete (which should be very quick), open up the notification drawer and tap on the “download complete” notification. This should begin the installation process. Depending on your Android version, you may also need to “allow installation of non-Market apps” — after fixing this, you can use the Downloads app on the emulator to try installing the APK again. Once FauxSender is installed, it will respond to your attempts to share a note.

In Our Next Episode...

... we will allow the user to [update the book's contents](#) over the Internet.

Services and the Command Pattern

As noted previously, Android services are for long-running processes that may need to keep running even when decoupled from any activity. Examples include playing music even if the “player” activity is destroyed, polling the Internet for RSS/Atom feed updates, and maintaining an online chat connection even if the chat client loses focus due to an incoming phone call.

Services are created when manually started (via an API call) or when some activity tries connecting to the service via inter-process communication (IPC). Services will live until specifically shut down or until Android is desperate for RAM and terminates the process. Running for a long time has its costs, though, so services need to be careful not to use too much CPU or keep radios active too much of the time, lest the service cause the device’s battery to get used up too quickly.

This chapter outlines the basic theory behind creating and consuming services, including a look at the “command pattern” for services.

Why Services?

Services are a “Swiss Army knife” for a wide range of functions that do not require direct access to an activity’s user interface, such as:

1. Performing operations that need to continue even if the user leaves the application’s activities, like a long download (as seen with the Play Store) or playing music (as seen with Android music apps)
2. Performing operations that need to exist regardless of activities coming and going, such as maintaining a chat connection in support of a chat application

3. Providing a local API to remote APIs, such as might be provided by a Web service
4. Performing periodic work without user intervention, akin to cron jobs or Windows scheduled tasks

Even things like home screen app widgets often involve a service to assist with long-running work.

The primary role of a service is as a flag to the operating system, letting it know that your process is still doing work, despite the fact that it is in the background. This makes it *somewhat* less likely that Android will terminate your process due to low memory conditions.

Many applications will not need any services. Very few applications will need more than one. However, the service is a powerful tool for an Android developer's toolbox and is a subject with which any qualified Android developer should be familiar.

Setting Up a Service

Creating a service implementation shares many characteristics with building an activity. You inherit from an Android-supplied base class, override some lifecycle methods, and hook the service into the system via the manifest.

The Service Class

Just as an activity in your application extends either Activity or an Android-supplied Activity subclass, a service in your application extends either Service or an Android-supplied Service subclass. The most common Service subclass is IntentService, used primarily for the command pattern, described [later in this chapter](#). That being said, many services simply extend Service.

Lifecycle Methods

Just as activities have onCreate(), onResume(), onPause() and kin, Service implementations have their own lifecycle methods, such as:

- onCreate(), which, as with activities, is called when the service process is created, by any means
- onStartCommand(), which is called each time the service is sent a command via startService()

- `onBind()`, which is called whenever a client binds to the service via `bindService()`
- `onDestroy()` which is called as the service is being shut down

As with activities, services initialize whatever they need in `onCreate()` and clean up those items in `onDestroy()`. And, as with activities, the `onDestroy()` method of a service might not be called, if Android terminates the entire application process, such as for emergency RAM reclamation.

The `onStartCommand()` and `onBind()` lifecycle methods will be implemented based on your choice of communicating to the client, as will be explained [later in this chapter](#).

Note that `Service` is an abstract class and `onBind()` is an abstract method, so even if you are not using `bindService()`, you will need to implement `onBind()` in order to successfully compile. A common approach here is to have `onBind()` simply return `null`.

Manifest Entry

Finally, you need to add the service to your `AndroidManifest.xml` file, for it to be recognized as an available service for use. That is simply a matter of adding a `<service>` element as a child of the application element, providing `android:name` to reference your service class.

Since the service class is in the same Java namespace as everything else in this application, we can use the shorthand (e.g., "PlayerService") to reference our class.

For example, here is a manifest showing the `<service>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.fakeplayer"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <service
        android:name="com.commonware.android.fakeplayer.PlayerService"
        android:exported="true">
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />
            <category android:name="android.intent.category.DEFAULT" />
        </intent-filter>
    </service>

</manifest>
```

```
<application
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
  <activity
    android:name="FakePlayer"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>

  <service android:name="PlayerService"/>
</application>

</manifest>
```

Communicating To Services

Clients of services — frequently activities, though not necessarily — have two main ways to send requests or information to a service. One approach is to send a command, which creates no lasting connection to the service. The other approach is to bind to the service, establishing a communications channel that lasts as long as the client needs it.

Sending Commands with `startService()`

The simplest way to work with a service is to call `startService()`. The `startService()` method takes an `Intent` parameter, much like `startActivity()` does. In fact, the `Intent` supplied to `startService()` has the same two-part role as it does with `startActivity()`:

1. Identify the service to communicate with
2. Supply parameters, in the form of `Intent` extras, to tell the service what it is supposed to do

For a local service — the focus of this chapter — the simplest form of `Intent` is one that identifies the class that implements the `Intent` (e.g., `new Intent(this, MyService.class);`).

The call to `startService()` is asynchronous, so the client will not block. The service will be created if it is not already running, and it will receive the `Intent` via a call to

the `onStartCommand()` lifecycle method. The service can do whatever it needs to in `onStartCommand()`, but since `onStartCommand()` is called on the main application thread, it should do its work very quickly. Anything that might take more than a handful of milliseconds should be delegated to a background thread.

The `onStartCommand()` method can return one of several values, mostly to indicate to Android what should happen if the service's process should be killed while it is running. The most likely return values are:

1. `START_STICKY`, meaning that the service should be moved back into the started state (as if `onStartCommand()` had been called), but do not re-deliver the Intent to `onStartCommand()`
2. `START_REDELIVER_INTENT`, meaning that the service should be restarted via a call to `onStartCommand()`, supplying the same Intent as was delivered this time
3. `START_NOT_STICKY`, meaning that the service should remain stopped until explicitly started by application code

By default, calling `startService()` not only sends the command, but tells Android to keep the service running until something tells it to stop. One way to stop a service is to call `stopService()`, supplying the same Intent used with `startService()`, or at least one that is equivalent (e.g., identifies the same class). At that point, the service will stop and will be destroyed. Note that `stopService()` does not employ any sort of reference counting, so three calls to `startService()` will result in a single service running, which will be stopped by a call to `stopService()`.

Another possibility for stopping a service is to have the service call `stopSelf()` on itself. You might do this if you use `startService()` to have a service begin running and doing some work on a background thread, then having the service stop itself when that background work is completed.

Binding to Services

Another approach to communicating with a service is to use the binding pattern. Here, instead of packaging commands to be sent via an Intent, you can obtain an actual API from the service, with whatever data types, return values, and so on that you wish. You then invoke that API no different than you would on some local object.

The benefit is the richer API. The cost is that binding is more complex to set up and more complex to maintain, particularly across configuration changes.

We will discuss the binding pattern [later in this book](#).

Scenario: The Music Player

Most audio player applications in Android — for music, audiobooks, or whatever — do not require the user to remain in the player application itself. Rather, the user can go on and do other things with their device, with the audio playing in the background.

The sample project reviewed in this section is [Service/FakePlayer](#).

The Design

We will use `startService()`, since we want the service to run even when the activity starting it has been destroyed. However, we will use a regular `Service`, rather than an `IntentService`. An `IntentService` is designed to do work and stop itself, whereas in this case, we want the user to be able to stop the music playback when the user wants to.

Since music playback is outside the scope of this chapter, the service will simply stub out those particular operations.

The Service Implementation

Here is the implementation of this `Service`, named `PlayerService`:

```
package com.commonware.android.fakeplayer;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.util.Log;

public class PlayerService extends Service {
    public static final String EXTRA_PLAYLIST="EXTRA_PLAYLIST";
    public static final String EXTRA_SHUFFLE="EXTRA_SHUFFLE";
    private boolean isPlaying=false;

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        String playlist=intent.getStringExtra(EXTRA_PLAYLIST);
        boolean useShuffle=intent.getBooleanExtra(EXTRA_SHUFFLE, false);

        play(playlist, useShuffle);
    }
}
```

```
        return(START_NOT_STICKY);
    }

    @Override
    public void onDestroy() {
        stop();
    }

    @Override
    public IBinder onBind(Intent intent) {
        return(null);
    }

    private void play(String playlist, boolean useShuffle) {
        if (!isPlaying) {
            Log.w(getClass().getName(), "Got to play()!");
            isPlaying=true;
        }
    }

    private void stop() {
        if (isPlaying) {
            Log.w(getClass().getName(), "Got to stop()!");
            isPlaying=false;
        }
    }
}
```

In this case, we really do not need anything for `onCreate()`, so that lifecycle method is skipped. On the other hand, we have to implement `onBind()`, because that is an abstract method on `Service`.

When the client calls `startService()`, `onStartCommand()` is called in `PlayerService`. Here, we get the `Intent` and pick out some extras to tell us what to play back (`EXTRA_PLAYLIST`) and other configuration details (e.g., `EXTRA_SHUFFLE`). `onStartCommand()` calls `play()`, which simply flags that we are playing and logs a message to `LogCat` — a real music player would use `MediaPlayer` to start playing the first song in the playlist. `onStartCommand()` returns `START_NOT_STICKY`, indicating that if Android terminates the process (e.g., low memory), it should not restart it once conditions improve.

`onDestroy()` stops the music from playing — theoretically, anyway — by calling a `stop()` method. Once again, this just logs a message to `LogCat`, plus updates our internal are-we-playing flag.

In [the upcoming chapter on notifications](#), we will revisit this sample and discuss the use of `startForeground()` to make it easier for the user to get back to the music

player, plus let Android know that the service is delivering part of the foreground experience and therefore should not be shut down.

Using the Service

The PlayerFragment demonstrating the use of PlayerService has a very elaborate UI, consisting of two large buttons:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/start"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/start_the_player"/>

    <Button
        android:id="@+id/stop"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/stop_the_player"/>

</LinearLayout>
```

The fragment itself is not much more complex:

```
package com.commonware.android.fakeplayer;

import android.app.Fragment;
import android.content.Intent;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PlayerFragment extends Fragment implements
    View.OnClickListener {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.main, parent, false);

        result.findViewById(R.id.start).setOnClickListener(this);
        result.findViewById(R.id.stop).setOnClickListener(this);
    }
}
```

```
        return(result);
    }

    @Override
    public void onClick(View v) {
        Intent i=new Intent(getActivity(), PlayerService.class);

        if (v.getId() == R.id.start) {
            i.putExtra(PlayerService.EXTRA_PLAYLIST, "main");
            i.putExtra(PlayerService.EXTRA_SHUFFLE, true);

            getActivity().startService(i);
        }
        else {
            getActivity().stopService(i);
        }
    }
}
```

The `onCreate()` method merely loads the UI. The `onClick()` method constructs an Intent with fake values for `EXTRA_PLAYLIST` and `EXTRA_SHUFFLE`, then calls `startService()`. After you press the “Start” button, you will see the corresponding message in LogCat. Similarly, `stopPlayer()` calls `stopService()`, triggering the second LogCat message. Notably, you do not need to keep the activity running in between those button clicks — you can exit the activity via BACK and come back later to stop the service.

Communicating *From* Services

Sending commands to a service, by default, is a one-way street. Frequently, though, we need to get results from our service back to our activity. There are a few approaches for how to accomplish this.

Broadcast Intents

One approach, first mentioned in the chapter on [Intent filters](#), is to have the service send a broadcast Intent that can be picked up by the activity... assuming the activity is still around and is not paused. The service can call `sendBroadcast()`, supplying an Intent that identifies the broadcast, designed to be picked up by a `BroadcastReceiver`. This could be a component-specific broadcast (e.g., `new Intent(this, MyReceiver.class)`), if the `BroadcastReceiver` is registered in the manifest. Or, it can be based on some action string, perhaps one even documented and designed for third-party applications to listen for.

The activity, in turn, can register a `BroadcastReceiver` via `registerReceiver()`, though this approach will only work for `Intent` objects specifying some action, not ones identifying a particular component. But, when the activity's `BroadcastReceiver` receives the broadcast, it can do what it wants to inform the user or otherwise update itself.

However, for local services, this is not a good choice. System broadcasts like this are intrinsically system-wide; for a local service, you should be using a communications channel that is private to your process.

Pending Results

Your activity can call `createPendingResult()`. This returns a `PendingIntent` – an object that represents an `Intent` and the corresponding action to be performed upon that `Intent` (e.g., use it to start an activity). In this case, the `PendingIntent` will cause a result to be delivered to your activity's implementation of `onActivityResult()`, just as if another activity had been called with `startActivityForResult()` and, in turn, called `setResult()` to send back a result.

Since a `PendingIntent` is `Parcelable`, and can therefore be put into an `Intent` extra, your activity can pass this `PendingIntent` to the service. The service, in turn, can call one of several flavors of the `send()` method on the `PendingIntent`, to notify the activity (via `onActivityResult()`) of an event, possibly even supplying data (in the form of an `Intent`) representing that event.

We will be seeing `PendingIntent` used many places later in this book, such as with notifications and `AlarmManager`.

Event Buses

Event bus implementations — like `LocalBroadcastManager` or greenrobot's `EventBus` — are a great solution for having a service communicate with objects elsewhere within your process. You can have the service raise events (e.g., `NewEmailEvent`, `UploadCompletedEvent`, `MartiansHaveLandedEvent`), which activities or fragments can listen for and respond to.

Messenger

Yet another possibility is to use a `Messenger` object. A `Messenger` sends messages to an activity's `Handler`. Within a single activity, a `Handler` can be used to send

messages to itself, as was mentioned briefly in the [chapter on threads](#). However, between components — such as between an activity and a service — you will need a Messenger to serve as the bridge.

As with a PendingIntent, a Messenger is Parcelable, and so can be put into an Intent extra. The activity calling `startService()` or `bindService()` would attach a Messenger as an extra on the Intent. The service would obtain that Messenger from the Intent. When it is time to alert the activity of some event, the service would:

1. Call `Message.obtain()` to get an empty Message object
2. Populate that Message object as needed, with whatever data the service wishes to pass to the activity
3. Call `send()` on the Messenger, supplying the Message as a parameter

The Handler will then receive the message via `handleMessage()`, on the main application thread, and so can update the UI or whatever is necessary.

Notifications

Another approach is for the service to let the user know directly about the work that was completed. To do that, a service can raise a Notification — putting an icon in the status bar and optionally shaking or beeping or something. This technique is covered in [an upcoming chapter](#).

We can also combine these techniques, such as using an event bus event and detecting when nothing in the UI layer receives the event, so we know that we need to display a Notification. We will be examining this pattern later in the book as well.

Scenario: The Downloader

If you elect to download something from the Play Store, you are welcome to back out of the Play Store application entirely. This does not cancel the download – the download and installation run to completion, despite no Play Store activity being on-screen.

You may have similar circumstances in your application, from downloading a purchased e-book to downloading a map for a game to downloading a file from some sort of “drop box” file-sharing service. And, perhaps `DownloadManager` is not

going to be a great choice, for any number of reasons (e.g., you want to download the file to internal storage).

The sample project reviewed in this section is [Service/Downloader](#), which implements such a downloading service.

The Design

This sort of situation is a perfect use for the command pattern and an `IntentService`. The `IntentService` has a background thread, so downloads can take as long as needed. An `IntentService` will automatically shut down when the work is done, so the service will not linger and you do not need to worry about shutting it down yourself. Your activity can simply send a command via `startService()` to the `IntentService` to tell it to go do the work.

Admittedly, things get a bit trickier when you want to have the activity find out when the download is complete. This example will show the use of `LocalBroadcastManager` for this.

Using the Service

The `DownloadFragment` demonstrating the use of `Downloader` has a trivial UI, consisting of one large button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/do_the_download"
/>
```

That UI is initialized in `onCreateView()`, as usual:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, parent, false);

    b=(Button)result.findViewById(R.id.button);
    b.setOnClickListener(this);

    return(result);
}
```

When the user clicks the button, `onClick()` is called to disable the button (to prevent accidental duplicate downloads) and call `startService()` to send over a command:

```
@Override
public void onClick(View v) {
    b.setEnabled(false);

    Intent i=new Intent(getActivity(), Downloader.class);

    i.setData(Uri.parse("http://commonsware.com/Android/excerpt.pdf"));

    getActivity().startService(i);
}
```

Here, the Intent we pass over has the URL of the file to download (in this case, a URL pointing to a PDF).

The Service Implementation

Here is the implementation of this IntentService, named Downloader:

```
package com.commonsware.android.downloader;

import android.app.IntentService;
import android.content.Intent;
import android.os.Environment;
import android.support.v4.content.LocalBroadcastManager;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class Downloader extends IntentService {
    public static final String ACTION_COMPLETE=
        "com.commonsware.android.downloader.action.COMPLETE";

    public Downloader() {
        super("Downloader");
    }

    @Override
    public void onHandleIntent(Intent i) {
        try {
            File root=
```

```
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

    root.mkdirs();

    File output=new File(root, i.getData().getLastPathSegment());

    if (output.exists()) {
        output.delete();
    }

    URL url=new URL(i.getData().toString());
    HttpURLConnection c=(HttpURLConnection)url.openConnection();

    FileOutputStream fos=new FileOutputStream(output.getPath());
    BufferedOutputStream out=new BufferedOutputStream(fos);

    try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[8192];
        int len=0;

        while ((len=in.read(buffer)) >= 0) {
            out.write(buffer, 0, len);
        }

        out.flush();
    }
    finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
    }

    LocalBroadcastManager.getInstance(this)
        .sendBroadcast(new Intent(ACTION_COMPLETE));
}
catch (IOException e2) {
    Log.e(getClass().getName(), "Exception in download", e2);
}
}
```

Our business logic is in `onHandleIntent()`, which is called on an Android-supplied background thread, so we can take whatever time we need. Also, when `onHandleIntent()` ends, the `IntentService` will stop itself automatically... assuming no other requests for downloads occurred while `onHandleIntent()` was running. In that case, `onHandleIntent()` is called again for the next download, and so on.

In `onHandleIntent()`, we first set up a `File` object pointing to where we want to download the file. We use `getExternalStoragePublicDirectory()` to find the public folder for downloads. Since this directory may not exist, we need to create it

using `mkdirs()`. We then use the `getLastPathSegment()` convenience method on `Uri`, which returns to us the filename portion of a path-style `Uri`. The result is that our output `File` object points to a file, named the same as the file we are downloading, in a public folder.

We then go through a typical `URLConnection` process to connect to the URL supplied via the `Uri` in the `Intent`, streaming the results from the connection (8KB at a time) out to our designated file. Then, we follow the requested recipe to ensure our file is saved:

- `flush()` the stream
- `sync()` the `FileDescriptor` (from `getFD()`)
- `close()` the stream

This recipe was explained back in [the chapter on file I/O](#).

Finally, it would be nice to let somebody know that the download has completed. So, we send a local broadcast `Intent`, with our own custom action (`ACTION_COMPLETE`), using `LocalBroadcastManager`.

Receiving the Broadcast

Our `DownloadFragment` is set up to listen for that local broadcast `Intent`, by registering a local `BroadcastReceiver` in `onResume()` and unregistering it in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    IntentFilter f=new IntentFilter(Downloader.ACTION_COMPLETE);

    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, f);
}

@Override
public void onPause() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);

    super.onPause();
}
```

The BroadcastReceiver itself re-enables our button, plus displays a Toast indicating that the download is complete:

```
private BroadcastReceiver onEvent=new BroadcastReceiver() {  
    public void onReceive(Context ctxt, Intent i) {  
        b.setEnabled(true);  
  
        Toast.makeText(getActivity(), R.string.download_complete,  
            Toast.LENGTH_LONG).show();  
    }  
};
```

Note that if the user leaves the activity (e.g., BACK, HOME), the broadcast will not be received by the activity. There are other ways of addressing this, particularly combining an ordered broadcast with a Notification, which we will examine [later in this book](#).

Tutorial #16 - Updating the Book

The app is designed to ship a copy of the book's chapters as assets, so a user can just download one thing and get everything they need: book and reader.

However, sometimes books get updated. This is a bit less likely with the material being used in this tutorial, as it is rather unlikely that H. G. Wells will rise from the grave to amend *The War of the Worlds*. However, other books, such as Android developer guides written by balding guys, might be updated more frequently.

Most likely, the way you would get those updates is by updating the entire app, so you get improvements to the reader as well. However, another approach would be to be able to download an update to the book as a separate ZIP file. The reader would use the contents of that ZIP file if one has been downloaded, otherwise it will “fall back” to the copy in assets. That is the approach that we will take in this tutorial, to experiment a bit with Internet access and services. Along the way, we will use [Retrofit](#) to call a Web service (of sorts) to find out if an update is available.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Adding a Stub DownloadCheckService

There are a few pieces to our download-the-book-update puzzle:

- We need to determine if there is an update available and, if so, where we can find the ZIP file that is the update
- We need to download the update's ZIP file, which could be a fairly large file
- We need to unpack that ZIP file into internal or external storage, so that it is more easily used by the rest of our code and performs more quickly than would dynamically reading the contents out of the ZIP on the fly
- All of that needs to happen in the background from a threading standpoint
- Ideally, all of that could happen either in the foreground or the background from a UI standpoint (i.e., user manually requests an update check, or an update check is performed automatically on a scheduled basis)

To address the first puzzle piece — determining if there is an update available — we can use an `IntentService`. That makes it easy for us to do the work not only in the background from a threading standpoint, but also be able to use it either from the UI or from some sort of background-work scheduler. So, let's add a `DownloadCheckService` to our project.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Service > "Service (IntentService)"` from the context menu. Fill in `DownloadCheckService` as the class name and uncheck the "helper methods" checkbox. Click `Finish` to generate the `DownloadCheckService` class and add an entry for you to the manifest.

Then, replace the generated implementation of `DownloadCheckService` with:

```
package com.commonware.empublite;

import android.app.IntentService;
import android.content.Intent;

public class DownloadCheckService extends IntentService {
    public DownloadCheckService() {
        super("DownloadCheckService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
    }
}
```

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `DownloadCheckService` in the “Name” field. Click the “Browse...” button next to the “Superclass” field and find `IntentService` to set as the superclass. Then, click “Finish” on the new-class dialog to create the `DownloadCheckService` class.

Then, with `DownloadCheckService` open in the editor, paste in the class definition seen in the Android Studio instructions above.

You will also need to add a new `<service>` node to the list of nodes in the Application sub-tab of `AndroidManifest.xml`, pointing to `DownloadCheckService`, following the same approach that we used for activities in this application — just be sure to define a service instead of an activity.

Step #2: Tying the Service Into the Action Bar

To allow the user to manually request that we update the book (if an update is available), we should add a new action bar item to `EmPubLiteActivity`.

First, copy the `01_core_refresh` icons from the `Action Bar Icons/holo_dark/` directory from the “Action Bar Icon Pack” into your project. In the `01_core_refresh` directory, you will see versions of this icon in various densities. Copy those icon files into their corresponding directories in your project. You can do this by dragging the file from your development desktop OS into the project explorer window and dropping it into the proper directory.

Then, modify the `res/menu/options.xml` file to include the following `<item>` element:

```
<item
    android:id="@+id/update"
    android:icon="@drawable/ic_action_refresh"
    android:showAsAction="ifRoom|withText"
    android:title="@string/download_update">
</item>
```

Android Studio users can simply edit the XML for this resource. Eclipse users can add this via the structured editor for `res/menu/options.xml`, following the instructions used for other action bar items.

TUTORIAL #16 - UPDATING THE BOOK

Note that this menu definition requires a new string resource, named `download_update`, with a value like `Download Update`.

That allows us to add a new case to the switch statement in `onOptionsItemSelected()` in `EmPubLiteActivity`:

```
case R.id.update:
    startService(new Intent(this, DownloadCheckService.class));

    return(true);
```

All we do here is send a command to our `DownloadCheckService` to see if a download is available.

Step #3: Defining Our Event

Our `IntentService` will do the work of updating the book in the background. However, we will want to let the rest of the app know when the book is updated. In particular, the `ModelFragment`, if it exists, needs to know that there is a new set of book contents to display. To accomplish this, we can use another event on our `EventBus`, a `BookUpdatedEvent` in this case.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookUpdatedEvent` as the name and click OK to create the empty class.

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `BookUpdatedEvent` in the “Name” field. Leave the “Superclass” field alone, as `BookUpdatedEvent` has no explicit superclass. Then, click “Finish” on the new-class dialog to create the empty `BookUpdatedEvent` class.

Step #4: Defining Our JSON

Under the covers, Retrofit uses GSON for parsing the JSON it retrieves from the Web service (or other URL). Hence, just as we needed to define a Java class that models our JSON for the book contents, we need a Java class that models the data we will get from our server as to whether or not a book update is available.

That JSON looks like:

```
{
  "updatedOn": "20120512",
  "updateUrl": "http://misc.commonsware.com/WarOfTheWorlds-Update.zip"
}
```

We can create a BookUpdateInfo class that mimics this structure.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookUpdateInfo` as the name and click OK to create the empty class.

Then, with `BookUpdateInfo` open in the editor, paste in the following class definition:

```
package com.commonsware.empublite;

public class BookUpdateInfo {
    String updatedOn;
    String updateUrl;
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Eclipse

Right click over the `com.commonsware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `BookUpdateInfo` in the “Name” field. Leave the “Superclass” field alone, as `BookUpdateInfo` has no

explicit superclass. Then, click “Finish” on the new-class dialog to create the BookUpdateInfo class.

Then, with BookUpdateInfo open in the editor, paste in the class definition found in the Android Studio instructions above.

Step #5: Defining Our Retrofit Interface

Retrofit then needs a Java *interface* that provides most of the details for how to fetch our JSON and convert it into a Java object. In our case, we will be using an HTTP GET operation to retrieve the JSON, and so we will use the Retrofit @GET annotation to point to a path on a server pointing to that JSON.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the com.commonware.empublite package in your java/ directory and choose New > Java Class from the context menu. Fill in BookUpdateInterface as the name, switch the “Kind” to be “Interface”, and click OK to create the empty interface.

Then, with BookUpdateInterface open in the editor, paste in the following interface definition:

```
package com.commonware.empublite;

import retrofit.http.GET;

public interface BookUpdateInterface {
    @GET("/misc/empublite-update.json")
    BookUpdateInfo update();
}
```

If you prefer, you can view this file’s contents in your Web browser via [this GitHub link](#).

Here, we define our interface as having an update() method, returning an instance of our BookUpdateInfo structure, with the @GET annotation pointing to a path where the corresponding JSON can be found on a server to be designated later.

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Interface` from the context menu. Fill in `BookUpdateInterface` in the “Name” field. Then, click “Finish” on the new-interface dialog to create the `BookUpdateInterface` interface.

Then, with `BookUpdateInterface` open in the editor, paste in the interface definition shown in the Android Studio instructions above.

Step #6: Retrieving Our JSON Via Retrofit

Now, we can actually use Retrofit to retrieve our `BookUpdateInfo` and see if we have a book update.

First, we need to add the `INTERNET` permission to our app, as we are going to be downloading materials from the `INTERNET`.

Android Studio users can add the following `<uses-permission>` element as children of the root `<manifest>` element in `AndroidManifest.xml`:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

Eclipse users can double-click on `AndroidManifest.xml` and switch over to the `Permissions` tab. There, click the `Add...` button and choose to add a new “Uses Permission” entry. In the drop-down that appears on right, choose `android.permission.INTERNET`. Then, save your changes.

Next, in `DownloadCheckService`, add an `OUR_BOOK_DATE` static data member, representing the edit date of the book baked into our APK, in `YYYYMMDD` format:

```
private static final String OUR_BOOK_DATE="20120418";
```

Then, add a `getUpdateUrl()` method to `DownloadCheckService`:

```
private String getUpdateUrl() {
    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("http://commonware.com")
                                .build();
    BookUpdateInterface updateInterface=
        restAdapter.create(BookUpdateInterface.class);
    BookUpdateInfo info=updateInterface.update();
}
```

```
if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {
    return(info.updateUrl);
}

return(null);
}
```

Here, we create a Retrofit RestAdapter, pointing to the server that is our “Web service” (really a static JSON file, but that does not matter from the standpoint of the client code). We then use the RestAdapter to create an instance of a BookUpdateInterface implementation, code-generated by Retrofit. We then call update() on that object to get our BookUpdateInfo. If the date in the updatedOn field of our BookUpdateInfo is newer than OUR_BOOK_DATE, we return the updateUrl field of the BookUpdateInfo, which will be a URL pointing to a ZIP archive containing the updated book. If the updatedOn value is older than OUR_BOOK_DATE, we return null to signify that no updates are available.

This is not a particularly well-optimized approach. In particular, we never take into account that, once we have downloaded an update, we are only interested in updates newer than the one we downloaded. As it stands, we always compare the updatedOn value to OUR_BOOK_DATE, not the last updatedOn value that we used. A production-grade app would aim to handle this, such as by saving the last-used updatedOn value in a SharedPreferences and comparing against it, where available.

Finally, update onHandleIntent() to call getUpdateUrl():

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            // do something really cool here
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Step #7: Downloading the Update

While the above code gets us the URL of the ZIP archive, it does not actually download it. We need more code to accomplish that.

TUTORIAL #16 - UPDATING THE BOOK

Add a private static final String data member named UPDATE_FILENAME to DownloadCheckService, representing the name of the file to be stored locally representing the downloaded ZIP file:

```
private static final String UPDATE_FILENAME="book.zip";
```

Then, in DownloadCheckService, add the following download() method:

```
private File download(String url) throws MalformedURLException,
                                   IOException {
    File output=new File(getFilesDir(), UPDATE_FILENAME);

    if (output.exists()) {
        output.delete();
    }

    HttpURLConnection c=
        (HttpURLConnection)new URL(url).openConnection();

    FileOutputStream fos=new FileOutputStream(output.getPath());
    BufferedOutputStream out=new BufferedOutputStream(fos);

    try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[16384];
        int len=0;

        while ((len=in.read(buffer)) > 0) {
            out.write(buffer, 0, len);
        }

        out.flush();
    }
    finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
    }

    return(output);
}
```

This is your typical sort of HttpURLConnection download logic, downloading the contents of the designated URL into a File in our internal storage (getFilesDir()), with the UPDATE_FILENAME as the file's name.

Then, update onHandleIntent() in DownloadCheckService to call download() when we have something to download:

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            File book=download(url);

            // do something almost as cool here

            book.delete();
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Here, we delete the file after downloading it, so we do not clutter up our internal storage with the downloaded ZIP. This would appear to defeat the purpose of downloading the ZIP file in the first place, but we will add some code to use the ZIP file in the next step of the tutorial.

Step #8: Unpacking the Update

The last step in the book-download process is to unpack the ZIP archive onto internal storage, so we can start using the downloaded contents.

Add the following `unzip()` method to `DownloadCheckService`:

```
private static void unzip(File src, File dest) throws IOException {
    InputStream is=new FileInputStream(src);
    ZipInputStream zis=new ZipInputStream(new BufferedInputStream(is));
    ZipEntry ze;

    dest.mkdirs();

    while ((ze=zis.getNextEntry()) != null) {
        byte[] buffer=new byte[16384];
        int count;
        FileOutputStream fos=
            new FileOutputStream(new File(dest, ze.getName()));
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
            while ((count=zis.read(buffer)) != -1) {
                out.write(buffer, 0, count);
            }
        }
    }
}
```

```
        out.flush();
    }
    finally {
        fos.getFD().sync();
        out.close();
    }

    zis.closeEntry();
}

zis.close();
}
```

This is a fairly typical Java recipe for unZIPping a ZIP file (src) into a destination directory (dest).

Next, add a public static final String data member named UPDATE_BASEDIR to DownloadCheckService:

```
public static final String UPDATE_BASEDIR="updates";
```

This will point to the directory on internal storage where the latest book update will reside.

Then, update onHandleIntent() on DownloadCheckService once again, this time to add in the call to unzip() and some other necessary changes:

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            File book=download(url);
            File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

            updateDir.mkdirs();
            unzip(book, updateDir);
            book.delete();
            EventBus.getDefault().post(new BookUpdatedEvent());
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception downloading update",
            e);
    }
}
```

Here, we:

- Create the UPDATE_BASEDIR directory if it does not already exist
- Call unzip() to unZIP the ZIP file into that directory
- Post a BookUpdatedEvent to signify that a book update is ready

This is a bit sloppy. It is possible that different book updates will have different files, and our UPDATE_BASEDIR will have some extra files as a result. Ideally, we should clean out UPDATE_BASEDIR before unpacking the ZIP archive. Adding in some recursive delete-all-the-files-in-a-directory logic is left as an exercise for the reader.

At this point, DownloadCheckService should resemble:

```
package com.commonware.empublite;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;
import java.io.BufferedInputStream;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileInputStream;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.MalformedURLException;
import java.net.URL;
import java.util.zip.ZipEntry;
import java.util.zip.ZipInputStream;
import de.greenrobot.event.EventBus;
import retrofit.RestAdapter;

public class DownloadCheckService extends IntentService {
    private static final String OUR_BOOK_DATE="20120418";
    private static final String UPDATE_FILENAME="book.zip";
    private static final String UPDATE_BASEDIR="updates";

    public DownloadCheckService() {
        super("DownloadCheckService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        try {
            String url=getUpdateUrl();

            if (url != null) {
                File book=download(url);
                File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);
```

```
        updateDir.mkdirs();
        unzip(book, updateDir);
        book.delete();
        EventBus.getDefault().post(new BookUpdatedEvent());
    }
}
catch (Exception e) {
    Log.e(getClass().getSimpleName(), "Exception downloading update",
        e);
}
}

private String getUpdateUrl() {
    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("http://commonsware.com")
            .build();
    BookUpdateInterface updateInterface=
        restAdapter.create(BookUpdateInterface.class);
    BookUpdateInfo info=updateInterface.update();

    if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {
        return(info.updateUrl);
    }

    return(null);
}

private File download(String url) throws MalformedURLException,
    IOException {
    File output=new File(getFilesDir(), UPDATE_FILENAME);

    if (output.exists()) {
        output.delete();
    }

    HttpURLConnection c=
        (HttpURLConnection)new URL(url).openConnection();

    FileOutputStream fos=new FileOutputStream(output.getPath());
    BufferedOutputStream out=new BufferedOutputStream(fos);

    try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[16384];
        int len=0;

        while ((len=in.read(buffer)) > 0) {
            out.write(buffer, 0, len);
        }

        out.flush();
    }
    finally {
```

```
        fos.getFD().sync();
        out.close();
        c.disconnect();
    }

    return(output);
}

private static void unzip(File src, File dest) throws IOException {
    InputStream is=new FileInputStream(src);
    ZipInputStream zis=new ZipInputStream(new BufferedInputStream(is));
    ZipEntry ze;

    dest.mkdirs();

    while ((ze=zis.getNextEntry()) != null) {
        byte[] buffer=new byte[16384];
        int count;
        FileOutputStream fos=
            new FileOutputStream(new File(dest, ze.getName()));
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
            while ((count=zis.read(buffer)) != -1) {
                out.write(buffer, 0, count);
            }

            out.flush();
        } finally {
            fos.getFD().sync();
            out.close();
        }

        zis.closeEntry();
    }

    zis.close();
}
```

Step #9: Using the Update

All this work is nice. However, nothing else in the app knows about this UPDATE_BASEDIR copy of the book to actually display it.

In fact, we have two scenarios to consider:

- The user taps the update action bar item, and we download the update and want to show the updated book to the user right now

TUTORIAL #16 - UPDATING THE BOOK

- Later on, when the user opens the book, we need to realize that we already have an update and use it, rather than using the copy baked into the APK

That will require some changes to our data model, how we populate it from `ModelFragment`, and how we use the results in our `ContentsAdapter`.

First, add a `File baseDir` data member to `BookContents`, along with an accompanying setter method:

```
File baseDir=null;

void setBaseDir(File baseDir) {
    this.baseDir=baseDir;
}
```

Then, add a `getChapterPath()` method to `BookContents` that uses `getChapterFile()` for getting the relative path from the book's JSON, then uses that in conjunction with `baseDir` or the `android_asset` path to come up with a full `WebView`-friendly path to the file, whether it is in assets or a local file:

```
String getChapterPath(int position) {
    String file=getChapterFile(position);

    if (baseDir == null) {
        return("file:///android_asset/book/" + file);
    }

    return(Uri.fromFile(new File(baseDir, file)).toString());
}
```

Next, change the `getItem()` method on `ContentsAdapter` to use this new `getChapterPath()` method on `BookContents`:

```
@Override
public Fragment getItem(int position) {
    return(SimpleContentFragment.newInstance(contents.getChapterPath(position)));
}
```

Then, modify the `run()` method of the `LoadThread` in `ModelFragment` to try to use the update:

```
@Override
public void run() {
    prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);

    Gson gson=new Gson();
```

TUTORIAL #16 - UPDATING THE BOOK

```
File baseDir=
    new File(ctxt.getFilesDir(),
        DownloadCheckService.UPDATE_BASEDIR);

try {
    InputStream is;

    if (baseDir.exists()) {
        is=new FileInputStream(new File(baseDir, "contents.json"));
    }
    else {
        is=ctxt.getAssets().open("book/contents.json");
    }

    BufferedReader reader=
        new BufferedReader(new InputStreamReader(is));

    contents=gson.fromJson(reader, BookContents.class);
    is.close();

    if (baseDir.exists()) {
        contents.setBaseDir(baseDir);
    }

    EventBus.getDefault().post(new BookLoadedEvent(contents));
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
}
}
```

Here, we do the following, in addition to our original logic:

- See if the UPDATE_BASEDIR directory exists or not
- If it does, we use the contents.json in it; otherwise, we fall back to the one in assets/ as before
- Update the BookContents with the update directory if we used that for loading the contents

This will handle the case where an update exists when we fire up the app and go to view the book. However, we still need some code that responds to the BookUpdatedEvent and arranges to use the updated contents at that point.

With that in mind, augment onAttach() on ModelFragment to register with the EventBus:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);
```

```
EventBus.getDefault().register(this);

if (contents == null) {
    new LoadThread(host).start();
}
}
```

We also now need a corresponding `onDetach()` method on `ModelFragment` to unregister from the `EventBus`:

```
@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
}
```

Finally, we can respond to the `BookUpdatedEvent`, via a new `onEventBackgroundThread()` method on `ModelFragment`:

```
public void onEventBackgroundThread(BookUpdatedEvent event) {
    if (getActivity() != null) {
        new LoadThread(getActivity()).start();
    }
}
```

The name `onEventBackgroundThread()` signals to the `EventBus` that we want to receive this event on a background thread. In our case, the event is posted on a background thread (the one from the `IntentService`). Hence, our `onEventBackgroundThread()` method is called on that thread. If, however, we were to post a `BookUpdatedEvent` from the main application thread, `EventBus` would deliver our `BookUpdatedEvent` to `onEventBackgroundThread()` on an `EventBus`-supplied background thread, to ensure that we do not tie up the main application thread.

Here, we just kick off a fresh `LoadThread` to reload the `BookContents`, assuming that the user has not just pressed `BACK` or otherwise destroyed our activity. The new `LoadThread` will see that the update is available and use it, posting its own event to have our UI layer apply the update to the screen.

At this point, if you build and run the app, you will see the update action bar item:

TUTORIAL #16 - UPDATING THE BOOK

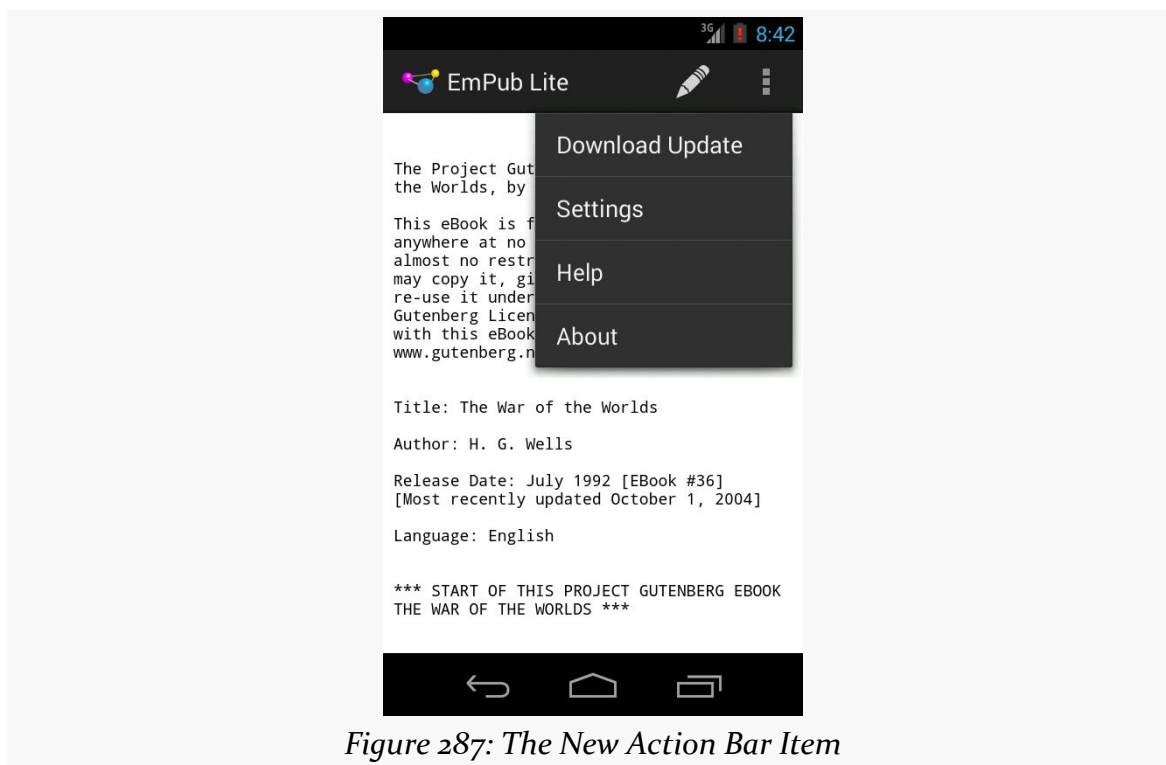

Figure 287: The New Action Bar Item

Pressing that and waiting a moment should cause your book to be updated with new contents downloaded from the Internet:

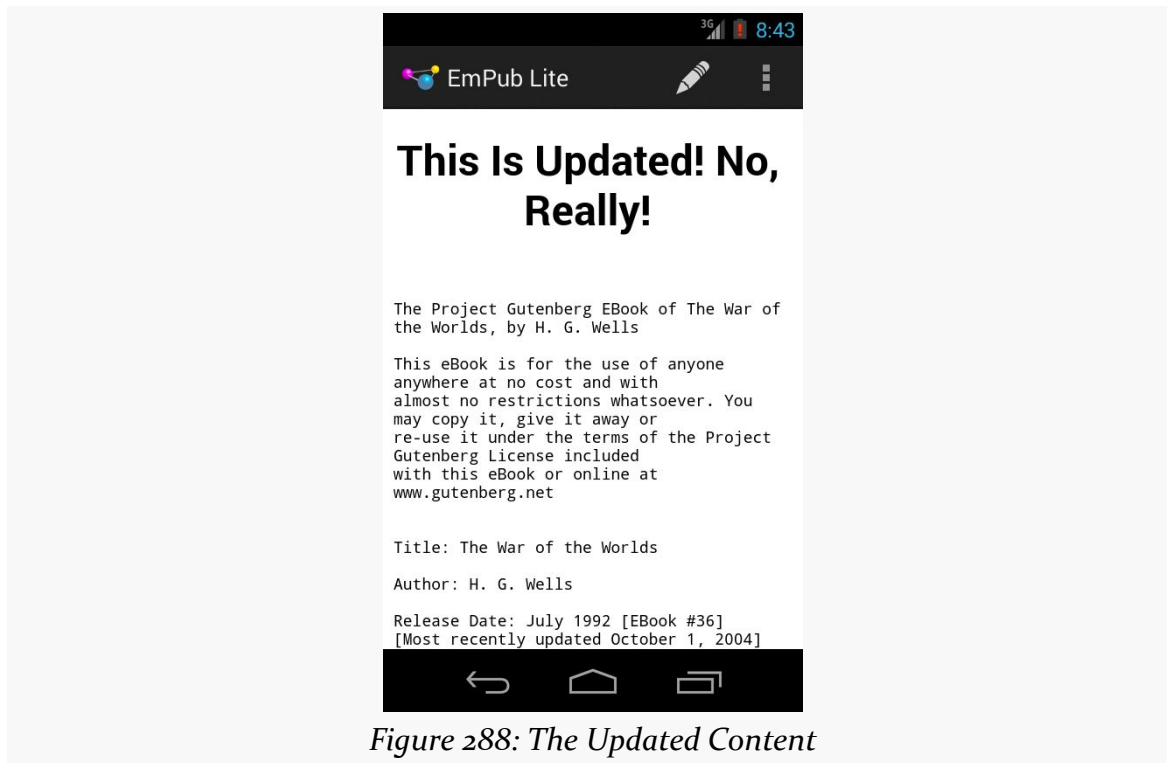

Figure 288: The Updated Content

In Our Next Episode...

... we will [update the book's contents ourselves, periodically](#) in the background.

AlarmManager and the Scheduled Service Pattern

Many applications have the need to get control every so often to do a bit of work. And, many times, those applications need to get control in the background, regardless of what the user may be doing (or not doing) at the time.

The solution, in most cases, is to use `AlarmManager`, which is roughly akin to `cron` on Linux and OS X and Scheduled Tasks in Windows. You teach `AlarmManager` when you want to get control back, and `AlarmManager` will give you control at that time.

Scenarios

The two main axes to consider with scheduled work are frequency and foreground (vs. background).

If you have an activity that needs to get control every second, the simplest approach is to use a `postDelayed()` loop, scheduling a `Runnable` to be invoked after a certain delay, where the `Runnable` reschedules itself to be invoked after the delay in addition to doing some work. We saw this in [the chapter on threads](#). This has the advantages of giving you control back on the main application thread and avoiding the need for any background threads.

On the far other end of the spectrum, you may need to get control on a somewhat slower frequency (e.g., every 15 minutes), and do so in the background, even if nothing of your app is presently running. You might need to poll some Web server for new information, such as downloading updates to an RSS feed. This is the scenario that `AlarmManager` excels at. While `postDelayed()` works *inside* your process (and therefore does not work if you no longer have a process), `AlarmManager`

maintains its schedule *outside* of your process. Hence, it can arrange to give you control, even if it has to start up a new process for you along the way.

Options

There are a variety of things you will be able to configure about your scheduled alarms with AlarmManager.

Wake Up... Or Not?

The biggest one is whether or not the scheduled event should wake up the device.

A device goes into a sleep mode shortly after the screen goes dark. During this time, nothing at the application layer will run, until something wakes up the device. Waking up the device does not necessarily turn on the screen — it may just be that the CPU starts running your process again.

If you choose a “wakeup”-style alarm, Android will wake up the device to give you control. This would be appropriate if you need this work to occur even if the user is not actively using the device, such as your app checking for critical email messages in the middle of the night. However, it does drain the battery some.

Alternatively, you can choose an alarm that will not wake up the device. If your desired time arrives and the device is asleep, you will not get control until something else wakes up the device.

Repeating... Or Not?

You can create a “one-shot” alarm, to get control once at a particular time in the future. Or, you can create an alarm that will give you control periodically, at a fixed period of your choice (e.g., every 15 minutes).

If you need to get control at multiple times, but the schedule is irregular, use a “one-shot” alarm for the nearest time, where you do your work *and* schedule a “one-shot” alarm for the next-nearest time. This would be appropriate for scenarios like a calendar application, where you need to let the user know about upcoming appointments, but the times for those appointments may not have any fixed schedule.

However, for most polling operations (e.g., checking for new messages every NN minutes), a repeating alarm will typically be the better answer.

Inexact... Or Not?

If you do choose a repeating alarm, you will have your choice over having (relatively) precise control over the timing of event or not.

If you choose an “inexact” alarm, while you will provide Android with a suggested time for the first event and a period for subsequent events, Android reserves the right to shift your schedule somewhat, so it can process your events and others around the same time. This is particularly important for “wakeup”-style alarms, as it is more power-efficient to wake up the device fewer times, so Android will try to combine multiple apps’ events to be around the same time to minimize the frequency of waking up the device.

However, inexact alarms are annoying to test and debug, simply because you do not have control over when they will be invoked. Hence, during development, you might start with an exact alarm, then switch to inexact alarms once most of your business logic is debugged.

Note that Android 4.4 changes the behavior of AlarmManager, such that it is more difficult to actually create an exact-repeating alarm schedule. This will be examined in greater detail shortly, as we review the various methods and flags for scheduling AlarmManager events.

Absolute Time... Or Not?

As part of the alarm configuration, you will tell Android when the event is to occur (for one-shot alarms) or when the event is to *first* occur (for repeating alarms). You can provide that time in one of two ways:

- An absolute “real-time clock” time (e.g., 4am tomorrow), or
- A time relative to now

For most polling operations, particularly for periods more frequent than once per day, specifying the time relative to now is easiest. However, some alarms may need to tie into “real world time”, such as alarm clocks and calendar alerts — for those, you will need to use the real-time clock (typically by means of a Java Calendar object) to indicate when the event should occur.

What Happens (Or Not???)

And, of course, you will need to tell Android what to do when each of these timer events occurs. You will do that in the form of supplying a `PendingIntent`. First mentioned in [the chapter on services](#), a `PendingIntent` is a `Parcelable` object, one that indicates an operation to be performed upon an `Intent`:

- start an activity
- start a service
- send a broadcast

While the service chapter discussed an Android activity using `createPendingResult()` to craft such a `PendingIntent`, that is usually not very useful for `AlarmManager`, as the `PendingIntent` will only be valid so long as the activity is in the foreground. Instead, there are static factory methods on `PendingIntent` that you will use instead (e.g., `getBroadcast()` to create a `PendingIntent` that calls `sendBroadcast()` on a supplied `Intent`). That being said, our next sample will use `createPendingResult()`, to keep the sample as simple as possible.

A Simple Example

A trivial sample app using `AlarmManager` can be found in [AlarmManager/Simple](#).

This application consists of a single activity, `SimpleAlarmDemoActivity`, that will both set up an alarm schedule and respond to alarms:

```
package com.commonware.android.alarm;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.os.SystemClock;
import android.widget.Toast;

public class SimpleAlarmDemoActivity extends Activity {
    private static final int ALARM_ID=1337;
    private static final int PERIOD=5000;
    private PendingIntent pi=null;
    private AlarmManager mgr=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);
setContentView(R.layout.main);

mgr=(AlarmManager)getSystemService(ALARM_SERVICE);
pi=createPendingResult(ALARM_ID, new Intent(), 0);
mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
                SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
}

@Override
public void onDestroy() {
    mgr.cancel(pi);

    super.onDestroy();
}

@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == ALARM_ID) {
        Toast.makeText(this, R.string.toast, Toast.LENGTH_SHORT).show();
    }
}
}
```

In `onCreate()`, in addition to setting up the “hello, world”-ish UI, we:

- Obtain an instance of `AlarmManager`, by calling `getSystemService()`, asking for the `ALARM_SERVICE`, and casting the result to be an `AlarmManager`
- Create a `PendingIntent` by calling `createPendingResult()`, supplying an empty `Intent` as our “result” (since we do not really need it here)
- Calling `setRepeating()` on `AlarmManager`

The call to `setRepeating()` is a bit complex, taking four parameters:

1. The type of alarm we want, in this case `ELAPSED_REALTIME`, indicating that we want to use a relative time base for when the first event should occur (i.e., relative to now) and that we do not need to wake up the device out of any sleep mode
2. The time when we want the first event to occur, in this case specified as a time delta in milliseconds (`PERIOD`) added to “now” as determined by `SystemClock.elapsedRealtime()` (the number of milliseconds since the device was last rebooted)
3. The number of milliseconds to occur between events
4. The `PendingIntent` to invoke for each of these events

When the event occurs, since we used `createPendingResult()` to create the `PendingIntent`, our activity gets control in `onActivityResult()`, where we simply display a `Toast` (if the event is for our alarm's request ID). This continues until the activity is destroyed (e.g., pressing the BACK button), at which time we `cancel()` the alarm, supplying a `PendingIntent` to indicate which alarm to cancel. While here we use the same `PendingIntent` object as we used for scheduling the alarm, that is not required — it merely has to be an *equivalent* `PendingIntent`, meaning:

- The `Intent` inside the `PendingIntent` matches the scheduled alarm's `Intent`, in terms of component, action, data (`Uri`), MIME type, and categories
- The ID of the `PendingIntent` (here, `ALARM_ID`) must also match

Running this simply brings up a `Toast` every five seconds until you BACK out of the activity.

The Five set...() Varieties

There are five methods that you can call on `AlarmManager` to establish an alarm, including the `setRepeating()` demonstrated above.

On Android 4.4 (API Level 19) and higher, `setExact()` is used for a one-shot alarm, where you want to get control at one specific time in the future. This would be used for specific events or for irregular alarm schedules.

On Android 4.3 and below, and for apps whose `android:targetSdkVersion` is set to 18 or lower, `set()` has the same behavior as `setExact()`. However, on Android 4.4 and above, apps with their `android:targetSdkVersion` set to be 19 or higher will have different, *inexact* behavior for `set()`. The time of the event is considered a minimum — your `PendingIntent` will not be invoked before your desired time, but it can occur any time thereafter... and you do not have control over how long that delay will be. As with all “inexact” schedules, the objective is for Android to be able to “batch” these events, to do several around the same time, for greater efficiency, particularly when waking up the device.

On Android 4.4 and higher, you have a `setWindow()` option that is a bit of a hybrid between the new-style `set()` and `setExact()`. Here, you specify the time you want the event to occur and an amount of time that Android can “flex” the actual event. So, for example, you might set up an event to occur every hour, with a “window” of five minutes, to allow Android the flexibility to invoke your `PendingIntent` within that five-minute window. This allows for better battery optimization than with

`setExact()`, while still giving you some control over how far “off the mark” the event can occur.

On Android 4.3 and below, and for apps whose `android:targetSdkVersion` is set to 18 or lower, `setRepeating()` is used for an alarm that should occur at specific points in time at a specific frequency. In addition to specifying the time of the first event, you also specify the period for future events. Android will endeavor to give you control at precisely those times, though since Android is not a real-time operating system (RTOS), microsecond-level accuracy is certainly not guaranteed.

`setInexactRepeating()` is used for an alarm that should occur on a general frequency, such as every 15 minutes. In addition to specifying the time of the first event, you also specify a general frequency, as one of the following public static data members on `AlarmManager`:

- `INTERVAL_FIFTEEN_MINUTES`
- `INTERVAL_HALF_HOUR`
- `INTERVAL_HOUR`
- `INTERVAL_HALF_DAY`
- `INTERVAL_DAY`

Android guarantees that it will give your app control somewhere during that time window, but precisely *when* within that window is up to Android.

Note that on Android 4.4 and above, for apps with their `android:targetSdkVersion` set to be 19 or higher, `setRepeating()` behaves identically to `setInexactRepeating()` – in other words, all repeating alarms are inexact. The only way to get exact repeating would be to use `setExact()` and to re-schedule the event yourself, rather than relying upon Android doing that for you automatically. Ideally, you use `setInexactRepeating()`, to help extend battery life.

The Four Types of Alarms

In the above sample, we used `ELAPSED_REALTIME` as the type of alarm. There are three others:

- `ELAPSED_REALTIME_WAKEUP`
- `RTC`
- `RTC_WAKEUP`

Those with `_WAKEUP` at the end will wake up a device out of sleep mode to execute the `PendingIntent` — otherwise, the alarm will wait until the device is awake for other means.

Those that begin with `ELAPSED_REALTIME` expect the second parameter to `setRepeating()` to be a timestamp based upon `SystemClock.elapsedRealtime()`. Those that begin with `RTC`, however, expect the second parameter to be based upon `System.currentTimeMillis()`, the classic Java “what is the current time in milliseconds since the Unix epoch” method.

When to Schedule Alarms

The sample, though, begs a bit of a question: when are we supposed to set up these alarms? The sample just does so in `onCreate()`, but is that sufficient?

For most apps, the answer is “no”. Here are the three times that you will need to ensure that your alarms get scheduled:

When User First Runs Your App

When your app is first installed, none of your alarms are set up, because your code has not yet run to schedule them. There is no means of setting up alarm information in the manifest or something that might automatically kick in.

Hence, you will need to schedule your alarms when the user first runs your app.

As a simplifying measure — and to cover another scenario outlined below — you might be able to simply get away with scheduling your alarms *every* time the user runs your app, as the sample app shown above does. This works for one-shot alarms (using `set()`) and for alarms with short polling periods, and it works because setting up a new alarm schedule for an equivalent `PendingIntent` will replace the old schedule. However, for repeating alarms with slower polling periods, it may excessively delay your events. For example, suppose you have an alarm set to go off every 24 hours, and the user happens to run your app 5 minutes before the next event was to occur — if you blindly reschedule the alarm, instead of going off in 5 minutes, it might not go off for another 24 hours.

There are more sophisticated approaches for this (e.g., using a `SharedPreferences` value to determine if your app has run before or not).

On Boot

The alarm schedule for alarm manager is wiped clean on a reboot, unlike `cron` or Windows Scheduled Tasks. Hence, you will need to get control at boot time to re-establish your alarms, if you want them to start up again after a reboot. We saw how to get control at boot time, via an `ACTION_BOOT_COMPLETED` BroadcastReceiver, back in [the chapter on broadcasts](#).

After a Force-Stop

There are other events that could cause your alarms to become unscheduled. The best example of this is if the user goes into the Settings app and presses “Force Stop” for your app. At this point, on Android 3.1+, nothing of your code will run again, until the user manually launches some activity of yours.

If you are rescheduling your alarms every time your app runs, this will be corrected the next time the user launches your app. And, by definition, you cannot do anything until the user runs one of your activities, anyway.

If you are trying to avoid rescheduling your alarms on each run, though, you have a couple of options.

One is to record the time when your alarm-triggered events occur, each time they occur, such as by updating a `SharedPreferences`. When the user launches one of your activities, you check the last-event time — if it was too long ago (e.g., well over your polling period), you assume that the alarm had been canceled, and you reschedule it.

Another is to rely on `FLAG_NO_CREATE`. You can pass this as a parameter to any of the `PendingIntent` factory methods, to indicate that Android should only return an *existing* `PendingIntent` if there is one, and not create one if there is not:

```
PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i,  
PendingIntent.FLAG_NO_CREATE);
```

If the `PendingIntent` is `null`, your alarm has been canceled — otherwise, Android would already have such a `PendingIntent` and would have returned it to you. This feels a bit like a side-effect, so we cannot rule out the possibility that, in future versions of Android, this technique could result in false positives (`null` `PendingIntent` despite the scheduled alarm) or false negatives (non-`null` `PendingIntent` despite a canceled alarm).

Archetype: Scheduled Service Polling

The classic AlarmManager scenario is where you want to do a chunk of work, in the background, on a periodic basis. This is fairly simple to set up in Android, though perhaps not quite as simple as you might think.

The Main Application Thread Strikes Back

When an AlarmManager-triggered event occurs, it is very likely that your application is not running. This means that the PendingIntent is going to have to start up your process to have you do some work. Since everything that a PendingIntent can do intrinsically gives you control on your main application thread, you are going to have to determine how you want to move your work to a background thread.

One approach is to use a PendingIntent created by `getService()`, and have it send a command to an `IntentService` that you write. Since `IntentService` does its work on a background thread, you can take whatever time you need, without interfering with the behavior of the main application thread. This is particularly important when:

- The AlarmManager-triggered event happens to occur when the user happens to have one of your activities in the foreground, so you do not freeze the UI, or
- You want the same business logic to be executed on demand by the user, such as via an action bar item, as once again you do not want to freeze the UI

Examining a Sample

An incrementally-less-trivial sample app using AlarmManager for the scheduled service pattern can be found in [AlarmManager/Scheduled](#).

This application consists of three components: a `BroadcastReceiver`, a `Service`, and an `Activity`.

This sample demonstrates scheduling your alarms at two points in your app:

- At boot time
- When the user runs the activity

For the boot-time scenario, we need a BroadcastReceiver set up to receive the ACTION_BOOT_COMPLETED broadcast, with the appropriate permission. So, we set that up, along with our other components, in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.schedsvc"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name=".ScheduledServiceDemoActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>

        <receiver android:name="PollReceiver">
            <intent-filter>
                <action android:name="android.intent.action.BOOT_COMPLETED"/>
            </intent-filter>
        </receiver>

        <service android:name="ScheduledService">
        </service>
    </application>
</manifest>
```

The PollReceiver has its onReceive() method, to be called at boot time, which delegates its work to a scheduleAlarms() static method, so that logic can also be used by our activity:

```
package com.commonware.android.schedsvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
```

ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

```
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=5000;

    @Override
    public void onReceive(Context ctxt, Intent i) {
        scheduleAlarms(ctxt);
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, ScheduledService.class);
        PendingIntent pi=PendingIntent.getService(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
            SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
    }
}
```

The `scheduleAlarms()` method retrieves our `AlarmManager`, creates a `PendingIntent` designed to call `startService()` on our `ScheduledService`, and schedules an exact repeating alarm to have that command be sent every five seconds.

The `ScheduledService` itself is the epitome of “trivial”, simply logging a message to `LogCat` on each command:

```
package com.commonware.android.schedsvc;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;

public class ScheduledService extends IntentService {
    public ScheduledService() {
        super("ScheduledService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        Log.d(getClass().getSimpleName(), "I ran!");
    }
}
```

That being said, because this is an `IntentService`, we could do much more in `onHandleIntent()` and not worry about tying up the main application thread.

Our activity — `ScheduledServiceDemoActivity` — is set up with `Theme.NoDisplay` in the manifest, never calls `setContentView()`, and calls `finish()` right from `onCreate()`. As a result, it has no UI. It simply calls `scheduleAlarms()` and raises a `Toast` to indicate that the alarms are indeed scheduled:

```
package com.commonware.android.schedsvc;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class ScheduledServiceDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PollReceiver.scheduleAlarms(this);

        Toast.makeText(this, R.string.alarms_scheduled, Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
```

On Android 3.1+, we also need this activity to move our application out of the stopped state and allow that boot-time `BroadcastReceiver` to work.

If you run this app on a device or emulator, after seeing the `Toast`, messages will appear in `LogCat` every five seconds, even though you have no activity running.

Staying Awake at Work

The sample shown above works... most of the time.

However, it has a flaw: the device might fall asleep before our service can complete its work, if we woke it up out of sleep mode to process the event.

To understand where this flaw would appear, and to learn how to address it, we need to think a bit more about the event flows and timing of the code we are executing.

Mind the Gap

For a `_WAKEUP`-style alarm, Android makes precisely one guarantee: *if* the `PendingIntent` supplied to `AlarmManager` for the alarm is one created by `getBroadcast()` to send a broadcast `Intent`, Android will ensure that the device will

stay awake long enough for `onReceive()` to be completed. Anything beyond that is not guaranteed.

In the sample shown above, we are not using `getBroadcast()`. We are taking the more straightforward approach of sending the command directly to the service via a `getService()` `PendingIntent`. Hence, Android makes no guarantees about what happens after `AlarmManager` wakes up the device, and the device could fall back asleep before our `IntentService` completes processing of `onHandleIntent()`.

The WakefulIntentService

For our trivial sample, where we are merely logging to `LogCat`, we could simply move that logic out of an `IntentService` and into a `BroadcastReceiver`. Then, Android would ensure that the device would stay awake long enough for us to do our work in `onReceive()`.

The problem is that `onReceive()` is called on the main application thread, so we cannot spend much time in that method. And, since our alarm event might occur when nothing else of our code is running, we need to have our `BroadcastReceiver` registered in the manifest, rather than via `registerReceiver()`. A side effect of this is that we cannot fork threads or do other things in `onReceive()` that might live past `onReceive()` yet be “owned” by the `BroadcastReceiver` itself. Besides, Android only ensures that the device will stay awake until `onReceive()` returns, so even if we did fork a thread, the device might fall asleep before that thread can complete its work.

Enter the `WakefulIntentService`.

`WakefulIntentService` is a reusable component, published by the author of this book.

`WakefulIntentService` allows you to implement “the handoff pattern”:

- You add the JAR, AAR, or library project to your project
- You create a subclass of `WakefulIntentService` to do your background work, putting that business logic in a `doWakefulWork()` method instead of `onHandleIntent()` (though it is still called on a background thread)
- You set up your alarm to route to a `BroadcastReceiver` of your design
- Your `BroadcastReceiver` calls `sendWakefulWork()` on the `WakefulIntentService` class, identifying your own subclass of `WakefulIntentService`
- You add a `WAKE_LOCK` permission to your manifest

WakefulIntentService will perform a bit of magic to ensure that the device will stay awake long enough for your work to complete in `doWakefulWork()`. Hence, we get the best of both worlds: the device will not fall asleep, and we will not have to worry about tying up the main application thread.

Android Studio users can add a reference to the CommonsWare Maven artifact repository in their top-level repositories closure:

```
repositories {
    mavenCentral()
    maven {
        url "https://repo.commonware.com.s3.amazonaws.com"
    }
}
```

(here shown alongside an existing `mavenCentral()` statement)

Then, adding the WakefulIntentService is merely a matter of adding a compile `'com.commonware.cwac:wakeful:...'` statement to the top-level dependencies closure (for some version of the library, denoted by `...`).

Eclipse users can download [a JAR](#) from [the project's GitHub repository](#).

WakefulIntentService is open source, licensed under the Apache License 2.0.

The Polling Archetype, Revisited

With that in mind, take a peek at the [AlarmManager/Wakeful](#) sample project. This is a near-clone of the previous sample, with the primary difference being that we will use WakefulIntentService.

The `libs/` directory of the project contains the `CWAC-WakefulIntentService.jar` library, so Eclipse/Ant users can make use of WakefulIntentService in our code. Android Studio users, instead, pull the AAR from the CommonsWare artifact repository:

```
repositories {
    maven {
        url "https://repo.commonware.com.s3.amazonaws.com"
    }
}

dependencies {
    compile 'com.commonware.cwac:wakeful:1.0.+'
}
```

Our manifest includes the WAKE_LOCK permission:

```
<uses-permission android:name="android.permission.WAKE_LOCK"/>
```

Our PollReceiver will now serve two roles: handling ACTION_BOOT_COMPLETED *and* handling our alarm events. We can detect which of these cases triggered onReceive() by inspecting the broadcast Intent, passed into onReceive(). We will use an explicit Intent for the alarm events, so any Intent with an action string must be ACTION_BOOT_COMPLETED:

```
package com.commonware.android.wakesvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=900000; // 15 minutes
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
            PERIOD, pi);
    }
}
```

If the Intent is our explicit Intent, we call sendWakefulWork() on WakefulIntentService, identifying our ScheduledService class as being the service that contains our business logic.

The other changes to `PollReceiver` is that we use `getBroadcast()` to create our `PendingIntent`, wrapping our explicit `Intent` identifying `PollReceiver` itself, and that we use more realistic polling periods (5 second initial delay, every 15 minutes thereafter).

`ScheduledService` has only two changes: it extends `WakefulIntentService` and has the LogCat logging in `doWakefulWork()`:

```
package com.commonware.android.wakesvc;

import android.content.Intent;
import android.util.Log;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class ScheduledService extends WakefulIntentService {
    public ScheduledService() {
        super("ScheduledService");
    }

    @Override
    protected void doWakefulWork(Intent intent) {
        Log.d(getClass().getSimpleName(), "I ran!");
    }
}
```

How the Magic Works

A `WakefulIntentService` keeps the device awake by using a `WakeLock`. A `WakeLock` allows a “userland” (e.g., Android SDK) app to tell the Linux kernel at the heart of Android to keep the device awake, with the CPU powered on, indefinitely, until the `WakeLock` is released.

This can be a wee bit dangerous, as you can accidentally keep the device awake much longer than you need to. That is why using a library like `WakefulIntentService` can be useful — to use more-tested code rather than rolling your own.

Warning: Not All Android Devices Play Nice

Some Android devices take liberties with the way `AlarmManager` works, in ways that may affect your applications.

One example of this today is the SONY Xperia Z. It has a [“STAMINA mode”](#) that the user can toggle on via the “Power Management” screen in Settings. This mode will

be entered when the device's screen turns off, if the device is not plugged in and charging. The user can add apps to a whitelist ("Apps active in standby"), where STAMINA mode does not affect those apps' behavior.

`_WAKEUP` style alarms do not wake up the device when it is in STAMINA mode. The behavior is a bit reminiscent of non-`_WAKEUP` alarms. Alarms that occur while the device is asleep are suppressed, and you get one invocation of your `PendingIntent` at the point the device wakes back up. At that point, the schedule continues as though the alarms had been going off all along. Apps on the whitelist are unaffected.

Mostly, you need to be aware of this from a support standpoint. If Xperia Z owners complain that your app behaves oddly, and you determine that your alarms are not going off, see if they have STAMINA mode on, and if they do, ask them to add your app to the whitelist.

If you are using "if my alarm has not gone off in X amount of time, the user perhaps force-stopped me, so let me reschedule my alarms" logic, you should be OK. Before one of your activities gets a chance to make that check, your post-wakeup alarm should have been invoked, so you can update your event log and last-run timestamp. Hence, you should not be tripped up by STAMINA and accidentally reschedule your alarms (potentially causing duplicates, depending upon your alarm-scheduling logic).

Other devices with similar characteristics include Sony's Xperia P, Xperia U, Xperia sola, and Xperia go.

Debugging Alarms

If you are encountering issues with your alarms, the first thing to do is to ensure that the alarm schedule in `AlarmManager` is what you expect it to be. To do that, run `adb shell dumpsys alarm` from a command prompt. This will dump a report of all the scheduled alarms, including when they are set to be invoked next (with portions replaced by vertical ellipses to keep this listing from being too long):

Current Alarm Manager state:

```
Realtime wakeup (now=2013-03-09 07:49:51):
RTC_WAKEUP #11: Alarm{429c6028 type 0 com.android.providers.calendar}
    type=0 when=+21h40m9s528ms repeatInterval=0 count=0
    operation=PendingIntent{42ec2f40: PendingIntentRecord{434fb2f8
com.android.providers.calendar broadcastIntent}}
RTC_WAKEUP #10: Alarm{42e17e28 type 0 com.google.android.gms}
    type=0 when=+18h10m8s480ms repeatInterval=86400000 count=1
```

ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

```
operation=PendingIntent{42e15d20: PendingIntentRecord{42e0cc28
com.google.android.gms startService}}
.
.
.

Elapsed realtime wakeup (now=+6d15h50m2s672ms):
ELAPSED_WAKEUP #16: Alarm{42cf26f0 type 2 com.google.android.apps.maps}
  type=2 when=+999d23h59m59s999ms repeatInterval=0 count=0
  operation=PendingIntent{42de2dc0: PendingIntentRecord{42ac73e8

```

You are given details of each outstanding alarm, including the all-important `when` value indicating the time the alarm should be invoked next, if it is not canceled first (e.g., `when=+5d15h10m7s782ms`), along with the package requesting the alarm. You can use this to identify your app's alarms and see when they should be invoked next.

You are also given:

- Per-app details about how frequently their alarms have gone off, which can be useful for battery impact analysis
- A list of “top alarms” by number of occurrences, also for device performance analysis

Note, though, that for inexact alarms, the when value may not indicate when the event will actually occur.

WakefulBroadcastReceiver

The Android Support package has added a `WakefulBroadcastReceiver`, which offers an alternative to `WakefulIntentService` for arranging to do work, triggered by a broadcast (such as an `AlarmManager` event), that may take a while.

`WakefulBroadcastReceiver` has its pros and cons compared to `WakefulIntentService`, making it worth considering.

Using WakefulBroadcastReceiver

Using `WakefulBroadcastReceiver` with `AlarmManager` is slightly different than is using `WakefulIntentService`. The [AlarmManager/WakeCast](#) sample project is a clone of the `WakefulIntentService` project, but one using `WakefulBroadcastReceiver` instead.

The activity is unchanged — it simply calls `scheduleAlarms()` on `PollReceiver`. `scheduleAlarms()` itself is unchanged, as it still uses `setRepeating()` on `AlarmManager` to arrange to periodically invoke a `PendingIntent`, targeting the `PollReceiver`.

But `PollReceiver` itself is now a `WakefulBroadcastReceiver` rather than just an ordinary `BroadcastReceiver`. This in turn requires a slightly different implementation of `onReceive()`:

```
package com.commonware.android.wakecast;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;
```

```
public class PollReceiver extends WakefulBroadcastReceiver {
    private static final int PERIOD=900000; // 15 minutes
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            startWakefulService(ctxt,
                               new Intent(ctxt, ScheduledService.class));
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                        SystemClock.elapsedRealtime() + INITIAL_DELAY,
                        PERIOD, pi);
    }
}
```

Now, when the AlarmManager broadcast arrives, we call `startWakefulService()`, passing it the Context supplied to `onReceive()`, plus an Intent identifying the service to start up. Under the covers, this works much like `sendWakefulWork()` on `WakefulIntentService` — it starts the identified service, but acquires a `WakeLock` first.

Our `ScheduledService` is now a regular `IntentService`, instead of a `WakefulIntentService`. This means that our background work moves back to the standard `onHandleIntent()` method, instead of `doWakefulWork()`. However, we have one extra bit of bookkeeping to do: we must call the static `completeWakefulIntent()` method on `WakefulBroadcastReceiver` (or, as shown, on `PollReceiver`, as that will point to the same static method):

```
package com.commonware.android.wakecast;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;

public class ScheduledService extends IntentService {
    public ScheduledService() {
```

```
    super("ScheduledService");
}

@Override
protected void onHandleIntent(Intent intent) {
    Log.d(getClass().getSimpleName(), "I ran!");

    PollReceiver.completeWakefulIntent(intent);
}
}
```

We pass the `Intent` supplied to `onHandleIntent()` to `completeWakefulIntent()`. Behind the scenes, `completeWakefulIntent()` will release the `WakeLock` that has been keeping our CPU powered on while we do our work.

Comparing to `WakefulIntentService`

One might think that `WakefulIntentService` would now be obsolete with the addition of `WakefulBroadcastReceiver`. In truth, there are some advantages to the current implementation of `WakefulBroadcastReceiver`:

- It uses a time-limited `WakeLock`, one set to auto-release after one minute, so there is no risk of an app somehow failing to release the lock and thereby keeping the CPU on indefinitely.
- To make the time-limited locks work, `WakefulBroadcastReceiver` uses one `WakeLock` per request, rather than the single static `WakeLock` that `WakefulIntentService` uses, making `WakefulBroadcastReceiver` incrementally more resilient in the face of various potential problems.
- Because it is not strictly tied to being used with an `IntentService`, `WakefulBroadcastReceiver` may offer greater flexibility. For example, an `IntentService` is not a good choice if the work you do is intrinsically asynchronous, such as trying to find the device's location. Any place where you find yourself registering a listener from a service, an `IntentService` will not work well, as the `IntentService` wants to shut down before your listener has received a result. A regular `Service` can work well, though, in this case, and `WakefulBroadcastReceiver` might be of use in this pattern (though the author has not tried this yet).

On the other hand:

- `WakefulBroadcastReceiver` requires an explicit call to `completeWakefulIntent()`, which a developer can easily forget, possibly causing the `WakeLock` to be leaked. While this is not disastrous, since the

- WakeLock will auto-release after a minute, it may still represent wasted power. WakefulIntentService is more “idiot-proof” and therefore avoids this issue.
- The time for the WakefulBroadcastReceiver WakeLock is locked to being one minute — no more, no less. This offers limited flexibility and can cause problems if the work you intend to do could easily exceed a minute. Unfortunately, the implementation of WakefulBroadcastReceiver offers no easy way to override this one-minute timeout value.
 - If Android terminates your process and restarts your service, the restarted service will *not* be under the control of a WakeLock, as Android will be starting the service directly, not via WakefulBroadcastReceiver. WakefulIntentService will suffer the same fate, but it will automatically grab a WakeLock for you when it detects this condition. In the case of WakefulBroadcastReceiver, your service will run without a WakeLock, unless you detect this case yourself (via a custom onStartCommand() that examines the passed-in flags, looking for START_FLAG_REDELIVERY) and grab your own WakeLock.

A future generation of WakefulIntentService will aim to adopt some of the advantages of WakefulBroadcastReceiver while avoiding its disadvantages. As it stands, either component is a reasonable choice if you are willing to live within their respective constraints.

Tutorial #17 - Periodic Book Updates

Now that we have the ability to update our book's prose by downloading some files from a Web site, we can take the next step: update the book automatically, on a scheduled basis.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Adding a Stub UpdateReceiver

This tutorial is going to use `AlarmManager`. Therefore, we will need a manifest-registered `BroadcastReceiver`, for two reasons:

1. We need to get control at boot time, to restore our alarm schedule
2. We need something to get control when the alarm events occur

In this step, to solve both needs, we will set up a stub `UpdateReceiver`.

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Other > "Broadcast Receiver"` from the context menu, to bring up the new-BroadcastReceiver dialog:

Figure 289: Android Studio New BroadcastReceiver Dialog

Fill in `UpdateReceiver` as the class name. Make sure that the `Exported` and `Enabled` checkboxes are checked. Then, click `Finish` to generate the `UpdateReceiver` class and add an entry for you to the manifest.

Update the generated `<receiver>` element in the manifest to look like:

```
<receiver android:name="UpdateReceiver">
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED"/>
  </intent-filter>
</receiver>
```

Also, add the following `<uses-permission>` element alongside the other such elements in the manifest:

```
<uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>
```

Finally, in the generated `UpdateReceiver` class, get rid of the completely incorrect zero-argument constructor that is [erroneously code-generated](#) for you.

Eclipse

Right click over the `com.commonware.empublite` package in the `src/` folder of your project, and choose `New > Class` from the context menu. Fill in `UpdateReceiver` in the “Name” field. Click the “Browse...” button next to the “Superclass” field and find `BroadcastReceiver` to set as the superclass. Then, click “Finish” on the new-class dialog to create the `UpdateReceiver` class.

You will also need to add a new receiver node to the list of nodes in the Application sub-tab of `AndroidManifest.xml`, pointing to `UpdateReceiver`, following the same approach that we used for other receivers in this application.

However, we also must add an `<intent-filter>` to the `<receiver>` element, identifying the broadcast which we wish to monitor. To do that:

- Click on the Receiver element associated with `UpdateReceiver` in the list of “Application Nodes”
- Click the “Add...” button next to the list of “Application Nodes” and choose “Intent Filter” from the list
- With the “Intent Filter” highlighted in the “Application Nodes” tree, click “Add...” again, this time choosing “Action” from the list
- In the details area on the right, choose `android.intent.action.BOOT_COMPLETED`

Also, in the Permissions sub-tab of the manifest editor, you will need to add the `RECEIVE_BOOT_COMPLETED` “Uses Permission” node.

Step #2: Scheduling the Alarms

Somewhere, we need code to schedule the alarms with `AlarmManager`. Ideally, this will be a static method, one we can use from both `EmPubLiteActivity` (for normal scheduling) and `UpdateReceiver` (for scheduling at boot time).

With that in mind, add the following `scheduleAlarm()` static method to `UpdateReceiver`:

TUTORIAL #17 - PERIODIC BOOK UPDATES

```
static void scheduleAlarm(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, UpdateReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);
    Calendar cal=Calendar.getInstance();

    cal.set(Calendar.HOUR_OF_DAY, 4);
    cal.set(Calendar.MINUTE, 0);
    cal.set(Calendar.SECOND, 0);
    cal.set(Calendar.MILLISECOND, 0);

    if (cal.getTimeInMillis() < System.currentTimeMillis()) {
        cal.add(Calendar.DAY_OF_YEAR, 1);
    }

    mgr.setRepeating(AlarmManager.RTC_WAKEUP, cal.getTimeInMillis(),
        AlarmManager.INTERVAL_DAY, pi);
}
```

Here we create a broadcast `PendingIntent` pointing back at `UpdateReceiver`, create a `Calendar` object for tomorrow at 4am, and call `setRepeating()` on `AlarmManager` to invoke our `PendingIntent` every day at 4am.

Then, modify `onReceive()` of `UpdateReceiver` to use `scheduleAlarm()`, if we are called with an action string (indicating that we are being called due to `ACTION_BOOT_COMPLETED`):

```
@Override
public void onReceive(Context context, Intent intent) {
    if (intent.getAction() != null) {
        scheduleAlarm(context);
    }
}
```

Finally, at the end of `onCreate()` of `EmPubLiteActivity`, add:

```
UpdateReceiver.scheduleAlarm(this);
```

This will schedule the alarms whenever the app is run. Between that and `UpdateReceiver`, the alarms should be active most of the time during normal operation.

Step #3: Adding the WakefulIntentService

It is possible that at 4am local time — or whenever the alarm goes off — that the user will not be using their device. Therefore, it is possible that the device will fall

TUTORIAL #17 - PERIODIC BOOK UPDATES

asleep while we try to download the update. Therefore, we need to switch to using `WakefulIntentService`.

Android Studio users can adjust their top-level repositories closure in `app/build.gradle` to be:

```
repositories {  
    mavenCentral()  
    maven {  
        url "https://repo.commonware.com.s3.amazonaws.com"  
    }  
}
```

Then, Android Studio users can add the following line to the dependencies closure, to pull in the CWAC-Wakeful AAR artifact from the CommonsWare repository:

```
compile 'com.commonware.cwac:wakeful:1.0.+'
```

If you get the yellow banner asking you to do a project sync, please do so.

Eclipse users should visit [the WakefulIntentService releases](#) and download the latest JAR file listed there. Put it in the `libs/` directory of your project — you can either:

- Do this work inside of Eclipse (e.g., drag-and-drop the JAR into Package Explorer), or
- Do this work outside of Eclipse (e.g., create the `libs/` directory directly using OS tools), then press <F5> over the project to get Eclipse to scan the project's directory and pick up your changes

Users of either IDE can then modify `DownloadCheckService` to inherit from `com.commonware.cwac.wakeful.WakefulIntentService` instead of from `IntentService`. This will cause you to need to rename your `onHandleIntent()` method to be `doWakefulWork()`.

Also, add the `WAKE_LOCK` permission in the manifest, along with the rest of our permissions. Eclipse users can add this from the Permissions sub-tab of the Eclipse manifest editor; non-Eclipse users can add another `<uses-permission>` element:

```
<uses-permission android:name="android.permission.WAKE_LOCK"/>
```

Step #4: Using WakefulIntentService

To correctly use WakefulIntentService, we need to use `sendWakefulWork()` to send commands to one, rather than `startService()`.

With that in mind, in `EmPubLiteActivity`, change the `R.id.update` case of the switch statement in `onOptionsItemSelected()` to use `sendWakefulWork()`:

```
case R.id.update:
    WakefulIntentService.sendWakefulWork(this, DownloadCheckService.class);

    return(true);
```

Step #5: Completing the UpdateReceiver

Finally, add an else block to the if statement in `onReceive()` of `UpdateReceiver`, to handle the case where we get control due to the alarm event, so we can use `sendWakefulWork()` to invoke the `DownloadCheckService`:

```
@Override
public void onReceive(Context context, Intent intent) {
    if (intent.getAction() != null) {
        scheduleAlarm(context);
    }
    else {
        WakefulIntentService.sendWakefulWork(context,
                                              DownloadCheckService.class);
    }
}
```

To test this:

1. Uninstall the existing `EmPubLite` application (e.g., by using the Settings app)
2. Install and run the revised app in your device or emulator, confirm that you are viewing the non-updated book, then press BACK to exit the activity
3. Temporarily modify the time of your emulator to be a few minutes before 4am either today (if the current time is between midnight and 4am) or tomorrow (if the current time is after 4am)
4. Return `EmPubLite` to the foreground (due to a bug in the current tutorial that will be fixed sometime in 2015...)
5. Find something to pass the time for the rest of those few minutes, such as procuring liquid refreshment suitable for the time of day and locale

6. A few minutes after the simulated 4am, confirm that you have downloaded the updated book (check the first page of the ViewPager), then fix your emulator's clock back to normal

In Our Next Episode...

... we will [let the user know about updates from the background](#) via a Notification.

Notifications

Pop-up messages. Tray icons and their associated “bubble” messages. Bouncing dock icons. You are no doubt used to programs trying to get your attention, sometimes for good reason.

Your phone also probably chirps at you for more than just incoming calls: low battery, alarm clocks, appointment notifications, incoming text message or email, etc.

Not surprisingly, Android has a whole framework for dealing with these sorts of things, collectively called “notifications”.

What’s a Notification?

A service, running in the background, needs a way to let users know something of interest has occurred, such as when email has been received. Moreover, the service may need some way to steer the user to an activity where they can act upon the event – reading a received message, for example. For this, Android supplies status bar icons, flashing lights, and other indicators collectively known as “notifications”.

Your current phone may well have such icons, to indicate battery life, signal strength, whether Bluetooth is enabled, and the like. With Android, applications can add their own status bar icons, with an eye towards having them appear only when needed (e.g., a message has arrived).

Notifications will appear in one of two places. On most devices, they will appear in the status bar, on the top of the screen, left-aligned:

NOTIFICATIONS

Figure 290: Notifications, on a Galaxy Nexus

On a pre-Android 4.2 tablet (and occasionally on other tablets newer than that), they will appear in the system bar, on the bottom of the screen, towards the lower-right corner:

Figure 291: Notifications, on a Galaxy Tab 2

In either case, you can expand the “notification drawer” to get more details about the active notifications, either by sliding down the status bar:

NOTIFICATIONS

Figure 292: Notification Drawer, on a Galaxy Nexus

or by tapping on the clock on the system bar on some tablets:

Figure 293: Notification Drawer, on a Galaxy Tab 2

Some notifications will be complex, showing real-time information, such as the progress of a long download. More often, notifications are fairly simple, providing just a couple of lines of information, plus an identifying icon. Tapping on the notification drawer entry will typically trigger some action, such as starting an activity — an email app letting the user know that “you’ve got mail” can have its notification bring up the inbox activity when tapped.

Showing a Simple Notification

Previously in the book, we had [an example of using DownloadManager](#). There, we would let the user know about the completion of our download by sending a broadcast Intent back to the activity, so it could do something — in our case, display a Toast.

An alternative would be for the background service doing the download to raise a Notification when the download is complete. That would work even if the activity was no longer around (e.g., user pressed BACK to exit it). A modified version of the original DownloadManager sample taking this Notification approach can be found in the [Notifications/DownloadNotify](#) sample project.

Our DownloadFragment for triggering the download has two changes:

1. We dispense with the BroadcastReceiver and logic related to it, including disabling and enabling the Button
2. On the Intent we use with startService(), we include not only the Uri of the file to download, but also its MIME type, by calling setDataAndType() on the Intent object

```
package com.commonware.android.downloader;

import android.app.Fragment;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.Button;

public class DownloadFragment extends Fragment implements
    View.OnClickListener {
    private Button b=null;

    @Override
```

NOTIFICATIONS

```
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, parent, false);

    b=(Button)result.findViewById(R.id.button);
    b.setOnClickListener(this);

    return(result);
}

@Override
public void onClick(View v) {
    Intent i=new Intent(getActivity(), Downloader.class);

    i.setDataAndType(Uri.parse("http://commonsware.com/Android/excerpt.pdf"),
        "application/pdf");

    getActivity().startService(i);
    getActivity().finish();
}
}
```

The download logic in the `onHandleIntent()` method of `Downloader` is nearly identical. The difference is that at the end, rather than sending a broadcast `Intent`, we call a private `raiseNotification()` method. We also call this method if there is an exception during the download. The `raiseNotification()` method takes the `Intent` command that was delivered to `onHandleIntent()`, the `File` object representing the downloaded results (if we succeeded), and the `Exception` that was raised (if we crashed). As one might guess given the method's name, `raiseNotification()` will raise a `Notification`:

```
private void raiseNotification(Intent inbound, File output,
                              Exception e) {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_ALL);

    if (e == null) {
        b.setTitle(getString(R.string.download_complete))
        .setText(getString(R.string.fun))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.download_complete));

        Intent outbound=new Intent(Intent.ACTION_VIEW);

        outbound.setDataAndType(Uri.fromFile(output), inbound.getType());

        b.setContentIntent(PendingIntent.getActivity(this, 0, outbound, 0));
    }
    else {
        b.setTitle(getString(R.string.exception))
    }
}
```

NOTIFICATIONS

```
.setContentText(e.getMessage())
.setSmallIcon(android.R.drawable.stat_notify_error)
.setTicker(getString(R.string.exception));
}

NotificationManager mgr=
    (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

mgr.notify(NOTIFY_ID, b.build());
}
```

The first thing we do in `raiseNotification()` is create a `Builder` object to help construct the `Notification`. On API Level 11 and higher, there is a `Notification.Builder` class that you can use.

However, the notification system in Android has been changing frequently over the past few OS updates, and there are signs that this will continue. Hence, you may prefer to use `NotificationCompat.Builder`. First, this will work back to API Level 4, in case you are supporting notifications on older devices. More importantly, `NotificationCompat.Builder` is updated to reflect the latest `Notification.Builder` API, offering a backwards-compatible implementation of that API. Some newer features are not supported on older devices, but the `NotificationCompat.Builder` API lets you code to the new API, and it quietly ignores things that cannot be done on older devices.

We can call methods on the `Builder` to configure the `Notification` that we want to display. Whether our download succeeded or failed, we use various methods on `Builder`:

- `setAutoCancel(true)` means that when the user slides open the notification drawer and taps on our entry, the `Notification` is automatically canceled and goes away
- `setDefaults(Notification.DEFAULT_ALL)` means that we want the device's standard notification tone, LED light flash, and vibration to occur when the `Notification` is displayed

If we succeeded (the passed-in `Exception` is `null`), we further configure our `Notification` via more calls to the `Builder`:

- `setContentTitle()` and `setContentText()` supply the prose to display in the two lines of the notification drawer entry for our `Notification`

NOTIFICATIONS

- `setSmallIcon()` indicates the icon to display in the status bar or system bar when the Notification is active (in this case, specifying one supplied by Android itself)
- `setTicker()` supplies some text to be displayed in the status bar or system bar for a few seconds right when the Notification is displayed, so users who happen to be looking at their device at that time will get more information at a glance about what just happened that is demanding their attention

In addition, `setContentIntent()` supplies a `PendingIntent` to be invoked when the notification drawer entry for our Notification is tapped. In our case, we create an `ACTION_VIEW` Intent for our File (using `Uri.fromFile()` to get a `Uri` pointing to our file on external storage) with the MIME type supplied from `DownloadFragment`. Hence, if the user taps on our notification drawer entry, we will attempt to bring up a PDF viewer on the downloaded PDF file – whether this will succeed or not will depend upon whether there is a PDF viewer installed on the device.

If, instead, we did have an Exception, we use the same methods on Builder (minus `setContentIntent()`) to configure the Notification, but using different text and icons.

To actually display the Notification, we need to get a `NotificationManager`, which is another system service. Calling `getSystemService()` and asking for the `NOTIFICATION_SERVICE` will give us our `NotificationManager`, albeit after a cast. Then, we can call `notify()` on the `NotificationManager`, supplying our Notification (from `build()` on the Builder) and a locally-unique integer (`NOTIFY_ID`, defined as a static data member on the service). That integer can later be used with a `cancel()` method to remove the Notification from the screen, even if the user has not canceled it themselves (e.g., via tapping on it with `setAutoCancel(true)`).

NOTE: You may see some samples using `getNotification()` with `NotificationBuilder` instead of `build()`. `getNotification()` was the original method, but it has since been deprecated in favor of `build()`.

Also, because we are using `setDefaults(Notification.DEFAULT_ALL)`, and since the default behavior for a Notification may involve vibrating the phone, we need to hold the `VIBRATE` permission in the manifest:

```
<uses-permission android:name="android.permission.VIBRATE"/>
```

NOTIFICATIONS

Note that as of Android 4.4, you no longer need the `VIBRATE` permission, if you are using `DEFAULT_ALL` or `DEFAULT_VIBRATE` for `setDefaults()`. If you specify a custom vibration pattern, via `setVibrate()`, you still need the `VIBRATE` permission.

Running this in a device or emulator will display the Notification upon completion of the download:

Figure 294: Sample Notification, on Android 4.4

Opening the notification drawer displays our Notification details:

Figure 295: Sample Notification in Drawer, on a Galaxy Nexus

Tapping on the drawer entry will try to start a PDF viewer, perhaps bringing up a chooser if there are multiple such viewers on the device. Also, tapping on the drawer entry will cancel the Notification and remove it from the screen.

The Activity-Or-Notification Scenario

Let us suppose that you are writing an email app. In addition to an “inbox” activity, you have an `IntentService`, scheduled via `AlarmManager`, to go check for new email messages every so often. This means, when your service discovers and downloads new messages, there are two possibilities:

- The user has your inbox activity in the foreground, and that activity should update to reflect the fact that there are new messages
- The user does *not* have your inbox activity in the foreground, so you want to display a `Notification` to alert the user of the new messages and lead them back to the inbox

However, ideally, the service neither knows nor cares whether the inbox activity is in the foreground, exists in the process but is not in the foreground, or does not exist in the process (e.g., Android started a new process to handle this middle-of-the-night check for new email messages).

One way to handle this is via an event bus.

The recipe for the Activity-or-Notification pattern is:

1. Define an event (e.g., event class for greenrobot’s `EventBus`, custom action string for `LocalBroadcastManager`)
2. Have your activity or fragment register to respond to these events while in the foreground (e.g., in `onResume()`) and unregister when leaving the foreground (e.g., `onPause()`). The activity or fragment can then update the UI in response to the event.
3. The service raises the event bus event at appropriate times.
4. By some means appropriate to the event bus implementation, the service needs to know whether an activity or fragment responded to the event, so it can raise a `Notification` if the event has not already been handled.

We will see three implementations of this pattern [in the chapter on event bus alternatives](#).

Big (and Rich) Notifications

Android 4.1 introduced new `Notification` styles that automatically expand into a “big” area when they are the top `Notification` in the drawer. These expanded

NOTIFICATIONS

Notifications can display more text (or a larger thumbnail of an image), plus add some action buttons to allow the user to directly perform more actions straight from the Notification itself.

And while these new Notification styles are only available on API Level 16 and higher, a familiar face has created a compatibility layer so our code can request the larger styles and still work on older devices.

The Styles

There are three main styles supplied for expanded Notifications. There is the BigText style:

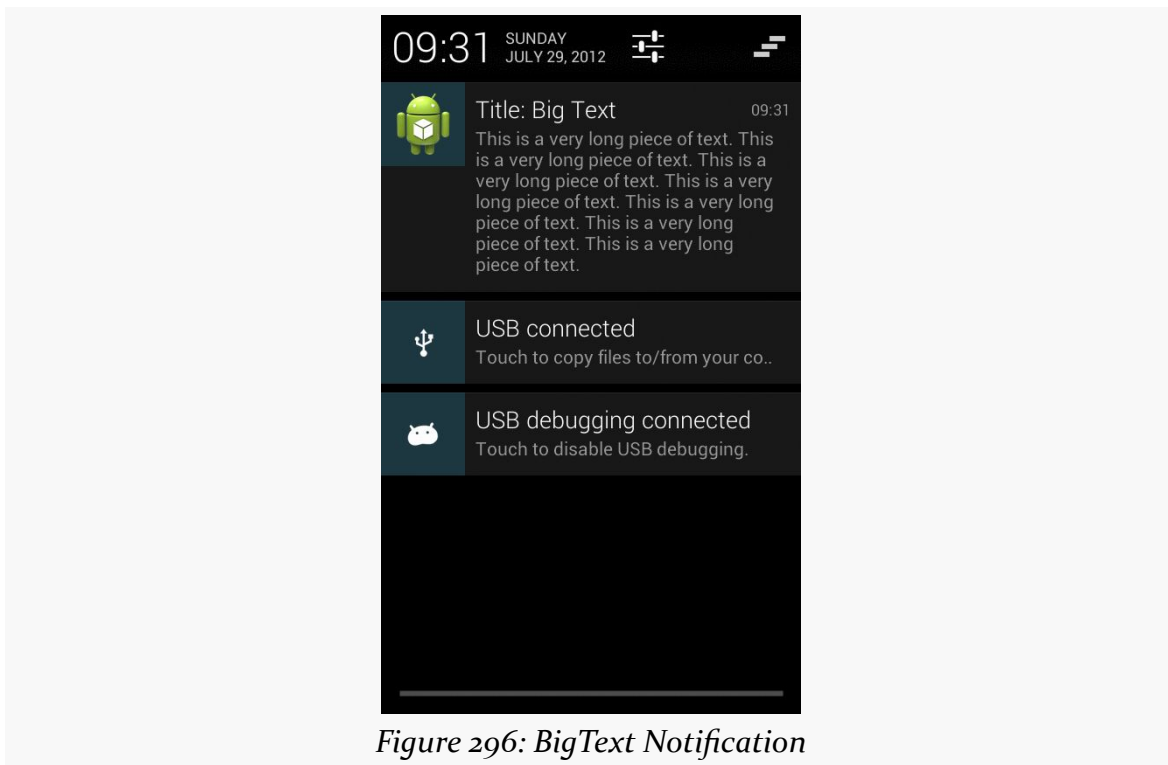

Figure 296: BigText Notification

We also have the Inbox style, which is the same basic concept but designed, for several discrete lines of text:

NOTIFICATIONS

Figure 297: Inbox Notification

And, we have the BigPicture style, ideal for a photo, album cover, or the like:

Figure 298: BigPicture Notification

(as noted in the screenshot, the photo is courtesy of Romain Guy, a former engineer on the core Android team and photography buff)

The Builders

`Notification.Builder` and `NotificationCompat.Builder` have been enhanced to support these new styles. Specifically:

- There is an `addAction()` method on the `Builder` class to define the action buttons, in terms of icon, caption, and `PendingIntent` that should be executed when the button is clicked
- There are style-specific builders, such as `Notification.InboxStyle`, that take a `Notification.Builder` and define the alternative expanded definition to be used when the `Notification` is at the top

The Sample

To see expanded notifications, take a peek at the [Notifications/BigNotify](#) sample application. This application consists of a single activity (`MainActivity`) that will raise a `Notification` and `finish()`, using `@style/Theme.NoDisplay` to suppress the

NOTIFICATIONS

activity's own UI. Hence, the result of running the app is to display the Notification and do nothing else. While silly, it minimizes the amount of ancillary code involved in the project.

The process of displaying an expanded Notification is to first create the basic Notification, containing what you want to display for any non-expanded circumstance:

- Older devices that cannot display expanded Notifications, or
- Newer devices where the Notification is not the top-most entry in the notification drawer, and therefore appears in the classic non-expanded form

Hence, in `onCreate()`, after getting our hands on a `NotificationManager`, we use `NotificationCompat.Builder` to create a regular Notification, wrapped in a private `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setDialogTitle(getString(R.string.download_complete))
      .setContentText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setPriority(Notification.PRIORITY_HIGH)
      .addAction(android.R.drawable.ic_media_play,
                  getString(R.string.play),
                  buildPendingIntent(Settings.ACTION_SETTINGS));

    return(b);
}
```

Most of what `buildNormal()` does is the same sort of stuff we saw with `NotificationCompat.Builder` earlier in this chapter. There are two things, though, that are new:

1. We call `setPriority()` to set the priority of the Notification to `PRIORITY_HIGH`. This means that this Notification *may* be displayed higher in the notification drawer than it might ordinarily appear.
2. We call `addAction()` to add an action button to the Notification, to be shown in the expanded form. We are able to supply an icon, caption, and `PendingIntent`, the latter created by a `buildPendingIntent()` method that

NOTIFICATIONS

wraps our desired Intent action string (here, `Settings.ACTION_SETTINGS`) in an Intent:

```
private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(action);

    return(PendingIntent.getActivity(this, 0, i, 0));
}
```

Ordinarily, we might use this Builder directly, to raise the Notification we described. And, if we just wanted the action button to appear and nothing else new in the expanded form, we could do just that. But in our case, we also want to change the look of the expanded widget to a new style, `InboxStyle`. To do that, we need to wrap our Builder in a `NotificationCompat.InboxStyle` builder:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle(normal);

    mgr.notify(NOTIFY_ID,
        big.setSummaryText(getString(R.string.summary))
           .addLine(getString(R.string.entry))
           .addLine(getString(R.string.another_entry))
           .addLine(getString(R.string.third_entry))
           .addLine(getString(R.string.yet_another_entry))
           .addLine(getString(R.string.low)).build());

    finish();
}
```

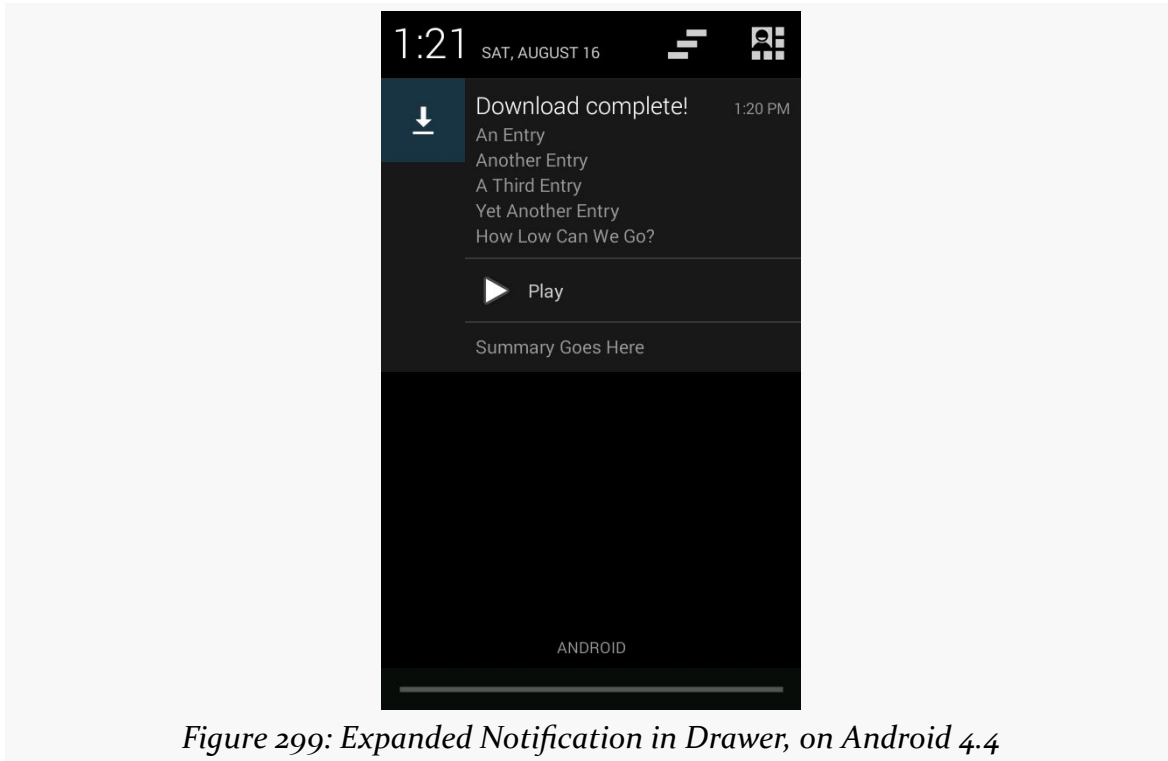

Each of these “big” builders has a set of methods that are unique to that type of builder to configure the look beyond what a standard Notification might have. Specifically, in this case, we call:

- `setSummaryText()`, to provide “the first line of text after the detail section in the big form of the template”, in the words of the JavaDocs, though this does not necessarily mean what you think it does
- `addLine()`, to append several lines of text to appear in the Notification

It is the Notification created by our `NotificationCompat.InboxStyle` builder that we use with the call to `notify()` on `NotificationManager`.

The Results

If we run our app, we get this:

From top to bottom, we have:

- Our content text
- Our appended lines of text
- Our action button
- Our summary text

Note that this is the appearance when we are in expanded mode, at the top of the notification drawer. If our Notification is not at the top, or if it is displayed on a pre-4.1 device, the appearance is the normal style, as defined by our `buildNormal()` method, though on Android 4.1+ devices the user can use a two-finger downward swipe gesture to expand the un-expanded Notification.

The Target Requirement

Note that to use action buttons successfully, you need to have your `android:targetSdkVersion` set to 11 or higher. Technically, they will work with lower values, but the contents of the button will be rendered incorrectly, with a gray-on-gray color scheme that makes the buttons all but unreadable. Using 11 or higher will cause the buttons to be rendered with an appropriate color scheme.

Foreground Services

If you have a service that will run for a substantial period of time, there is a risk that your process will still be terminated. That could be triggered by the user, or it could be the OS's own decision, based on the age of your process.

Generally speaking, this is a good thing for the user, because too many developers “leak” services, causing them to run unnecessarily, without adding value to the user, and tying up system RAM as a result.

But, what about services that *are* delivering value to the user for a long period? For example, what about a music player, where, in theory, the service is delivering value until the user presses some sort of “stop” button somewhere to turn off the music?

For those sorts of situations, you can flag a service as being a “foreground service”.

Isn't “Foreground Service” an Oxymoron?

You might be forgiven for thinking that “foreground” and “service” are not designed to go together.

Partly, that is because we have overloaded the term “foreground”.

A foreground service is *not* one that somehow takes over the screen. A foreground service *is* one that runs with foreground priority. That means:

- It will be treated similarly to the app that is in the UI foreground, from the standpoint of determining processes eligible for termination
- It will be classified as foreground from a CPU standpoint, rather than being relegated to the standard background process group

The former is what many developers want: a service (and process) that will not go away.

The latter is what many users fear: a service (and process) that is capable of stealing chunks of CPU time away from the game, video, or whatever else is truly in the foreground from a UI standpoint.

Services themselves, while useful, are best when used *sparingly*, only running when they are actively delivering value to the user. “This goes double” for foreground services.

Putting Your Service in the Foreground

Putting a service into the foreground is a matter of calling `startForeground()`. This method takes two parameters, the same two parameters that you would pass to `notify()` of `NotificationManager`:

- A prepared `Notification`
- A unique ID for that `Notification`

Android will then display the `Notification`. So long as the `Notification` is visible, your app’s process will be given foreground priority.

You undo this by calling `stopForeground()`. `stopForeground()` takes a boolean parameter, indicating if the `Notification` should be removed (`true`) or not (`false`). Typically, you will pass `true`, so the `Notification` only clutters up the screen while you need it.

The [Notifications/Foreground](#) sample project is a clone of the `Notifications/DownloadNotify` sample that opened this chapter, adding in the use of `startForeground()` and `stopForeground()`.

Towards the top of `onHandleIntent()`, we call `startForeground()`, to *really* ensure that our process will remain intact long enough to complete the requested download:

```
startForeground(FOREGROUND_ID,  
               buildForegroundNotification(filename));
```

This, in turn, uses a `buildForegroundNotification()` method to build the Notification that will be displayed while the service is categorized as being in the foreground:

```
private Notification buildForegroundNotification(String filename) {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setOngoing(true);

    b.setTitle(getString(R.string.downloading))
      .setContentText(filename)
      .setSmallIcon(android.R.drawable.stat_sys_download)
      .setTicker(getString(R.string.downloading));

    return(b.build());
}
```

Note that we use `setOngoing(true)`, to indicate that this is an “ongoing” operation. This precludes the user from removing the Notification manually, as doing that would drop our process out of foreground priority.

Towards the end of `onHandleIntent()`, we call `stopForeground()`, before calling `raiseNotification()`:

```
stopForeground(true);
raiseNotification(i, output, null);
```

There is a similar `stopForeground()` call in the catch block that raises the failure Notification in case of an I/O error.

In both cases, we pass `true` to `stopForeground()` to remove the Notification. From the user’s perspective, we could just as easily have passed `false`, as the Notification used with `startForeground()` will also be removed once our service is destroyed, which will happen shortly after `onHandleIntent()` ends.

The Malformed Notification

Of course, some developers do not play nicely with the other kids.

A technique that had been around for a while was for an app to pass an intentionally-flawed Notification to `startForeground()`. While Android would blow up silently somewhere internally actually trying to display the Notification, the foreground status was still granted. This resulted in behavior reminiscent of the long-since-deprecated `setForeground()` method.

`setForeground()` allowed a service to get foreground priority with no repercussions. Not surprisingly, lots of developers used it, as they decided that their app was more important than any other apps on the device. `setForeground()` was replaced by `startForeground()`, adding in the Notification requirement, to put a “cost” on foreground status. The malformed-Notification trick allowed developers to avoid that cost.

In Android 4.3, if you pass a malformed Notification to `startForeground()`, Android will create one for you, featuring your app’s launcher icon, and use it instead. Hence, on Android 4.3 and higher, you cannot hide your foreground status from the user.

Needless to say, when this behavior was mentioned in [a Google+ post by Dianne Hackborn](#), a number of developers complained.

That being said, if you were using this hack, you will really need to consider alternative strategies, as users do get irritated with everlasting services when they are made aware of them:

- If you were using a foreground service to fix some bug in your app caused by your process being terminated and later restarted (e.g., `START_STICKY`), fix the bug.
- Consider making foreground behavior optional. Since the decision of marking a service as a foreground service is made in Java, not the manifest, it is relatively easy for you to add a checkbox to your app settings to allow the user to indicate whether the benefits of foreground-ness are worth the cost of having the Notification around.
- Consider making the service optional, if the foreground status is needed for the service to be useful, but the features enabled by the service itself are not absolutely essential.
- There is no need to have more than one simultaneous foreground service. One service can have multiple threads to do disparate operations.

Disabled Notifications

Because apps have the ability to display larger-than-normal Notifications, plus force them towards the top of the list via priority levels, Android has given users the ability to disable Notifications on a per-app basis. The degree of control, and the way the user sets up that control, depends upon Android version.

Android 4.x

Users visiting an app's page in Settings will see a “Show notifications” checkbox:

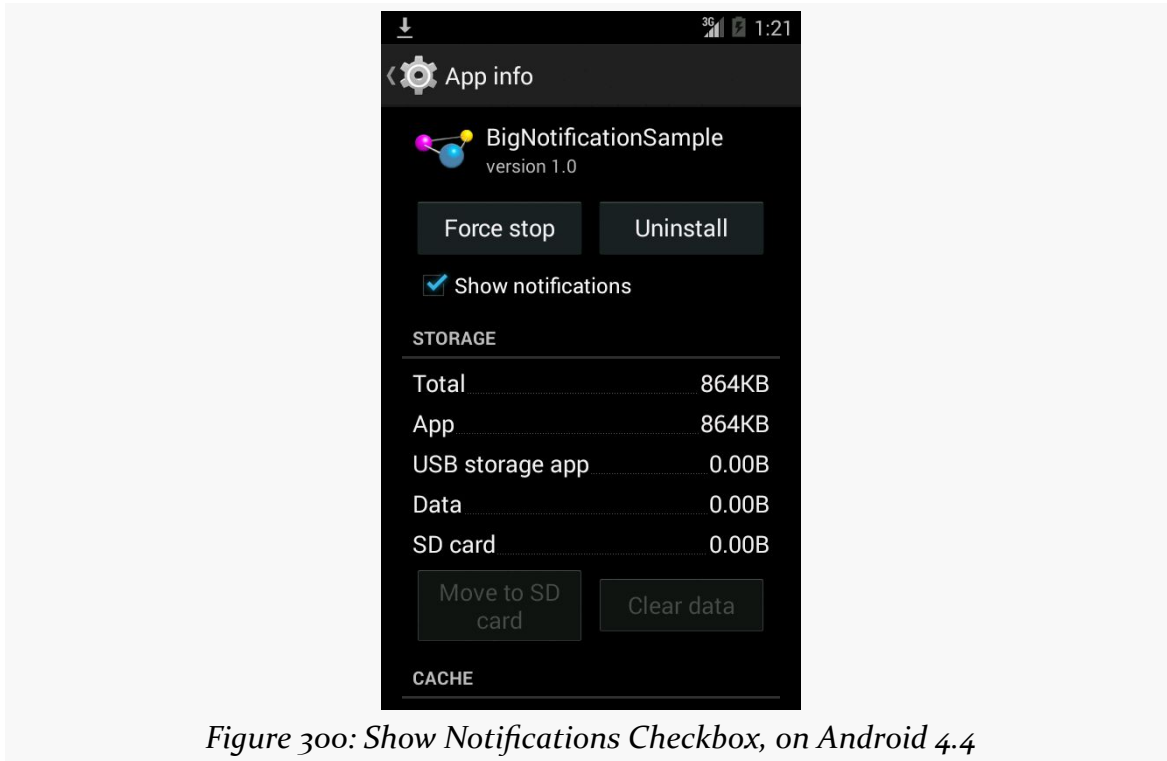

Figure 300: Show Notifications Checkbox, on Android 4.4

If the user unchecks the checkbox and agrees on the resulting confirmation dialog, your requests to raise a Notification will be largely ignored. An error message will appear in LogCat (“Suppressing notification from package ... by user request”), but no exception will be raised. Further, there does not appear to be an API for you to determine if the notification will actually be displayed.

Also note that, on Android 4.2+, if the user blocks notifications, it also blocks Toast requests from your app.

And, also note that this setting survives an uninstall of your app. If the user unchecks this checkbox, uninstalls your app, then reinstalls your app, the checkbox is still unchecked, meaning that notifications will still be blocked.

The one notable exception to this blocking, as of Android 4.3, is that the Notification associated with a foreground service will not be blocked. It will always appear, even if the user unchecked “Show notifications” for your app in Settings.

Android 5.0+

In the “Sound & notification” area of Settings, the user can tap on an “App notifications” option, and from there choose an app. This brings up a screen where the user can “block” (i.e., disable) notifications:

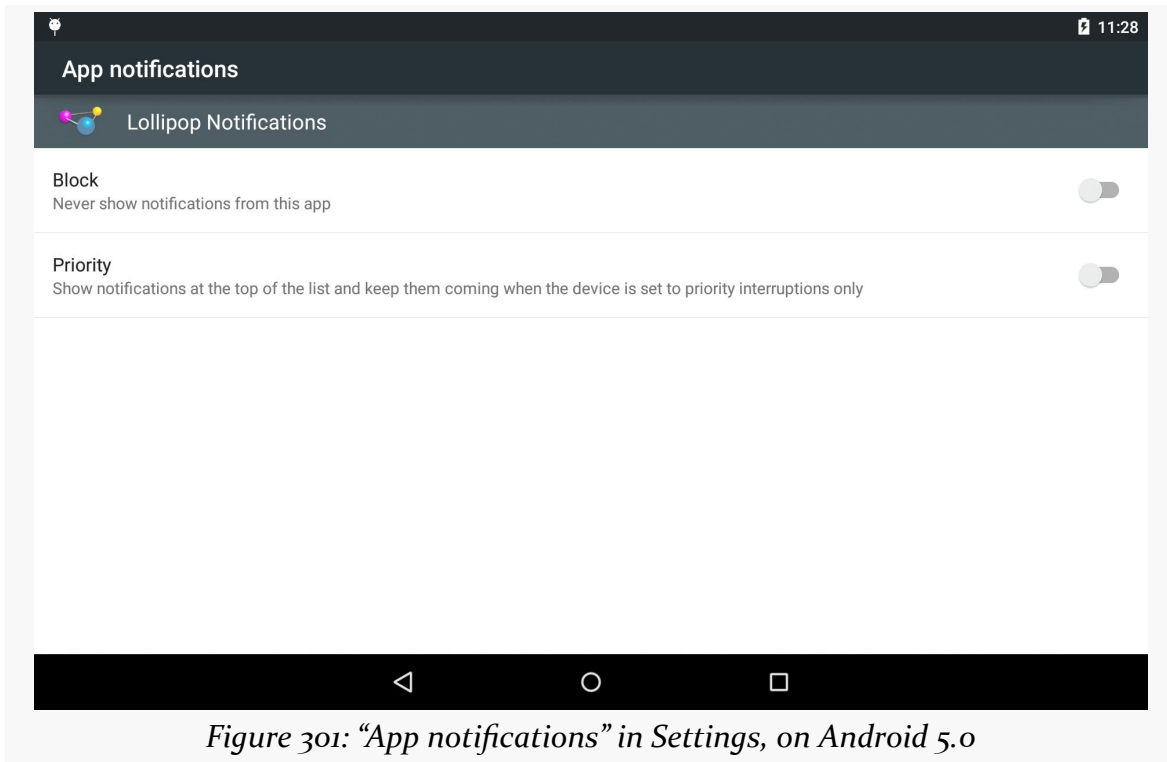

Figure 301: “App notifications” in Settings, on Android 5.0

The top “Block” `SwitchPreference`, if toggled on, will prevent app notifications from being displayed.

The bottom “Priority” `SwitchPreference`, if toggled on, marks this app’s notifications as being “priority”. Then, in the main “Sound & notifications” area of Settings, the user can tap on an “Interruptions” option:

NOTIFICATIONS

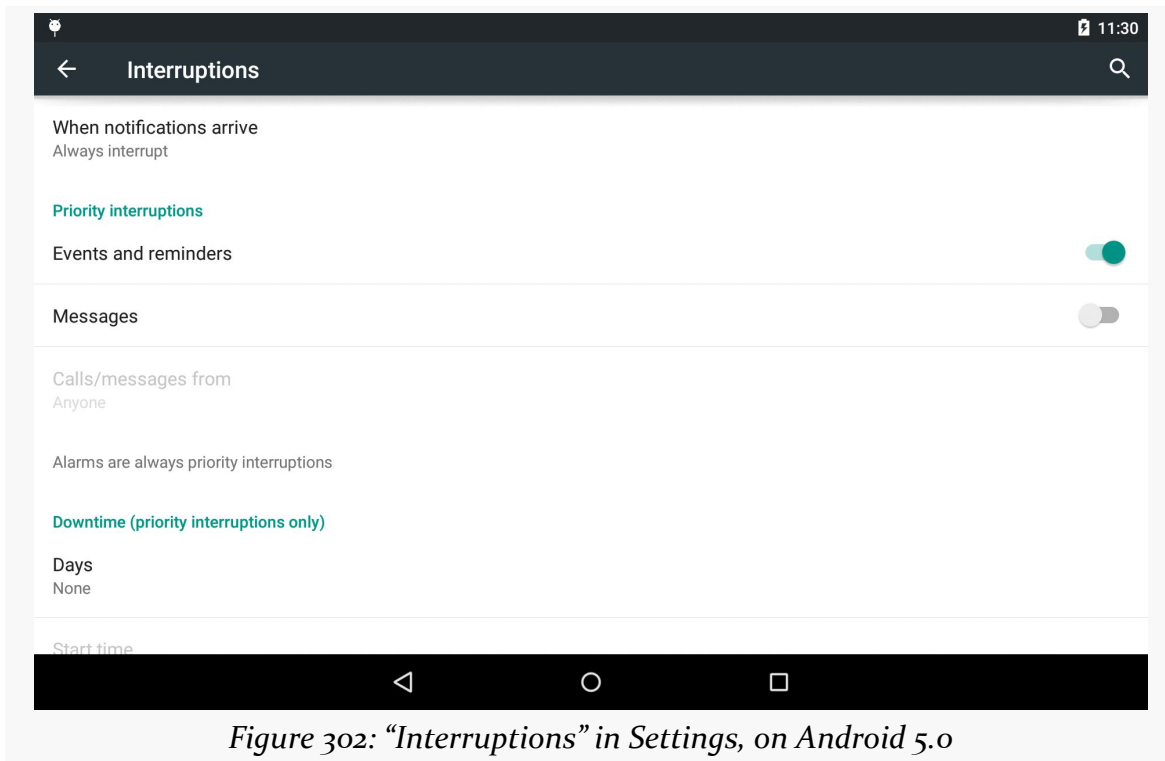

Figure 302: “Interruptions” in Settings, on Android 5.0

If the user toggles the “When notifications arrive” option to “Allow only priority interruptions”, then those apps that the user configures as “Priority” in “App notifications” will behave normally. Other apps’ notifications will appear, but will not play a ringtone or vibrate the device.

If the user toggles the “When notifications arrive” option to “Don’t interrupt”, all notifications — even those marked as “Priority” — will have their ringtones and vibrations suppressed.

Tutorial #18 - Notifying the User

In the last tutorial, we added automatic updating. However, the user will not know that the book was updated in the background, unless they open the book and see an update. It would be nice to let the user know that an update succeeded, if `EmPubLiteActivity` is not in the foreground, and a `Notification` is a likely solution.

But we only want to show the `Notification` if our UI is not in the foreground, as it would be silly to show a `Notification` telling the user to go view the book that the user is already viewing. Hence, we will want to adjust our use of `greenrobot's EventBus` to allow us to update the UI if it is around, or else show the `Notification`.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Raising the Notification

We need to arrange to find out when the `BookUpdatedEvent` is not handled by the `ModelFragment` and raise a `Notification` in that case.

First, create two new string resources:

- `R.string.update_desc`, with a value of `Click here to open the updated book!`
- `R.string.update_complete`, with a value of `EmPub Lite Updated!`

TUTORIAL #18 - NOTIFYING THE USER

Next, add a NOTIFY_ID static data member to DownloadCheckService:

```
private static final int NOTIFY_ID=1337;
```

This will be used as a unique identifier of our notification when we raise it.

Then, modify doWakefulWork() in DownloadCheckService to handle the events a bit differently, registering and unregistering from the bus before posting:

```
@Override
protected void doWakefulWork(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            File book=download(url);
            File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

            updateDir.mkdirs();
            unzip(book, updateDir);
            book.delete();

            EventBus.getDefault().register(this);
            EventBus.getDefault().post(new BookUpdatedEvent());
            EventBus.getDefault().unregister(this);
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Note that post(), as we are now using it, will deliver its event to ModelFragment (if it is registered) on the same thread we are using to call post(), and so this work will happen synchronously.

Finally, add an onEvent() method to DownloadCheckService:

```
public void onEvent(NoSubscriberEvent event) {
    NotificationCompat.Builder builder=new NotificationCompat.Builder(this);
    Intent toLaunch=new Intent(this, EmPubLiteActivity.class);
    PendingIntent pi=PendingIntent.getActivity(this, 0, toLaunch, 0);

    builder.setAutoCancel(true).setContentIntent(pi)
        .setTitle(getString(R.string.update_complete))
        .setText(getString(R.string.update_desc))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.update_complete));
}
```

TUTORIAL #18 - NOTIFYING THE USER

```
NotificationManager mgr=
    ((NotificationManager) getSystemService(Context.NOTIFICATION_SERVICE));

mgr.notify(NOTIFY_ID, builder.build());
}
```

Here, we:

- Craft an Intent identifying EmPubLiteActivity
- Wrap it in a getActivity() PendingIntent
- Wrap that in a Notification created using a Notification.Builder, configured to let the user know that a book update is ready for download
- Raise that Notification using a NotificationManager

Because we are listening for NoSubscriberEvent, this will be triggered when our post() of the BookUpdatedEvent fails to be picked up by any subscriber. That means that our UI did not update itself to reflect the book update, and therefore it is the service's job to let the user know about the update.

To test this, repeat the test from [Step #5 of the previous tutorial](#). You should see the Notification appear once the update has completed. Sliding open the notification drawer and tapping on the notification should bring up the book for reading.

In Our Next Episode...

... we will [move some fragments into a sidebar](#) on large-screen devices, like tablets.

Large-Screen Strategies and Tactics

So far, we have been generally ignoring screen size. With the vast majority of Android devices being in a fairly narrow range of sizes (3" to just under 5"), ignoring size while learning is not a bad approach. However, when it comes time to create a production app, you are going to want to strongly consider how you are going to handle other sizes, mostly larger ones (e.g., tablets).

Objective: Maximum Gain, Minimum Pain

What you want is to be able to provide a high-quality user experience without breaking your development budget — time *and* money — in the process.

An app designed around a phone, by default, may look fairly lousy on a tablet. That is because Android is simply going to try to stretch your layouts and such to fill the available space. While that will work, technically, the results may be unpleasant, or at least ineffective. If we have the additional room, it would be nice to allow the user to do something with that room.

At the same time, though, you do not have an infinite amount of time to be dealing with all of this. After all, there are a variety of tablet sizes. While ~7" and ~10" screens are the most common, there are certainly others that are reasonably popular (e.g., Amazon's Kindle Fire HD 8.9").

The Fragment Strategy

Some apps will use the additional space of a large screen directly. For example, a painting app would use that space mostly to provide a larger drawing canvas upon which the user can attempt to become the next Rembrandt, Picasso, or Pollock. The

LARGE-SCREEN STRATEGIES AND TACTICS

app might elect to make more tools available directly on the screen as well, versus requiring some sort of pop-up to appear to allow the user to change brush styles, choose a different color, and so forth.

However, this can be a lot of work.

Some apps can make a simplifying assumption: the tablet UI is really a bunch of phone-sized layouts, stitched together. For example, if you take a 10" tablet in landscape, it is about the same size as two or three phones side-by-side. Hence, one could imagine taking the smarts out of a few activities and having them be adjacent to one another on a tablet, versus having to be visible only one at a time as they are on phones.

For example, consider Gmail.

On a phone, you see conversations in a particular label on one screen:

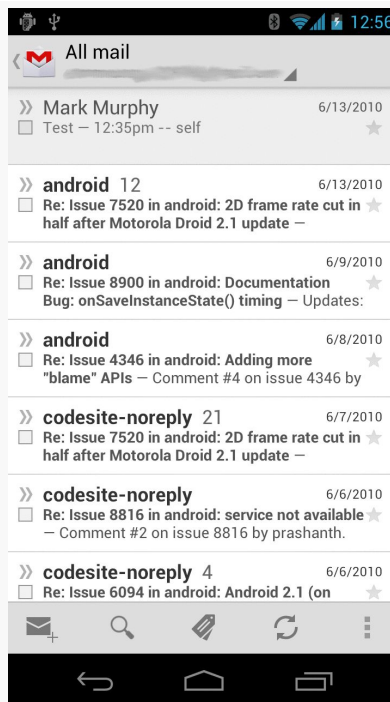

Figure 303: Gmail, On a Galaxy Nexus, Showing Conversations

... and the list of labels on another screen:

Figure 304: Gmail, On a Galaxy Nexus, Showing Labels

... and the list of messages in some selected conversation in a third screen:

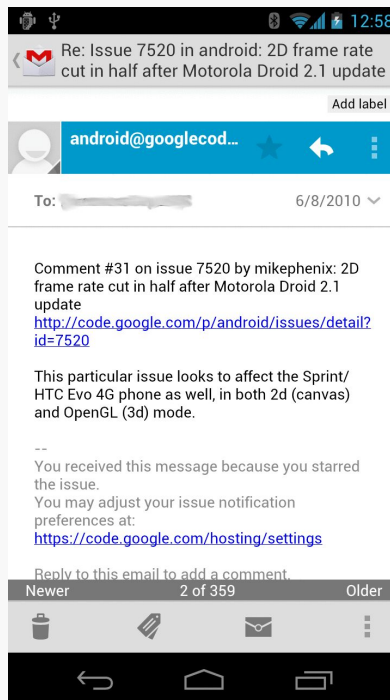

Figure 305: Gmail, On a Galaxy Nexus, Showing Messages

Whereas on a 7" tablet, you see the list of labels and the conversations in a selected label at the same time:

LARGE-SCREEN STRATEGIES AND TACTICS

Figure 306: Gmail, On a Galaxy Tab 2, Showing Labels and Conversations

On that 7" tablet, tapping on a specific conversation brings up the list of messages for that conversation in a new screen. But, on a 10" tablet, tapping on a specific conversation shows it, plus the list of conversations, side-by-side:

LARGE-SCREEN STRATEGIES AND TACTICS

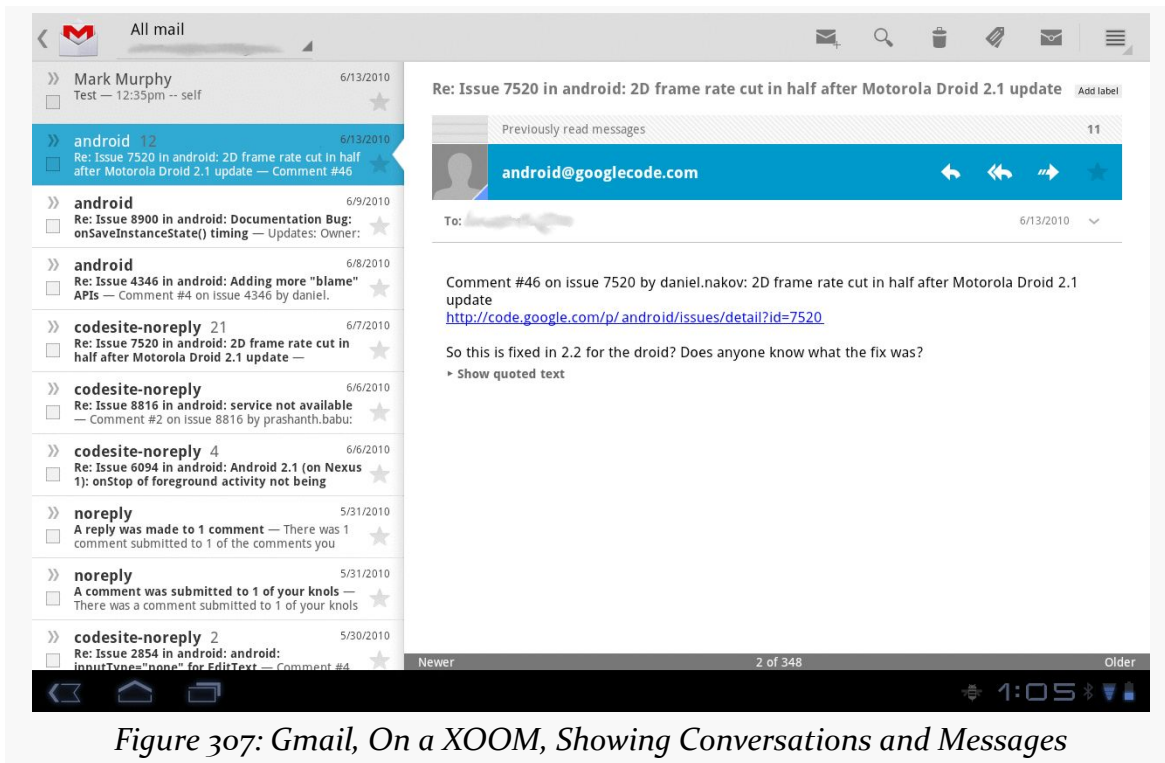

Figure 307: Gmail, On a XOOM, Showing Conversations and Messages

Yet all of that was done with one app with very little redundant logic, by means of fragments.

The list-of-labels, list-of-conversations, and list-of-messages bits of the UI were implemented as fragments. On a smaller screen (e.g., a phone), each one is displayed by an individual activity. Yet, on a larger screen (e.g., a tablet), more than one fragment is displayed by a single activity. In fact — though it will not be apparent from the static screenshots — on the 10" tablet, the activity showed *all three fragments*, using animated effects to slide the list of labels off-screen and the list of conversations over to the left slot when the user taps on a conversation to show the messages.

The vision, therefore, is to organize your UI into fragments, then choose which fragments to show in which circumstances based on available screen space:

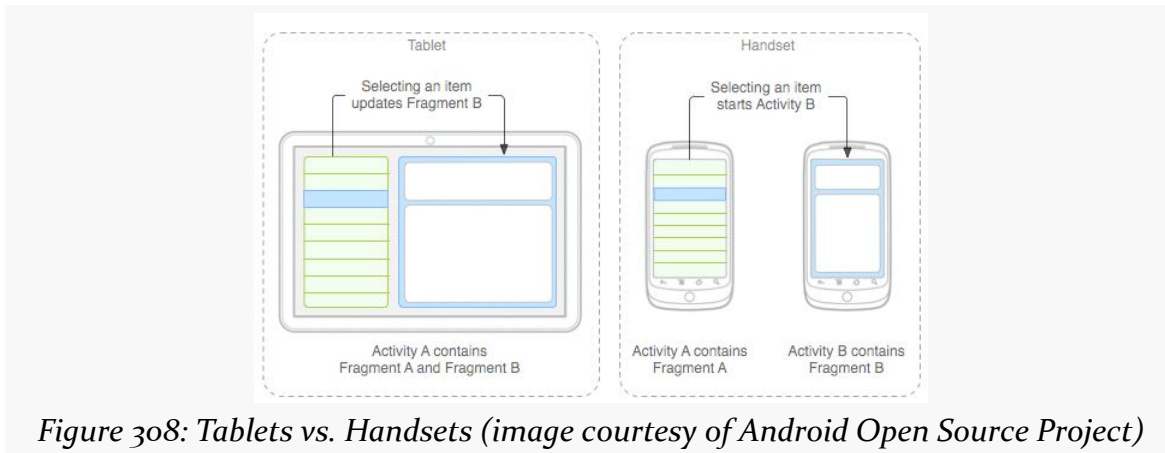

Figure 308: Tablets vs. Handsets (image courtesy of Android Open Source Project)

Changing Layout

One solution is to say that you have the same fragments for all devices and all configurations, but that the sizing and positioning of those fragments varies. This is accomplished by using different layouts for the activity, ones that provide the sizing and positioning rules for the fragments.

So far, most of our fragment examples have been focused on activities with a single fragment, like you might use on smaller screens (e.g., phones). However, activities can most certainly have more than one fragment, though you will need to provide the “slots” into which to plug those fragments.

For example, you could have the following in `res/layout-w720dp/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <FrameLayout
        android:id="@+id/countries"
        android:layout_weight="30"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
    <FrameLayout
        android:id="@+id/details"
        android:layout_weight="70"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

Here we have a horizontal `LinearLayout` holding a pair of `FrameLayout` containers. Each of those `FrameLayout` containers will be a slot to load in a fragment, using code like:

```
getSupportFragmentManager().beginTransaction()  
    .add(R.id.countries, someFragmentHere)  
    .commit();
```

In principle, you could also have a `res/layout-h720dp/main.xml` that holds both of the same `FrameLayout` containers, but just in a vertical `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:orientation="vertical"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent">  
    <FrameLayout  
        android:id="@+id/countries"  
        android:layout_weight="30"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
    />  
    <FrameLayout  
        android:id="@+id/details"  
        android:layout_weight="70"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
    />  
</LinearLayout>
```

As the user rotates the device, the fragments will go in their appropriate slots.

Changing Fragment Mix

However, for larger changes in screen size, you will probably need to have larger changes in your fragments. The most common pattern is to have fewer fragments on-screen for an activity on a smaller-screen device (e.g., one fragment at a time on a phone) and more fragments on-screen for an activity on a larger-screen device (e.g., two fragments at a time on a tablet).

So, for example, as the counterpart to the `res/layout-w720dp/main.xml` shown in the previous section, you might have a `res/layout/main.xml` that looks like this:

```
<?xml version="1.0" encoding="utf-8"?>  
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/countries"
```

```
android:layout_width="match_parent"  
android:layout_height="match_parent"  
</>
```

This provides a single slot, `R.id.countries`, for a fragment, one that fills the screen. For a larger-screen device, held in landscape, you would use the two-fragment layout; for anything else (e.g., tablet in portrait, or phone in any orientation), you would use the one-fragment layout.

Of course, the content that belongs in the second fragment would have to show up *somewhere*.

Sometimes, when you add another fragment for a large screen, you only want it to be there some of the time. For example, a digital book reader (like the one we are building in the tutorials) might normally take up the full screen with the reading fragment, but might display a sidebar fragment based upon an action bar item click or the like. If you would like the BACK button to reverse your `FragmentManager` that added the second fragment — so pressing BACK removes that fragment and returns you to the single-fragment setup — you can add `addToBackStack()` as part of your `FragmentManager` construction:

```
getSupportFragmentManager().beginTransaction()  
    .addToBackStack(null)  
    .replace(R.id.sidebar, f)  
    .commit();
```

We will see this in [the next tutorial](#).

The Role of the Activity

So, what is the activity doing?

First, the activity is the one loading the overall layout, the one indicating which fragments should be loaded (e.g., the samples shown above). The activity is responsible for populating those “slots” with the appropriate fragments. It can determine which fragments to create based on which slots exist, so it would only try to create a fragment to go in `R.id.details` if there actually is an `R.id.details` slot to use.

Next, the activity is responsible for handling any events that are triggered by UI work in a fragment (e.g., user clicking on a `ListView` item), whose results should impact other fragments (e.g., displaying details of the clicked-upon `ListView` item). The activity knows which fragments exist at the present time. So, the activity can

either call some method on the second fragment if it exists, or it can call `startActivity()` to pass control to another activity that will be responsible for the second fragment if it does not exist in the current activity.

Finally, the activity is generally responsible for any model data that spans multiple fragments. Whether that model data is held in a “model fragment” (as outlined [in the chapter on fragments](#)) or somewhere else is up to you.

Fragment Example: The List-and-Detail Pattern

This will make a bit more sense as we work through another example, this time focused on a common pattern: a list of something, where clicking on the list brings up details on the item that was clicked upon. On a larger-screen device, in landscape, both pieces are typically displayed at the same time, side-by-side. On smaller-screen devices, and sometimes even on larger-screen devices in portrait, only the list is initially visible — tapping on a list item brings up some other activity to display the details.

Describing the App

The sample app for this section is [LargeScreen/EU4You](#). This app has a list of member nations of the European Union (EU). Tapping on a member nation will display the mobile Wikipedia page for that nation in a `WebView` widget.

The data model — such as it is and what there is of it — consists of a `Country` class which holds onto the country name (as a string resource ID), flag (as a drawable resource ID), and mobile Wikipedia URL (as another string resource ID):

```
Country(int name, int flag, int url) {  
    this.name=name;  
    this.flag=flag;  
    this.url=url;  
}
```

The `Country` class has a static `ArrayList` of `Country` objects representing the whole of the EU, initialized in a static initialization block:

```
static {  
    EU.add(new Country(R.string.austria, R.drawable.austria,  
        R.string.austria_url));  
    EU.add(new Country(R.string.belgium, R.drawable.belgium,  
        R.string.belgium_url));  
    EU.add(new Country(R.string.bulgaria, R.drawable.bulgaria,
```

```
        R.string.bulgaria_url));
EU.add(new Country(R.string.cyprus, R.drawable.cyprus,
        R.string.cyprus_url));
EU.add(new Country(R.string.czech_republic,
        R.drawable.czech_republic,
        R.string.czech_republic_url));
EU.add(new Country(R.string.denmark, R.drawable.denmark,
        R.string.denmark_url));
EU.add(new Country(R.string.estonia, R.drawable.estonia,
        R.string.estonia_url));
EU.add(new Country(R.string.finland, R.drawable.finland,
        R.string.finland_url));
EU.add(new Country(R.string.france, R.drawable.france,
        R.string.france_url));
EU.add(new Country(R.string.germany, R.drawable.germany,
        R.string.germany_url));
EU.add(new Country(R.string.greece, R.drawable.greece,
        R.string.greece_url));
EU.add(new Country(R.string.hungary, R.drawable.hungary,
        R.string.hungary_url));
EU.add(new Country(R.string.ireland, R.drawable.ireland,
        R.string.ireland_url));
EU.add(new Country(R.string.italy, R.drawable.italy,
        R.string.italy_url));
EU.add(new Country(R.string.latvia, R.drawable.latvia,
        R.string.latvia_url));
EU.add(new Country(R.string.lithuania, R.drawable.lithuania,
        R.string.lithuania_url));
EU.add(new Country(R.string.luxembourg, R.drawable.luxembourg,
        R.string.luxembourg_url));
EU.add(new Country(R.string.malta, R.drawable.malta,
        R.string.malta_url));
EU.add(new Country(R.string.netherlands, R.drawable.netherlands,
        R.string.netherlands_url));
EU.add(new Country(R.string.poland, R.drawable.poland,
        R.string.poland_url));
EU.add(new Country(R.string.portugal, R.drawable.portugal,
        R.string.portugal_url));
EU.add(new Country(R.string.romania, R.drawable.romania,
        R.string.romania_url));
EU.add(new Country(R.string.slovakia, R.drawable.slovakia,
        R.string.slovakia_url));
EU.add(new Country(R.string.slovenia, R.drawable.slovenia,
        R.string.slovenia_url));
EU.add(new Country(R.string.spain, R.drawable.spain,
        R.string.spain_url));
EU.add(new Country(R.string.sweden, R.drawable.sweden,
        R.string.sweden_url));
EU.add(new Country(R.string.united_kingdom,
        R.drawable.united_kingdom,
        R.string.united_kingdom_url));
}
```

CountriesFragment

The fragment responsible for rendering the list of EU nations is `CountriesFragment`. It is a `ListFragment`, using a `CountryAdapter` to populate the list:

```
class CountryAdapter extends ArrayAdapter<Country> {
    CountryAdapter() {
        super(getActivity(), R.layout.row, R.id.name, Country.EU);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        CountryViewHolder wrapper=null;

        if (convertView == null) {
            convertView=
                LayoutInflater.from(getActivity()).inflate(R.layout.row,
                                                            parent, false);

            wrapper=new CountryViewHolder(convertView);
            convertView.setTag(wrapper);
        }
        else {
            wrapper=(CountryViewHolder)convertView.getTag();
        }

        wrapper.populateFrom(getItem(position));

        return(convertView);
    }
}
```

This adapter is somewhat more complex than the ones we showed in the [chapter on selection widgets](#). We will get into what `CountryAdapter` is doing, and the `CountryViewHolder` it references, in [a later chapter of this book](#). Suffice it to say for now that the rows in the list contain both the country name and its flag.

When the user taps on a row in our `ListView`, something needs to happen – specifically, the details of that country need to be displayed. However, displaying those details is not the responsibility of `CountriesFragment`, as it simply displays the list of countries and nothing else. Hence, we need to pass the event up to the hosting activity to handle.

We could accomplish this using an event bus, as seen in other examples earlier in the book. The EU4You series of samples, though, use a different approach, referred to as the contract pattern. In this pattern, the fragment defines an interface, which is the “contract” that all hosting activities of that fragment must implement. This requirement is enforced by the superclass, `ContractListFragment`:

 */

// derived from https://gist.github.com/JakeWharton/2621173

package com.commonsware.android.eu4you;

import android.app.Activity;
import android.app.ListFragment;

public class ContractListFragment<T> extends ListFragment {
    private T contract;

    @SuppressWarnings("unchecked")
    @Override
    public void onAttach(Activity activity) {
        super.onAttach(activity);

        try {
            contract=(T)activity;
        }
        catch (ClassCastException e) {
            throw new IllegalStateException(activity.getClass()
                .getSimpleName()
                + " does not implement contract interface for "
                + getClass().getSimpleName(), e);
        }
    }

    @Override
    public void onDetach() {
        super.onDetach();

        contract=null;
    }

    public final T getContract() {
        return(contract);
    }
}
```

`onAttach()` is called when the fragment has been attached to an activity, whether that is from when the activity was initially created, after a configuration change, or whenever. In those cases, we cast the activity to be the contract interface (provided via the data type in the declaration), raising an exception if the cast fails. Subclasses can then access the contract object via the `getContract()` method.

`CountriesFragment` inherits from `ContractListFragment` and defines its contract. Hence, any activity that hosts a `CountriesFragment` is responsible for implementing this contract interface, so we can call `onCountrySelected()` when the user clicks on a row in the list:

```
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    if (getContract().isPersistentSelection()) {
        getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
        l.setItemChecked(position, true);
    }
    else {
        getListView().setChoiceMode(ListView.CHOICE_MODE_NONE);
    }

    getContract().onCountrySelected(Country.EU.get(position));
}
```

`CountriesFragment` also has quite a bit of code dealing with clicked-upon rows being in an “activated” state. This provides visual context to the user and is often used in the list-and-details pattern. For example, in the tablet renditions of Gmail shown earlier in this chapter, you will notice that the list on the left (e.g., list of labels) has one row highlighted with a blue background. This is the “activated” row, and it indicates the context for the material in the adjacent fragment (e.g., list of conversations in the label). Managing this “activated” state is a bit beyond the scope of this section, however, so we will delay discussion of that topic to [a later chapter in this book](#).

DetailsFragment

The details to be displayed come in the form of a URL to a mobile Wikipedia page for a country, designed to be displayed in a `WebView`. The `EU4You` sample app makes use of the same `WebViewFragment` that we saw earlier in this book, such as in the tutorials. `DetailsFragment` itself, therefore, simply needs to expose some method to allow a hosting activity to tell it what URL to display:

```
package com.commonware.android.eu4you;
```

```
import android.webkit.WebViewFragment;

public class DetailsFragment extends WebViewFragment {
    public void loadUrl(String url) {
        getWebView().loadUrl(url);
    }
}
```

You will notice that this fragment is not retained via `setRetainInstance()`. That is because, as you will see, we will not always be displaying this fragment. Fragments that are displayed in some configurations (e.g., landscape) but not in others (e.g., portrait), where a device might change between those configurations at runtime, cannot be retained without causing crashes.

The Activities

Our launcher activity is also named `EU4You`. It uses two of the layouts shown above. Both are `main.xml`, but one is in `res/layout-w720dp/`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <FrameLayout
        android:id="@+id/countries"
        android:layout_weight="30"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
    <FrameLayout
        android:id="@+id/details"
        android:layout_weight="70"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

The other is in `res/layout/`:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/countries"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

Both have a `FrameLayout` for the `CountriesFragment` (`R.id.countries`), but only the `res/layout-w720dp/` edition has a `FrameLayout` for the `DetailsFragment` (`R.id.details`).

Here is the complete implementation of the `EU4You` activity:

```
package com.commonware.android.eu4you;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
    private CountriesFragment countries=null;
    private DetailsFragment details=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        countries=
            (CountriesFragment)getFragmentManager().findFragmentById(R.id.countries);

        if (countries == null) {
            countries=new CountriesFragment();
            getFragmentManager().beginTransaction()
                .add(R.id.countries, countries)
                .commit();
        }

        details=
            (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

        if (details == null && findViewById(R.id.details) != null) {
            details=new DetailsFragment();
            getFragmentManager().beginTransaction()
                .add(R.id.details, details).commit();
        }
    }

    @Override
    public void onCountrySelected(Country c) {
        String url=getString(c.url);

        if (details != null && details.isVisible()) {
            details.loadUrl(url);
        }
        else {
            Intent i=new Intent(this, DetailsActivity.class);
        }
    }
}
```

```
        i.putExtra(DetailsActivity.EXTRA_URL, url);
        startActivity(i);
    }
}

@Override
public boolean isPersistentSelection() {
    return(details != null && details.isVisible());
}
}
```

The job of `onCreate()` is to set up the UI. So, we:

- See if we already have an instance of `CountriesFragment`, by asking our `FragmentManager` to give us the fragment in the `R.id.countries` slot — this might occur if we underwent a configuration change, as `CountriesFragment` would be recreated in that case
- If we do not have a `CountriesFragment` instance, create one and execute a `FragmentTransaction` to load it into `R.id.countries` of our layout
- Find the `DetailsFragment` (which, since `DetailsFragment` is not retained, should always return `null`, but, as they say, “better safe than sorry”)
- If we do not have a `DetailsFragment` *and* the layout has a `R.id.details` slot, create a `DetailsFragment` and execute the `FragmentTransaction` to put it in that slot... but otherwise do nothing

The net result is that `EU4You` can correctly handle either situation, where we have both fragments or just one.

Similarly, the `onCountrySelected()` method (required by the `Contract` interface) will see if we have our `DetailsFragment` or not (and whether it is visible, or is hidden because we created it but it is not visible in the current screen orientation). If we do, we just call `loadUrl()` on it, to populate the `WebView`. If we do not have a visible `DetailsFragment`, we need to do something to display one. In principle, we could elect to execute a `FragmentTransaction` to replace the `CountriesFragment` with the `DetailsFragment`, but this can get complicated. Here, we start up a separate `DetailsActivity`, passing the URL for the chosen Country in an `Intent` extra.

`DetailsActivity` is similar:

```
package com.commonware.android.eu4you;

import android.app.Activity;
import android.os.Bundle;

public class DetailsActivity extends Activity {
```

```
public static final String EXTRA_URL=
    "com.commonware.android.eu4you.EXTRA_URL";
private String url=null;
private DetailsFragment details=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    details=
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

    if (details == null) {
        details=new DetailsFragment();

        getFragmentManager().beginTransaction()
            .add(android.R.id.content, details)
            .commit();
    }

    url=getIntent().getStringExtra(EXTRA_URL);
}

@Override
public void onResume() {
    super.onResume();

    details.loadUrl(url);
}
}
```

We create the `DetailsFragment` and load it into the layout, capture the URL from the Intent extra, and call `loadUrl()` on the `DetailsFragment`. However, since we are executing a `FragmentManager` transaction, the actual UI for the `DetailsFragment` is not created immediately, so we cannot call `loadUrl()` right away (otherwise, `DetailsFragment` will try to pass it to a non-existent `WebView`, and we crash). So, we delay calling `loadUrl()` to `onResume()`, at which point the `WebView` should exist.

The Results

On a larger-screen device, in landscape, we have both fragments, though there is nothing initially loaded into the `DetailsFragment`:

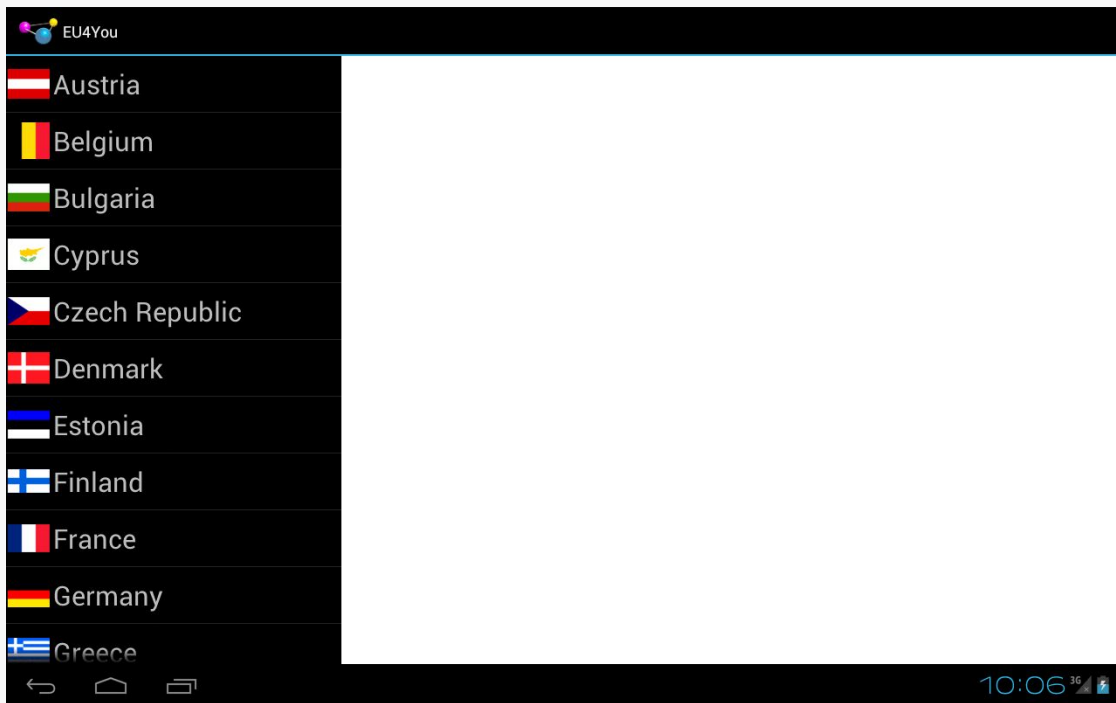

Figure 309: EU4You, On a Tablet Emulator, Landscape

Tapping on a country brings up the details on the right:

Figure 310: EU4You, On a Tablet Emulator, Landscape, With Details

In any other configuration, such as a smaller-screen device, we only see the CountriesFragment at the outset:

Figure 311: EU4You, On a Phone Emulator

Tapping on a country brings up the DetailsFragment full-screen in the DetailsActivity:

Figure 312: EU4You, On a Phone Emulator, Showing Details

Other Master-Detail Strategies

The EU4You sample from above is one way of approaching this master-detail pattern. It is not the only one. In this section, we will review other implementations of EU4You that use other techniques for implementing the master-detail pattern.

Static CountriesFragment

In the original EU4You activity, both fragments were dynamic, each added via a `FragmentManager`. `DetailsFragment` has to be dynamic, as whether or not it is visible depends upon screen size and orientation. However, there is no particular need for our `CountriesFragment` to be dynamic, as you will see in the [LargeScreen/EU4YouStaticCountries](#) sample project.

Here, our single-pane layout uses a `<fragment>` element to wire in the `CountriesFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/countries"
```

```
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.eu4you3.CountriesFragment"
/>
```

Similarly, our dual-pane layout uses a <fragment> element for the CountriesFragment, alongside the FrameLayout for the details:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:baselineAligned="false"
    android:orientation="horizontal">

    <fragment
        android:id="@+id/countries"
        android:name="com.commonware.android.eu4you3.CountriesFragment"
        android:layout_width="0px"
        android:layout_height="match_parent"
        android:layout_weight="30"/>

    <FrameLayout
        android:id="@+id/details"
        android:layout_width="0px"
        android:layout_height="match_parent"
        android:layout_weight="70"/>

</LinearLayout>
```

Our onCreate() for EU4You is simpler, in that we do not need to mess with the CountriesFragment at all:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    details=
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

    if (details == null && findViewById(R.id.details) != null) {
        details=new DetailsFragment();
        getFragmentManager().beginTransaction()
            .add(R.id.details, details).commit();
    }
}
```

Neither CountriesFragment or anything involving the details necessarily needs to change.

Going With One Activity

You might wonder why we need to bother with `DetailsActivity`. After all, the `EU4You` activity is perfectly capable of showing the `DetailsFragment` in a second pane — why not have it display the `DetailsFragment` in the first pane as well, in single-pane scenarios? Surely, this will be much simpler, as we can dispense with the activity and its entry in the manifest!

Yes, this is possible. No, it is not simpler.

The reason for the complexity is now managing all of our possible mix of fragments. We already had to deal with the following possibilities:

- Single-pane, showing the countries
- Single-pane, showing the countries, but on a large screen in portrait mode, after the activity had been launched in landscape, so the `DetailsFragment` exists in the `FragmentManager`, but is not visible
- Dual-pane, showing both fragments

If we get rid of `DetailsActivity` and dump all the responsibility onto `EU4You`, we have more scenarios:

- Single-pane, showing the details, having replaced the countries via a `FragmentTransaction`
- Single-pane, showing the countries, after having shown the details and the user then pressing `BACK`

Basically, what we must do now is `replace()` the `CountriesFragment` with the `DetailsFragment`, when we are in single-pane mode, when the user taps on a country in the list. This requires a fairly extensive number of changes, as you will see in the [LargeScreen/EU4YouSingleActivity](#) sample project.

The Revised Layouts

In our single-pane mode, our one pane will either hold the `CountriesFragment` or the `DetailsFragment`, depending upon what the user has done. Right now, our `FrameLayout` is named `R.id.countries`, which was fine before, but now seems like an inappropriate name. So, the new project's layouts change this to `R.id.mainfrag`, without changing anything else:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/mainfrag"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

The New onCountrySelected()

The “simple” part of the changes comes in the revised onCountrySelected() method in EU4You:

```
@Override
public void onCountrySelected(Country c) {
    String url=getString(c.url);

    details.loadUrl(url);

    if (details.getId() != R.id.details) {
        getFragmentManager().beginTransaction()
            .replace(R.id.mainfrag, details,
                TAG_DETAILS)
            .addToBackStack(null).commit();
    }
}
```

In our revised scenario, we will *always* have a DetailsFragment. The question is merely whether it is presently visible. Hence, we can call loadUrl() on details directly.

However, there are two possible scenarios for the status of our DetailsFragment at the point in time of onCountrySelected() being called:

1. It exists in the details FrameLayout of our dual-pane layout resource
2. It exists, perhaps due to a configuration change, but is not presently in a container

You might think that there would be a third scenario, where it is the visible fragment in the mainfrag FrameLayout. Indeed, sometimes DetailsFragment will be in that container... just not now. The only time that onCountrySelected() will be called is if the user tapped on an item in our CountriesFragment, which means that CountriesFragment must be in mainfrag.

The ID of a fragment, from getId(), is the ID of its container, when used with dynamic fragments. So, we check to see whether our DetailsFragment is in the

details `FrameLayout` by comparing ID values. If they differ, then we `commit()` a `replace()` `FragmentManager` transaction to put `DetailsFragment` into `mainfrag`. Note, though, that we use `addToBackStack()`, so if the user presses the BACK button, we will roll back this transaction and return to the `CountriesFragment`.

The New `onCreate()`

If you thought that was messy, you will not like the changes required to `onCreate()` of `EU4You` much more:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    countries=
        (CountriesFragment)getFragmentManager().findFragmentByTag(TAG_COUNTRIES);
    details=
        (DetailsFragment)getFragmentManager().findFragmentByTag(TAG_DETAILS);

    if (countries == null) {
        countries=new CountriesFragment();
        getFragmentManager().beginTransaction()
            .add(R.id.mainfrag, countries,
                TAG_COUNTRIES).commit();
    }

    if (details == null) {
        details=new DetailsFragment();

        if (findViewById(R.id.details) != null) {
            getFragmentManager().beginTransaction()
                .add(R.id.details, details,
                    TAG_DETAILS).commit();
        }
    }
    else {
        if (details.getId() == R.id.mainfrag) {
            if (findViewById(R.id.details) != null) {
                getFragmentManager().popBackStackImmediate();
            }
        }
        else {
            getFragmentManager().beginTransaction().remove(details)
                .commit();
        }
    }

    if (findViewById(R.id.details) != null) {
        getFragmentManager().beginTransaction()
            .add(R.id.details, details,
                TAG_DETAILS).commit();
    }
}
```

```
}  
}  
}
```

This sample is derived from the original EU4You sample, and so we are still using a `FragmentManager` to set up the `CountriesFragment` in `mainfrag`, if we did not create `CountriesFragment` earlier.

Dealing with `DetailsFragment`, though, is decidedly more complicated. The flow that we want is if we were in dual-pane mode and switch to single-pane mode, that we show the `CountriesFragment` in that single pane. If we switch from single-pane mode to dual-pane mode, both fragments will be shown, of course.

First, we have the case where our `DetailsFragment` does not yet exist. This is much like the original sample: we need to create the fragment and put it into the details `FrameLayout`, if the details `FrameLayout` exists.

If the `DetailsFragment` exists, we need to make sure that it winds up in the details `FrameLayout`, if one exists.

To do that, we first check its ID to see if it is presently located in `mainfrag`. If it is, and if we have a details `FrameLayout`, we have switched to dual-pane mode and need to pop our back stack, in preparation for moving the `DetailsFragment` to the details `FrameLayout`.

If the `DetailsFragment` exists but is not in `mainfrag`, we `remove()` it entirely.

Then, if the `DetailsFragment` exists, regardless of where it was before, we `add()` it to the details `FrameLayout`.

The “OMG! Our Fragments Have No Views!” Changes

In testing, there are now scenarios in which `CountriesFragment` is called with `onSaveInstanceState()`, but without its views having been created (i.e., `onCreateView()` was not called). This would cause us to fail when trying to use `getListView()`, as that method would return `null`, since the `ListView` did not exist. So, we modify `onSaveInstanceState()` to be a bit more robust:

```
@Override  
public void onSaveInstanceState(Bundle state) {  
    super.onSaveInstanceState(state);  
  
    if (getView() != null) {
```

```
        state.putInt(STATE_CHECKED,
                    listView().getCheckedItemPosition());
    }
}
```

We also need to beef up `DetailsFragment` a bit. Before, we relied on the fact that, on a configuration change, our extras on our Intent for `DetailsActivity` would still be available. Now, though, there is no `DetailsActivity`, which means that `DetailsFragment` has to maintain its state, so that we do not lose the URL we were viewing when the user rotates the screen or causes another configuration change. And, to top it off, we have the same potential issue as with `CountriesFragment`, where the fragment might exist but not have `onCreateView()` called (e.g., we were in dual-pane mode and switched to single-pane mode, and `DetailsFragment` has not yet been displayed), so we cannot assume that `getWebView()` will always return a non-null value.

To that end, `DetailsFragment` gets complicated:

```
package com.commonware.android.eu4you2;

import android.os.Bundle;
import android.webkit.WebViewFragment;

public class DetailsFragment extends WebViewFragment {
    private static final String STATE_URL="url";
    private String url=null;

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        if (url == null && savedInstanceState != null) {
            url=savedInstanceState.getString(STATE_URL);
        }

        if (url != null) {
            loadUrl(url);
            url=null;
        }
    }

    @Override
    public void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        if (url == null) {
            outState.putString(STATE_URL, getWebView().getUrl());
        }
        else {
            outState.putString(STATE_URL, url);
        }
    }
}
```

```
    }  
}  
  
void loadUrl(String url) {  
    if (getView() == null) {  
        this.url=url;  
    }  
    else {  
        getWebView().loadUrl(url);  
    }  
}
```

The `url` data member will temporarily hold the URL of the page we should be viewing, particularly when we have no `WebView` to work with. So, our `loadUrl()` method now puts the URL into `url` if we have no `WebView` or loads it into the `WebView` if the `WebView` exists. `onSaveInstanceState()` will put the URL — whether from `url` or from the `WebView` — into the state `Bundle`. `onActivityCreated()` will attempt to populate `url` from the `Bundle` (if we do not already have a URL), then use that to populate the `WebView` (which should exist if `onActivityCreated()` is called). `url` is set to `null` to indicate that the `WebView` holds our URL, once that is completed.

The Results

From a user experience standpoint, things have not significantly changed. The user still sees the list, still sees the details when tapping on an entry in the list, and still gets the dual-pane experience on larger screens.

However, the transition between the list and the details in single-pane mode is a bit faster, as a `FragmentManager` takes less time than does starting up another activity. However, by default, our `FragmentManager` does not apply any transition effects, and so the fragment changes “just happen” without any fades, zooms, or the like. It is certainly possible to specify fragment transition effects, if desired, though this is outside the scope of this chapter.

The Mashup Possibilities

It should be possible to combine the two revised versions of `EU4You`, having a single activity manage all the fragments, with `CountriesFragment` set up as a static fragment. The proof that this is possible is left to the reader.

The SlidingPaneLayout Variant

The R13 update to the Android Support package introduced `SlidingPaneLayout`, another way of handling this sort of master-detail pattern. `SlidingPaneLayout` significantly reduces the level of effort for setting up master-detail, as it handles all of the “dirty work” of showing the different fragments in different scenarios (normal screen, large screen, etc.).

Note that while the JavaDocs for `SlidingPaneLayout` contain “Experimental. This class may be removed”, it is reasonably likely that somebody will continue maintaining this should Google abandon it.

The Role of SlidingPaneLayout

In the master-detail pattern, we are showing both the master and the detail fragment, side-by-side, on larger screens, while showing only one at a time on smaller screens. In the preceding examples, we had to manage all of that ourselves, in terms of deciding how many fragments to show and for switching between those fragments as needed.

`SlidingPaneLayout` encapsulates that logic.

`SlidingPaneLayout` will detect the screen size. If the screen size is big enough, `SlidingPaneLayout` will display its two children side-by-side. If the screen size is not big enough, `SlidingPaneLayout` will display one child at a time. However, by default, when the “master” child is visible, a thin strip on the right will allow the user to return to the “detail” child. Similarly, a swiping gesture can switch from the “detail” back to the “master” child. These are in addition to any changes in context you might introduce based on UI operations (e.g., tapping on an element in a master `ListView` automatically switching to the detail child).

Converting to SlidingPaneLayout

The [LargeScreen/EU4YouSlidingPane](#) sample project represents a rework of the EU4You core sample, this time using `SlidingPaneLayout` for handling the master-detail pattern.

Since `SlidingPaneLayout` encapsulates the master-detail logic, we can drop a lot of stuff that we used before but no longer need, including:

- DetailsActivity (as SlidingPanelLayout works akin to our single-activity implementation)
- the dedicated large-screen layout (as SlidingPanelLayout “bakes in” the logic for handling different screen sizes)
- dynamic fragments (as SlidingPanelLayout will work better with static fragments, anyway)
- isPersistentSelection() (as we will always want to use activated rows, on API Level 11+, as the user can more readily switch back and forth between master and detail on smaller screens, and we want to indicate in the master what the context is that is displayed in the detail)

However, we did have to add a bit of pane management, plus move around some list-related behaviors in our CountriesFragment.

For starters, our res/layout/main.xml file now contains a SlidingPanelLayout, along with our two fragments, each set up as static <fragment> elements:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.widget.SlidingPanelLayout
xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/countries"
        android:name="com.commonware.android.eu4you4.CountriesFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent"/>

    <fragment
        android:id="@+id/details"
        android:name="com.commonware.android.eu4you4.DetailsFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

</android.support.v4.widget.SlidingPanelLayout>
```

By putting an android:layout_weight on our details fragment, we indicate that we want that one to take up all remaining room when the two fragments are shown side-by-side. You might think that we should then set the width of the details fragment to 0dp; however, for some reason, this does not work.

The size of the countries (master) fragment will be honored on larger screens. On smaller screens, the size of the master fragment will be dictated by the width of the

screen, minus a strip to allow the user to see a portion of the detail fragment and swipe that to display the detail fragment *in toto*.

Our CountriesFragment now always sets up the ListView to be single-choice mode, in `onActivityCreated()`. It also calls `onCountrySelected()` on our `CountriesFragment.Contract`, to ensure that the master is highlighting the last selection — this is needed to make sure that everything is displayed properly after a configuration change:

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    setListAdapter(new CountryAdapter());
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    if (state != null) {
        int position=state.getInt(STATE_CHECKED, -1);

        if (position > -1) {
            getListView().setItemChecked(position, true);
            getContract().onCountrySelected(Country.EU.get(position));
        }
    }
}
```

`onListItemClick()` of `CountriesFragment` becomes a bit simpler:

```
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);
    getContract().onCountrySelected(Country.EU.get(position));
}
```

The `EU4You` activity overall becomes *substantially* simpler:

```
package com.commonware.android.eu4you4;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.widget.SlidingPaneLayout;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
    private DetailsFragment details=null;
    private SlidingPaneLayout panes=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
```

```
setContentView(R.layout.main);

details=
    (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);
panes=(SlidingPaneLayout)findViewById(R.id.panes);
panes.openPane();
}

@Override
public void onBackPressed() {
    if (panes.isOpen()) {
        super.onBackPressed();
    }
    else {
        panes.openPane();
    }
}

@Override
public void onCountrySelected(Country c) {
    details.loadUrl(getString(c.url));
    panes.closePane();
}
}
```

In `SlidingPaneLayout` terminology, the pane is “open” if the *master* is shown on smaller screens, and the pane is “closed” if the *detail* is shown on smaller screens. If this feels a bit counter-intuitive to you, you are not alone in that regard.

By default, the `SlidingPaneLayout` is closed. So, if we want to start (on smaller screens) with the master pane shown, we need to call `openPane()`, as we do in `onCreate()`. Similarly:

- If we want to show the details when the user clicks on a country in the `CountriesFragment`, we need to call `closePane()` in `onCountrySelected()`
- If we want to show the master pane if the user presses BACK while viewing the detail pane, we need to override `onBackPressed()` and consume that event (calling `openPane()`), instead of performing the normal superclass behavior

What `SlidingPaneLayout` Looks Like

On a larger screen, the `SlidingPaneLayout` edition of the EU4You activity looks the same as the prior examples.

However, on a smaller screen, things look slightly different. Specifically:

- Our master perspective has a thin strip on the right, showing a peek of the detail fragment

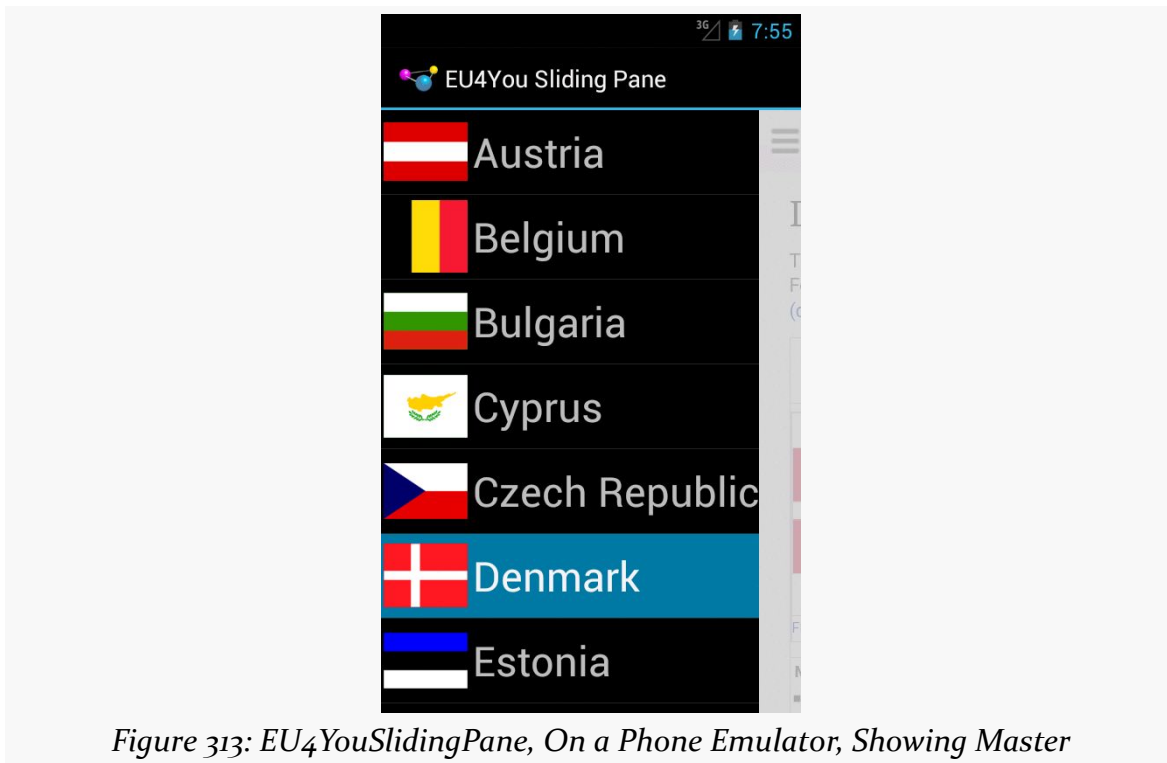

Figure 313: EU4YouSlidingPane, On a Phone Emulator, Showing Master

- The user can switch to the detail pane either by swiping open the detail pane or clicking on a country
- The user can switch back to the master pane either by swiping the detail pane back closed or by pressing the BACK button

Showing More Pages

ViewPager is a popular container in Android, as horizontal swiping is an increasingly popular navigational model, to move between peer pieces of content (e.g., swiping between contacts, swiping between book chapters). In some cases, when the ViewPager is on a larger screen, we simply want larger pages — a digital book reader, for example, would simply have a larger page in a bigger font for easier reading.

Sometimes, though, we might not be able to take advantage of the full space offered by the large screen, particularly when our ViewPager takes up the whole screen. In cases like this, it might be useful to allow ViewPager, in some cases, to show more

than one page at a time. Each “page” is then designed to be roughly phone-sized, and we choose whether to show one, two, or perhaps more pages at a time based upon the available screen space.

Mechanically, allowing ViewPager to show more than one page is fairly easy, involving overriding one more method in our PagerAdapter: `getPageWidth()`. To see this in action, take a look at the [ViewPager/MultiView1](#) sample project.

Each page in this sample is simply a TextView widget, using the activity’s style’s “large appearance”, centered inside a LinearLayout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="center"
    android:orientation="vertical">

    <TextView
        android:id="@+id/text"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

</LinearLayout>
```

The activity, in `onCreate()`, gets our ViewPager from the `res/layout/activity_main.xml` resource, and sets its adapter to be a `SampleAdapter`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    pager.setAdapter(new SampleAdapter());
    pager.setOffscreenPageLimit(6);
}
```

In this case, `SampleAdapter` is not a `FragmentPagerAdapter`, nor a `FragmentStatePagerAdapter`. Instead, it is its own implementation of the `PagerAdapter` interface:

```
/*
 * Inspired by
 * https://gist.github.com/8cbe094bb7a783e37ad1
 */
private class SampleAdapter extends PagerAdapter {
    @Override
```

```
public Object instantiateItem(ViewGroup container, int position) {
    View page=
        getLayoutInflater().inflate(R.layout.page, container, false);
    TextView tv=(TextView)page.findViewById(R.id.text);
    int blue=position * 25;

    final String msg=
        String.format(getString(R.string.item), position + 1);

    tv.setText(msg);
    tv.setOnClickListener(new OnClickListener() {
        @Override
        public void onClick(View v) {
            Toast.makeText(MainActivity.this, msg, Toast.LENGTH_LONG)
                .show();
        }
    });

    page.setBackgroundColor(Color.argb(255, 0, 0, blue));
    container.addView(page);

    return(page);
}

@Override
public void destroyItem(ViewGroup container, int position,
                        Object object) {
    container.removeView((View)object);
}

@Override
public int getCount() {
    return(9);
}

@Override
public float getPageWidth(int position) {
    return(0.5f);
}

@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}
}
```

To create your own PagerAdapter, the big methods that you need to implement are:

- `instantiateItem()`, where you create the page itself and add it to the supplied container. In this case, we inflate the page, set the text of the `TextView` based on the supplied position, set the background color of the page itself to be a different shade of blue based on the position, set up a click

listener to show a Toast when the TextView is tapped, and use that for our page. We return some object that identifies this page; in this case, we return the inflated View itself. A fragment-based PagerAdapter would probably return the fragment.

- `destroyItem()`, where we need to clean up a page that is being removed from the pager, where the page is identified by the Object that we had previously returned from `instantiateItem()`. In our case, we just remove it from the supplied container.
- `isViewFromObject()`, where we confirm whether some specific page in the pager (represented by a View) is indeed tied to a specific Object returned from `instantiateItem()`. In our case, since we return the View from `instantiateItem()`, we merely need to confirm that the two objects are indeed one and the same.
- `getCount()`, as with the built-in PagerAdapter implementations, to return how many total pages there are.

In our case, we also override `getPageWidth()`. This indicates, for a given position, how much horizontal space in the ViewPager should be given to this particular page. In principle, each page could have its own unique size. The return value is a float, from 0.0f to 1.0f, indicating what fraction of the pager's width goes to this page. In our case, we return 0.5f, to have each page take up half the pager.

The result is that we have two pages visible at a time:

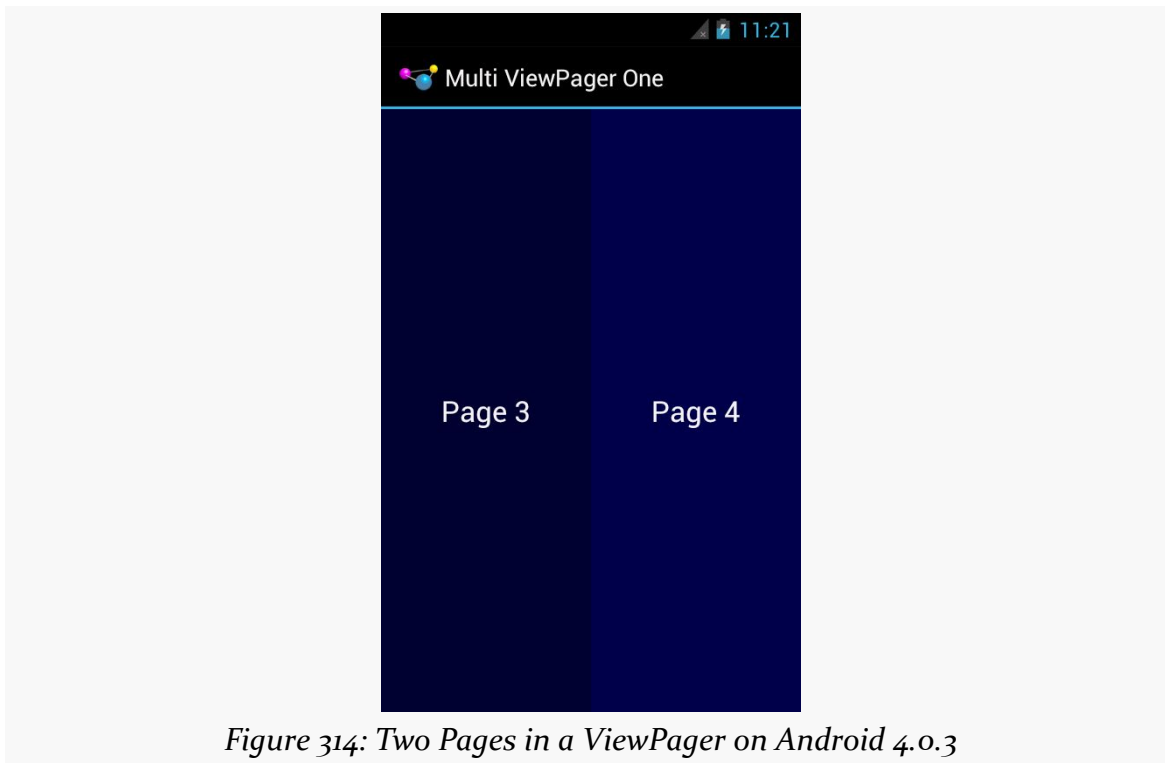

Figure 314: Two Pages in a ViewPager on Android 4.0.3

It is probably also a good idea to call `setOffscreenPageLimit()` on the `ViewPager`, as we did in `onCreate()`. By default (and at minimum), `ViewPager` will cache three pages: the one presently visible, and one on either side. However, if you are showing more than one at a time, you should bump the limit to be 3 times the number of simultaneous pages. For a page width of $0.5f$ — meaning two pages at a time — you would want to call `setOffscreenPageLimit(6)`, to make sure that you had enough pages cached for both the current visible contents and one full swipe to either side.

`ViewPager` even handles “partial swipes” — a careful swipe can slide the right-hand page into the left-hand position and slide in a new right-hand page. And `ViewPager` stops when you run out of pages, so the last page will always be on the right, no matter how many pages at a time and how many total pages you happen to have.

The biggest downside to this approach is that it will not work well with the current crop of indicators. `PagerTitleStrip` and `PagerTabStrip` assume that there is a single selected page. While the indicator will adjust properly, the visual representation shows that the left-hand page is the one selected (e.g., the tab with the highlight), even though two or more pages are visible. You can probably overcome this with a custom indicator (e.g., highlight the selected tab and the one to its right).

Also note that this approach collides a bit with `setPageMargin()` on `ViewPager`. `setPageMargin()` indicates an amount of whitespace that should go in a gutter between pages. In principle, this would work great with showing multiple simultaneous pages in a `ViewPager`. However, `ViewPager` does not take the gutter into account when interpreting the `getPageWidth()` value. For example, suppose `getPageWidth()` returns 0.5f and we `setPageMargin(20)`. On a 480-pixel-wide `ViewPager`, we will actually use 500 pixels: 240 for the left page, 240 for the right page, and 20 for the gutter. As a result, 20 pixels of our right-hand page are off the edge of the pager. Ideally, `ViewPager` would subtract out the page margin *before* applying the page width. One workaround is for you to derive the right `getPageWidth()` value based upon the `ViewPager` size and gutter yourself, rather than hard-coding a value. Or, build in your gutter into your page contents (e.g., using `android:layout_marginLeft` and `android:layout_marginRight`) and skip `setPageMargin()` entirely.

Columns or Pages

Another pattern — using pages for smaller screens and having the “pages” side-by-side in columns for larger screens — will be explored [later in the book](#).

The Grid Pattern

Yet another approach for taking advantage of larger screen sizes is to always show a full-size master and a full-size detail — perhaps using different activities — but to use a grid rather than a list for the master. This works well when the data being shown in the grid can be represented as “cards”, often dominated by some photo or other image.

The basic approach is to use fewer grid columns (e.g., 1 or 2) on smaller screen sizes and more grid columns (e.g., 3 or 4) on larger screen sizes. This way, the application flow is identical across screen sizes, yet the screen usage on larger screens is more effective. This is particularly true if you use one of the “staggered” grid widgets available from third parties, like [Etsy’s `AndroidStaggeredGrid`](#) or [Maurycy Wojtowicz’s `StaggeredGridView`](#):

Figure 315: StaggeredGridView Demo (image courtesy of Maurycy Wojtowicz)

Fragment FAQs

Here are some other common questions about the use of fragments in support of large screen sizes:

Does *Everything* Have To Be In a Fragment?

In a word, no.

UI constructs that do not change based on screen size, configurations, and the like could simply be defined in the activity itself. For example, the activity can add items to the action bar that should be there regardless of what fragments are shown.

What If Fragments Are Not Right For Me?

While fragments are useful, they do not solve all problems. Few games will use fragments for the core of game play, for example. Applications with other forms of specialized user interfaces — painting apps, photo editors, etc. — may also be better served by eschewing fragments *for those specific activities* and doing something else.

That “something else” might start with custom layouts for the different sizes and orientations. At runtime, you can determine what you need either by inspecting what you got from the layout, or by using `Configuration` and `DisplayMetrics` objects to determine what the device capabilities are (e.g., screen size). The activity would then need to have its own code for handling whatever you want to do differently based on screen size (e.g., offering a larger painting canvas plus more on-screen tool palettes).

Do Fragments Work on TVs?

Much of the focus on “larger-screen devices” has been on tablets, because, as of the time of this writing, they are the most popular “larger-screen devices” in use. However, there are plenty of scenarios involving Android on TV to consider. A TV or other external display will present itself as a `-large` (720p) or `-xlarge` (1080p) screen. Fragments can certainly help with displaying a UI for a TV, but there are other design considerations to take into account, based upon the fact that the user sits much further from a TV than they do from a phone or tablet (so-called “10-foot user experience”). This is covered in greater detail [later in the book](#).

Screen Size and Density Tactics

Even if we take the “tablet = several phones” design approach, the size of the “phone” will vary, depending on the size of the tablet. Plus, there are real actual *phones*, and those too vary in size. Hence, our fragments (or activities hosting their own UI directly) need to take into account micro fluctuations in size, as well as the macro ones.

Screen density is also something that affects us tactically. It is rare that an application will make wholesale UI changes based upon whether the screen is 160dpi or 240dpi or 320dpi or something else. However, changes in density can certainly impact the sizes of things, like images, that are intrinsically tied to pixel sizes. So, we need to take density into account as we are crafting our fragments to work well in a small range of sizes.

Dimensions and Units

As a unit of measure, the pixel (px) is a poor choice, because its size varies by density. Two phones might have very similar screen sizes but radically different densities. Anything specified in terms of pixels will be smaller on the higher-density device, and typically you would want them to be about the same size. For example, a

Button should not magically shrink for a ~4" phone just because the phone happens to have a much higher screen density than some other phone.

The best answer is to avoid specifying concrete sizes where possible. This is why you tend to see containers, and some widgets, use `match_parent` and `wrap_content` for their size — those automatically adjust based upon device characteristics.

Some places, though, you have to specify a more concrete size, such as with padding or margins. For these, you have two major groups of units of measure to work with:

- Those based upon pixels, but taking device characteristics into account. These include density-independent pixels (dp or dip), which try to size each dp to be about 1/160 of an inch. These also include scaled pixels (sp), which scales the size based upon the default font size on the device — sp is often used with `TextView` (and subclasses) for `android:textSize` attributes.
- Those based purely on physical units of measure: mm (millimeters), in (inches), and pt (points = 1/72 of an inch).

Any of those tends to be better than px. Which you choose will depend on which you and your graphics designer are more comfortable with.

If you find that there are cases where the dimensions you want to use vary more widely than the automatic calculations from these density-aware units of measure, you can use dimension resources. Create a `dimens.xml` file in `res/values/` and related resource sets, and put in there `<dimen>` elements that give a dimension a name and a size. In addition to perhaps making things a bit more DRY (“don’t repeat yourself”), you can perhaps create different values of those dimensions for different screen sizes, densities, or other cases as needed.

Layouts and Stretching

Web designers need to deal with the fact that the user might resize their browser window. The approaches to deal with this are called “fluid” designs.

Similarly, Android developers need to create “fluid” layouts for fragments, rows in a `ListView`, and so on, to deal with similar minor fluctuations in size.

Each of “The Big Three” container classes has its approach for dealing with this:

- Use `android:layout_weight` with `LinearLayout` to allocate extra space

- Use `android:stretchColumns` and `android:shrinkColumns` with `TableLayout` to determine which columns should absorb extra space and which columns should be forcibly “shrunk” to yield space for other columns if we lack sufficient horizontal room
- Use appropriate rules on `RelativeLayout` to anchor widgets as needed to other widgets or the boundaries of the container, such that extra room flows naturally wherever the rules call for

Drawables That Resize

Images, particularly those used as backgrounds, will need to be resized to take everything into account:

- screen size and density
- size of the widget, and its contents, for which it serves as the background (e.g., amount of prose in a `TextView`)

Android supports what is known as the “nine-patch” PNG format, where resizing information is held in the PNG itself. This is typically used for things like rounded rectangles, to tell Android to stretch the straight portions of the rectangle but to not stretch the corners. Nine-patch PNG files will be examined in greater detail in [a later chapter of this book](#).

The `ShapeDrawable` XML drawable resource uses an ever-so-tiny subset of SVG (Scalable Vector Graphics) to create a vector art definition of an image. Once again, this tends to be used for rectangles and rounded rectangles, particularly those with a gradient fill. Since Android interprets the vector art definition at runtime, it can create a smooth gradient, interpolating all intervening colors from start to finish. Stretching a PNG file — even a nine-patch PNG file — tends to result in “banding effects” on the gradients. `ShapeDrawable` is also covered later in this book.

Third-party libraries can also help. The [svg-android](#) project supplies a JAR that handles more SVG capabilities than does `ShapeDrawable`, though it too does not cover the entire SVG specification. Also, `WebView` has some ability to view SVG files on Android 3.0+.

Drawables By Density

Sometimes, though, there is no substitute for your traditional bitmap image. Icons and related artwork are not necessarily going to be stretched at runtime, but they are still dependent upon screen density. A 80x80 pixel image may look great on a

Samsung Galaxy Nexus or other -xhdpi device, coming in at around a quarter-inch on a side. However, when viewed on a -mdpi device, that same icon will be a half-inch on a side, which may be entirely too large.

The best answer is to create multiple renditions of the icon at different densities, putting each icon in the appropriate drawable resource directory (e.g., `res/drawable-mdpi`, `res/drawable-hdpi`). This is what Android Asset Studio did for us in the tutorials, creating launcher icons from some supplied artwork for all four densities. Even better is to create icons tailored for each density — rather than just reducing the pixel count, take steps to draw an icon that will still make sense to the user at the lower pixel count, exaggerating key design features and dropping other stuff off. Google’s Kiril Grouchnikov has [an excellent blog post on this aspect](#)

However, Android will let you cheat.

If you supply only some densities, but your app runs on a device with a different density, Android will automatically resample your icons to try to generate one with the right density, to keep things the same size. On the plus side, this saves you work — perhaps you only ship an -xhdpi icon and let Android do the rest. And it can reduce your APK size by a bit. However, there are costs:

- This is a bit slower at runtime and consumes a bit more battery
- Android’s resampling algorithm may not be as sophisticated as that of your preferred image editor (e.g., Photoshop)
- You cannot finesse the icon to look better than a simple resampling (e.g., drop off design elements that become unidentifiable)

Other Considerations

There are other things you should consider when designing your app to work on multiple screen sizes, beyond what is covered above.

Small-Screen Devices

It is easy to think of screen size issues as being “phones versus tablets”. However, not only do tablets come in varying sizes (5” Samsung Galaxy Note to a bunch of 10.1” tablets), but phones come in varying sizes. Those that have less than a 3” diagonal screen size will be categorized as -small screen devices, and you can have different layouts for those.

Getting things to work on small screens is sometimes more difficult than moving from normal to larger screens, simply because you lack sufficient room. You can only shrink widgets so far before they become unreadable or “untappable”. You may need to more aggressively use `ScrollView` to allow your widgets to have more room, but requiring the user to pan through your whole fragment’s worth of UI. Or, you may need to divide your app into more fragments than you originally anticipated, and use more activities or other tricks to allow the user to navigate the fragments individually on small-screen devices, while stitching them together into larger blocks for larger phones.

Avoid Full-Screen Backgrounds

Android runs in lots of different resolutions.

Lots and lots of different resolutions.

Trying to create artwork for each and every resolution in use today will be tedious and fragile, the latter because new resolutions pop up every so often, ones you may not be aware of.

Hence, try to design your app to avoid some sort of full-screen background, where you are expecting the artwork to perfectly fit the screen. Either:

- Do not use a background, or
- Use a background, but one that is designed to be cropped to fit and will look good in its cropped state, or
- Use a background, but one that can naturally bleed into some solid fill to the edges (e.g., a starfield that simply lacks stars towards the edges), so you can “fill in” space around your background with that solid color to fill the screen, or
- Dynamically draw the background (e.g., a starfield where you place the stars yourself at runtime using 2D graphics APIs)

For most conventional apps, just using the background from your stock theme will typically suffice. This problem is much bigger for 2D games, which tend to rely upon backgrounds as a game surface.

Manifest Elements for Screen Sizes

There are two elements you can add to your manifest that impact how your application will behave with respect to screen sizes.

LARGE-SCREEN STRATEGIES AND TACTICS

`<compatible-screens>` serves as an advertisement of your capabilities, to the Google Play Store and similar “markets”. You can have a `<compatible-screens>` element with one or more child `<screen>` elements — each `<screen>` enumerates a combination of screen size and screen density that you support:

```
<compatible-screens>
  <!-- all possible normal size screens -->
  <screen android:screenSize="normal" android:screenDensity="ldpi" />
  <screen android:screenSize="normal" android:screenDensity="mdpi" />
  <screen android:screenSize="normal" android:screenDensity="hdpi" />
  <screen android:screenSize="normal" android:screenDensity="xhdpi" />
  <!-- all possible large size screens -->
  <screen android:screenSize="large" android:screenDensity="ldpi" />
  <screen android:screenSize="large" android:screenDensity="mdpi" />
  <screen android:screenSize="large" android:screenDensity="hdpi" />
  <screen android:screenSize="large" android:screenDensity="xhdpi" />
</compatible-screens>
```

The Google Play Store will filter your app, so it will not show up on devices that have screens that do not meet one of your `<screen>` elements. However, new densities show up every year or so, and devices running those densities will *not* be supported by your `<compatible-screens>` element unless you add the appropriate `<screen>` element for that density. For example, the above `<compatible-screens>` element does not cover `tvdpi` or `xxhdpi` devices. As a result, Google discourages the use of `<compatible-screens>`.

There is also a `<supports-screens>` element, as we saw when we set up our initial project in the tutorials. Here, you indicate what screen sizes you support, akin to `<compatible-screens>` (minus any density declarations). And, the Google Play Store will filter your app, so it will not show up on devices that have screens *smaller than what you support*.

So, for example, suppose that you have a `<supports-screens>` element like this:

```
<supports-screens android:smallScreens="false"
                  android:normalScreens="true"
                  android:largeScreens="true"
                  android:xlargeScreens="false"
/>
```

You will not show up in the Google Play Store for any `-small` screen devices. However, you *will* show up in the Google Play Store for any `-xlarge` screen devices — Android will merely apply some runtime logic to try to help your app run well on such screens. So, while `<compatible-screens>` is purely a filter, `<supports-screens>`

is a filter for smaller-than-supported screens, and a runtime “give me a hand!” flag for larger-than-supported screens.

Considering Newer Densities

-tvdpi — around 213dpi — was added for Android TV, and is the density used for 720p Android TV devices. However, Google *also* elected to use -tvdpi for the Nexus 7 tablet. However, not even Google bothered to create many -tvdpi-specific resources, allowing the OS to downsample from the -hdpi edition.

-xxhdpi was added in late 2012 and is for devices with a screen density around 480dpi. While Android can up-sample an -xhdpi image for -xxhdpi, the results may not be as crisp as you would like. Hence, you may wish to consider creating -xxhdpi as your “top tier” density, so other devices can downsample if needed. At the time of this writing, about 15% of Play Store-equipped Android devices are -xxhdpi.

-xxxhdpi is for devices with screens around 640dpi. At the time of this writing -xxxhdpi is not in significant use.

Tutorial #19 - Supporting Large Screens

So far, we have created a variety of fragments that are being used one at a time in a hosting activity: notes, help, and about. And, on smaller-screen devices, like phones, that is probably the best solution. But on devices like 10" tablets, it might be nice to be able to have some of those fragments take over a part of the main activity's space. For example, the user could be reading the chapter and reading the online help.

Hence, in this tutorial, we will arrange for the help and about fragments to be loaded into `EmPubLiteActivity` directly on tablets, while retaining our existing functionality for other devices.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the previous tutorial and the results of this tutorial in the book's GitHub repository:

- Android Studio [previous tutorial](#) and [this tutorial](#)
- Eclipse [previous tutorial](#) and [this tutorial](#)

Step #1: Creating Our Layouts

The simplest way to both add a place for these other fragments and to determine when we should be using these other fragments in the main activity is to create new layout resource sets for larger-screen devices, with customized versions of `main.xml` to be used by `EmPubLiteActivity`.

TUTORIAL #19 - SUPPORTING LARGE SCREENS

The following sections contain instructions for Android Studio and Eclipse — choose the instructions appropriate for the IDE you are using for these tutorials.

Android Studio

Right-click over the `res/` directory in your app, then choose `New > “Android Resource Directory”` from the context menu. As before, this brings up the new resource directory dialog:

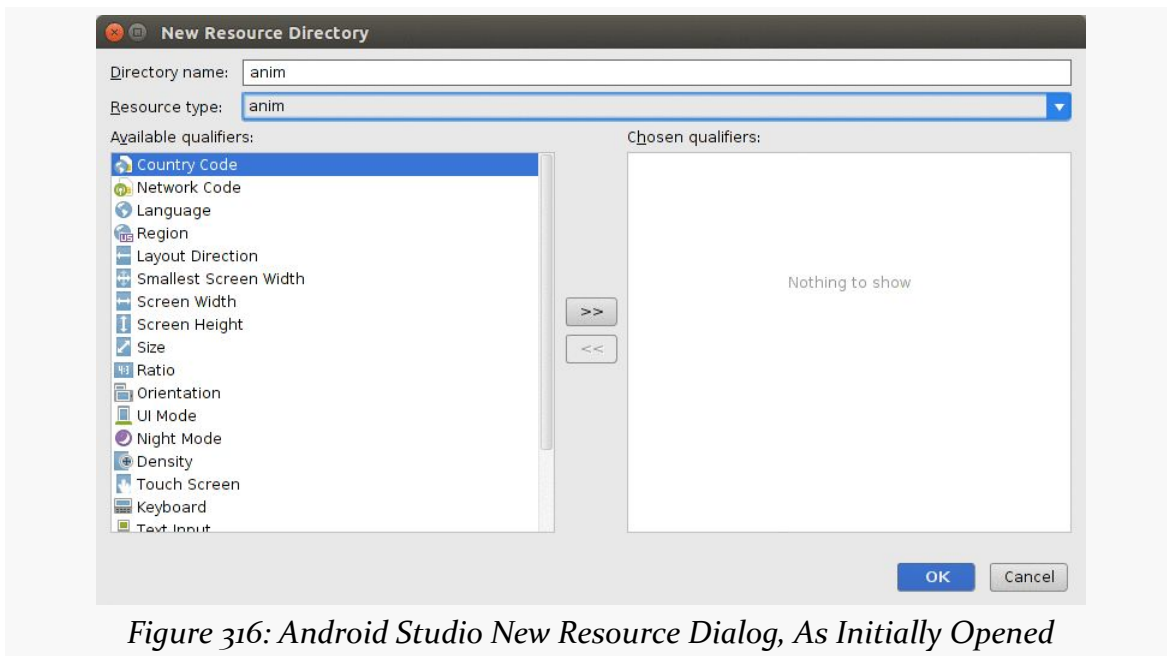

Figure 316: Android Studio New Resource Dialog, As Initially Opened

Choose “layout” from the “Resource type” drop-down. Then, click on “Screen Width” in the list of qualifiers on the left, and click the “>>” button to add that to the list on the right:

TUTORIAL #19 - SUPPORTING LARGE SCREENS

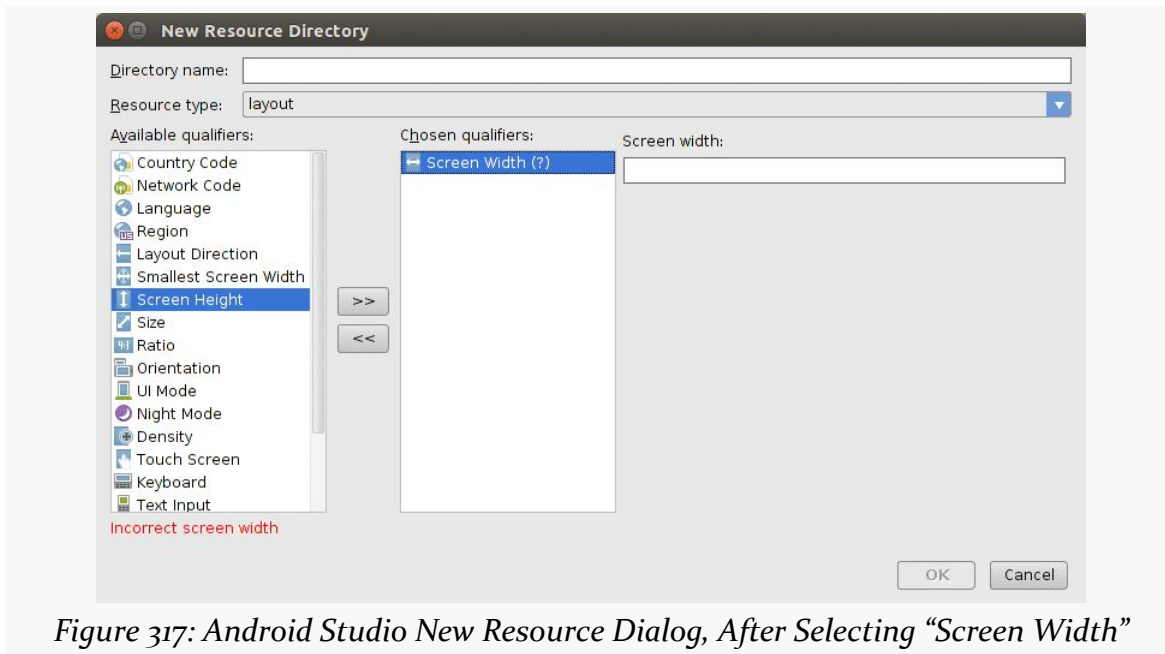

Figure 317: Android Studio New Resource Dialog, After Selecting “Screen Width”

In the “Screen width” field, fill in 880:

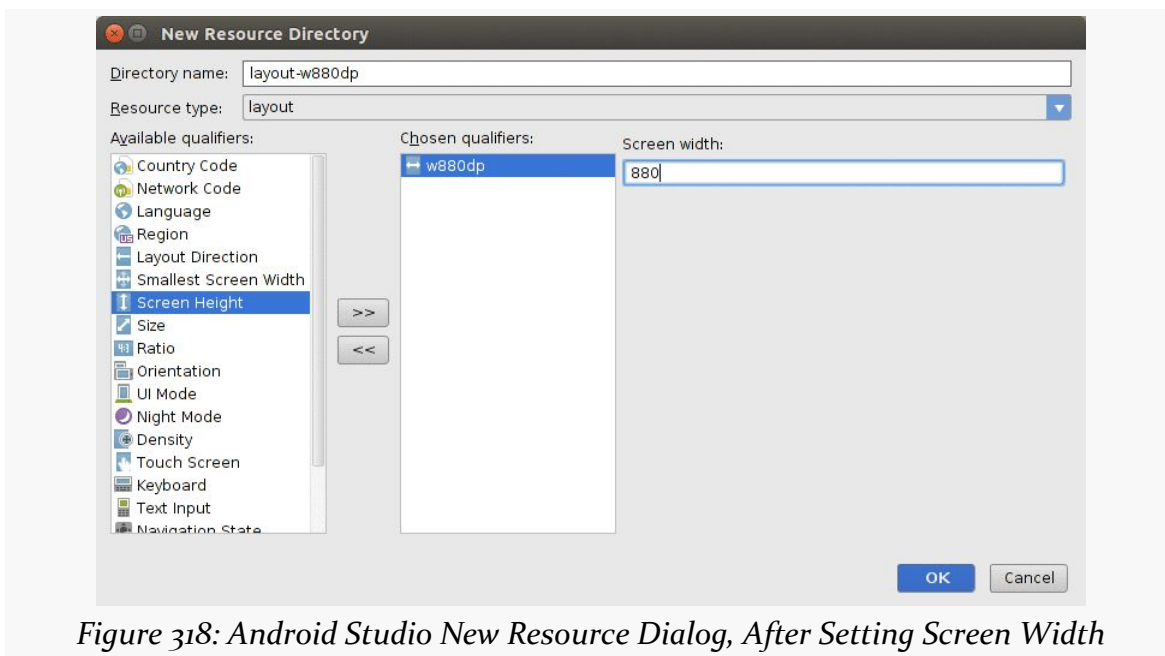

Figure 318: Android Studio New Resource Dialog, After Setting Screen Width

Click OK to create the directory. Repeat that process to create a `res/layout-h880dp/` directory, this time choosing “Screen Height” rather than “Screen Width”.

TUTORIAL #19 - SUPPORTING LARGE SCREENS

Then, right-click over the `res/layout/main.xml` file and choose “Copy” from the context menu. After that, right-click over the new `res/layout-w880dp/` directory and choose “Paste” from the context menu. This brings up the copy dialog:

Figure 319: Android Studio Copy Dialog

Check the “Open copy in editor” checkbox and click OK. This will bring up the graphical layout editor on this copy of the main layout.

Unfortunately, what we want to do is not readily supported by Android Studio’s edition of the drag-and-drop GUI builder. So, switch over to the XML for this layout, and replace it with:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/something"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RelativeLayout
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="7"
        tools:context=".EmPubLiteActivity">

        <ProgressBar
            android:id="@+id/progressBar1"
            style="?android:attr/progressBarStyleLarge"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_centerHorizontal="true"
            android:layout_centerVertical="true"/>

        <android.support.v4.view.ViewPager
            android:id="@+id/pager"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:visibility="gone"/>
    </RelativeLayout>
```

```
<View
    android:id="@+id/divider"
    android:layout_width="2dp"
    android:layout_height="match_parent"
    android:background="#AA000000"
    android:visibility="gone" />

<FrameLayout
    android:id="@+id/sidebar"
    android:layout_width="0dp"
    android:layout_height="match_parent">

</FrameLayout>

</LinearLayout>
```

Repeat the same process, copying `res/layout/main.xml` into the `res/layout-h880dp/` directory, and replacing the copy's contents with:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/something"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <RelativeLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="7"
        tools:context=".EmPubLiteActivity">

        <ProgressBar
            android:id="@+id/progressBar1"
            style="?android:attr/progressBarStyleLarge"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_centerHorizontal="true"
            android:layout_centerVertical="true" />

        <android.support.v4.view.ViewPager
            android:id="@+id/pager"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:visibility="gone" />
    </RelativeLayout>

    <View
        android:id="@+id/divider"
        android:layout_width="match_parent"
        android:layout_height="2dp"
        android:background="#AA000000"
        android:visibility="gone" />
```

```
<FrameLayout
    android:id="@+id/sidebar"
    android:layout_width="match_parent"
    android:layout_height="0dp">
</FrameLayout>
</LinearLayout>
```

Eclipse

First, right-click over the `res/` folder, and choose `New > Folder` from the context menu. Fill in `layout-w880dp` as the folder name, then click “Finish” to create the folder. This resource set will be used on devices where the current width (given the current orientation) is 880dp or wider (a.k.a., 5.5" wide or wider).

Then, right-click over the `res/layout/main.xml` file and choose “Copy” from the context menu. After that, right-click over the new `res/layout-w880dp/` folder and choose “Paste” from the context menu. This makes a copy of your `main.xml` resource that we can use for -w880dp devices.

Double-click on the `res/layout-w880dp/main.xml` file to bring it up in the graphical layout editor. In the Outline pane, right-click on the `RelativeLayout` and choose “Wrap in Container...” from the context menu. Choose “`LinearLayout (horizontal)`” in the drop-down list of available containers, and give the container some ID (the value does not matter, as we will not be using it, but the dialog requires it). Click OK to wrap our `RelativeLayout` in the horizontal `LinearLayout`.

Click on the `RelativeLayout` in the Outline pane. In the Properties pane, in the “Layout Parameters” group, fill in 7 in the “Weight” field, and fill in 0dp for the “Width”.

In the Palette, switch to the Advanced group of widgets, and drag a `View` over to the Outline pane and drop it on the `LinearLayout`, which will add it to the end of the `LinearLayout` roster of children. You may find it easier to drop it on the `LinearLayout` in the Outline view. Make the following adjustments to the properties of the `View` using the Properties pane:

- Set the Id to `@+id/divider`
- Set the Height to `match_parent`
- Set the Width to `2dp`
- Set the Background to `#AA000000`
- Set the Visibility to `gone`

Then, switch over to the XML, and if you see an erroneous `android:layout_weight` attribute on this View, get rid of it.

Back in the Palette, switch to the Layouts group of widgets, and drag a `FrameLayout` over to the Outline pane and drop it on the `LinearLayout`, adding it as a third child. Make the following adjustments to the properties of the `FrameLayout` using the Properties pane:

- Set the Id to `@+id/sidebar`
- Set the Weight to 0
- Set the Width to 0dp

Save your changes (e.g., `<Ctrl>-<S>`).

Then, right-click over the `res/layout-w880dp` folder, and choose Copy from the context menu.

Next, right-click over the `res/` folder, and choose Paste from the context menu. When the dialog appears asking for a name for the pasted copy, set it to `layout-h880dp`. This folder's resources will be used on devices where the current *height* is 880dp.

Double-click on `res/layout-h880dp/main.xml` file, to bring it up in the graphical layout editor. Click on the `LinearLayout` and, in the Properties pane, set the "Orientation" to be vertical.

Then, switch over to the XML view, and swap the `android:layout_width` and `android:layout_height` values for the `RelativeLayout`, the View, and the `FrameLayout`. When you are done, each should have an `android:layout_width` of `match_parent` and an `android:layout_height` of 0dp (except the View, which should be 2dp).

Save your changes (e.g., `<Ctrl>-<S>`).

Step #2: Loading Our Sidebar Widgets

Now that we added the divider widget and sidebar container to (some of) our layouts, we need to access those widgets at runtime.

So, in `EmPubLiteActivity`, add data members for them:

```
private View sidebar=null;
private View divider=null;
```

Then, in onCreate() of EmPubLiteActivity, initialize those data members, sometime after the call to setContentView():

```
sidebar=findViewById(R.id.sidebar);
divider=findViewById(R.id.divider);
```

Step #3: Opening the Sidebar

A real production-grade app would use animated effects to hide and show our sidebar. However, we have not yet covered animations in this book, so we will simply:

- Cause the divider to become visible
- Adjust the android:layout_weight of our sidebar to be 3 instead of 0, giving it ~30% of the screen (with the original RelativeLayout getting 70%, courtesy of its android:layout_weight="7")

With that in mind, add the following implementation of an openSidebar() method to EmPubLiteActivity:

```
private void openSidebar() {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)sidebar.getLayoutParams();
    if (p.weight == 0) {
        p.weight=3;
        sidebar.setLayoutParams(p);
    }
    divider.setVisibility(View.VISIBLE);
}
```

Here, we:

- Get the existing LinearLayout.LayoutParams from the sidebar
- If it is still 0 (meaning the sidebar has not been opened), assign it a weight of 3, update the layout via setLayoutParams(), and toggle the visibility of the divider

Step #4: Loading Content Into the Sidebar

Now that we can get our sidebar to appear, we need to load content into it... but only if we have the sidebar. If `EmPubLiteActivity` loads a layout that does not have the sidebar, we need to stick with our existing logic that starts up an activity to display the content.

With that in mind, add data members to `EmPubLiteActivity` to hold onto our help and about fragments:

```
private SimpleContentFragment help=null;
private SimpleContentFragment about=null;
```

Also add a pair of static data members that will be used as tags for identifying these fragments in our `FragmentManager`:

```
private static final String HELP="help";
private static final String ABOUT="about";
```

Also add a pair of static data members that will hold the paths to our help and about assets, since we will be referring to them from more than one place when we are done:

```
private static final String FILE_HELP=
    "file:///android_asset/misc/help.html";
private static final String FILE_ABOUT=
    "file:///android_asset/misc/about.html";
```

In `onCreate()` of `EmPubLiteActivity`, initialize the fragments from the `FragmentManager`:

```
help=
    (SimpleContentFragment)getFragmentManager().findFragmentByTag(HELP);
about=
    (SimpleContentFragment)getFragmentManager().findFragmentByTag(ABOUT);
```

The net result is that *if* we are returning from a configuration change, we will have our fragments, otherwise we will not at this point.

Next, add the following methods to `EmPubLiteActivity`:

```
private void showAbout() {
    if (sidebar != null) {
        openSidebar();
    }
}
```

```
    if (about == null) {
        about=SimpleContentFragment.newInstance(FILE_ABOUT);
    }

    getFragmentManager().beginTransaction().addToBackStack(null)
        .replace(R.id.sidebar, about).commit();
}
else {
    Intent i=new Intent(this, SimpleContentActivity.class);

    i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_ABOUT);
    startActivity(i);
}
}

private void showHelp() {
    if (sidebar != null) {
        openSidebar();

        if (help == null) {
            help=SimpleContentFragment.newInstance(FILE_HELP);
        }

        getFragmentManager().beginTransaction().addToBackStack(null)
            .replace(R.id.sidebar, help).commit();
    }
    else {
        Intent i=new Intent(this, SimpleContentActivity.class);

        i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_HELP);
        startActivity(i);
    }
}
}
```

Both of these methods follows the same basic recipe:

- Check to see if sidebar is null, to see if we have a sidebar or not
- If we have a sidebar, call openSidebar() to ensure the user can see the sidebar, create our Fragment if we do not already have it, and use a FragmentTransaction to replace whatever was in the sidebar with the new Fragment
- If we do not have the sidebar, launch an activity with an appropriately-configured Intent

Note a couple of things with our FragmentTransaction objects:

- We use addToBackStack(null), so if the user presses BACK, Android will reverse this transaction

- We use `replace()` instead of `add()`, as there may already be a fragment in the sidebar (`replace()` will behave the same as `add()` for an empty sidebar)

Then, in the `onOptionsItemSelected()` of `EmPubLiteActivity`, replace the `about`, and `help` case blocks to use the newly-added methods, replacing their existing implementations:

```
case R.id.about:
    showAbout();

    return(true);

case R.id.help:
    showHelp();

    return(true);
```

Step #5: Removing Content From the Sidebar

While `addToBackStack(null)` will allow Android to automatically remove fragments as the user presses BACK, that will not cause our sidebar to magically close. Rather, we need to do that ourselves.

The easiest way to track this is to track the state of the “back stack”. So, add `implements FragmentManager.OnBackStackChangedListener` to the declaration of `EmPubLiteActivity`, and in `onCreate()` of `EmPubLiteActivity`, add the following line, sometime after you initialized the sidebar and divider data members:

```
getFragmentManager().addOnBackStackChangedListener(this);
```

The first statement registers our activity as receiving events related to changes in the state of the back stack.

To make this compile, we need to implement `onBackStackChanged()` in `EmPubLiteActivity`:

```
@Override
public void onBackStackChanged() {
    if (getFragmentManager().getBackStackEntryCount() == 0) {
        LinearLayout.LayoutParams p =
            (LinearLayout.LayoutParams)sidebar.getLayoutParams();
        if (p.weight > 0) {
            p.weight=0;
            sidebar.setLayoutParams(p);
            divider.setVisibility(View.GONE);
        }
    }
}
```

```
}  
}  
}
```

Here, if our back stack is empty, we reverse the steps from `openSidebar()` and close it back up again, hiding the divider and setting the sidebar's weight to 0.

The complete revised `EmPubLiteActivity` should now look something like:

```
package com.commonware.empublite;  
  
import android.app.Activity;  
import android.app.FragmentManager;  
import android.content.Intent;  
import android.content.SharedPreferences;  
import android.os.Bundle;  
import android.os.StrictMode;  
import android.support.v4.view.ViewPager;  
import android.view.Menu;  
import android.view.MenuItem;  
import android.view.View;  
import android.widget.LinearLayout;  
import com.commonware.cwac.wakeful.WakefulIntentService;  
import de.greenrobot.event.EventBus;  
  
public class EmPubLiteActivity extends Activity implements  
    FragmentManager.OnBackStackChangedListener {  
    private static final String MODEL="model";  
    private static final String PREF_LAST_POSITION="lastPosition";  
    private static final String PREF_SAVE_LAST_POSITION="saveLastPosition";  
    private static final String PREF_KEEP_SCREEN_ON="keepScreenOn";  
    private static final String HELP="help";  
    private static final String ABOUT="about";  
    private static final String FILE_HELP=  
        "file:///android_asset/misc/help.html";  
    private static final String FILE_ABOUT=  
        "file:///android_asset/misc/about.html";  
    private ViewPager pager=null;  
    private ContentsAdapter adapter=null;  
    private ModelFragment mfrag=null;  
    private View sidebar=null;  
    private View divider=null;  
    private SimpleContentFragment help=null;

Note that a tablet emulator usually will only run acceptably fast if you are using the x86 emulator images.

Backwards Compatibility Strategies and Tactics

Android is an ever-moving target, averaging about 2.5 API level increments per year. The Android Developer site maintains a chart and table showing the most recent [breakdown of OS versions](#) making requests of the Play Store.

Most devices tend to be clustered around 1–3 minor releases. However, these are never the most recent release, which takes time to percolate through the device manufacturers and carriers and onto devices, whether those are new sales or upgrades to existing devices.

Some developers panic when they realize this.

Panic is understandable, if not necessary. This is a well-understood problem, that occurs frequently within software development — ask any Windows developer who had to simultaneously support everything from Windows 98 to Windows XP, or Windows XP through Windows 8.1. Moreover, there are many things in Android designed to make this problem as small as possible. What you need are the strategies and tactics to make it all work out.

Think Forwards, Not Backwards

Android itself tries very hard to maintain backwards compatibility. While each new Android release adds many classes and methods, relatively few are marked as deprecated, and almost none are outright eliminated. And, in Android, “deprecated” means “there’s probably a better solution for what you are trying to accomplish, though we will maintain this option for you as long as we can”.

Despite this, many developers aim purely for the lowest common denominator. Aiming to support older releases is noble. Ignoring what has happened since those releases is stupid, if you are trying to distribute your app to the public via the Play Store or similar mass-distribution means.

Why? You want your app to be distinctive, not decomposing.

For example, as we saw in the chapter on the action bar, adding one line to the manifest (`android:targetSdkVersion="11"`) gives you the action bar, the holographic widget set (e.g., `Theme.Holo`), the new style of options menu, and so on. Those dead-set on avoiding things newer than Android 2.1 would not use this attribute. As a result, on Android 3.0+ devices, their apps will tend to look old. Some will not, due to other techniques they are employing (e.g., running games in a full-screen mode), but many will.

You might think that this would not matter. After all, how many people in 2011 were even using Android 3.x? 5%?

However, those in position to trumpet your application — Android enthusiast bloggers chief among them — will tend to run newer equipment. Their opinion matters, if you are trying to have their opinion sway others relative to your app. Hence, if you look out-of-touch to them, they may be less inclined to provide glowing recommendations of your app to their readers.

Besides, not everything added to newer versions of Android is pure “eye candy”. It is entirely possible that features in the newer Android releases might help make your app stand out from the competition, whether it is making greater use of NFC or offering tighter integration to the stock Calendar application or whatever. By taking an “old features only” approach, you leave off these areas for improvement.

And, to top it off, the world moves faster than you think. It takes about a year for a release to go from release to majority status (or be already on the downslope towards oblivion, passed over by something newer still). You need to be careful that the decisions you make today do not doom you tomorrow. If you focus on “old features only”, how much rework will it take you to catch up in six months, or a year?

Hence, this book advocates an approach that differs from that taken by many: aim high. Decide what features you want to use, whether those features are from older releases or the latest-and-greatest release. Then, write your app using those features, and take steps to ensure that everything still works reasonably well (if not as full-featured) on older devices. This too is a well-trodden path, used by Web developers

for ages (e.g., support sexy stuff in Firefox and Safari, while still gracefully degrading for IE6). And the techniques that those Web developers use have their analogous techniques within the Android world.

Aim Where You Are Going

One thing to bear in mind is that the OS distribution chart and table from the Android Developers blog shown above is based on requests to the Android Market.

This is only directly relevant if you are actually distributing through the Play Store.

If you are distributing through the Amazon AppStore, or to device-specific outlets (e.g., BlackBerry World), you will need to take into account what sorts of devices are using those means of distribution.

If you are specifically targeting certain non-Play Store devices, like the Kindle Fire, you will need to take into account what versions of Android they run.

If you are building an app to be distributed by a device manufacturer on a specific device, you need to know what Android version will (initially) be on that device and focus on it.

If you are distributing your app to employees of a firm, members of an organization, or the like, you need to determine if there is some specific subset of devices that they use, and aim accordingly. For example, some enterprises might distribute Android devices to their employees, in which case apps for that enterprise should run on those devices, not necessarily others.

A Target-Rich Environment

There are a few places in your application where you will need to specify Android API levels of relevance to your code.

The most important one is the `android:minSdkVersion` attribute, as discussed early in this book. You need to set this to the oldest version of Android you are willing to support, so you will not be installed on devices older than that.

There is also `android:targetSdkVersion`, mentioned in passing earlier in this chapter. In the abstract, this attribute tells Android “this is the version of Android I was thinking of when I wrote the code”. Android can use this information to help

both backwards and forwards compatibility. Historically, this was under-utilized. However, with API Level 11 and API Level 14, `android:targetSdkVersion` took on greater importance. Specifying 11 or higher gives you the action bar and all the rest of the look-and-feel introduced in the Honeycomb release. Specifying 14 or higher will give you some new features added in Ice Cream Sandwich, such as automatic whitespace between your app widgets and other things on the user's home screen. In general, use a particular `android:targetSdkVersion` when instructions tell you to.

The third place — and perhaps the one that confuses developers the most — is the build target. This shows up as `compileSdkVersion` in `build.gradle` for Android Studio users, or in Project > Properties > Android for Eclipse users.

Part of the confusion is the multiple uses of the term “target”. The build target has nothing to do with `android:targetSdkVersion`. Nor is it strictly tied to what devices you are targeting.

Rather, it is a very literal term: it is the target **of the build**. It indicates:

- What version of the Android class library you wish to compile against, dictating what classes and methods you will be able to refer to directly
- What rules to apply when interpreting resources and the manifest, to complain about things that are not recognized

The net is that you set your build target to be the lowest API level that has everything you are using directly.

Lint: It's Not Just For Belly Buttons

In the old days, the only way to find out that you were using a newer class or method than what was in your `minSdkVersion` would be to set your build target to be the same as your `minSdkVersion`. That way, any attempt to use something newer than your minimum would be greeted with compile errors. This works, but at a high cost: it makes *intentionally* using newer capabilities very painful, forcing you to use reflection to access them.

Nowadays, this is no longer needed, thanks to Lint.

Lint is part of the standard build process, adding new errors and warnings for things that are syntactically valid but probably not the right answer. In particular, Lint will

tell you if you are using classes or methods that are newer than your `minSdkVersion`, *even if they are valid for your build target*.

Hence, the targeting strategy nowadays is:

- Set your `minSdkVersion` to be the oldest version that you are willing to support
- Set your build target to be the version of Android that has all of the classes and methods you intend to use, allowing Lint to point out places where you need to pay attention to what sort of device you are running on ([more on this later](#))
- Set your `targetSdkVersion` to be something relatively recent, unless you have specific reasons to use some specific version

A Little Help From Your Friends

The simplest way to use a feature yet support devices that lack the feature is to use a compatibility library that enables the feature for more devices. The Android Support package is one such compatibility library, though it also offers other classes as well.

With a compatibility library, the API for using the library is nearly identical to using the native Android capability, mostly involving slightly different package names (e.g., `android.support.v4.app.Fragment` instead of `android.app.Fragment`).

So, if there is something new that you want to use on older devices, and the new feature is not obviously tied to hardware, see if there is a “backport” of the feature available to you. Examples include backports of:

- `CalendarView` (<https://github.com/SimonVT/android-calendarview>)
- `Switch` (<https://github.com/BoD/android-switch-backport>)
- `DatePicker` (<https://github.com/SimonVT/android-datepicker>)
- `NumberPicker` (<https://github.com/SimonVT/android-numberpicker>)
- `TimePicker` (<https://github.com/SimonVT/android-timepicker>)

Avoid the New on the Old

If the goal is to support new capabilities on new devices, while not losing support for older devices, that implies we have the ability to determine what devices are newer and what devices are older. There are a few techniques for doing this, involving Java and resources.

Java

If you wish to conditionally execute some lines of code based on what version of Android the device is running, you can check the value of `Build.VERSION`, referring to the `android.os.Build` class. For example:

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {  
    // do something only on API Level 9 and higher  
}
```

Any device running an older version of Android will skip the statements inside this version guard and therefore will not execute.

That technique is sufficient for Android 2.0 and higher devices. If you are still supporting Android 1.x devices, the story gets a bit more complicated, and that will be discussed later in the book.

If you decide that you want your build target to match your `minSdkVersion` level — as some developers elect to do — your approach will differ. Rather than *blocking* some statements from being executed on *old* devices, you will *enable* some statements to be executed on *new* devices, where those statements use Java reflection (e.g., `Class.forName()`) to reference things that are newer than what your build target supports. Since using reflection is extremely tedious in Java, it is usually simpler to have your build target reflect the classes and methods you are actually using.

@TargetAPI

One problem with this technique is that Eclipse will grumble at you, saying that you are using classes and methods not available on the API level you set for your `minSdkVersion`. To quiet down these Lint messages, you can use the `@TargetAPI` annotation.

For example, earlier in the book, we saw code like this:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)  
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task, T... params) {  
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {  
        task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);  
    }  
    else {  
        task.execute(params);  
    }  
}
```

This utility method executes an `AsyncTask` using a multi-threaded thread pool. That is the default behavior of `execute()` on API Level 10 and below. On higher versions of Android, we can explicitly opt into the multi-threaded thread pool by using `executeOnExecutor()`, but that method does not exist prior to API Level 11. Hence, we check our API level at runtime via `Build.VERSION.SDK_INT`, see if we are on HONEYCOMB or higher, and branch accordingly. However, for a project with a `minSdkVersion` of 10 or below, Lint will still complain — Lint is just not sophisticated enough to realize that we are correctly handling newer API levels. The `@TargetApi(Build.VERSION_CODES.HONEYCOMB)` annotation tells Lint that we have indeed confirmed that we are “doing the right thing”, at least through API Level 11.

However, by using `@TargetApi(Build.VERSION_CODES.HONEYCOMB)`, we are implicitly saying that we have *not* checked to see if we are doing things properly for higher versions of Android. So long as all the classes, methods, and such that we reference in this `executeAsyncTask()` method are available in API Level 11, we are fine. If we change the implementation to reference something from, say, API Level 14, now Lint will start complaining again. **This is what we want**, so we are alerted to the problem and can fix it. Hence, *only* set the `@TargetApi()` annotation to the API level that are you explicitly handling. Do not just set it to some arbitrarily high level (or, worse, use `@SuppressWarnings` to try to get Lint to shut up entirely).

Resources

The aforementioned version guards only work for Java code. Sometimes, you will want to have different resources for different versions of Android. For example, you might want to make a custom style that inherits from `Theme.Holo` for Android 3.0 and higher. Since `Theme.Holo` does not exist on earlier versions of Android, trying to use a style that inherits from it will fail miserably on, say, an Android 2.2 device.

To handle this scenario, use the `-vNN` suffix to have two resource sets. One (e.g., `res/values-v11/`) would be restricted to certain Android versions and higher (e.g., API Level 11 and higher). The default resource set (e.g., `res/values/`) would be valid for any device. However, since Android chooses more specific matches first, an Ice Cream Sandwich phone would go with the resources containing the `-v11` suffix. So, in the `-v11` resource directories, you put the resources you want used on API Level 11 and higher, and put the backwards-compatible ones in the set without the suffix. This works for Android 2.0 and higher. You can also use `-v3` for resources that *only* will be used on Android 1.5 (and no higher) or `-v4` for resources that *only* will be used on Android 1.6.

Components

One variation on the above trick allows you to conditionally enable or disable components, based on API level.

Every `<activity>`, `<receiver>`, or `<service>` in the manifest can support an `android:enabled` attribute. A disabled component (`android:enabled="false"`) cannot be started by anyone, including you.

We have already seen string resources be used in the manifest, for things like `android:label` attributes. Boolean values can also be created as resources. By convention, they are stored in a `bools.xml` file in `res/values/` or related resource sets. Just as `<string>` elements provide the definition of a string resource, `<bool>` elements provide the definition of a boolean resource. Just give the boolean resource a name and a value:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="on_honeycomb">false</bool>
</resources>
```

The above example has a boolean resource, named `on_honeycomb`, with a value of `false`. That would typically reside in `res/values/bools.xml`. However, you might also have a `res/values-v11/bools.xml` file, where you set `on_honeycomb` to `true`.

Now, you can use `@bool/on_honeycomb` in `android:enabled` to conditionally enable a component for API Level 11 or higher, leaving it disabled for older devices.

This can be a useful trick in cases where you might need multiple separate implementations of a component, based on API level. For example, later in the book we will examine app widgets — those interactive elements users can add to their home screens. App widgets have limited user interfaces, but API Level 11 added a few new capabilities that previously were unavailable, such as the ability to use `ListView`. However, the code for a `ListView`-backed app widget may be substantially different than for a replacement app widget that works on older devices. And, if you leave the `ListView` app widget enabled in the manifest, the user might try choosing it and crashing. So, you would only enable the `ListView` app widget on API Level 11 or higher, using the boolean resource trick.

Testing

Of course, you will want to make sure your app really does work on older devices as well as newer ones.

At build time, one trick to use periodically is to change your build target to match your `minSdkVersion`, then see where the compiler complains (or, in Eclipse, where you get all the red squiggles). If everything is known (e.g., resource attributes that will be ignored on older versions) or protected (e.g., Java statements inside a version guard `if` statement), then you are OK. If, however, you see complaints about something you forgot was only in newer Android releases, you can take steps to fix things.

You will also want to think about Android versions when it comes to testing, a topic that will be covered later in this book.

Keeping Track of Changes

Each Android SDK release is accompanied by API release notes, such as [this set for Android 4.4/API Level 19](#).

Similarly, each Android SDK release is accompanied by its “API Differences Report”, a roster of each added, removed, or modified class or method. For example, this [API Differences Report](#) points out the changes between API Level 18 and API Level 19.

Other changes are called out in [the JavaDocs for Build.VERSION_CODES](#), with particular emphasis on what happens when you set a specific API level as your `android:targetSdkVersion`. Note that this roster is not complete, but may mention some things not mentioned in the other locations.

Each class, method, and field in the JavaDocs has a notation as to what API level that particular item was added. Class API levels appear towards the top of the page; method and field API levels appear on the right side of the gray bar containing the method signature or field declaration. Also, in the JavaDocs “Android APIs” column on the left, there is a drop-down that allows you to filter the contents based upon API level.

Getting Help

Obviously, this book does not cover everything. And while your #1 resource (besides the book) is going to be the Android SDK documentation, you are likely to need information beyond what's covered in either of those places.

Searching online for “android” and a class name is a good way to turn up tutorials that reference a given Android class. However, be sure to check the age of the blog post or whatever that you are reading. The older it is, the more likely that it is out of date, based upon changes in Android or just better solutions that have evolved over time.

Beyond randomly hunting around for tutorials, though, this chapter outlines some other resources to keep in mind.

Questions. Sometimes, With Answers.

The “official” places to get assistance with Android are the Android Google Groups. With respect to the SDK, there are three to consider following:

1. Stack Overflow's [android](#) tag
2. [android-developers](#), for SDK questions and answers
3. [adt-dev](#), for questions and answers about the official Android development tools

The author of this book also maintains [the AndGlobe site](#), a list of Android developer support sites, with an emphasis on ones operating in languages other than English.

It is important, particularly for Stack Overflow and the Google Groups, to write well-written questions:

1. Include relevant portions of the source code (e.g., the method in which you are getting an exception) and the stack trace from LogCat, if the problem is an unhandled exception.
2. On Stack Overflow, make sure your source code and stack trace are formatted as source code; on Google Groups, consider posting long listings on gist.github.com or a similar sort of code-paste site.
3. Explain thoroughly what you are trying to do, how you are trying to do it, and why you are doing it this way (if you think your goal or approach may be a little offbeat).
4. On Stack Overflow, respond to answers and comments with your own comments, addressing the person using the @ syntax (e.g., @CommonsWare), to maximize the odds you will get a reply. However, only use that for people who are already involved in your question.
5. On the Google Groups, do not “ping” or reply to your own message to try to elicit a response until a reasonable amount of time has gone by (e.g., 24 hours).

Heading to the Source

The source code to Android is now available. Mostly this is for people looking to enhance, improve, or otherwise fuss with the insides of the Android operating system. But, it is possible that you will find the answers you seek in that code, particularly if you want to see how some built-in Android component “does its thing”.

The source code and related resources can be found at <http://source.android.com>. Here, you can:

1. [Download](#) the source code
2. File [bug reports](#) against the operating system itself
3. [Submit patches](#) and learn about the process for how such patches get evaluated and approved
4. Join a separate set of [Google Groups](#) for Android platform development

Getting Your News Fix

Ed Burnette, a nice guy who happened to write his own Android book, is also the manager of [Planet Android](#), a feed aggregator for a number of Android-related blogs. Subscribing to the planet's feed will let you monitor quite a bit of Android-related blog posts, though not exclusively related to programming.

Trail: Code Organization and Gradle

Working with Library Projects

Android library projects are the primary unit of Android source reuse, particularly where that source involves more than just Java source code, such as Android resources.

In this chapter, we will explore the basics of setting up and using an Android library project.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Creating a Library Project

An Android library project, in many respects, looks like a regular Android project. It has source code and resources. It has a manifest.

What it does not do, though, is build an APK file. Instead, it represents a basket of programming assets that the Android build tools know how to blend in with regular Android projects.

How you set up an Android library project depends upon your IDE.

Android Studio

Making a project be an Android library project is simply a matter of choosing the right Gradle for Android plugin.

Rather than have:

```
apply plugin: 'com.android.application'
```

use:

```
apply plugin: 'com.android.library'
```

That's it — the `com.android.library` plugin now knows that it is creating a library, not an app.

The real question is, *where* are you making this library? In many cases, you will do so as a module in a project, where there is another module that is an app. This covers both:

- A library designed to be standalone, but with a sample app demonstrating its use
- A library designed to be used by the app, and perhaps other app modules in this project

Adding new modules to an Android Studio project is handled most simply via the new-module wizard, which you can bring up via `File > New Module...` from the main menu. This brings up the first page of the new-module wizard:

WORKING WITH LIBRARY PROJECTS

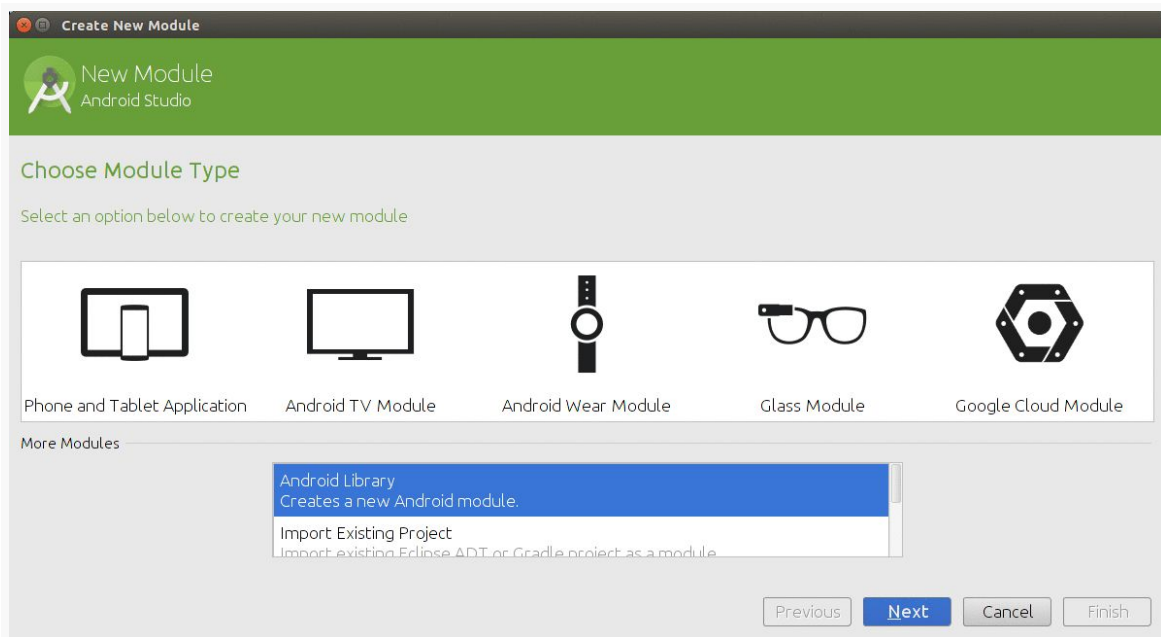

Figure 321: Android Studio New-Module Wizard, First Page

To add a library project as a module to an existing project, choose “Android Library” in the list of module types, then click Next to proceed to the second page of the wizard:

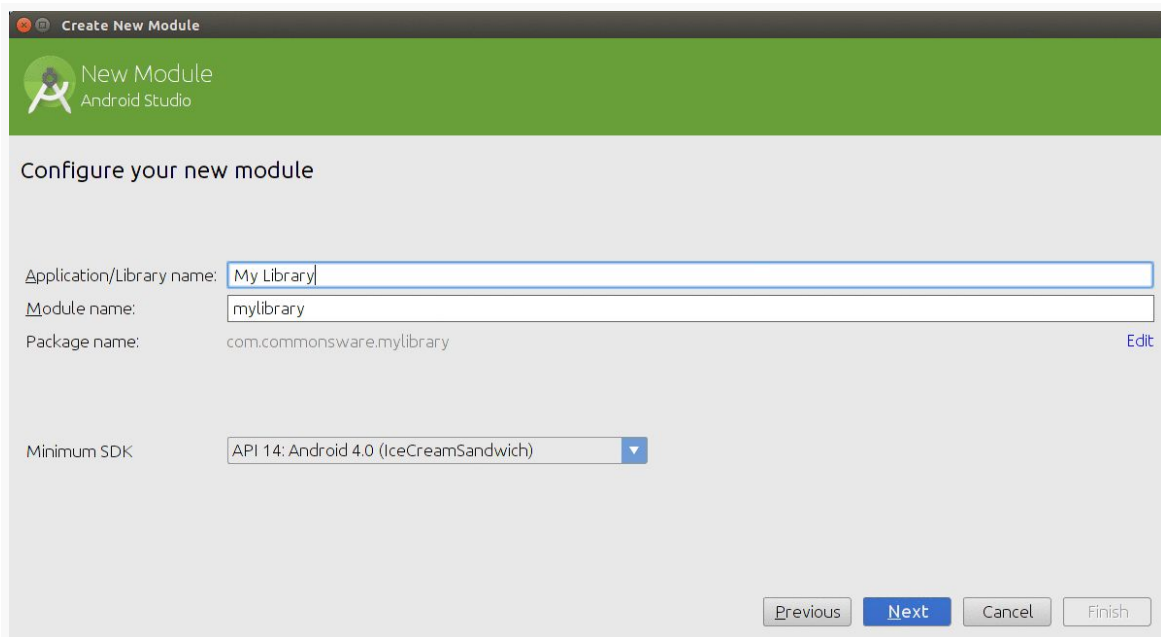

Figure 322: Android Studio New-Module Wizard, Second Page

This collects some bits of information, including:

- the “application name”, whose use in this case is unclear
- the “module name”, which will be the directory in this project into which this library will be created
- the “package name”, which will go into the manifest of the generated library
- your `minSdkVersion`

At this point, clicking **Next** will take you to the same new-activity flow that you saw when creating a new project. If you want an activity to be generated for you in this library, proceed by selecting the activity template and providing the activity template configuration data. If you do not want an activity, choose “Add No Activity” in the grid of templates, then click “Finish” to create the module.

In the end, the new-module wizard will set up the new module for you, in your designated subdirectory of the project, including modifying `settings.gradle` to list this subdirectory as being a module within the project. At this point, you will be able to start using the library within the project itself.

Eclipse

To create a library project in Eclipse, start by creating a normal Android project. Then, in the project properties window (e.g., right-click on the project and choose Properties), in the Android area, check the “Is Library” checkbox. Click “Apply”, and you are done.

Figure 323: Android Library Project Properties, Library Section

Using a Library Project, Part II

Once you have a library project, you can attach it to a regular Android project, so the regular Android project has access to everything in the library. We covered simple scenarios for this [earlier in the book](#). With Android Studio, you have two other major possibilities, besides what was covered previously.

If the library exists in support of a couple of your own applications, you could organize all of that into a single project with several modules (e.g., `app/` and `app2/` for the apps, with `myCoolLibrary/` for the library). How to set up this structure will be covered in [the chapter on Gradle dependencies](#).

If the library exists in support of applications that you are not writing, such as one for another development team in your organization, or one for public distribution — you will probably wind up publishing an AAR file compiled from the library. This too is covered in [the chapter on Gradle dependencies](#).

Library Projects and the Manifest

Library projects can publish their own `AndroidManifest.xml` file, which contributes to the overall manifest used by apps that incorporate the library. Hence, a library can:

- request permissions that perhaps are not in the app's own manifest
- publish activities or other components, without the app developer having to add entries to the app's own manifest
- stipulate a minimum SDK version required by the library code, which might be higher than the minimum SDK version required by the app itself

However, merging these manifests is a rather complex topic, and as such will be covered [much later in the book](#).

Limitations of Library Projects

While library projects are useful for code organization and reuse, they do have their limits, such as:

- As noted above, if more than one project (main plus libraries) defines the same resource, the higher-priority project's copy gets used. Generally, that is a good thing, as it means that the main project can replace resources defined by a library (e.g., change icons). However, it does mean that two libraries might collide. It is important to keep your resource names distinct to minimize the odds of this occurrence.
- Since you are using the source code of the other project, you are subject to the limitations of its code. For example, if the third-party project is using `@Override` annotations on its implementations of interface methods, you will need to ensure that, in Eclipse, you have the compiler compliance level set to 1.6 or 1.7 — sometimes, this is set to 1.5, which complains about such annotations.

Gradle and Eclipse Projects

Projects fall into two main categories: those using the new Gradle-specific directory structure, and those that use the legacy structure that everyone used from 2008 through 2013 (and, to some extent, beyond) — mostly, projects created using Eclipse.

However, Gradle is capable of building projects in either directory layout. This chapter will review how to add Gradle support to an Eclipse Android project, without having to change your directory structure.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapter that [introduces Gradle](#).

“Legacy”?

Here, “legacy directory structure” means a project tree that looks a bit like this:

Figure 324: Legacy Directory Structure

It is dominated by a traditional Java `src/` tree, plus the Android-specific items like `res/`, `AndroidManifest.xml`, and so forth.

This directory structure will work perfectly fine with Gradle, and you may need to keep this structure for a while in order to maintain compatibility with other tools, like Eclipse.

Creating Your Gradle Build File

You need a `build.gradle` file to be able to build your project with Gradle.

As noted in [the introductory chapter on Gradle](#), Gradle is the native build system for Android Studio. Hence, if you are using that IDE, you should get a `build.gradle` file automatically. Also, if you are moving from Eclipse to Android Studio, use the Android Studio import wizard, as it is better than your alternatives and will also help reorganize your code into the sourceset-based project structure that Android Studio (and Gradle for Android) use natively.

If you are not using Android Studio, though, there are two main ways of getting a `build.gradle` file today: export one from an Eclipse project, or create one by hand. In theory, exporting from Eclipse would be the best bet. But with Eclipse being unsupported, you may wind up having to create it fully by hand. After all, as you will see, what you get from the Eclipse export process is out of date.

Exporting from Eclipse

If you have an existing Eclipse project, the easiest way to get a `build.gradle` file for that project is to let the ADT plugin export one for you.

Performing the Export

To export `build.gradle`, either choose `File > Export` from the Eclipse main menu, or choose “Export...” from the context menu in the Package Explorer. Either of those should bring up a wizard-style dialog where you can choose what you want to export:

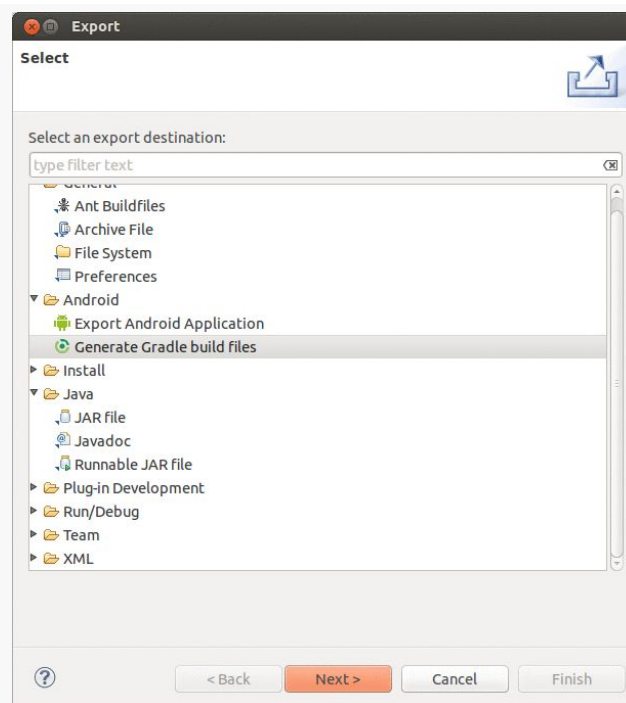

Figure 325: Eclipse Export Wizard, First Page

GRADLE AND ECLIPSE PROJECTS

Here, choose “Generate Gradle build files”. If that is not an option, you may be on an older version of the ADT plugin and would need to upgrade.

Clicking Next will then bring up a list of all installed projects, where you will need to check the project that you wish to export:

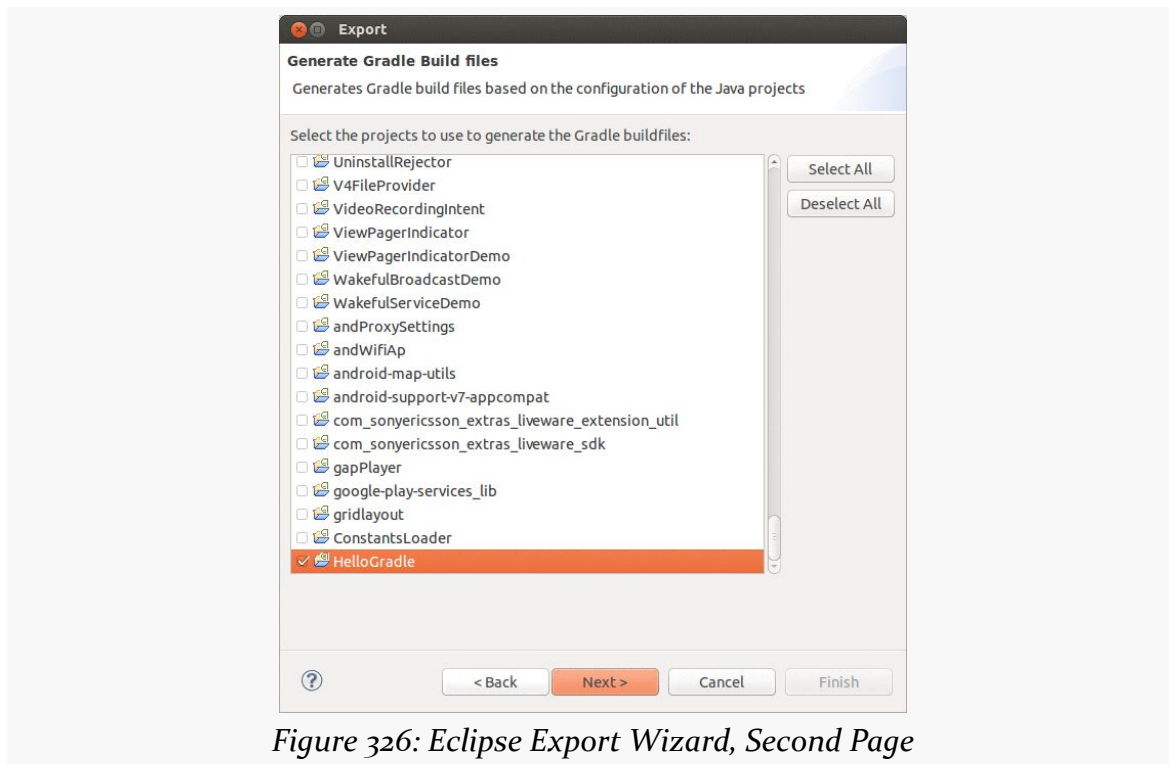

Figure 326: Eclipse Export Wizard, Second Page

Note that your project may not already be checked, due to a bug in the wizard.

Once you have checked the project, the Next button should be enabled. Clicking that will bring up a confirmation wizard page:

GRADLE AND ECLIPSE PROJECTS

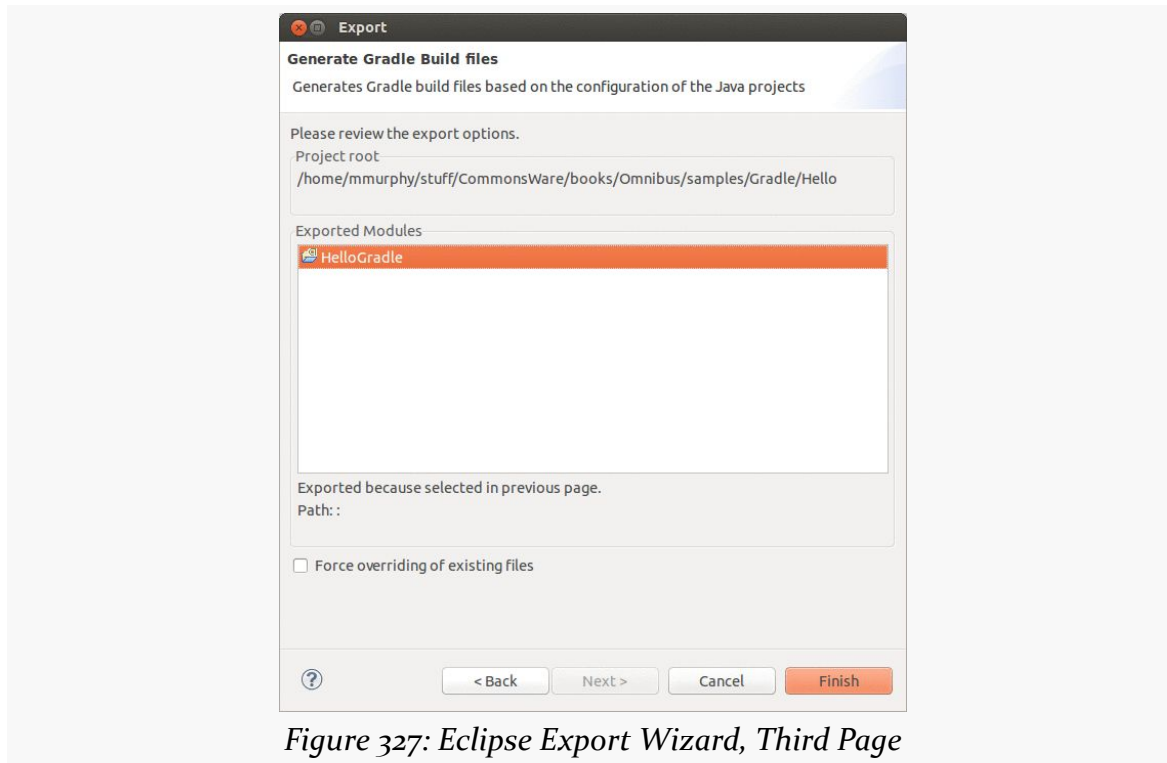

Figure 327: Eclipse Export Wizard, Third Page

It should show the project you checked in the wizard. There is a “Force overriding of existing files” checkbox — use that if you had previously exported the Gradle files and wish to replace them with a freshly-exported copy.

Clicking the Finish button will do the export and bring up a report page:

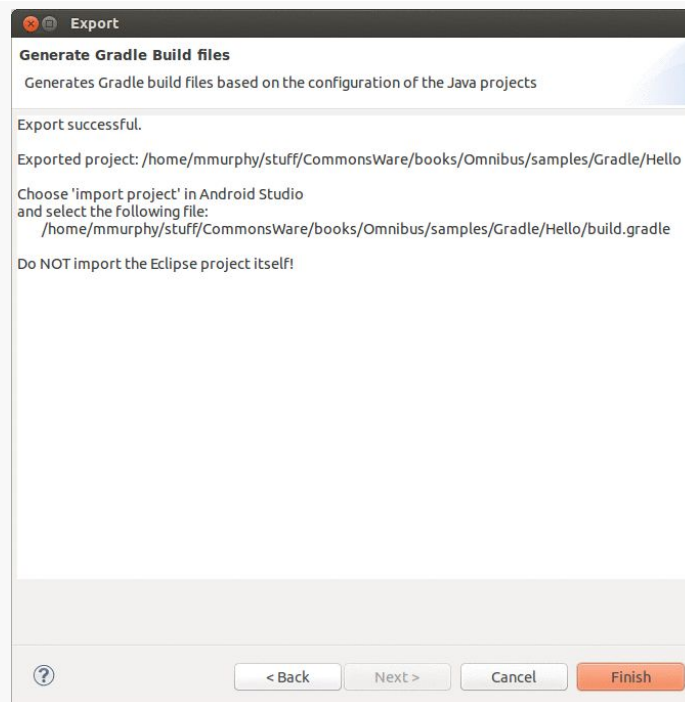

Figure 328: Eclipse Export Wizard, Fourth Page

After carefully reviewing the notes here (or possibly just ignoring them), click Finish to close the wizard.

What Gets Generated

What you get for your troubles is:

- A build.gradle file.
- A Gradle wrapper, in the form of a gradlew and/or gradlew.bat file and a gradle/ subdirectory, as was discussed [in the previous chapter](#). If you will not be using the wrapper, feel free to delete these files, except for the gradle-wrapper.properties file.
- A .gradle/ hidden subdirectory, containing cached data used by the Gradle build process, such as a parsed copy of your build.gradle file, for faster execution if you run Gradle without having modified build.gradle since your last Gradle run.

What Needs Fixing

To have the resulting project work well with Android Studio, change:

- the version of the Gradle for Android plugin to 1.0.0 or higher (classpath 'com.android.tools.build:gradle:0.12.+' to classpath 'com.android.tools.build:gradle:1.0.0')
- the apply plugin: 'android' statement to apply plugin: 'com.android.application'
- the distributionUrl in the gradle/wrapper/gradle-wrapper.properties file to <https://services.gradle.org/distributions/gradle-2.2.1-all.zip>

Examining the Gradle File

The book's sample code contains a [Gradle/Hello](#) sample project. This is just a stock "Hello, world" app, as created by the Eclipse new-project wizard.

However, it also contains a build.gradle, exported by Eclipse:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}
apply plugin: 'com.android.application'

dependencies {
    compile fileTree(dir: 'libs', include: '*.jar')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }
    }
}
```

```
    }

    // Move the tests to tests/java, tests/res, etc...
    instrumentTest.setRoot('tests')

    // Move the build types to build-types/<type>
    // For instance, build-types/debug/java, build-types/debug/
    AndroidManifest.xml, ...
    // This moves them out of their default location under src/<type>/...
    // which would
    // conflict with src/ being used by the main source set.
    // Adding new build types or product flavors should be accompanied
    // by a similar customization.
    debug.setRoot('build-types/debug')
    release.setRoot('build-types/release')
  }
}
```

Most of the contents of this file is covered in [the introductory chapter on Gradle](#). The one bit that is not — the `sourcesets` closure — is covered in [an upcoming chapter](#).

Gradle and Tasks

A `build.gradle` file teaches Gradle how to execute tasks, such as how to compile an Android project. Outside of a Gradle-aware IDE like Android Studio, you use Gradle itself to run these tasks. If you have installed your own copy of Gradle, you would use the `gradle` command; if you are relying upon a trusted copy of the Gradle Wrapper, you would use the `./gradlew` script in your project root.

For the purposes of this book, the `gradle` command will be shown – just substitute `./gradlew` where you see `gradle` if you are using the Gradle Wrapper script.

Key Build-Related Tasks

To find out what tasks are available to you, you can run `gradle tasks` from the project directory. That will result in output akin to:

```
:tasks

-----
All tasks runnable from root project
-----

Android tasks
-----
androidDependencies - Displays the Android dependencies of the project
signingReport - Displays the signing info for each variant

Build tasks
-----
assemble - Assembles all variants of all applications and secondary packages.
assembleDebug - Assembles all Debug builds
assembleDebugTest - Assembles the Test build for the Debug build
assembleRelease - Assembles all Release builds
build - Assembles and tests this project.
buildDependents - Assembles and tests this project and all projects that depend
```

GRADLE AND TASKS

on it.

buildNeeded - Assembles and tests this project and all projects it depends on.

clean - Deletes the build directory.

Build Setup tasks

init - Initializes a new Gradle build. [incubating]

wrapper - Generates Gradle wrapper files. [incubating]

Help tasks

components - Displays the components produced by root project 'Decktastic'.

[incubating]

dependencies - Displays all dependencies declared in root project 'Decktastic'.

dependencyInsight - Displays the insight into a specific dependency in root project 'Decktastic'.

help - Displays a help message.

projects - Displays the sub-projects of root project 'Decktastic'.

properties - Displays the properties of root project 'Decktastic'.

tasks - Displays the tasks runnable from root project 'Decktastic'.

Install tasks

installDebug - Installs the Debug build

installDebugTest - Installs the Test build for the Debug build

uninstallAll - Uninstall all applications.

uninstallDebug - Uninstalls the Debug build

uninstallDebugTest - Uninstalls the Test build for the Debug build

uninstallRelease - Uninstalls the Release build

Verification tasks

check - Runs all checks.

connectedAndroidTest - Installs and runs the tests for Build 'debug' on connected devices.

connectedCheck - Runs all device checks on currently connected devices.

deviceCheck - Runs all device checks using Device Providers and Test Servers.

lint - Runs lint on all variants.

lintDebug - Runs lint on the Debug build

lintRelease - Runs lint on the Release build

Other tasks

compileDebugSources

compileDebugTestSources

compileReleaseSources

Rules

Pattern: clean<TaskName>: Cleans the output files of a task.

Pattern: build<ConfigurationName>: Assembles the artifacts of a configuration.

Pattern: upload<ConfigurationName>: Assembles and uploads the artifacts belonging to a configuration.

```
To see all tasks and more detail, run with --all.
```

```
BUILD SUCCESSFUL
```

```
Total time: 9.669 secs
```

This list is dynamically generated based on the contents of `build.gradle`, notably including tasks defined by the `com.android.application` plugin.

In principle, you are supposed to specify the entire task name when running that task. However, you can use shorthand, so long as it uniquely identifies the task.

Probably the most common task that a developer will use, at least in the short term, is `installDebug` (or `id` for short). This will build a debug version of the app and install it on an available device or emulator. This roughly corresponds to `ant install debug` for those familiar with legacy Ant-based command-line builds.

Just as there is `installDebug`, there can also be `installRelease`. The Debug and Release portions of the task are not hard-coded, but rather are derived from the “build types” defined in the `build.gradle` file. The concept, role, and usage of build types will be covered in [the next chapter](#). However, `installRelease` is not available by default, because installing an app requires that the APK be signed, and Gradle for Android does not know how to sign it. We will address this in [the next chapter](#) as well.

If you just want to build the app, without installing it, `assembleDebug` (`aD`) or `assembleRelease` (`aR`) will accomplish that aim. If you want to uninstall the app from a device or emulator, `uninstallDebug` (`uD`) and `uninstallRelease` (`uR`) should work.

Discussion of other tasks, such as the “check” tasks, will be covered in later chapters.

Results

With Eclipse, the build output went in a `bin/` directory, and generated source code (e.g., `R.java`) went in a `gen/` directory. With Gradle, all build output goes into a `build/` directory.

Specifically, your APKs will go into `build/outputs/apk`, with different APK editions based upon whether you did a debug or release build.

GRADLE AND TASKS

Gradle has a `clean` task that wipes out the `build/` directory. However, note that Eclipse does not use the `build/` directory, so a Gradle `clean` will not “clean” the pre-compiled classes and such that Eclipse uses.

Gradle and the New Project Structure

A [previous chapter](#) showed how you can use Gradle, and the Gradle for Android plugin, to do command-line builds of projects that can also work with Eclipse, IntelliJ IDEA, Ant, etc.

However, while the legacy project directory structure works, it does not let you leverage the full power of the Gradle for Android plugin. To take advantage of the build flexibility of the new build system, you will need to organize your source, resources, assets, and related files somewhat differently.

This chapter will outline this “new project structure” and show you how Gradle for Android’s concepts of build types and product flavors will make it easier for you to have multiple different forms of output from a single, albeit reorganized, project tree. This project structure is native to Android Studio, so Android Studio projects are already set up to be able to support these sorts of advanced capabilities.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, in the context of [covering the use of Gradle with the legacy project structure](#).

Objectives of the New Project Structure

In the beginning, Android apps tended to be pretty simple, as we only had a handful of devices, a smattering of users, one primary distribution channel (the then-Android Market) and few major investors in the Android ecosystem.

Times have changed.

Now, Android apps for public consumption can be terribly complex, let alone apps for internal enterprise use (which seem to be complex as a side effect of being developed by an enterprise). We have multiple distribution channels, such as the Amazon AppStore for Android and Yandex.Store. We have a billion devices and nearly a billion users. Brands large and small are flocking to Android, bringing with them their own challenges.

The new build system is designed to simplify creating complex Android applications, while, ideally, not making simple Android applications a lot harder. It is designed for scenarios like:

- Supporting multiple distribution channels, which may require multiple in-app purchasing engines
- Supporting one app that is customized for individual clients, such as for use by different enterprises
- Supporting an app that really needs to have different APKs for different types of devices, despite all efforts to support all devices from a single APK
- Supporting an app that is part of a much larger integrated system and needing to be built as part and parcel of that larger system
- Supporting a fleet of apps that depend upon common code, resources, third-party libraries, and the like
- And so on

The new project structure, coupled with the Gradle for Android plugin and Gradle itself, makes all of this possible... albeit with a bit of a learning curve.

Terminology

To understand what the new project structure entails, we need to define a few terms, from Gradle and the Gradle for Android plugin.

Sourcesets

To quote [the Gradle documentation](#): “A sourceset is simply a group of source files which are compiled and executed together.” Here, “source” means all the inputs that you are creating for the app, such as Java source code, Android resources and manifest files, and the like. This is in contrast to *dependencies*, which are inputs that you are (usually) obtaining from other developers, such as reusable libraries.

Sourcesets, on their own, have no particular semantic meaning. You can elect to have your project use a single sourceset, or several sourcesets, for organizing your code. You might have different sourcesets for:

- Production code versus test code, replacing the separate test project that we historically used in Android development
- Interface code versus implementation code
- Different major functional areas within the app, particularly if they are maintained by separate teams or developer pairs
- And so on

As we will see, the new project structure assumes the existence of at least one sourceset, typically named `main`, but other features of the new build system will involve additional sourcesets.

Build Types

A build type is one axis of possible alternative outcomes from the build process.

By default, the Gradle for Android plugin assumes that you want two build types: `release` and `debug`. These may go through somewhat different build steps, such as applying ProGuard to the `release` build but skipping it for the `debug` build.

With Eclipse, those two build types were “baked in” — you had them, you had *only* them, and you had limited ability to configure anything different beyond what the build tools would do differently automatically.

The Gradle for Android plugin though allows build types to have slightly different configurations, such as adding a `.debug` suffix to the APK’s package name, so that you can have a `release` build and a `debug` build of your app on the same device at the same time. You also can create new build types for handling different scenarios. The new build system documentation, for example, suggests a separate “`jnidebug`” build

type, where you can indicate that the Linux `.so` files for a project should be compiled in debug mode.

As we will see, creating a new build type involves modifications to the `build.gradle` file and adding a matching `sourceset`.

Product Flavors

A build type is one axis for varying your output. A product flavor is another, independent axis for varying your output.

Product flavors are designed for scenarios where you want different release output for different cases. For example, you may want to have one version of your app built to use Google's in-app purchasing APIs (for distribution through the Play Store) and another version of your app built to use Amazon's in-app purchasing APIs (for distribution through the Amazon AppStore for Android). In this case, both versions of the app will be available in release form, and you may wish to have separate debug builds as well. And *most* of the code for the two versions of the app will be the same. However, you will have different code for the different distribution channels — not only does the right code have to run for the right channel, but there is no particular value in distributing the code for one channel through the other channel.

Another example would be an app that is branded and configured for different enterprise customers. You see this a lot with Web apps — the vendor sells a branded-and-configured version of the Web app to the customer, whether that app runs on vendor-supplied hardware or customer-supplied hardware. Similarly, the maker of an Android app for collecting employee timesheets might want to offer to its customers for *their* version of the timesheet app to sport the customer's logo, tie into the customer's specific accounting server, enable or disable features based upon how the customer uses timesheets, and so on. However, *most* of the code is shared between all customers, and so when the app is updated to add features or fix bugs, new builds are needed for *all* of the customers. In this case, each customer can be set up as an independent product flavor, sharing much of the code, but with slightly different code, resources (e.g., logo), and configuration based upon that customer's needs.

Product flavors are optional. If you do not describe any product flavors in your `build.gradle` file, it is assumed that you have a single product flavor, referred to internally as `default`. Many apps will not need product flavors; this is a feature that you will opt into as needed.

As we will see, creating a new product flavor involves modifications to the `build.gradle` file and adding a matching `sourceset`.

Build Variants

The term “build variant” is used for the cross product of the build types and the product flavors. So, a project with debug and release build types and google and amazon product flavors will result in a total of four build variants by default:

1. debug + google
2. debug + amazon
3. release + google
4. release + amazon

Flavor Dimensions

Sometimes, even this is insufficient flexibility, such as the google and amazon scenario described earlier in this section. Or, you might need separate free versus paid editions, if you want to have an up-front fee for accessing a premium version of your app.

By default, product flavors are considered to be part of a single “flavor dimension”. However, you can organize your flavors into your own separate flavor dimensions (e.g., one for free versus paid, one for distribution channel).

These then add another factor into the cross-product that determines your build variants. Suppose we have a `dist` flavor dimension, consisting of free and paid product flavors, and we have a `channel` flavor dimension, consisting of google and amazon flavors. Now, we have a total of 8 possible build variants, when we factor in the build types:

1. debug + google + free
2. debug + amazon + free
3. release + google + free
4. release + amazon + free
5. debug + google + paid
6. debug + amazon + paid
7. release + google + paid
8. release + amazon + paid

Creating a Project in the New Structure

As of the time of this writing, there are two major ways of getting a project into the new project structure: use Android Studio, or do it by hand.

As noted in the book's earliest chapters, Android Studio's native build system is Gradle with the Gradle for Android plugin. When you create a new project through that IDE, it will automatically be set up with the new project structure.

Unfortunately, at the time of this writing, there is no way to get a project organized into the new structure out of Eclipse, simply because Eclipse does not support the new structure. Similarly, there is no command-line tool, akin to `android create project` that will create a Gradle project.

Hence, in the short term, if you are not using Android Studio, and you want a project in the new structure, you will need to craft the directory tree and `build.gradle` file yourself. That could be a matter of creating them from scratch, or it could be a matter of copying a project structure from an existing source. Martin Liersch (a.k.a., "Goddchen") has published [a GitHub repository with a variety of sample projects](#) that you can use as a source of inspiration, along with the samples presented over the rest of this chapter.

What the New Project Structure Looks Like

With all that as background, let's take a look at the [Gradle/HelloNew](#) sample project. This project started as an Eclipse project, then had a `build.gradle` file added to it via the Eclipse export wizard. Later, though, it was reorganized to fit the new project structure.

The Directory Tree

The pre-reorganization directory tree for the project is fairly conventional, just with some added Gradle-specific files:

```
Hello
|— AndroidManifest.xml
|— assets/
|— build.gradle
|— libs/
|   |— android-support-v4.jar
|— local.properties
```

```
|— proguard-project.txt
|— project.properties
|— res/
|   |— drawable-hdpi/
|   |   |— ic_launcher.png
|   |— drawable-ldpi/
|   |— drawable-mdpi/
|   |   |— ic_launcher.png
|   |— drawable-xhdpi/
|   |   |— ic_launcher.png
|   |— layout/
|   |   |— activity_main.xml
|   |— menu/
|   |   |— main.xml
|   |— values/
|   |   |— dims.xml
|   |   |— strings.xml
|   |   |— styles.xml
|   |— values-sw600dp/
|   |   |— dims.xml
|   |— values-sw720dp-land/
|   |   |— dims.xml
|   |— values-v11/
|   |   |— styles.xml
|   |— values-v14/
|   |   |— styles.xml
|— src/
|   |— com/
|   |   |— commonsware/
|   |   |   |— android/
|   |   |       |— gradle/
|   |   |           |— hello/
|   |   |               |— MainActivity.java
```

(note: above listing includes only files of relevance for the current discussion)

The new project structure, though, is a bit different:

```
HelloNew
|— build.gradle
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/
|   |— main/
|       |— AndroidManifest.xml
```

```
|— assets/
|— java/
|   |— com/
|       |— commonsware/
|           |— android/
|               |— gradle/
|                   |— hello/
|                       |— MainActivity.java
|— res/
|   |— drawable-hdpi/
|       |— ic_launcher.png
|   |— drawable-ldpi/
|   |— drawable-mdpi/
|       |— ic_launcher.png
|   |— drawable-xhdpi/
|       |— ic_launcher.png
|   |— layout/
|       |— activity_main.xml
|   |— menu/
|       |— main.xml
|   |— values/
|       |— dims.xml
|       |— strings.xml
|       |— styles.xml
|   |— values-sw600dp/
|       |— dims.xml
|   |— values-sw720dp-land/
|       |— dims.xml
|   |— values-v11/
|       |— styles.xml
|   |— values-v14/
|       |— styles.xml
```

While the `libs/` directory is in its original spot, along with `build.gradle` and related build files, the rest has shifted.

With the new project structure, `src/` is the root of the source *sets*, not just where the source *code* goes. There is one sourceset, named `main`, in the `src/main/` directory. In there is where the `assets/` and `res/` directories go, along with the `AndroidManifest.xml` file. And, there is a `java/` directory that contains the Java source tree (what had been in the original `src/` directory).

The `build.gradle` File

The `build.gradle` file is much like what we profiled back in [the introductory chapter on Gradle](#):

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

We have the `buildscript` closure to describe what we need for our build tools, the `com.android.application` plugin, and details for what version of Android we are compiling against and what version of the build tools we are using.

And, as a result, we have [the standard tasks](#), including `installDebug`.

Configuring the Stock Build Types

The debug and release build types are ready “out of the box” for your use, with a reasonable set of defaults. However, you can change those defaults and make other adjustments to how those build types work, in addition to [defining your own build types](#). Here, we will look at the options for changing the behavior of any build type, focusing on the stock debug and release build types.

Specifically, we will examine the [Gradle/HelloConfig](#) sample project, which builds upon the previous sample, modifying the behavior of both debug and release.

Sourceset

Each build type can have its own associated sourceset. If you skip the directory for it, that means that the build type is not contributing changes to the main sourceset.

So, in the [Gradle/HelloConfig](#) sample project, we have a replacement version of the `strings.xml` resource, in a debug sourceset:

```
HelloConfig
|— build.gradle
|— HelloConfig.keystore
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/

|   |   |   |   |— dims.xml
|   |   |   |   |— strings.xml
|   |   |   |   |— styles.xml
|   |   |   |— values-sw600dp/
|   |   |   |   |— dims.xml
|   |   |   |— values-sw720dp-land/
|   |   |   |   |— dims.xml
|   |   |   |— values-v11/
|   |   |   |   |— styles.xml
|   |   |   |— values-v14/
|   |   |   |   |— styles.xml
```

That `strings.xml` contains a revised version of the `app_name`, to help make it more obvious that we are running the debug version of the app:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <string name="app_name">HelloGradle DEBUG</string>

</resources>
```

As we will see, resources in build types' sourcesets *replace* their counterparts in the main. Or, a build type could add a new resource that is missing from main, if desired.

build.gradle Settings

We can also use the `buildTypes` closure in `build.gradle` to configure the behavior of the debug and/or release build types. In this sample project, we alter both, plus make some other changes:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }
}
```

```
    }  
  }  
  
  buildTypes {  
    debug {  
      applicationIdSuffix ".d"  
      versionNameSuffix "-debug"  
    }  
  
    release {  
      signingConfig signingConfigs.release  
    }  
  }  
}
```

As was noted back in [the introduction to Gradle for Android](#), the `defaultConfig` closure allows us to change aspects of what is found in the `AndroidManifest.xml` file, replacing anything found in the actual file from the main sourceset.

The `buildTypes` closure is where we configure the behavior of the build types. Each build type to be configured gets its own closure inside of `buildTypes`, and in there we can override various properties.

Notable properties that we can specify for a build type include:

- `debuggable` (to override `android:debuggable` from the `<application>` element in the manifest, to indicate that the app should be considered debuggable)
- `applicationIdSuffix` (to append to the package name specified by the manifest or the `defaultConfig` `applicationId` property)
- `versionNameSuffix` (to append to the version name specified by the manifest or the `defaultConfig` `versionName` property)

(NOTE: `applicationIdSuffix` was formerly known as `packageNameSuffix` prior to the Gradle for Android 0.11 release)

Our debug build type adds suffixes to the version name and the application ID role for the package name. Note that altering the application ID *only* affects the package name as seen by Android when the app is installed and when the app is run. It does *not* affect the directory in which the R class is built, which uses the package name from the `AndroidManifest.xml` file. It also does not affect any of the Java packages for our own classes, which are whatever we used when we wrote them. Hence, much of our code will be oblivious to the package name change. However, if you want to reference the *real* package name, such as for looking things up in

PackageManager or for use with constructing a ComponentName, use `getPackageName()` on any Context (like an Activity), rather than some hard-coded string, as `getPackageName()` returns what the runtime environment thinks the package is, which will include any suffixes added during the build process. Or, use `BuildConfig.APPLICATION_ID`, in cases where you do not have a Context handy on which to call `getPackageName()`.

We can also have a `signingConfig` property, for configuring how our APK files are digitally signed. This will be covered [in a later chapter](#).

Order of Precedence

Properties defined for a build type, and the properties defined for the `defaultConfig` will override their equivalents in the `AndroidManifest.xml` file. However, a build type's sourceset can *also* have its own `AndroidManifest.xml` file. The overall order of precedence is:

- What is in `build.gradle` takes precedence over...
- ...what is in a build type's `AndroidManifest.xml` file, which takes precedence over...
- ...what is in the main `AndroidManifest.xml` file

However, merging manifests in general is a complex topic, with [a separate chapter](#) later in this book.

Resources from the build type's sourceset are merged into the resources from the main sourceset, and if there are collisions, the build type's resource takes precedence. The same is true for assets.

However, the behavior of Java source is slightly different. The build type's source set is still merged with the main sourceset, but if there is a collision, the result is a build error. Either the build type or the main sourceset can define any given source file, not both. So, while debug could have one version of your `/package/name/Foo.java` and release could have a different version of your `/package/name/Foo.java`, main could not *also* have your `/package/name/Foo.java`. Hence, if you define a class in a build type, you may need to define that class in *all* build types, so that any references from main to that class are satisfied for all build types.

One case where this would not be required would be for debug-only activities. Suppose that you wanted an activity in your app to provide diagnostic information to developers of that app regarding the state of caches and other in-memory

constructs. While you could get at that stuff via a debugger, that is sometimes annoying, and just tapping on a launcher icon can be easier. But you do not want, let alone need, this diagnostic activity in your release builds. To make this work, you would put the activity's Java class only in the debug sourceset, along with its resources and manifest entry (complete with MAIN/LAUNCHER <intent-filter>). Since the main sourceset does not refer to your diagnostic activity, there is no requirement for the release build type to have an implementation of that Java class.

Adding Build Types

Many developers will fare just fine with the debug and release build types, perhaps with some adjustments as shown above. A few developers, though, will have other scenarios that warrant new build types. Fortunately, adding a new build type is rather easy, as seen in the [Gradle/HelloBuildType](#) sample project, which builds upon the previous sample, adding a new build type.

As with the built-in build types, your new build types can have their own sourcesets, by adding the appropriately-named directories underneath `src/`. And, as with the built-in build types, you can configure the new build types in the `buildTypes` closure in `build.gradle`:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }
}
```

```
signingConfigs {
    release {
        storeFile file('HelloConfig.keystore')
        keyAlias 'HelloConfig'
        storePassword 'laser.yams.heady.testy'
        keyPassword 'fw.stabs.steady.wool'
    }
}

buildTypes {
    debug {
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
    }

    release {
        signingConfig signingConfigs.release
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
    }
}
```

In this project, we want a third build type, named mezzanine, representing a “middle ground” between a regular debug build and the release build.

To tell Android about the new build type, we need to initialize one. That is handled by the `mezzanine.initWith(buildTypes.release)` statement, which initializes the new mezzanine build type configuration based upon the already-defined release build type. From there, the subsequent mezzanine closure can amend the properties of that build type. In this case we:

- Put a `.mezz` suffix on the package name
- Flag the project as debuggable
- Sign with the release signing key

Since the mezzanine build type started with the release build configuration, the net effect is that we have a build that is equivalent to the release build, just with the debuggable flag set (and a unique package name).

Now, we gain Gradle tasks with Mezzanine in the name, like `installMezzanine`, to go along with their Debug and Release counterparts.

Adding Product Flavors and Getting Build Variants

Many apps will not need product flavors, but some will. Adding a product flavor is similar, in many respects, to adding a build type, as we will see in the [Gradle/HelloProductFlavors](#) sample project, which builds upon the previous sample, adding a pair of product flavors: vanilla and chocolate.

(note: product flavors do not have to be named after actual flavors)

Each product flavor, as with each build type, can have its own sourceset. In this sample, we have `src/vanilla/` and `src/chocolate/` directories representing a source set for each product flavor:

```
HelloProductFlavors
|— build.gradle
|— HelloConfig.keystore
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/
|   |— chocolate/
|   |   |— java/
|   |   |   |— com/
|   |   |   |   |— commonsware/
|   |   |   |   |   |— android/
|   |   |   |   |   |   |— gradle/
|   |   |   |   |   |   |   |— hello/
|   |   |   |   |   |   |   |— MainActivityOptionsStrategy.java
|   |— debug/
|   |   |— res/
|   |   |   |— values/
|   |   |   |   |— strings.xml
|   |— main/
|   |   |— AndroidManifest.xml
|   |   |— assets/
|   |   |— java/
|   |   |   |— com/
|   |   |   |   |— commonsware/
|   |   |   |   |   |— android/
|   |   |   |   |   |   |— gradle/
|   |   |   |   |   |   |   |— hello/
|   |   |   |   |   |   |   |— MainActivity.java
|   |   |— res/
|   |   |   |— drawable-hdpi/
```

```
|
|   |— ic_launcher.png
|   — drawable-ldpi/
|   — drawable-mdpi/
|       |— ic_launcher.png
|   — drawable-xhdpi/
|       |— ic_launcher.png
|   — layout/
|       |— activity_main.xml
|   — menu/
|       |— main.xml
|   — values/
|       |— dims.xml
|       |— strings.xml
|       |— styles.xml
|   — values-sw600dp/
|       |— dims.xml
|   — values-sw720dp-land/
|       |— dims.xml
|   — values-v11/
|       |— styles.xml
|   — values-v14/
|       |— styles.xml
|— vanilla/
|   |— java/
|       |— com/
|           |— commonsware/
|               |— android/
|                   |— gradle/
|                       |— hello/
|                           |— MainActivityOptionsStrategy.java
```

In the sourcesets, we have a MainActivityOptionsStrategy class, one implementation per product flavor. This class is referenced by a new implementation of the MainActivity class in the main sourceset, to delegate the handling of onOptionsItemSelected():

```
package com.commonsware.android.gradle.hello;

import android.os.Bundle;
import android.app.Activity;
import android.view.Menu;
import android.view.MenuItem;

public class MainActivity extends Activity {

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
    }
}
```

```
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
    // Inflate the menu; this adds items to the action bar
    // if it is present.
    getMenuInflater().inflate(R.menu.main, menu);
    return true;
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    return(MainActivityOptionsStrategy.onOptionsItemSelected(item));
}
}
```

Since we do not have anything much to do in the menu option, each product flavor's implementation of `MainActivityOptionsStrategy` simply logs a flavor-specific message to LogCat, such as the one shown here for vanilla:

```
package com.commonware.android.gradle.hello;

import android.util.Log;
import android.view.MenuItem;

public class MainActivityOptionsStrategy {
    public static boolean onOptionsItemSelected(MenuItem item) {
        Log.d("HelloProductFlavors", "vanilla!");

        return(false);
    }
}
```

To tell Gradle for Android about our product flavors, and to configure their behavior, we have a new `productFlavors` closure in the `build.gradle` file:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
}
```

```
buildToolsVersion "21.1.2"

defaultConfig {
    versionCode 2
    versionName "1.1"
    minSdkVersion 14
    targetSdkVersion 18
}

signingConfigs {
    release {
        storeFile file('HelloConfig.keystore')
        keyAlias 'HelloConfig'
        storePassword 'laser.yams.heady.testy'
        keyPassword 'fw.stabs.steady.wool'
    }
}

buildTypes {
    debug {
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
    }

    release {
        signingConfig signingConfigs.release
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        signingConfig signingConfigs.release
    }
}

productFlavors {
    vanilla {
        applicationId "com.commonware.android.gradle.hello.vanilla"
    }

    chocolate {
        applicationId "com.commonware.android.gradle.hello.chocolate"
    }
}
```

The `defaultConfig` is implemented using the same object type as is used for product flavors. Hence, we can configure the same things on a product flavor that we can on the `defaultConfig`, such as `applicationId`, as is done in this `build.gradle` file.

In terms of order of precedence:

- Product flavors override the main sourceset and the defaultConfig
- Build types override the product flavors

So, a debug build of the vanilla product flavor will result in a package name of `com.commonware.android.gradle.hello.vanilla.d`.

Our task names get more numerous and more complicated, to reflect the cross product of the product flavors and build types. Now, rather than `installDebug`, `installMezzanine`, and `installRelease`, we have:

- `installChocolateDebug`
- `installChocolateMezzanine`
- `installChocolateRelease`
- `installVanillaDebug`
- `installVanillaMezzanine`
- `installVanillaRelease`

Doing the Splits

Gradle for Android 0.13 introduced splits as a lightweight canned replacement for product flavors for two scenarios:

- Having different APK files with different NDK binaries for ARM vs. x86 (vs. anything else)
- Having different APK files with resources for a specific screen density, important for those apps that have so many graphics that they are bumping up against distribution channel limits (e.g., 50MB on the Play Store)

All you as a developer do is request that a particular split be enabled, with limited configuration. Notably, you do not have separate Gradle configuration (e.g., `applicationId`) nor sourcesets for splits. That allows splits to be processed more quickly at build time, as the build tools can make some simplifying assumptions and avoid a lot of recompiling.

Scoping Your Splits

A split, by default, will generate one APK per *possible* type of output. For example, splitting on density will give you one APK for `ldpi`, `mdpi`, `tvdpi`, `hdpi`, `xhdpi`, `xxhdpi`,

and xxxhdpi. Plus, in the case of density, you also get one “universal” APK containing support for all densities by default.

That’s nice... but what if you do not need separate APKs for all of those densities? For example, if you do not ship tvdpi resources, there is little reason to set up an APK for it separate from, say, the hdpi APK.

There are two basic patterns to controlling the scope of what gets built:

1. Use an `exclude` statement to start with the defaults and remove some options
2. Use a `reset()` method to wipe out the defaults, then use an `include` statement to list what you want

In other words, `exclude` implements a blacklist, and the `reset()/include` combination implements a whitelist. All else being equal, a whitelist is probably a better choice, so you can explicitly line it up with what you have written in your app.

Requesting NDK Splits

In your `android` closure, you can add a `splits` closure, containing an `abi` closure, which in turn sets up the APK splits by CPU architecture:

```
splits {  
    abi {  
        enable true  
        reset()  
        include 'armeabi-v7a', 'x86'  
        universalApk true  
    }  
}
```

Here, we:

- Enable the split (`enable true`)
- Remove the default ABIs to be included (`reset()`)
- List the ABIs that we want to be included (`include 'armeabi-v7a', 'x86'`)
- Request that a “universal APK” also be created, containing all ABIs (`universalApk true`)

The latter would be useful for distribution channels that do not allow you to upload multiple APK files for different CPU architectures. This way, you can at least

distribute your app there, even if it takes up more disk space than you like. By default, for the CPU architectures, you do not get a “universal APK”.

Requesting Density Splits

The same basic pattern can be implemented for densities:

```
splits {
    density {
        enable true
        reset()
        include 'hdpi', 'xhdpi', 'xxhdpi'
    }
}
```

Once again, we enable the split, reset the defaults, then opt into the densities that we want.

Note, though, that a “universal APK” is always generated for densities. We do not need to have `universalApk true`, and it would appear that `universalApk false` is not an option at the present time.

Revisiting the Legacy Gradle File

Given all of this, let’s revisit the `build.gradle` file exported from Eclipse:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}
apply plugin: 'com.android.application'

dependencies {
    compile fileTree(dir: 'libs', include: '*.jar')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
        }
    }
}
```

```
        java.srcDirs = ['src']
        resources.srcDirs = ['src']
        aidl.srcDirs = ['src']
        renderscript.srcDirs = ['src']
        res.srcDirs = ['res']
        assets.srcDirs = ['assets']
    }

    // Move the tests to tests/java, tests/res, etc...
    instrumentTest.setRoot('tests')

    // Move the build types to build-types/<type>
    // For instance, build-types/debug/java, build-types/debug/
    // AndroidManifest.xml, ...
    // This moves them out of their default location under src/<type>/...
    // which would
    // conflict with src/ being used by the main source set.
    // Adding new build types or product flavors should be accompanied
    // by a similar customization.
    debug.setRoot('build-types/debug')
    release.setRoot('build-types/release')
}
```

The bulk of the android-specific configuration in the exported build.gradle file comes in the sourceSets closure inside the android closure. Here, we specify what should be compiled.

Gradle allows for separate locations for items presently all dumped into src/: Java source, AIDL interface definitions, RenderScript source files, and Java-style resources (not to be confused with Android resources). Since this build file is for a classic directory structure, though, each of those types of input files will still be found in src/, so the main sourceSet points Android to src/ for each of them. In addition, main indicates the name of the manifest file and the location of the res/ and assets/ trees.

The main closure in the sourceSets closure overrides the default locations of files that comprise the sourceSet. For example, in the new project structure, the Java source code goes in java/ within the sourceSet, but in the old project structure, it goes in a src/ directory in the project root.

The setRoot() calls on the stock debug and release build types indicate that their sourceSets, if they exist, should be in a separate build-types/ directory, as the normal src/ location is being used for Java source code.

Working with the New Project Structure in Android Studio

Not surprisingly, Android Studio has a few features designed to help you work with the various sourcesets that you elect to create and use.

The Build Variants View

When we run our project, Android Studio does not prompt us for a build type or a product flavor. It just runs the project. This begs the question of how Android Studio is determining which build variant is the one to run.

This is handled by the Build Variants view, usually docked on the left side of the Android Studio IDE window:

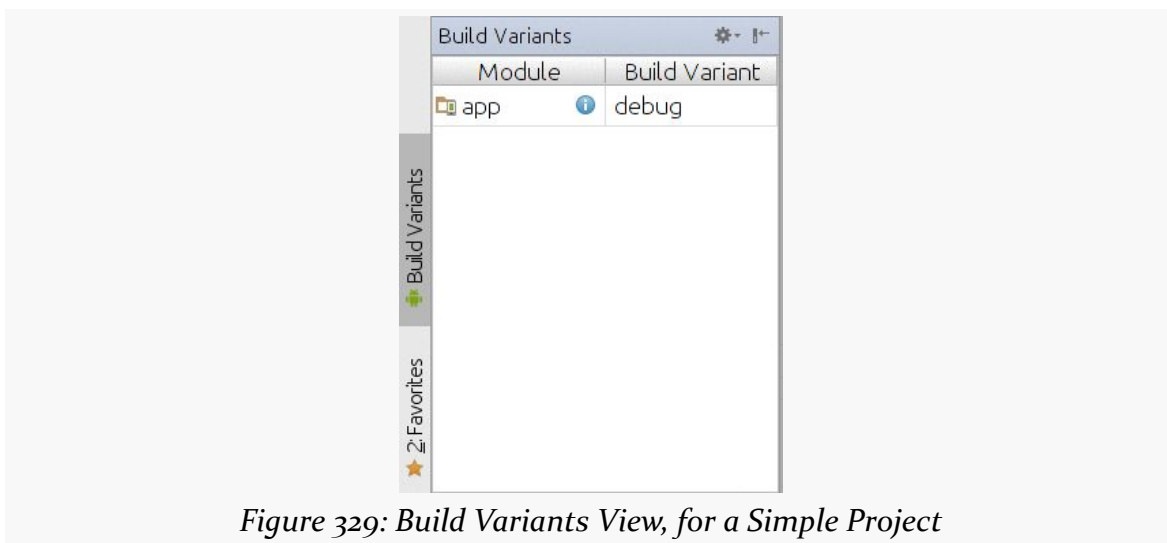

Figure 329: Build Variants View, for a Simple Project

Each of your app's modules is shown, along with the current build variant that will be used if you run that module. Tapping on the build variant will allow you to choose an alternative build variant:

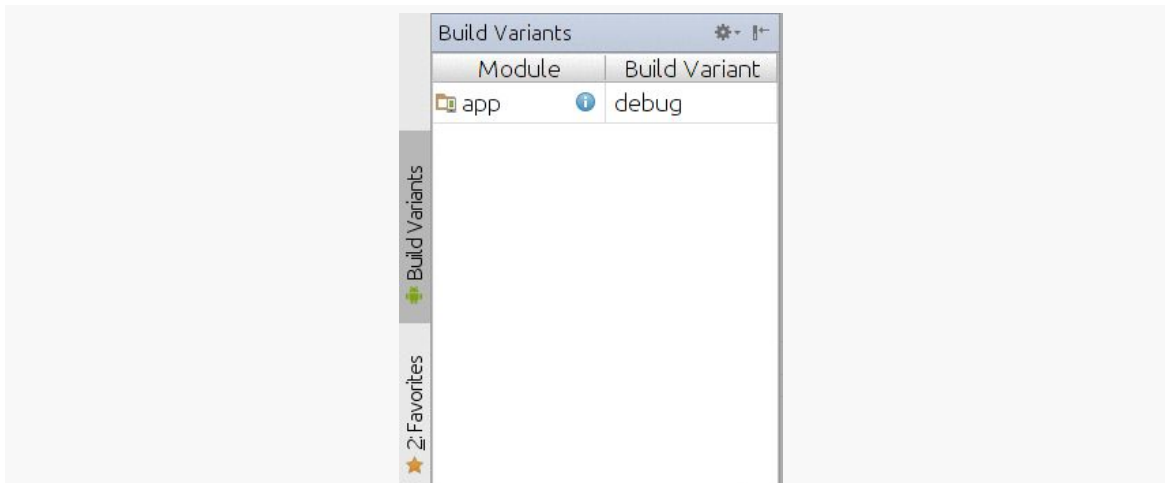

Figure 330: Build Variants View, for a Project with Custom Build Types and Product Flavors

The Android Project View

Earlier in the book, when introducing Android Studio, we saw [the Android project view](#). Elsewhere, we saw how the Android project view can help you manage resources across multiple resource sets.

Just as the Android project view “collapses” resource set, it also collapses sourcesets:

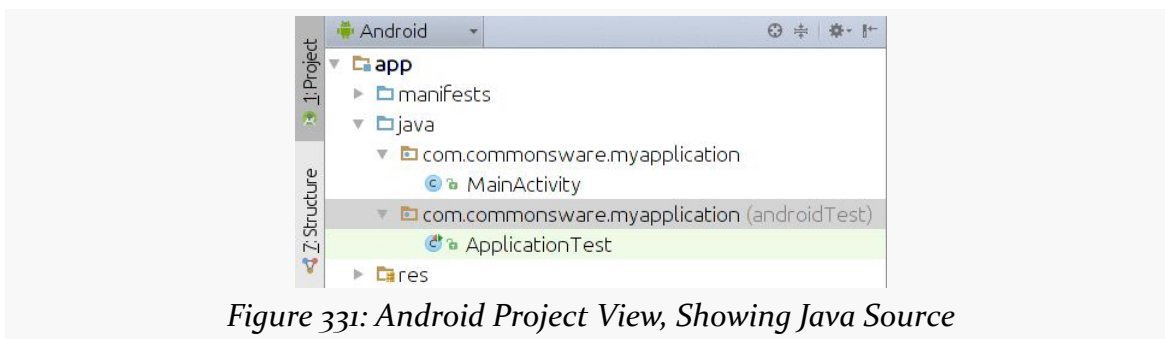

Figure 331: Android Project View, Showing Java Source

Here, we have two editions of the `com.commonware.myapplication` package. One is just the package name, while the other has “(androidTest)” appended to it. That, as you might imagine, reflects the main and androidTest sourceset, respectively:

Figure 332: Classic Project View, Showing Java Source

This may be a bit useful between main and androidTest. It is likely to be far more useful if you employ product flavors, as your classes for the flavors will appear side-by-side... at least for the currently-selected flavor in the Build Variants view. [At the present time](#), Android Studio only treats the active variant's sourcesets (plus main and androidTest) as “source”, with other build variant sourcesets being considered just plain files.

Gradle and Dependencies

John Donne wrote “no man is an island”. Nowadays, few apps are islands, either. It is the rare app that can avoid using all third-party code bases. Most apps will need a backport or other class (e.g., `ViewPager`) from the Android Support package, or will rely upon the Play Services SDK, or will use any number of third party JARs and Android library projects.

The good news is that Gradle adds a lot of power for referencing these third-party code bases when you build your app. While it increases the complexity a bit for “reuse in the small” (e.g., a simple JAR), it can greatly simplify “reuse in the large” (e.g., several Android library projects).

This chapter will outline what sorts of “dependencies” your app can have and how you can configure Gradle to support them.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including both [the legacy project structure](#) and [the new project structure](#).

“Dependencies”?

In case the term is new to you, in this chapter, and in the Gradle documentation, “dependencies” means “code external to your project that your project depends upon”.

In the case of Gradle-built Android apps, this includes:

- local JARs
- NDK-built local Linux .so files
- local Android library projects
- other types of “sub-projects”
- “artifacts” obtained from “repositories”, like Maven Central

Each of these will be covered in turn in this chapter.

A Tale of Two Dependencies Closures

A `build.gradle` file — or the pair of `build.gradle` files in a classic Android Studio project — will have two dependencies closures.

One will be inside the `buildscript` closure, and this set of dependencies are dependencies for the build process itself. Here, we will list dependencies such as the Android build tools, the ones that define the android options we can configure.

The dependencies closure that is a peer of `buildscript` and `android` lists the dependencies for the project that is being build by this particular `build.gradle` file.

In other words, the `buildscript` dependencies are tooling dependencies, while the regular dependencies are compile-time sources of third-party code.

Depending Upon a JAR

Since early 2012, Ant and Eclipse shared a common rule for third-party JARs: put them in your project’s `libs/` directory, and both build environments would take it from there. Specifically, they would:

- Add those JARs to the compile-time classpath, so your code that references those JARs’ public APIs would compile, and

- Add the contents of those JARs to your APK, so at runtime, your references to those JARs' classes can be resolved

And it worked.

The new Gradle-based build system does not automatically use the contents of your `libs/` directory in the same way. That is why our `build.gradle` files that use simple local JARs will wind up with a `dependencies` closure that looks like this:

```
dependencies {  
    compile fileTree(dir: 'libs', include: '*.jar')  
}
```

The `fileTree()` will walk the directory tree rooted in the `dir` property (here, `libs`) and look for files matching the `include` wildcard pattern (here, `*.jar`). This will return all JAR files in `libs/`, which are then added to the `compile` process.

And, while we do not explicitly say to include those JARs in the resulting APK file, that is actually handled for us as part of android processing.

Note that this is configurable. So, if for some reason, you would prefer to have your JARs be in a directory other than `libs/`, such as `jars/` or `localDependencies/` or `whenMakingLongDirectoryNamesIsFun/`, you are welcome to do so.

...And Why Some Do Not Like This

However, using simple JARs this way is frowned upon, at least in the absence of better options.

One reason is that a JAR file does not necessarily contain any information about the *version* of that JAR file. JARs are frequently updated, and unless the author of the JAR is “mangling in” the version information into the filename, you cannot tell by looking at a JAR whether it is old or new.

For example, the classic Android Support package's JAR is `android-support-v4.jar`. Some developers see the `-v4` part and assume that this means that this specific JAR is version 4 of the library. In reality, `-v4` means that it contains primarily the classes from `android.support.v4` and is designed for use with apps looking to support back to API Level 4. However, this JAR is updated every couple of months with new classes and bug fixes. Hence, two files named `android-support-v4.jar` may have radically different contents, if one is from 2011 and one is from 2013, for example.

This is what causes the Ant/Eclipse build process to hiccup when it encounters multiple copies of the same JAR file (e.g., one in your project and one with the same name in an Android library project). Name alone cannot distinguish whether they are the same. The build tools wound up using MD5 hashes to try to determine if the contents were indeed identical, which works but is not an ideal solution.

Another reason why people frown upon bare JARs is that there is nothing to manage the dependencies of the JAR itself. Many times a JAR depends upon other JARs, but the JAR has no way of expressing that. Instead, developers are supposed to take care of that on their own, perhaps through reading documentation and following those instructions. And, since developers do not always read documentation or follow those instructions, manual dependency management is fraught with peril.

In classic Java development, “artifacts” and “repositories” were introduced to help provide some wrapper metadata around a JAR, to help developers find the right version and determine when updates are needed. Using artifacts and repositories is recommended with Gradle, and Gradle makes it comparatively easy to use these structures, as we will see [later in this chapter](#).

Depending Upon NDK Binaries

It is possible to use the NDK with Gradle for Android. However, this is complicated enough that it is relegated to [the chapter on advanced Gradle for Android techniques](#).

Depending Upon an Android Library Project

[Android library projects](#) have become popular ways of sharing code between projects, as they encompass resources in addition to Java code. Some developers will use Android library projects purely internally, for reusable code between projects. Some developers will depend upon third-party library projects, such as widget libraries or Google’s appcompat-v7 backport of the action bar pattern. Some developers will publish their own libraries for third-party use.

At their core, Android library projects do not change a lot when built with Gradle as opposed to being built with Ant or Eclipse. However, the way you tell Android that a project is a library project, and how you consume such library projects, has changed substantially.

Creating a Library Project

As noted in [the chapter on the Android library project](#), the primary difference between a regular Android project and an Android library project, in terms of Gradle configuration, is which plugin you use. Regular application projects will use the `com.android.application` plugin, while Android library projects use the `com.android.library` plugin:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.library'

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

Source sets will behave the same as they do for regular apps, and otherwise your code is no different than it would be for a regular app. However, as always, an Android library project is not designed to create an APK file, but rather to serve as a library.

However, Android library projects *can* have associated test code, which is covered in the chapter on [unit testing](#).

Depending Upon the Library Project

You have two major choices for depending upon a library project:

1. If the library project is yours, and particularly if it is only really to serve one app, you could set up the library project as a module or sub-project of the project containing that app, as we will see in [the next section](#).
2. You can [publish the library project to some repository as an AAR artifact](#), such as [a local repository](#), then [reference that AAR as a dependency](#). Coverage of artifacts and repositories appears [later in this chapter](#).

These are not mutually exclusive. The CWAC libraries published by the author of this book, for example, use *both* techniques. These projects are published as an Android library project plus one (or more) demo app(s) demonstrating the use of the library. In debug builds, the demo app(s) depend upon the library as a sub-project. In release builds, though, the demo app(s) depend upon a published AAR of the library, to better model what other developers would see. We will see how to have dependencies vary by build type [later in this chapter](#).

Depending Upon Sub-Projects

In classic Eclipse projects, we did not have the concept of a sub-project. However, Gradle and Android Studio both support a structure of a top-level directory (sometimes referred to as a “module”) containing a series of projects.

For example, the [Gradle/HelloMultiProject](#) directory contains:

- a HelloLibraryConsumer project
- a libraries/ subdirectory containing a HelloLibrary project

In this case, HelloLibrary is an Android library project, the one from which we saw the build.gradle file earlier in this chapter. HelloLibraryConsumer is a regular app that uses code found in the HelloLibrary Android library project.

If your library project is solely for use with one app, you might elect to structure your code using this approach.

The top-level directory must have a settings.gradle file, listing the Gradle projects found in the directory (and any of its subdirectories):

```
include ':HelloLibraryConsumer', ':libraries:HelloLibrary'
```

The leading : refers to the overall root directory, so :HelloLibraryConsumer is a reference to the HelloLibraryConsumer/ directory under the root. Other : values represent levels in the hierarchy, so :libraries:HelloLibrary refers to the libraries/HelloLibrary/ subdirectory. : is used instead of / as / is used by Gradle for other purposes.

Hence, the include statement tells Gradle that this aggregate project is made up of the two sub-projects.

To indicate that `HelloLibraryConsumer` wishes to consume code from the `HelloLibrary` library, another line is added to the dependencies closure, referencing the sub-project:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
    compile project(':libraries:HelloLibrary')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

Whereas `fileTree()` is finding the JARs in the `libs/` directory, `project(':libraries:HelloLibrary')` is identifying the sub-project, and we are telling Gradle to compile that sub-project into our project.

From the overall root directory (the one with the `settings.gradle` file), you can run gradle tasks for the overall app. This also works from the main app's directory (in this case, `HelloLibraryConsumer/`).

While this approach is fine for some applications, this structure will not work well if the library has multiple possible consuming apps, particularly if those apps might be by other authors. In that case, the library will need to be published as an artifact to a repository, which is covered in the next section.

Depending Upon Artifacts

While JARs and sub-projects are certainly possible using Gradle for Android, the predominant approach for specifying dependencies is by referencing artifacts hosted in repositories.

What Is an Artifact?

In the context of Java-based programming, an artifact usually refers to a JAR (or other compiled output, like a Java EE WAR), accompanied by metadata that provides version information, a roster of the artifact's own dependencies, and related information.

What Is a Repository?

A repository is a collection of artifacts, stored in some location, that can be referred to in order to find and resolve requests for dependencies.

Such repositories tend to be sub-divided into “local” and “remote”. A local repository is one that resides on your own development machine; a remote repository is one that resides on some server. That server could be *relatively* local (e.g., a repository in support of a corporate development team), or it could be somewhere else. Perhaps the best-known “somewhere else” is Maven Central, a repository used by many open source projects for distributing their artifacts.

Types of Artifacts and Repositories

There are two types of repositories, and associated artifact structures, supported by Gradle: Maven and Ivy. Each has their own format for the metadata and their own structure for how the files are stored.

Maven

[Apache Maven](#) is a full-fledged build system. Part of that build system is a system of artifacts and repositories. While Gradle does not use Maven's build system — rather, it largely replaces it — Gradle can consume artifacts published in a Maven-structured repository. Maven Central, as one might expect, is one such repository, but it is eminently possible to set up your own, and some organizations have done that.

As Maven seems to be the more popular of the two, this book will focus on Maven-structured repositories and Maven-style artifacts.

Ivy

[Apache Ivy](#) is an off-shoot of the Apache Ant project that gave us the Ant build system. Ivy is simply a way of declaring dependencies between components, including handling “transitive dependencies” (i.e., App A depends upon Library B, which in turn depends upon Libraries C and D).

General Artifact Dependency Setup

To depend upon artifacts, you need to teach Gradle two things:

1. Where can artifacts be found?
2. What artifact(s) do you need?

The former comes from a `repositories` closure in your `build.gradle` file, to specify the repositories that you wish to search for artifacts.

The latter comes from other variations on the `compile` statement in your `dependencies` closure. Rather than using `compile` with something like a `fileTree()`, you will specify the artifacts that you wish to use.

Artifacts are identified by three pieces of data:

1. A group
2. An artifact ID
3. A version number

These are separated by colons, so `compile` `'com.commonware.cwac:colormixer:0.5.0'` would indicate that you are seeking the artifact that:

- ...is in the `com.commonware.cwac` group...
- ...has the `colormixer` artifact ID, and...
- ...is version `0.5.0`

Depending Upon Maven Central Artifacts

The single most common place to get artifacts is [Maven Central](#). This is roughly analogous to the RubyGems repository for Ruby developers, or CPAN for Perl developers. Maven Central is a warehouse of many, many artifacts, only a subset of

which will be relevant for Android, as Maven Central has been used for many other Java environments (e.g., Java Web containers).

Your `build.gradle` file will need a `repositories` closure, at the top level (i.e., distinct from the one inside the `buildscript` closure), that requests `mavenCentral()`:

```
repositories {  
    mavenCentral()  
}
```

Then, you can have `compile` statements in your `dependencies` closure that list artifacts that can be found on Maven Central. One way to find out what you can include is to visit the [“Gradle, please” Web site](#), where you can type in the name of a popular library (e.g., `otto`) and get the corresponding `dependencies` closure:

```
dependencies {  
    compile 'com.squareup:otto:1.3.4'  
}
```

If you have several dependencies, list them in the one `dependencies` closure, one after the next. So, for example, to depend both upon `Otto` and local JARs, you would have:

```
dependencies {  
    compile 'com.squareup:otto:1.3.4'  
    compile fileTree(dir: 'libs', include: '*.jar')  
}
```

You may recall that an Android Studio project’s top-level `build.gradle` file contains something like:

```
allprojects {  
    repositories {  
        jcenter()  
    }  
}
```

The `allprojects` closure represents configuration that should be applied to all modules (sub-projects) in the project. Hence, the `repositories` defined here will be defined for all modules, above and beyond any `repositories` closure in the module’s own `build.gradle` file.

The `jcenter()` statement sets up Bintray’s JCenter, a competitor to Maven Central.

Depending Upon Googly Artifacts

However, not all artifacts are stored at Maven Central.

One important set of artifacts stored elsewhere are Google's. Rather than have you depend upon Maven Central, they offer their own repositories, ones that you can download to your development machine via the SDK Manager. They are called "Android repository" and "Google repository", where the former is the home for things like the Android Support package, and the latter is the home for things like the Play Services SDK.

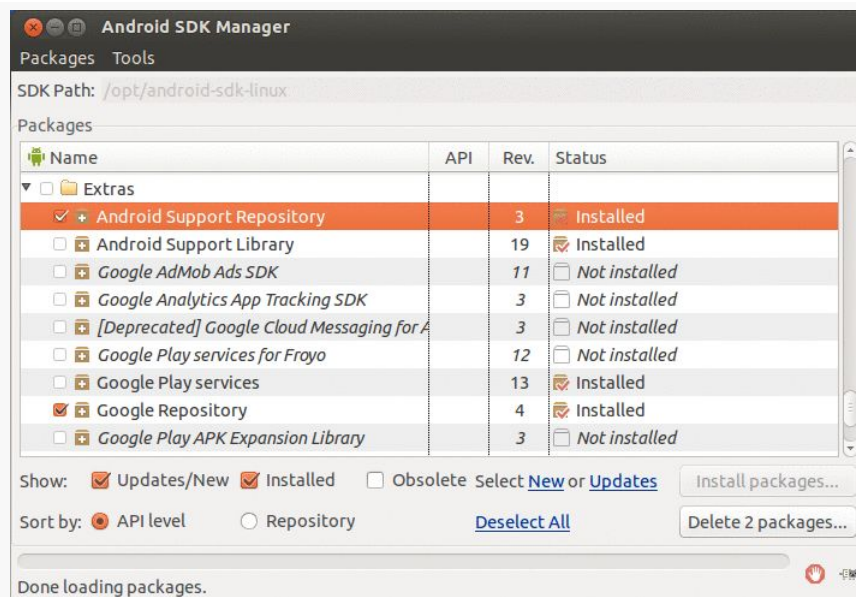

Figure 333: SDK Manager Showing Downloadable Repositories

These repositories, if found, are automatically added to your Gradle environment. So, unlike with Maven Central, you do not need to add them manually to a repositories closure.

If you read through the core chapters of this book, you learned about the support-v4 and support-v13 artifacts, providing classes like ViewPager and NotificationCompat. There are dozens of others combined between the Android Repository and Google Repository, many of which are covered elsewhere in this book.

By referencing these artifacts, you no longer need to mess around with copying JARs or attaching Android library projects to your own projects.

Depending Upon Other Artifact Repositories

Gradle supports custom artifact repositories, in Maven or Ivy style, for retrieval of artifacts. For example, your development team might have a common artifact repository for your projects, shared among the developers and a continuous integration server. Or, you may elect to publish your reusable components in your own repository, eschewing Maven Central.

The [Gradle documentation](#) covers the various possibilities, such as how to include authentication credentials for secured repositories. Typically, though, you will use a simple URL:

```
repositories {  
    maven {  
        url "http://repo.commonware.com"  
    }  
}
```

This `repositories` closure adds a Maven-style repository, located at `http://repo.commonware.com`.

```
repositories {  
    maven {  
        url "https://repo.commonware.com.s3.amazonaws.com"  
    }  
}
```

This is an equivalent `repositories` closure, but specifies `https` as the scheme, for secure downloads of the artifacts. Since this particular repository happens to be hosted at Amazon S3, the SSL certificate requires that we use the full Amazon S3 domain name (`repo.commonware.com.s3.amazonaws.com`) rather than the CNAME shorthand (`repo.commonware.com`).

From there, you can then request to compile against whatever artifacts the publisher of that repository makes available.

Your Very Own Repository

You may want to have your own local repository, just on your own development machine. For example, if you are writing an Android library project, and using sub-projects to reference it is inappropriate (e.g., the library is being used by several disparate apps), you can publish your AAR artifact to your local repository, then have your other apps depend upon that artifact as found in that repository.

Consuming artifacts from your local repository is just a matter of having a `mavenLocal()` entry in your `repositories` closure:

```
repositories {  
    mavenLocal()  
}
```

The precise location of this repository will be platform-dependent. On Linux, for example, it is in `~/.m2/`. However, it will be on your local machine.

NOTE: On some versions of Gradle, `mavenLocal()` does not work. The workaround is:

```
repositories {  
    maven { url "${System.env.HOME}/.m2/repository" } // mavenLocal()  
}
```

You can have your own hosted repository, if you wish. For example, the author of this book is slowly converting his CWAC projects over to be available as JAR and AAR artifacts from the `repo.commonware.com` repository mentioned above. From Gradle's (and Maven's) standpoint, there is no real difference between a repository hosted on a nearby file server or some remote Web server. A discussion of how to get your artifacts to such a repository is outside the scope of this book.

Publishing Libraries as Artifacts

Of course, having a local (or remote) repository is only as good as is your ability to put things into that repository. And, right now, that is a place where the current Gradle for Android plugin falls down. The documentation mentions the AAR format but offers no instructions related to publishing it, and changes in the plugin have broken many cobbled-together solutions from 2013.

The current simplest solution comes in the form of the `maven` plugin, which, as the name suggests, is a plugin for Gradle that adds support for the publishing of Maven artifacts from Gradle builds.

As this is a standard Gradle plugin, all you need to do is have `apply plugin: 'maven'` in your `build.gradle` file to use it.

Then, you can configure where and how the Maven plugin should publish your AAR, via an `uploadArchives` closure, as a top-level closure (i.e., a peer of your `android` closure):

```
apply plugin: 'maven'

uploadArchives {
    repositories.mavenDeployer {
        pom.groupId = 'com.commonware.cwac'
        pom.artifactId = 'everything-is-awesome'
        pom.version = '0.0.1'

        repository(url: 'file:///home/somebody/put/a/real/path/in/here/kthxbye')
    }
}
```

The `groupId` and `artifactId` form the basis of the name of your artifact (in this case, a fictitious `com.commonware.cwac:everything-is-awesome` library). The version, of course, is the version of the artifact. The `url` parameter on the `repository` call indicates where the artifact should be uploaded to, and this can point to a public repository (e.g., Maven Central), a private enterprise hosted repository, a local repository (as is the case here), etc.

At this point, the `gradle uploadArchives` command will build your AAR and deploy it to your designated Maven repository.

Publishing Legacy-Structured Libraries as Artifacts

Note that there is no particular requirement that your AARs be created from Android projects that use the new build system's preferred directory structure. Your AARs can come from a project that retains the legacy directory structure. This is key for the next few years, while AAR support slowly becomes dominant, so that you can support your Android library project being used in traditional source form as well.

We will see examples of using legacy structures for AAR-creating library projects [later in this chapter](#).

About Artifact Updates

The version of the artifact that you get is determined by the version qualified in your stated dependency. There does not appear to be anything in Gradle itself to tell you about cases where there are artifacts with upgraded versions available to you. Ben Manes has published [a Gradle plugin](#) that adds a `dependencyUpdates` task that generates a report of what the status is of all of your dependencies.

Creating Android JARs from Gradle

Gradle has a long history of being used in Java development, and the standard java plugin for Gradle knows how to create JAR files.

However, we are not using the java plugin. Instead, we are using the android or android-library plugin. In the latter case, you could argue that it should support JAR-creation tasks, for libraries that do not actually use resources and so forth. Unfortunately, it does not, at least as of the time of this writing. Hence, there is no JAR-creation task available from android or android-library projects.

As is common in these cases, Jake Wharton has come to the rescue.

Jake posted [an answer on a Stack Overflow question](#) providing a quick-and-dirty bit of Gradle code to add JAR-creation tasks to an android-library project:

```
android.libraryVariants.all { variant ->
    def name = variant.buildType.name
    if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {
        return; // Skip debug builds.
    }
    def task = project.tasks.create "jar${name.capitalize()}", Jar
    task.dependsOn variant.javaCompile
    task.from variant.javaCompile.destinationDir
}
```

The Gradle DSL in Groovy primarily involves building up data structures. Hence, all of our build variants wind up in a collection of objects available at `android.libraryVariants`. Jake's snippet iterates over those, tosses out those that are for debug builds, and *dynamically defines a new task*. That new task will be named `jar...`, where the `...` is the name of the build type. His snippet then configures that task to create a JAR file, after the Java code has been compiled, putting the result in the destination directory for Java compilation.

The net result is that including this snippet at the bottom of your `build.gradle` file will add tasks like `jarRelease` that will create a JAR in `build/libs/` of your project. Note that the `jarRelease` task does not appear when you run `gradle tasks`, though it will appear if you run `gradle tasks --all` to get the complete list.

This does not create a full artifact around the JAR, so if your plan was to submit this JAR to an artifact repository, you would have additional work to do. However, for the simple case of creating a JAR for manual distribution (e.g., through the “releases” area of a GitHub repository), it should work fine.

A Property of Transitive (Dependencies)

One thing to watch out for when specifying dependencies is where your dependencies' dependencies come from. Short of examining configuration files for those dependencies (e.g., their Maven POM file), you have no good way to know what your dependencies' dependencies are, let alone where they are supposed to come from.

Despite that, [according to Gradleware](#):

Only the repository declarations for the project whose configuration is currently resolved are taken into account, even when transitive dependencies are involved.

So, for example, suppose App A depends upon Library B, which in turn depends upon Library C. Library B is in your team's own Maven repository, while Library C comes from Maven Central. App A will need to have *both* your own Maven repository *and* Maven Central defined in the repositories closure, in order for Gradle to be able to obtain both libraries.

Dependencies By Build Type

A build type can have its own dependencies.

The `compile` statement in a dependencies closure defines dependencies for all build types. However, each build type has its own version of the `compile` statement, like `debugCompile`, that will add a dependency for use solely by that build type.

If you create your own custom build types, note that you will need to have your dependencies closure *after* you define the build type in the `build.gradle` file. Only after Gradle has defined your build type will your custom `compile` statement be available.

There is also `androidTestCompile`, which defines dependencies solely for use with testing. This is covered in greater detail [in the chapter on unit testing](#).

Dependencies By Flavor

Similarly, if you define product flavors, you can have dependencies that are tied only to a particular flavor.

For example, suppose you were writing an app for various wearables, and you set up three product flavors:

```
productFlavors {
    standard {
        applicationId "com.commonware.android.wearable.qr"
    }

    imwatch {
        applicationId "com.commonware.android.wearable.qr.imwatch"
    }

    sony {
        applicationId "com.commonware.android.wearable.qr.sony"
    }
}
```

A dependencies closure *after* the android closure containing the above productFlavors configuration could have a mix of per-flavor dependencies and flavor-specific dependencies, such as:

```
dependencies {
    compile 'com.android.support:support-v4:19.0.1'
    compile 'com.google.code.gson:gson:2.2.4'
    compile 'com.squareup.okhttp:okhttp:1.3.0'
    compile 'com.squareup.retrofit:retrofit:1.4.0'
    compile 'com.squareup.picasso:picasso:2.2.0'
    sonyCompile 'com.sonyericsson.extras.liveware.aef:SmartExtensionUtils:2.1.0'
}
```

Here, the last dependency uses `sonyCompile`, rather than `compile`, indicating that it is a dependency to be used only for the sony product flavor.

Note that the artifact listed for the `sonyCompile` directive does not actually exist, at least as of the time of this writing. It is possible to convert SONY's code samples into local artifacts, for reference via `mavenLocal()`, until such time as SONY starts hosting them on Maven Central or their own artifact repository.

Examining Some CWAC Builds

The author of this book publishes several open source libraries, known as the CommonsWare Android Components (CWAC). These pose an interesting challenge for conversion to Gradle, insofar as the libraries have many existing users, some of whom are still using Eclipse, Ant, or other tools based on the legacy project structure. Hence, these projects need to be able to be built sans Gradle, yet still be able to publish artifacts that can be used by Gradle.

In this section, we will examine a few of these projects, to see how the Gradle support was implemented, with a particular eye on dependencies.

A Simple CWAC Project: `cwac-layouts`

Most of the CWAC projects are fairly simple. Beyond having relatively few classes, most CWAC projects have no dependencies beyond Android itself. These are fairly straightforward to support with Gradle, both for building the library itself and for publishing a Gradle-compatible artifact.

For example, [the CWAC-Layouts project](#) is discussed in [the chapter on custom Views](#), as it offers a few such views, particularly the mirroring classes.

The CWAC-Layouts repository has two projects: `layouts` and `demo`. The `layouts` project is the one for the library itself, while `demo` demonstrates the use of the library.

When built using Eclipse, Ant, or related tools, `layouts` is an Android library project, which `demo` depends upon via its `project.properties` file:

```
# This file is automatically generated by Android Tools.
# Do not modify this file -- YOUR CHANGES WILL BE ERASED!
#
# This file must be checked in Version Control Systems.
#
# To customize properties used by the Ant build system edit
# "ant.properties", and override values to adapt the script to your
# project structure.
#
# To enable ProGuard to shrink and obfuscate your code, uncomment this
# (available properties: sdk.dir, user.home):
#proguard.config=${sdk.dir}/tools/proguard/
#proguard-android.txt:proguard-project.txt
# Project target.
```

```
target=android-17
android.library.reference.1=../layouts
```

For the Gradle build, demo and layouts turn into modules, courtesy of settings.gradle in the project root directory:

```
include ':layouts', ':demo'
```

The demo module depends upon the layouts module, as it does with Eclipse/Ant builds. However, it does so in one of two ways:

- if this is a debug build, it depends on the layouts module, so the demo app can use the under-development version of that module
- if this is a release build, it depends upon the AAR artifact in the CommonsWare artifact repository

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://repo.commonware.com.s3.amazonaws.com"
    }
}

dependencies {
    debugCompile project(':layouts')
    releaseCompile 'com.commonware.cwac:layouts:0.4.+'
}

android {
    compileSdkVersion 17
    buildToolsVersion "19.1.0"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
    }
}
```

In all other respects, the demo project's `build.gradle` file is a conventional “please use the legacy project structure” implementation.

The library's `build.gradle` file is a bit more involved:

```
apply plugin: 'com.android.library'

android {
    compileSdkVersion 17
    buildToolsVersion "19.1.0"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
    }
}

// from http://stackoverflow.com/a/19484146/115145

android.libraryVariants.all { variant ->
    def name = variant.buildType.name
    if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {
        return; // Skip debug builds.
    }
    def task = project.tasks.create "jar${name.capitalize()}", Jar
    task.dependsOn variant.javaCompile
    task.from variant.javaCompile.destinationDir
    task.baseName = "cwac-${PUBLISH_ARTIFACT_ID}"
    task.version = PUBLISH_VERSION
    task.exclude('com/commonsware/cwac/**/BuildConfig.**')
}

apply plugin: 'maven'

uploadArchives {
    repositories.mavenDeployer {
        pom.groupId = PUBLISH_GROUP_ID
        pom.artifactId = PUBLISH_ARTIFACT_ID
        pom.version = PUBLISH_VERSION

        repository(url: LOCAL_REPO)
    }
}
```

It uses the maven plugin to enable the `uploadArchives` task, as mentioned [earlier in this chapter](#). That will compile the library project into an AAR and publish it to the development machine's local CWAC Maven repository. Separately, the author has a script that will push the necessary files to the Amazon S3-hosted CommonsWare Maven repository.

The constants referred to in the `repositories.mavenDeployer` closure come from a `gradle.properties` file, which will be covered [in an upcoming chapter](#).

The library's `build.gradle` file also contains the custom Gradle code that adds a `jarRelease` task, as described [earlier in this chapter](#). This task also uses values like `PUBLISH_VERSION` and `PUBLISH_ARTIFACT_ID` from the `gradle.properties` file. Hence, when the author wishes to push a new version of the library, the steps are:

1. Modify the `PUBLISH_VERSION` in the `gradle.properties` file
2. Run `gradle uploadArchives` to generate the AAR and publish it locally
3. Use an external mechanism to publish the AAR to the CommonsWare repo
4. Run `gradle jarRelease` to generate the JAR version of the project
5. Publish that JAR via the GitHub "releases" portion of the GitHub repository

CWAC-Upon-CWAC: cwac-presentation

One CWAC project that has a dependency is [the CWAC-Presentation project](#). This is discussed in [the chapter on Presentation and external display support](#), offering the `PresentationHelper` and related classes to ease the creation of apps that support external displays.

Some of those related classes use the CWAC-Layouts mirroring classes. For example, `MirrorPresentationFragment` is designed to display a mirror of a part of the primary display on an external display, such as mirroring only the slides, with the primary display also having controls for the slide presenter. Hence, CWAC-Presentation depends upon CWAC-Layouts, and that needs to be taken into account in the project build files.

As with CWAC-Layouts, the CWAC-Presentation repository has the library (presentation) and a demo project (demo). It also has a separate `demoService` project, which is set up to demonstrate another portion of the library. And, as before, for the purposes of an Ant/Eclipse build, the demo and `demoService` projects each have a `project.properties` file that adds a dependency upon the presentation library project:

GRADLE AND DEPENDENCIES

```
# This file is automatically generated by Android Tools.
# Do not modify this file -- YOUR CHANGES WILL BE ERASED!
#
# This file must be checked in Version Control Systems.
#
# To customize properties used by the Ant build system edit
# "ant.properties", and override values to adapt the script to your
# project structure.
#
# To enable ProGuard to shrink and obfuscate your code, uncomment this
# (available properties: sdk.dir, user.home):
#proguard.config=${sdk.dir}/tools/proguard/
#proguard-android.txt:proguard-project.txt
# Project target.
target=android-17
android.library.reference.1=../presentation
```

And, other than switching the dependency to be on presentation rather than layouts, the build.gradle file of the demo and demoService projects are the same as the one for the CWAC-Layouts:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}

dependencies {
    debugCompile project(':presentation')
    releaseCompile 'com.commonsware.cwac:presentation:0.4.+
}

android {
    compileSdkVersion 17
    buildToolsVersion "19.1.0"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
```

```
}  
}
```

The library's `build.gradle` file is the same as the one for the CWAC-Layouts library, with two exceptions:

1. It contains a `repositories` closure, supplying the URL to the CommonsWare Maven repository
2. It adds a dependency on the CWAC-Layouts library in its `dependencies` closure

```
repositories {  
    maven {  
        url "https://repo.commonware.com.s3.amazonaws.com"  
    }  
}  
  
dependencies {  
    compile 'com.commonware.cwac:layouts:0.4.+'  
}
```

The resulting AAR will have, in its Maven POM metadata file, a dependency upon CWAC-Layouts. Hence, when we build the demo project, it will download both the presentation AAR and the layouts AAR, to fulfill all its dependencies.

Manifest Merger Rules

When Android library projects were added as an option for app development, one problem became apparent: while libraries could contribute code and resources, they could not contribute manifest entries. Developers using libraries would sometimes have to add elements to their app manifest at the request of library authors, to add permissions, define components, and the like.

Eclipse gained some limited amount of ability to merge things from a library's manifest into a hosting app's manifest somewhere along the line, but it was all undocumented.

Gradle for Android, as of 0.10, has a much more robust and well-defined set of rules for “manifest merger”. While the term “manifest merger” is still used, in reality, Gradle for Android synthesizes a manifest for your app from a variety of sources, including apps, libraries, and `build.gradle` files, also varying based upon build types and product flavors.

This chapter will help to explain a bit more about what is possible what the rules are for the manifest merger process.

Prerequisites

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including [the new project structure](#) and [Gradle dependencies](#).

The discussion of placeholders uses [Google Cloud Messaging](#) as an example.

Manifest Scenarios

You might be wondering “why do we need all of this?” That is a fair question. Certainly, we were able to get by for quite a while without this sort of flexibility and accompanying confusion.

Here are some scenarios which help explain what you will get out of the manifest merger capabilities.

Library Manifest and App Manifest

A library — whether one of yours or one obtained via an AAR artifact from some repository — may need to augment the app’s manifest. For example:

- a library for an ad network might require the `INTERNET` permission, so that apps that do not directly use the Internet still wind up requesting that permission
- a library providing a canned “about” activity might want to inject the `<activity>` element that you can use without requiring the developer to add it manually
- a library needs to be able to specify the `minSdkVersion` that it requires, which might supersede the value specified by the app, so the combined whole uses the most conservative value

App Manifest and Build Types

You may have particular needs for your main application that vary based upon build type that affect the manifest versus other things (e.g., ProGuard configuration).

For example, it may be that in debug builds, you want to have an activity that you can bring up, perhaps through `adb shell am`, that will give you diagnostic information about the app itself, or starts some diagnostic service that you can then access through your development machine’s Web browser. In this case, that activity and that service would only be desired in debug builds, not release builds. And while the activity and the service code would simply be in the debug sourceset, you also need to merge in the manifest `<activity>` and `<service>` elements, plus perhaps other things (e.g., extra `<uses-permission>` elements that those diagnostic components need but the rest of the app does not).

App Manifest and Product Flavors

Product flavors can override values from the `defaultConfig`, such as defining distinct `applicationId` values, and that needs to be taken into account in the combined app.

Also, product flavors might need their own manifest entries to accommodate distribution channel-specific APIs, such as swapping between Play Services and Amazon equivalents for in-app purchasing or maps.

Combo Platters

And, of course, you may have some mix of all of the above.

Pieces of Manifest Generation

When you build your app, the build tools will combine information from all of the aforementioned sources to synthesize “one true manifest” that is used for the build.

However, there may be overlaps in what the sources provide, such as both a library and the app specifying a `minSdkVersion`. Hence, there are some basic rules and control structures that you have to manage the generation process, at least somewhat.

Merger Rules

Generally speaking:

- the manifests and Gradle configurations for product flavors and build types will override...
- the app’s `main/` manifest, which will override...
- the manifest of any libraries

Libraries will be considered in the order of declaration — in other words, the order that they appear in the `dependencies` closure. This includes transitive dependencies, where one dependency requires another dependency, though the exact rules here are presently unclear.

For any given element or attribute, there are specific rules for how conflicts are resolved. We will explore those later in this chapter.

Note that values in `build.gradle`, such as the `defaultConfig` closure and its `minSdkVersion` and such, trump everything that result from the merger of disparate manifests from different sources.

Markers and Selectors

Through `tools:` attributes in the manifests that you control (i.e., not manifests from third-party libraries), you will be able to override the default rules for conflict resolution.

For example, a library might declare a particular theme to use for an activity that it publishes. That might be a reasonable default theme, but you may wish to override that theme in your app. A `tools:replace` attribute, in your `<activity>` element, will be able to teach the build tools that your `android:theme` value should replace the one from the library, whereas normally a conflict on an attribute like this would result in a build error.

You can also use “selectors” to help control in which scenarios a particular marker is applied, such as applying a marker only for a conflict arising from a specific library.

These markers and selectors will be explored in greater detail later in this chapter.

Placeholders

Sometimes, the “merger” we want to do involves something more involved.

For example, the `applicationId` and `applicationIdSuffix` properties that we set in various places in `build.gradle` can be used to allow for different variants of our builds to be installed at the same time on the same device. However, that is only true some of the time. If an app publishes a `ContentProvider`, not only does the application ID have to be unique, but so does the authority (or authorities) supported by that `ContentProvider`. This is not handled automatically, and so even though you might have the application ID distinct for different build variants, they still would conflict at install time because their provider authorities were the same.

The manifest generation process supports the notion of placeholders, where for string values in the manifest — like the `android:authorities` attribute on a `<provider>` — you can “splice in” dynamic values. One dynamic value that you can use “out of the box” is your build variant’s `applicationId`, so you can have something like:

```
android:authorities="${applicationId}.provider"
```

to have the authority for the provider match the build variant's application, but with a `.provider` suffix.

We will explore the rules around these placeholders later in this chapter.

Examining the Merger Results

The generated manifest, combining the contents of all the manifests from the app, build types, product flavors, and libraries, will wind up in the `build/intermediates/manifests/` directory of your module (e.g., `app/`). Inside that directory will be subdirectories associated with each build variant, and in those subdirectories reside the generated manifest for that build variant.

The [Manifest/Merger](#) sample application is designed to illustrate how these merger rules work. Note that the application does not run — it exists merely to show the results of building the APK and, along the way, generating the manifests.

This project contains an app module (`app/`) and a library module (`lib/`), with the app depending upon the library. The app module has sourcesets for both `main/` and `debug/`, the latter for debug builds. The app module also defines two product flavors, `chocolate` and `vanilla`, with a sourceset for `vanilla/`. All three sourcesets (`main/`, `debug/`, `vanilla/`) have their own `AndroidManifest.xml` files. Adding in the manifest from the library, and you have four manifests in total that may be used to create the manifest for the app. In particular, for a `vanilla debug` build, all four manifests will be relevant and merged together.

If you build the project, particularly via the `gradle` command, you will get manifests based on what builds you create. For example, `gradle assembleVanillaDebug` will create a generated manifest in `build/intermediates/manifests/vanilla/debug/`.

As you are trying to determine how manifest merging is working in your project, you may find it useful to peek at these generated manifests from time to time... as we will here in this chapter.

Merging Elements and Attributes

Different sources of manifest data can contribute elements to the generated combined manifest. In many cases, these elements do not conflict, such as a library contributing a `<uses-permission>` element to an app. However, sometimes, what one source of manifest data wants is different than what another source of manifest data wants, and for that, we need to settle out what the generated manifest will contain.

Basic Merger Rules

Many element names can appear several times in a manifest, such as multiple `<uses-permission>` elements. Many of those have an identifier, usually `android:name`, that distinguishes one from the next. In general, if two manifest sources both contribute the same element (i.e., same element name, same `android:name` value), those two elements are themselves merged, which means:

- Any attributes that are in one, but not the other, are added to the combined element
- Any attributes that are in both, and are not identical in value, result in a merge conflict compile error, unless the resolution is specified via a [marker](#)
- All child elements (e.g., `<intent-filter>` inside of an `<activity>`) are merged, applying the same rules

Of course, if one manifest supplies a specific element instance, and others do not, then the specific element instance is simply included without worrying about any other merge logic.

Singleton elements — ones that could only ever appear once in the manifest — are treated as matching if they exist in more than one manifest. So, for example, the `android:versionCode` and `android:versionName` attributes of the `<manifest>` element are merged, as are attributes of `<support-screens>`, each of which can only exist once.

Example #1: Manifest Attributes

The main/ version of the manifest defines an `android:versionName` attribute:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.merger"
  android:versionName="1.0 Main">
```

MANIFEST MERGER RULES

```
// other stuff here  
</manifest>
```

None of the other manifest versions do. Hence, the main/ version of the manifest “wins”, and its `android:versionName` is used (only to perhaps be overridden by `build.gradle` values):

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"  
  package="com.commonware.android.merger.vanilla"  
  android:versionCode="1"  
  android:versionName="1.0 Main" >  
  
  // other stuff here  
</manifest>
```

Here, we are showing the results of building the vanilla debug version of the app, so the package name reflects the `applicationId` defined in `build.gradle` for the vanilla product flavor:

```
productFlavors {  
  vanilla {  
    applicationId "com.commonware.android.merger.vanilla"  
  }  
  
  chocolate {  
    applicationId "com.commonware.android.merger.chocolate"  
  }  
}
```

Similarly, the `versionCode` shows up because it is defined in `build.gradle`:

```
defaultConfig {  
  applicationId "com.commonware.android.merger"  
  minSdkVersion 15  
  targetSdkVersion 19  
  versionCode 1  
}
```

However, since `build.gradle` did not specify `versionName`, the version name comes from the manifests.

If another manifest also defined `android:versionName`, its value would need to match that of the one in `main/`, or you will get a build error from Gradle for Android... unless you use a marker, described later in this chapter.

Example #2: Additional Permissions

The debug/ version of the manifest has a `<uses-permission>` element:

```
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

So does the vanilla/ version, though its has `android:maxSdkVersion` set to 18:

```
<uses-permission  
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"  
  android:maxSdkVersion="18" />
```

The manifest you get from a vanilla debug build has the `android:maxSdkVersion` attribute:

```
<uses-permission  
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"  
  android:maxSdkVersion="18" />
```

Example #3: Additional Components

The lib/ version of the manifest has an `<activity>`:

```
<activity android:name="ThisActivityDoesNotExist">  
  <intent-filter>  
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />  
    <category android:name="android.intent.category.DEFAULT" />  
  </intent-filter>  
</activity>
```

This is contributed by the library (or would be, if there actually was source code for the activity...). Neither the main/ nor the debug/ sourceset defines it, and so it is included verbatim in the result for chocolate builds:

```
<activity  
  android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist" >  
  <intent-filter>  
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />  
  
    <category android:name="android.intent.category.DEFAULT" />  
  </intent-filter>  
</activity>
```

Note that since the `android:name` attribute had a bare class name, the generated manifest expands that to include the *library's* package name (`com.commonware.android.merger.lib`).

Example #4: Intent Filter

However, the vanilla/ manifest also defines the same activity, this time with another `<intent-filter>`:

```
<activity
android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist">
  <intent-filter>
    <action android:name="com.commonware.android.merger.SOMETHING_VANILLA" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Note that here, we need to have the fully-qualified class name, as we are trying to affect the library-supplied activity.

In a vanilla build, *both* `<intent-filter>` elements will be included by default:

```
<activity
android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist" >
  <intent-filter>
    <action android:name="com.commonware.android.merger.SOMETHING_VANILLA" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

This allows an app developer to add new ways of accessing an activity (or other component) exposed by a library.

Some Unusual Scenarios

Not everything fits the neat-and-tidy rules from the above sections and require special explanation.

uses-sdk

The `android:minSdkVersion` and `android:targetSdkVersion` from the highest-priority manifest will be used. If, however, a library's manifest specifies higher values for either of these, you will get a build error.

Hence, it is incumbent upon library authors to correctly assess how old a version of Android they are able to support, setting `android:minSdkVersion` as low as possible.

Conversely, library authors should aim to support either old or new behavior that is controlled by `android:targetSdkVersion`. For example, a library that uses `AsyncTask` should not assume that the `android:targetSdkVersion` is below 13 and therefore `execute()` will result in multi-threaded behavior on Android 3.2+. Instead, the library should use `executeOnExecutor()` on API Level 11+ devices, to specifically opt into the multi-thread thread pool, as this avoids any behavior changes based upon `android:targetSdkVersion`.

uses-feature and uses-library

The `android:required` attribute is logically OR'd among all contributors of a `<uses-feature>` element for a specific `android:name` value. In other words, if any contributor says that the feature is required, it is required. Otherwise, if one or more contributors ask for the `<uses-feature>` element but say that it is not required, it is put in the combined manifest with `android:required="false"`.

The under-utilized `<uses-library>` uses the same rule for handling the merger of its `android:required` attribute.

Markers and Selectors

Sometimes, the default merger rules will not work to your satisfaction. In particular, when there are conflicts, the build will fail, and probably that is not a desired outcome.

To declare who wins in the case of conflicts, you can use `tools:*` attributes in the manifest elements. Specifically:

- `tools:node` indicates how to resolve a conflict between two editions of this particular XML element (e.g., an `<activity>` for the same `android:name`)
- `tools:replace` indicates that certain attributes from a lower-priority edition of the manifest should be overwritten by their replacement values from a higher-priority edition of the manifest
- `tools:remove` indicates that certain attributes from a lower-priority edition of the manifest should be removed entirely

Each of these, being in the `tools` namespace, will require you to have `xmlns:tools="http://schemas.android.com/tools"` on the root `<manifest>`

MANIFEST MERGER RULES

element, if it is not there already. These attributes only affect the build tools and have no runtime implications, other than in terms of how the build tools build your app based on the tools attributes.

For example, the main manifest has
android:uiOptions="splitActionBarWhenNarrow" on the <application> element:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:uiOptions="splitActionBarWhenNarrow">

  // other stuff here

</application>
```

The vanilla manifest wants to override this, replacing the value with none, so that the split action bar is not applied to the whole app. However, if the vanilla manifest just had android:uiOptions="none" in its <application> element, the build would fail, as that value conflicts with the one in the main manifest. Hence, the vanilla manifest also needs to indicate that its android:uiOptions value should replace the original one, via a tools:replace attribute:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:uiOptions="none"
  tools:replace="android:uiOptions">

  // other stuff here

</application>
```

In the output, android:uiOptions="none" wins:

```
<application
  android:allowBackup="true"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  android:uiOptions="none" >

  // other stuff here

</application>
```

Both `tools:replace` and `tools:remove` take a comma-delimited list of attributes that should be affected by that rule.

The `tools:node` attribute affects the entire XML element in which it resides. There are five primary values for `tools:node`:

1. `merge`, which is the default behavior described by the merger rules earlier in this chapter
2. `replace` says that the lower-priority manifest's version of this element should be replaced in its entirety with the higher-priority manifest's version of this element
3. `merge-only-attributes` says that the lower-priority manifest's version of this element should have its attributes replaced by the ones from the higher-priority manifest's version of this element, but child elements (e.g., an `<intent-filter>` underneath the annotated `<activity>` element) are left alone
4. `remove` says that the lower-priority manifest's version of this element should be removed without any replacement
5. `removeAll` says that all elements of this name (e.g., `<uses-permission>`) from lower-priority manifests should be removed, regardless of scopes like `android:name`

There is also a `strict` value that indicates that any duplication, even if it could be successfully merged, should result in a build failure. Most likely, this would be used sparingly.

By default, these `tools` attributes affect all manifests. However, it could be that you only want to affect a specific manifest, such as one coming from a certain library. In that case, `tools:selector`, in the same XML element as the other `tools:*` attributes, provides the package name of the library that the other `tools:*` attributes affect.

Employing Placeholders

The [Google Cloud Messaging](#) (GCM) system has some unusual requirements for the manifest of apps that use GCM:

- The app needs to define a custom permission, based on the application ID, via a `<permission>`

MANIFEST MERGER RULES

- The app needs to hold that custom permission, via a `<uses-permission>` element
- The app needs to have a `BroadcastReceiver` whose `<intent-filter>` has a `<category>` whose name is the application ID

Hence, in a GCM client app's manifest, there are three places where the application ID needs to appear. This needs to be the app's actual application ID, as may be defined either via manifests or via `applicationId` or `applicationIdSuffix` statements in a `build.gradle` file. Since the application ID can be overridden by those Gradle statements, we cannot just hard-code the application ID into the spots in the manifest.

Fortunately, part of what we get with manifest generation are placeholders.

Placeholders allow us to inject values from `build.gradle` into the manifest, particularly in XML attribute values. An `applicationId` placeholder is available automatically, and we can define custom ones via a `manifestPlaceholders` map.

For example, the main manifest for the sample project uses the `applicationId` placeholder in the requisite locations:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.merger"
    android:versionName="1.0 Main">

    <permission android:name="${applicationId}.C2D_MESSAGE"
        android:protectionLevel="signature" />
    <uses-permission android:name="${applicationId}.C2D_MESSAGE" />

    <application android:allowBackup="true"
        android:label="@string/app_name"
        android:icon="@drawable/ic_launcher"
        android:theme="@style/AppTheme"
        android:uiOptions="splitActionBarWhenNarrow">
        <receiver
            android:name=".GcmBroadcastReceiver"
            android:permission="com.google.android.c2dm.permission.SEND" >
            <intent-filter>
                <action android:name="com.google.android.c2dm.intent.RECEIVE" />
                <category android:name="${applicationId}" />
            </intent-filter>
        </receiver>
    </application>

</manifest>
```

MANIFEST MERGER RULES

The vanilla debug version of the generated manifest replaces those `${applicationId}` placeholders with the actual `applicationId`, such as the following for a vanilla build:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.merger.vanilla"
    android:versionCode="1"
    android:versionName="1.0 Main" >

    <uses-sdk
        android:minSdkVersion="15"
        android:targetSdkVersion="19" />

    <uses-permission
        android:name="android.permission.WRITE_EXTERNAL_STORAGE"
        android:maxSdkVersion="18" />

    <permission
        android:name="com.commonware.android.merger.vanilla.C2D_MESSAGE"
        android:protectionLevel="signature" />

    <uses-permission
        android:name="com.commonware.android.merger.vanilla.C2D_MESSAGE" />

    <application
        android:allowBackup="true"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/AppTheme"
        android:uiOptions="none" >
        <activity
            android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist" >
            <intent-filter>
                <action android:name="com.commonware.android.merger.SOMETHING_VANILLA"
            />

                <category android:name="android.intent.category.DEFAULT" />
            </intent-filter>
            <intent-filter>
                <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL"
            />

                <category android:name="android.intent.category.DEFAULT" />
            </intent-filter>
        </activity>

        <receiver
            android:name="com.commonware.android.merger.GcmBroadcastReceiver"
            android:permission="com.google.android.c2dm.permission.SEND" >
            <intent-filter>
                <action android:name="com.google.android.c2dm.intent.RECEIVE" />
```

MANIFEST MERGER RULES

```
<category android:name="com.commonware.android.merger.vanilla" />
</intent-filter>
</receiver>
</application>
</manifest>
```

Note that the entire XML attribute value does not have to be a placeholder. For example, the `android:name` values for the `<permission>` and `<uses-permission>` elements blend the `applicationId` in with a fixed string:
`android:name="${applicationId}.C2D_MESSAGE".`

If you want additional placeholders, you can define a `manifestPlaceholders` map in `defaultConfig` or in a product flavor:

```
android {
    defaultConfig {
        manifestPlaceholders = [ foo: "bar" ]
    }

    productFlavors {
        vanilla {
        }

        chocolate {
            manifestPlaceholders = [ foo: "baz" ]
        }
    }
}
```

Then, you can refer to any of your custom placeholders via the same `${}` syntax (e.g., `${foo}`), with the proper value being applied during manifest generation.

Signing Your App

Perhaps the most important step in preparing your application for production distribution is signing it with a production signing key. While mistakes here may not be immediately apparent, they can have significant long-term impacts, particularly when it comes time for you to distribute an update.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Role of Code Signing

There are many reasons why Android wants you to sign your application with a production key. Here are perhaps the top three:

- It will help distinguish your production applications from debug versions of the same applications
- Multiple applications signed with the same key can access each other's private files, if they are set up to use a shared user ID in their manifests
- You can only update an application if it has a signature from the same digital certificate

The latter one is the most important for you, if you plan on offering updates of your application. If you sign version 1.0 of your application with one key, and you sign version 2.0 of your application with another key, version 2.0 will not install over top version 1.0 — it will fail with a certificate-match error.

What Happens In Debug Mode

Of course, you may be wondering how you got this far in life without worrying about keys and certificates and signatures (unless you are using Google Maps, in which case you experienced a bit of this when you got your API key).

The Android build process creates a debug key for you automatically. That key is automatically applied when you create a debug version of your application (e.g., running the app in your IDE). This all happens behind the scenes, so it is very possible for you to go through weeks and months of development and not encounter this problem.

In fact, the most likely place where you might encounter this problem is in a distributed development environment, such as an open source project. There, you might have encountered the third bullet above, where a debug application compiled by one team member cannot install over the debug application from another team member, since they do not share a common debug key. You may have run into similar problems just on your own if you use multiple development machines (e.g., a desktop in the home office and a notebook for when you are on the road delivering Android developer training).

Finding Your Debug Keystore

The debug keystore is a `debug.keystore` file in your Android SDK data directory. This directory is not where your SDK is installed, but rather is where the tools store data unique to your account on your developer machine, such as your emulator AVDs.

This directory can be found at:

- `~/.android/` on OS X and Linux
- `C:\Documents and Settings\...\android\` on Windows XP
- `C:\Users\...\android\` on Windows environments newer than XP

(where ... is your Windows username)

Synchronizing Your Debug Signing Key

If you have a development team that, for better coordination, should all use the same `debug.keystore`, just pick one and copy it to all team members' development

machines, replacing their generated ones. The `debug.keystore` file is a binary file and should be transferrable between operating systems (e.g., from Linux to Windows).

Production Signing Keys

Beyond the debug keystore, though, you will need one for production use. Distribution channels like the Play Store do not accept apps signed with the debug signing key. So, you will need to create a key that *is* acceptable to those channels, plus arrange to use that key when creating your production apps.

How long your production signing key is valid for is important. Once your key expires, you can no longer use it for signing new applications, which means once the key expires, you cannot update existing Android applications. Also, the Play Store requires your key to be valid beyond October 22, 2033. When you create your key, you will indicate how long it should be valid for.

Note that both the debug signing key and its production counterpart are self-signed certificates — you do not have to purchase a certificate from Verisign or anyone. These keys are for creating immutable identity, but are not for creating confirmed identity. In other words, these certificates do not prove you are such-and-so person, but can prove that the same key signed two different APKs.

Creating a Production Signing Key

The mechanics of creating a production signing key depend on whether you will use an IDE (and, if so, which one) or will create one outside of any IDE.

Android Studio

Android Studio has support to create a production signing key as part of its overall process for creating a production-signed APK, which is covered [later in this chapter](#).

Eclipse

Eclipse also has support to create a production signing key as part of its overall process for creating a production-signed APK, which is covered [later in this chapter](#).

Manually

To manually create a production signing key, you will need to use `keytool`. This comes with the Java SDK, and so it should be available to you already.

The `keytool` utility manages the contents of a “keystore”, which can contain one or more keys. Each “keystore” has a password for the store itself, and keys can also have their own individual passwords. You will need to supply these passwords later on when signing an application with the key.

Here is an example of running `keytool`:

```
keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg RSA  
-validity 10000 -keysize 2048
```

The parameters used here are:

1. `-genkey`, to indicate we want to create a new key
2. `-v`, to be verbose about the key creation process
3. `-keystore`, to indicate what keystore we are manipulating (`cw-release.keystore`), which will be created if it does not already exist
4. `-alias`, to indicate what human-readable name we want to give the key (`cw-release`)
5. `-keyalg`, to indicate what public-key encryption algorithm to be using for this key (RSA)
6. `-validity`, to indicate how long this key should be valid, where 10,000 days or more is recommended
7. `-keysize`, for indicating the length of the signing key (2,048 bits recommended, or go higher if you prefer)

If you run the above command, you will be prompted for a number of pieces of information. If you have ever created an SSL certificate, the prompts will be familiar:

```
$ keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg  
RSA -validity 10000 -keysize 2048  
Enter keystore password:  
Re-enter new password:  
What is your first and last name?  
[Unknown]: Mark Murphy  
What is the name of your organizational unit?  
[Unknown]:  
What is the name of your organization?  
[Unknown]: CommonsWare, LLC  
What is the name of your City or Locality?
```

SIGNING YOUR APP

```
[Unknown]:  
What is the name of your State or Province?  
[Unknown]: PA  
What is the two-letter country code for this unit?  
[Unknown]: US  
Is CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US  
correct?  
[no]: yes  
  
Generating 2,048 bit RSA key pair and self-signed certificate (SHA256withRSA)  
with a validity of 10,000 days  
for: CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US  
Enter key password for <cw-release>  
(RETURN if same as keystore password):  
[Storing cw-release.keystore]
```

Signing with the Production Key

How you will apply this production signing key to sign your production app again varies by your tool chain.

Android Studio

Start by opening up your project and going to Build > Generate Signed APK from the main menu. This brings up the first page of a signing wizard:

Figure 334: Android Studio Generate Signed APK Wizard, First Page

If this is the first time you are going to sign a production app, you will need to create your production signing key, which you can do by clicking the “Create new...” button in the wizard. This brings up a separate dialog for describing the new signing key:

SIGNING YOUR APP

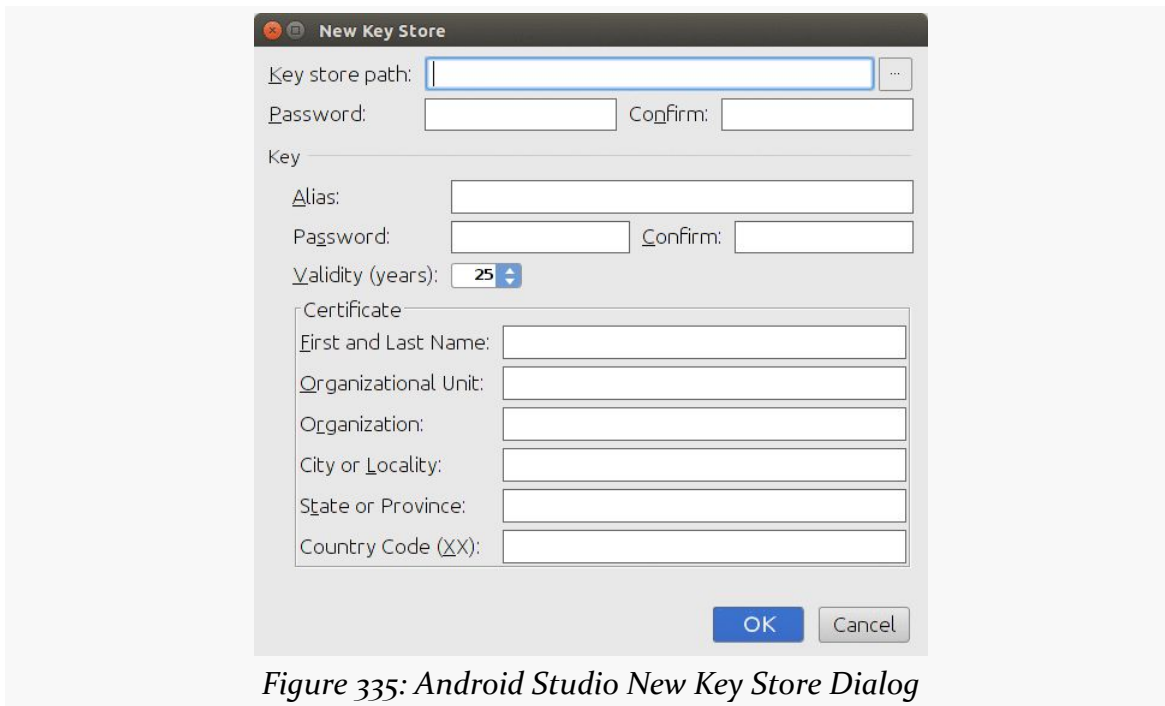

Figure 335: Android Studio New Key Store Dialog

You will need to provide a path to the keystore, manually or via the “...” button to pick a location via a dialog. You will also need to provide a password (twice) for the keystore.

You can then supply information for the signing key within the keystore, including:

- “Alias” to indicate what human-readable name we want to give the key
- “Password” and “Confirm”, to specify a password for this specific key in the keystore (independent of the keystore’s own password)
- “Validity”, to indicate how long this key should be valid, where 25 years or more is recommended
- Details about you and your organization, asking for the standard information used in generating SSL-style keys

Clicking “OK” will generate the keystore and save it where you specified. **Be sure to back up this keystore** and record the passwords that you used.

If you already have a keystore, though, back on the first page of the “Generate Signed APK” wizard, you can click “Choose existing” to bring up a file-open dialog where you can choose your keystore. Then, fill in the keystore password, the key alias, and the key password in the dialog.

SIGNING YOUR APP

Clicking Next in the wizard brings up a page allowing you to determine what will be generated:

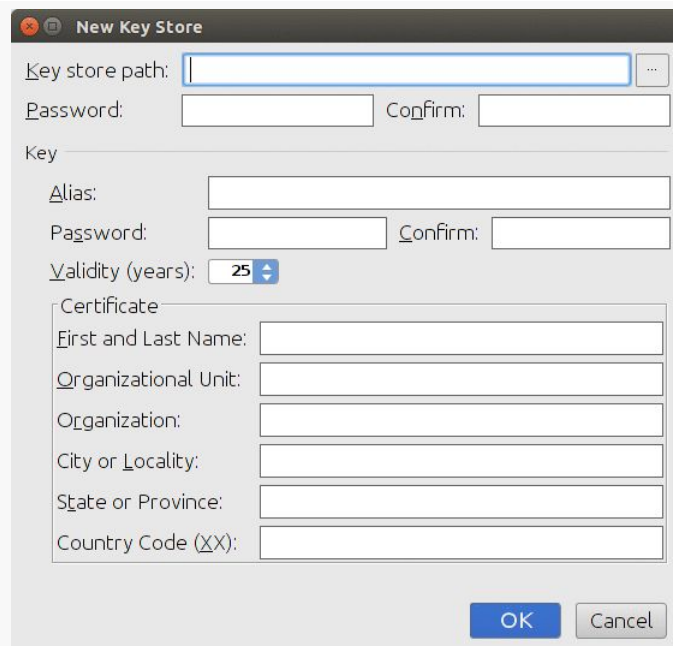

Figure 336: Android Studio Generate Signed APK Wizard, Second Page

You can indicate where the APK file should be written, what build type to use (release being the default), and which product flavors to use (where you can select one or several).

Clicking “Finish” will have Android Studio begin generating the APK files. This may take some time. When it is done, a dialog will appear indicating that the work is completed. In the directory that you specified, you will get one APK file per product flavor you chose, plus manifest merger reports for those APK files. And, of course, the APK files will be signed with your chosen keystore and signing key.

Gradle for Android

Gradle for Android can also be used to sign a production app. Curiously, this is completely independent of the mechanism that Android Studio uses to sign a production app. Filling in the dialogs in Android Studio does not affect your `build.gradle` file, and Android Studio’s “Generate Signed APK” completely ignores any manual signing configuration that you may set up in `build.gradle` (and is discussed in this section). What is covered in this section focuses on automating

SIGNING YOUR APP

the signing process, to be done via a build server or just running a Gradle task from the command line.

To be able to use Gradle for Android to sign your production app, you need to provide a signing configuration to the release build type:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {
            applicationIdSuffix ".d"
            versionNameSuffix "-debug"
        }

        release {
            signingConfig signingConfigs.release
        }
    }
}
```

Here, our release build type has a `signingConfig` property, referencing the name of a signing configuration specified in the `signingConfigs` closure. This is used to provide rules for how to sign the APK that is assembled by Gradle. In this project's `build.gradle` file, we have a release closure in `signingConfigs`, supplying the requisite information about the keystore:

- The `storeFile` path, specified as a `file()` pointing to a keystore in the project's root directory
- The `keyAlias` given to the signing key inside the keystore
- The `storePassword` and `keyPassword` used to access the keystore

The `signingConfig` property in the release closure in `buildTypes` references the signing configuration we want as `signingConfigs.release`. All of these Groovy closures of properties in the `build.gradle` file are effectively building up a data structure, which we can access. So, `signingConfigs.release` says to find the release definition in the `signingConfigs` closure.

This sample bakes in the keystore data into the `build.gradle` file, including the passwords, and has the keystore in the root of the project. That is for demonstration simplicity and will not be suitable for all projects. In particular, keystores and their credentials should *not* be stored in a publicly accessible repository, as that would allow others to sign *their* apps with *your* signing key, which is not good. There are a variety of strategies for handling this, from using environment variables to requesting the data be entered on the command line, as are discussed in [the chapter on advanced Gradle techniques](#).

Adding a `signingConfig` property in our release build type enables the `installRelease` task. Running `gradle tasks` will show `installRelease` as an available option, because now Gradle for Android knows how to sign the APK. Of course, there could be flaws in the signing configuration (e.g., mis-entered key alias), and that will result in build errors when you try to `installRelease` the project.

Eclipse

To create a production signed version of your app, right-click over the app in the Package Explorer and choose Export from the context menu. In the list of things to export, choose "Export Android Application":

SIGNING YOUR APP

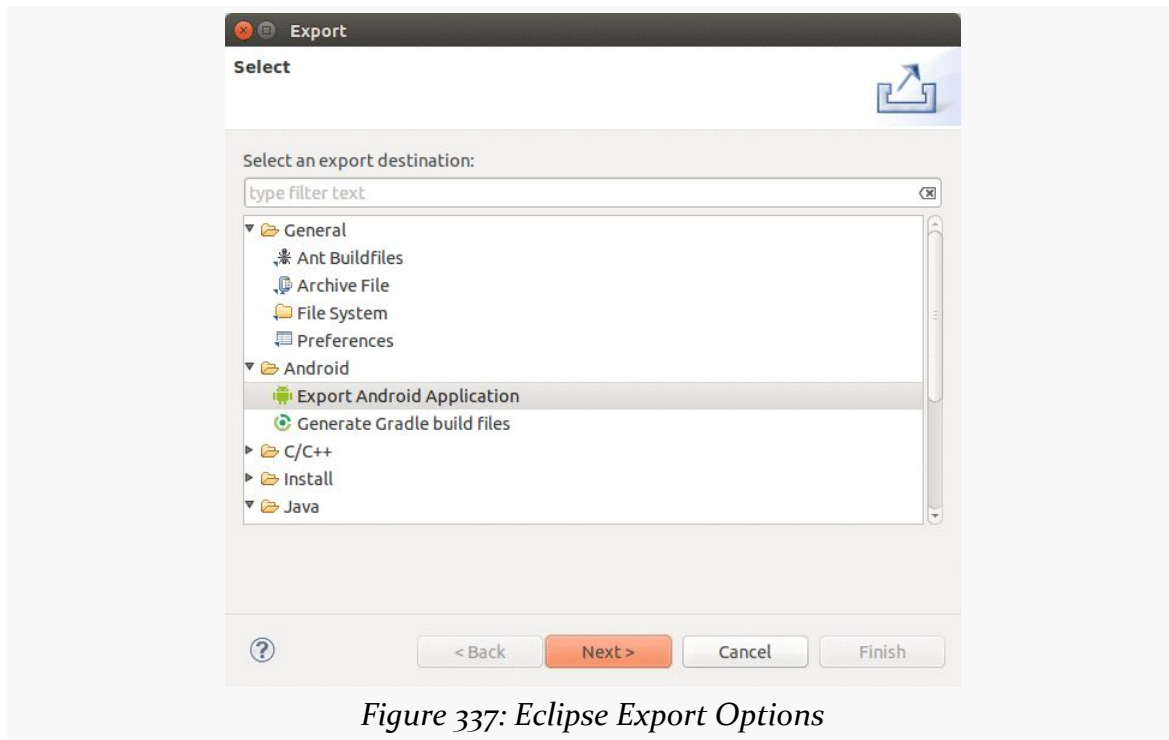

Figure 337: Eclipse Export Options

This kicks off a wizard where you can create the production-signed app. The first page of this wizard just confirms what you wish to export and whether or not there are any problems that would prevent the export, such as compile errors:

SIGNING YOUR APP

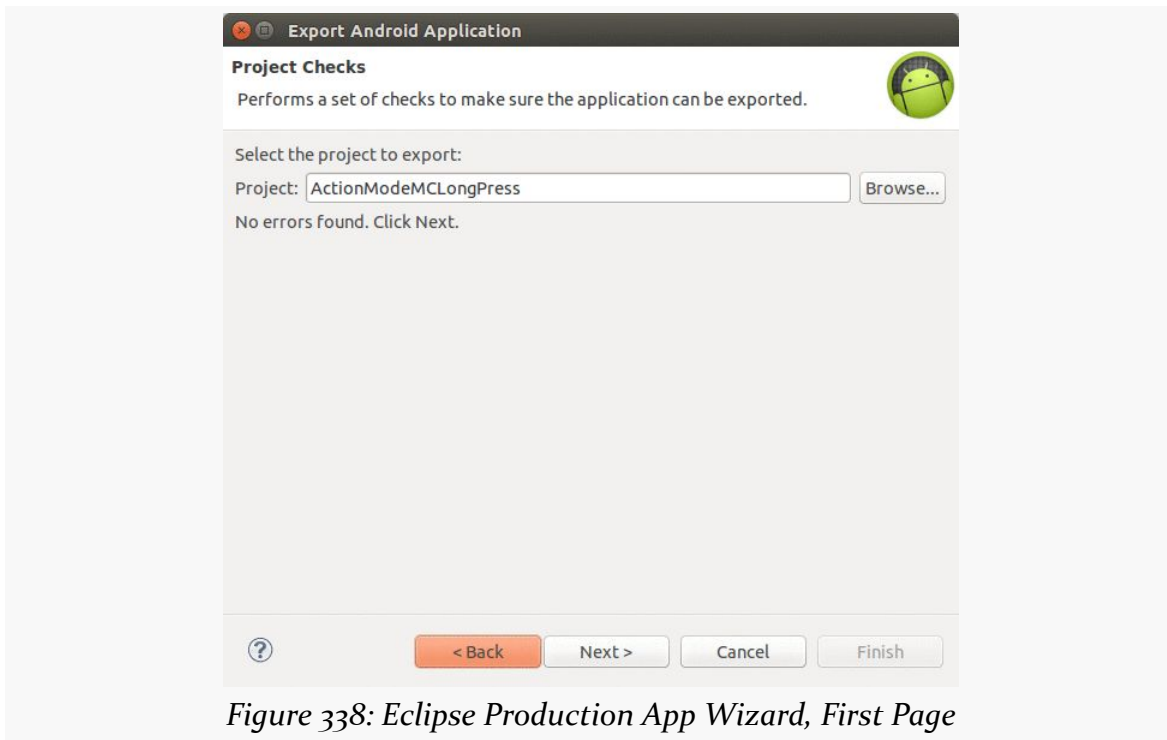

Figure 338: Eclipse Production App Wizard, First Page

Clicking the Next button brings up the second wizard page, focusing on the production keystore:

SIGNING YOUR APP

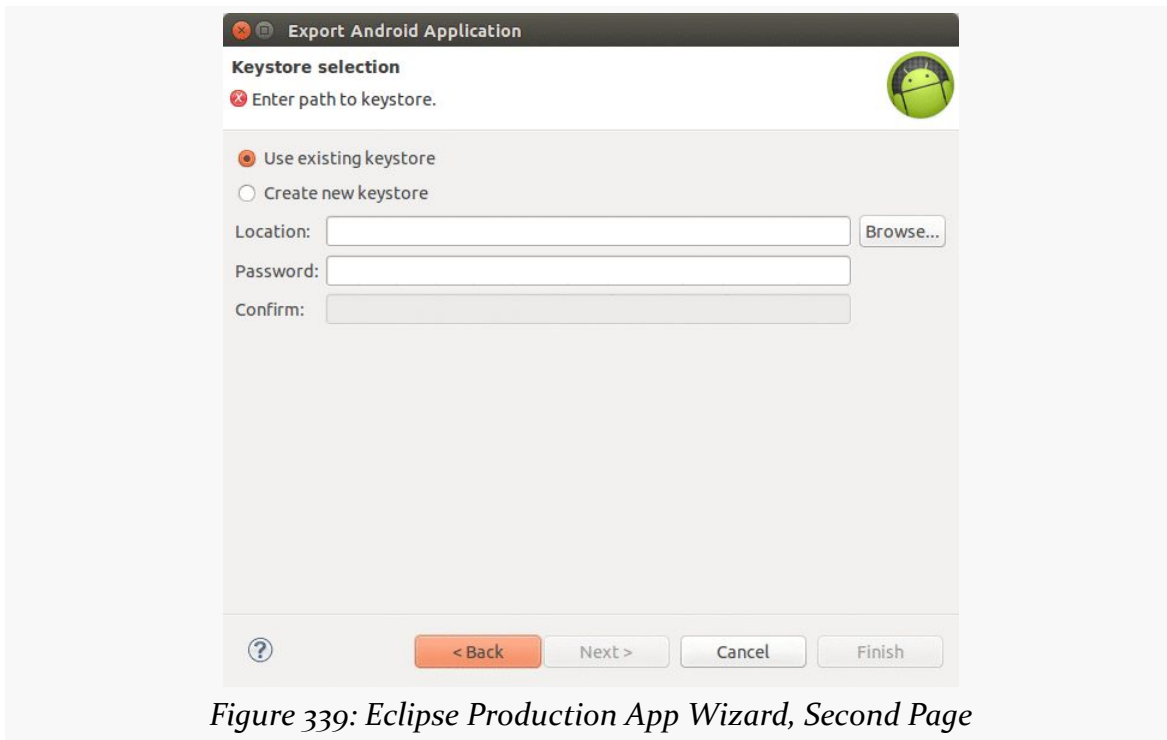

Figure 339: Eclipse Production App Wizard, Second Page

If you used this wizard previously, and you already have a production keystore, choose it via the “Browse...” button and fill in your keystore’s password. If you need to create a new keystore, choose the “Create new keystore” radio button, choose where to store the keystore via the “Browse...” button, and fill in your desired keystore password.

SIGNING YOUR APP

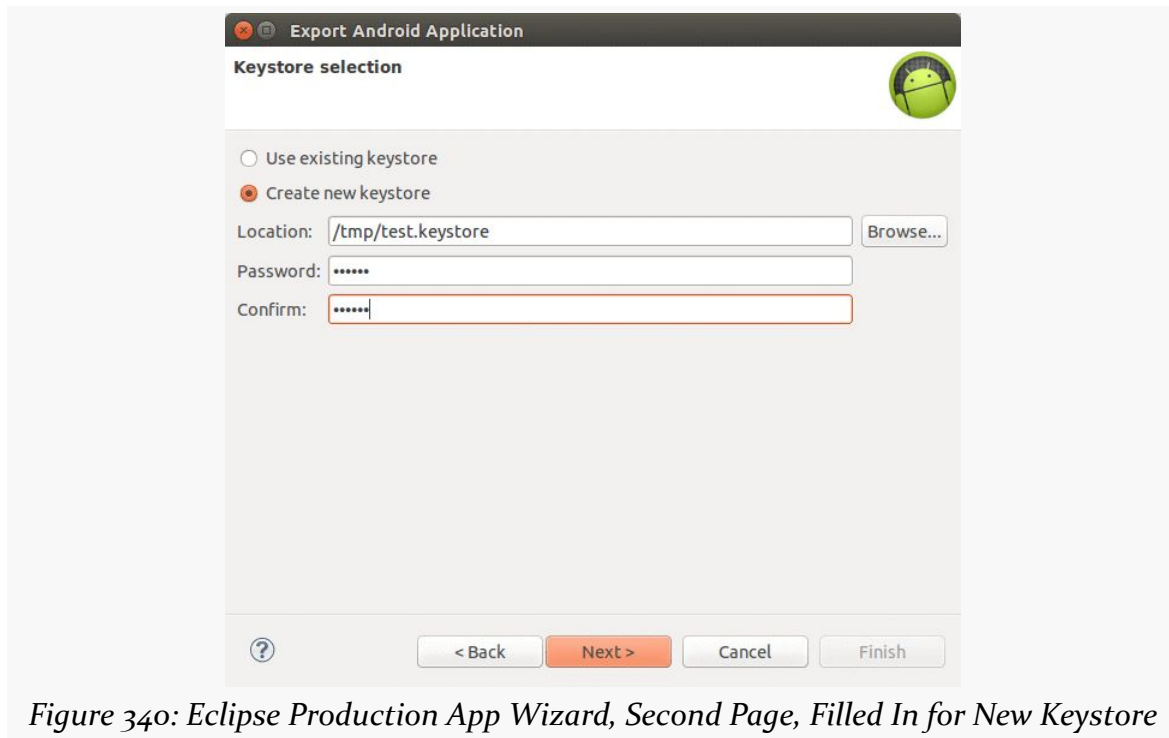

Figure 340: Eclipse Production App Wizard, Second Page, Filled In for New Keystore

If you chose to create a new keystore, the Next button brings up a dialog where you can fill in details of the production signing key:

SIGNING YOUR APP

Figure 341: Eclipse Production App Wizard, New-Keystore Page

This includes:

- “Alias” to indicate what human-readable name we want to give the key
- “Password” and “Confirm”, to specify a password for this specific key in the keystore (independent of the keystore’s own password)
- “Validity”, to indicate how long this key should be valid, where 25 years or more is recommended
- Details about you and your organization, asking for the standard information used in generating SSL-style keys

If, instead, you chose to open an existing keystore, the Next button would take you to a wizard page to choose your desired signing key and provide *its* password, or to create a new signing key within the keystore:

SIGNING YOUR APP

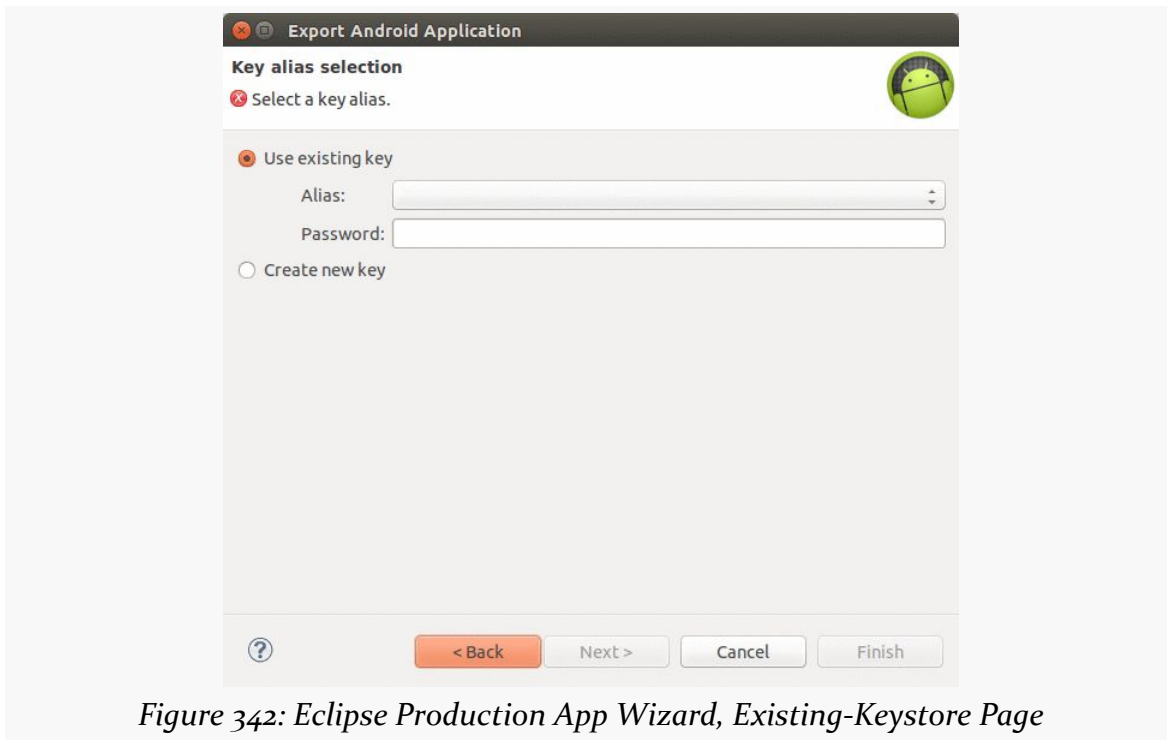

Figure 342: Eclipse Production App Wizard, Existing-Keystore Page

Once your keystore and key are set up or chosen, the last page of the wizard is where you indicate where the signed APK should be stored:

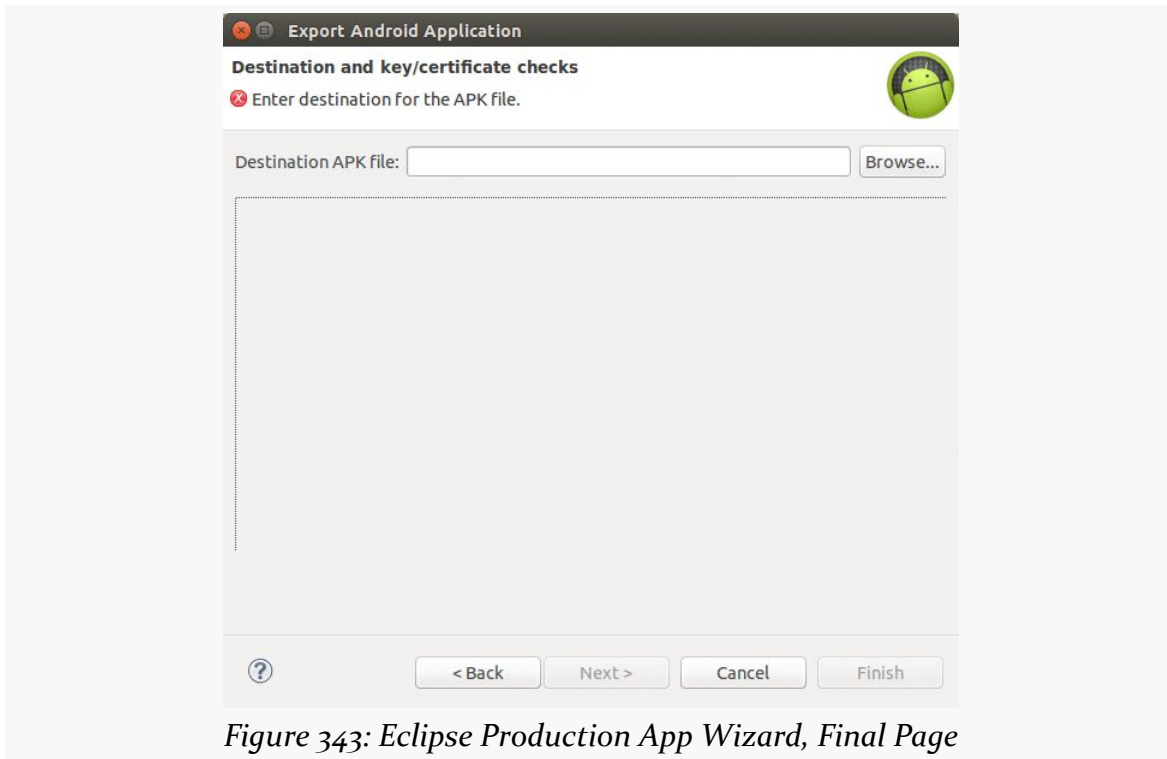

Figure 343: Eclipse Production App Wizard, Final Page

Providing a path and clicking Finish will export the signed production APK file.

Two Types of Key Security

There are two facets to securing your production key that you need to think about:

- You need to make sure nobody steals your production keystore and its password. If somebody does, they could publish replacement versions of your applications — since they are signed with the same key, Android will assume the replacements are legitimate.
- You need to make sure you do not lose your production keystore and its password. Otherwise, even you will be unable to publish replacement versions of your applications.

For solo developers, the latter scenario is more probable. There already have been **many** cases where developers had to rebuild their development machine and wound up with new keys, locking themselves out from updating their own applications. As with everything involving computers, having a solid backup regimen is highly recommended. In particular, consider a secure off-site backup, such as having your production keystore on a thumb drive in a bank safe deposit box.

SIGNING YOUR APP

For teams, the former scenario may be more likely. If more than one person needs to be able to sign the application, the production keystore will need to be shared, possibly even stored in the revision control system for the project. The more people who have access to the keystore, the more likely it is somebody will wind up doing something evil with it. This is particularly true for projects with public revision control systems, such as open source projects — developers might not think of the implications of putting the production keystore out for people to access.

Distribution

It is entirely possible that the user base for your app consists solely of yourself.

However, in most cases, you are going to be giving your app to others, free or for some sort of fee.

This chapter outlines things you will need to think about when distributing your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on [signing your app](#).

Get Ready To Go To Market

While being able to sign your application reliably with a production key is necessary for publishing a production application, it is not sufficient. Particularly for the Play Store, there are other things you must do, or should do, as part of getting ready to release your application.

Versioning

You need to supply `versionCode` and `versionName` values in your `build.gradle` file (or in your `<manifest>` element in your `AndroidManifest.xml` file for Eclipse users). The value of `versionName` is what users and prospective users will see in terms of the label associated with your application version (e.g., “1.0.1”, “System V”, “Loquacious Llama”). More important, though, is the value of `versionCode`, which

needs to be an integer increasing with each release — that is how Android tells whether some edition of your APK is an upgrade over what the user currently has.

Application ID

You also need to make sure that your application ID is going to be unique. If somebody tries downloading your application onto their device, and some other application is already installed with that same package name, your application will fail to install.

Your application ID defaults to be the value of your package attribute in your `<manifest>` element in the manifest. You can override the application ID using `applicationId` properties in `defaultConfig` or a product flavor in `build.gradle`. You can also append an `applicationIdSuffix` tied to a build type in Gradle as well.

Since the manifest's package also provides the base Java package for your project, and since you hopefully named your Java packages with something based off of a domain name you own or something else demonstrably unique, this should not cause a huge problem.

Also, bear in mind that your application ID must be unique across all applications on the Play Store, should you choose to distribute that way.

Icon and Label

Your `<application>` element needs to specify `android:icon` and `android:name` attributes, to supply the name and icon that will be associated with the application in the My Applications list on the device and related screens. Your activities will inherit the icon if they do not specify icons of their own.

If you have graphic design skills, the Android developer site has [guidelines](#) for creating icons that will match other icons in the system.

Logging

In production, try to minimize unnecessary logging, particularly at low logging levels (e.g., debug). Remember that even if Android does not actually log the information, whatever processing is involved in making the `Log.d()` call will still be done, unless you arrange to skip the processing somehow. You could outright delete the extraneous logging calls, or wrap them in an `if()` test:

```
if (BuildConfig.DEBUG) {  
    Log.d(TAG, "This is what happened");  
}
```

Here, `BuildConfig.DEBUG` is a public static final boolean value, supplied by Android, that indicates whether you are building for debug or production. Whether you adjust the definition by hand or by automating the build process is up to you. But, when `BuildConfig.DEBUG` is false, any work that would have been done to build up the actual Log invocation will be skipped, saving CPU cycles and battery life.

Conversely, error logs become even more important in production. Sometimes, you have difficulty reproducing bugs “in the lab” and only encounter them on customer devices. Being able to get stack traces from those devices could make a major difference in your ability to get the bug fixed rapidly.

First, in addition to your regular exception handlers, consider catching everything those handlers miss, notably runtime exceptions:

```
Thread.setDefaultUncaughtExceptionHandler(onBlooey);
```

This will route all uncaught exceptions to an `onBlooey` handler:

```
private Thread.UncaughtExceptionHandler onBlooey=  
    new Thread.UncaughtExceptionHandler() {  
        public void uncaughtException(Thread thread, Throwable ex) {  
            Log.e(TAG, "Uncaught exception", ex);  
        }  
    };
```

There, you can log it, raise a dialog if appropriate, etc.

Then, offer some means to get your logs off the device and to you, via email or a Web service. Some Android analytics firms, like [Flurry](#), offer exception stack trace collection as part of their service. There are also open source projects that support this feature, such as [ACRA](#).

Testing

As always, testing, particularly acceptance testing, is important.

Bear in mind that the act of creating the production signed version of your application could introduce errors, such as having the wrong Google Maps V2 API

key. Hence, it is important to do user-level testing of your application after you sign, not just before you sign, in case the act of signing messed things up. After all, what you are shipping to those users is the production signed edition — you do not want your users tripping over obvious flaws.

As you head towards production, also consider testing in as many distinct environments as possible, such as:

1. Trying more than one device, particularly if you can get devices with different display sizes
2. If you rely on the Internet, try your application with WiFi, with 3G, with EDGE/2G, and with the Internet unavailable
3. If you rely on GPS, try your application with GPS disabled, GPS enabled and working, and GPS enabled but not available (e.g., underground)

EULA

End-user license agreements — EULAs — are those long bits of legal prose you are supposed to read and accept before using an application, Web site, or other protected item. Whether EULAs are enforceable in your jurisdiction is between you and your qualified legal counsel to determine.

In fact, many developers, particularly of free or open source applications, specifically elect not to put a EULA in their applications, considering them annoying, pointless, or otherwise bad.

However, the Play Store developer distribution agreement has one particular clause that might steer you towards having a EULA:

You agree that if you use the Store to distribute Products, you will protect the privacy and legal rights of users. If the users provide you with, or your Product accesses or uses, user names, passwords, or other login information or personal information, you must make the users aware that the information will be available to your Product, and you must provide legally adequate privacy notice and protection for those users. Further, your Product may only use that information for the limited purposes for which the user has given you permission to do so. If your Product stores personal or sensitive information provided by users, it must do so securely and only for as long as it is needed. But if the user has opted into a separate agreement with you that allows you or your Product to store or use personal or sensitive information directly related to your Product (not including

other products or applications) then the terms of that separate agreement will govern your use of such information. If the user provides your Product with Google Account information, your Product may only use that information to access the user's Google Account when, and for the limited purposes for which, the user has given you permission to do so.

Hence, if you are concerned about being bound by what Google thinks appropriate privacy is, you may wish to consider a EULA just to replace their terms with your own.

Unfortunately, having a EULA on a mobile device is particularly annoying to users, because EULAs tend to be long and screens tend to be short.

Again, please seek professional legal assistance on issues regarding EULAs.

Advanced Gradle for Android Tips

There are *lots* of things you can do given a full scripting language as the basis for your build system. This chapter represents a collection of tips for things that you can do that go beyond stock capabilities provided by the Gradle for Android plugin.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including both [the legacy project structure](#) and [the new project structure](#). Having read [the chapter on Gradle dependencies](#) would also be a pretty good idea.

The chapter on [using the NDK](#) is a prerequisite for one section of this chapter, covering using Gradle with the NDK.

Gradle, DRY

Ideally, your build scripts do not repeat themselves any more than is logically necessary. For example, a project and sub-projects probably should use the same version of the build tools, yet by default, we define them in each `build.gradle` file. This section outlines some ways to consolidate this sort of configuration

It's build.gradle All The Way Down

If you have sub-projects, you can have build.gradle files at each level of your project hierarchy. Your top-level build.gradle file is also applied to the sub-projects when they are built.

In particular, you can “pass data” from the top-level build.gradle file to sub-projects [by configuring the ext object via a closure](#). In the top-level build.gradle file, you would put common values to be used:

```
ext {  
    compileSdkVersion=19  
}
```

(note the use of the = sign here)

Sub-projects can then reference rootProject.ext to retrieve those values:

```
android {  
    compileSdkVersion rootProject.ext.compileSdkVersion  
}
```

By this means, you can ensure that whatever needs to be synchronized at build time is synchronized, by defining it once.

Another way that a top-level build.gradle file can configure subprojects is via the subprojects closure. This contains bits of configuration that will be applied to each of the subprojects as a part of their builds.

The HelloAIDL sample project demonstrates this. The build.gradle in the overall project root (outside the Client/ and Service/ sub-projects) has a subprojects closure to define the code-signing rules for these two applications and common values for the two sub-projects:

```
buildscript {  
    repositories {  
        mavenCentral()  
    }  
    dependencies {  
        classpath 'com.android.tools.build:gradle:1.0.0'  
    }  
}  
  
subprojects {  
    buildscript {
```

```
repositories {
    mavenCentral()
}
dependencies {
    classpath 'com.android.tools.build:gradle:1.0.0'
}

apply plugin: 'com.android.application'

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    signingConfigs {
        release {
            storeFile file('HelloAIDL.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        release {
            signingConfig signingConfigs.release
        }
    }
}
```

The subprojects closure contains its own reference to the android plugin for Gradle, in addition to android closure for configuring the signingConfigs and buildTypes. Because this code is written in the root project's build.gradle file, file() references refer to the root project's directory, which is why file('HelloAIDL.keystore') will find the keystore in the root project's directory.

Note that subprojects applies to *all* sub-projects, which limits its utility. For example, a top-level project with one sub-project for an app and another sub-project for a library used by that app cannot readily use subprojects. That is because the library sub-project needs to configure the com.android.library plugin, while the application sub-project needs to configure the com.android.application plugin. The subprojects closure is only good for common configuration to apply to all sub-projects regardless of project type.

gradle.properties

Another approach would be to add a `gradle.properties` file to your project root directory. Those properties are automatically read in and would be available up and down your project hierarchy.

Per-developer properties can go in a `gradle.properties` file in the user's Gradle home directory (e.g., `~/.gradle` on Linux), where they will not be accidentally checked into version control.

So, to achieve the synchronized `compileSdkVersion` value, you could have a `gradle.properties` file with:

```
COMPILE_SDK_VERSION=19
```

Then, your projects' `build.gradle` files could use:

```
android {  
    compileSdkVersion COMPILE_SDK_VERSION  
}
```

The [Gradle/HelloProperties](#) sample project illustrates this. It is a clone of the HelloAIDL sample application from earlier in this chapter, but one where we have a `gradle.properties` file in the root project's directory:

```
BUILD_TOOLS_VERSION=21.1.2
```

Here, we are defining a build tools version for use with the `buildToolsVersion` property in the `android` closure. The sub-projects use the `BUILD_TOOLS_VERSION` property that we defined in `gradle.properties` in their own `build.gradle` files, courtesy of a `subprojects` closure defined in the top-level `build.gradle` file:

```
buildToolsVersion BUILD_TOOLS_VERSION
```

Custom Properties Files

You are also welcome to use your own custom properties files. For example, perhaps you want to use `gradle.properties` for properties that you are willing to put in version control (e.g., `BUILD_TOOLS_VERSION`), but you would *also* like to use a properties file to keep your code-signing details outside of your `build.gradle` file and out of version control.

Loading in custom properties files is slightly clunky, as it does not appear to be built into Gradle itself. However, you can take advantage of the fact that Gradle is backed by Groovy and use some ordinary Groovy code to load the properties.

This can also be seen in the HelloProperties sample project, where the `build.gradle` in the root project's directory uses a `signing.properties` file to isolate sensitive data:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

subprojects {
    buildscript {
        repositories {
            mavenCentral()
        }
        dependencies {
            classpath 'com.android.tools.build:gradle:1.0.0'
        }
    }

    apply plugin: 'com.android.application'

    android {
        compileSdkVersion 19
        buildToolsVersion BUILD_TOOLS_VERSION

        def signingPropFile = rootProject.file('signing.properties')
        if (signingPropFile.canRead()) {
            def Properties signingProps = new Properties()

            signingProps.load(new FileInputStream(signingPropFile))

            signingConfigs {
                release {
                    storeFile rootProject.file('HelloAIDL.keystore')
                    keyAlias signingProps['KEY_ALIAS']
                    storePassword signingProps['STORE_PASSWORD']
                    keyPassword signingProps['KEY_PASSWORD']
                }
            }

            buildTypes {
                release {
                    signingConfig signingConfigs.release
                }
            }
        }
    }
}
```

```
    }  
  }  
}
```

Let's look at the key lines, one at a time:

```
def signingPropFile = rootProject.file('signing.properties')
```

This statement grabs the `signing.properties` file from the root project and assigns it to the `signingPropFile` variable. Groovy, by default, is a dynamic language and does not use data types for its variables. Under the covers, `signingPropFile` is a `java.io.File` object, just like you are used to in ordinary Java/Android development.

```
if (signingPropFile.canRead()) {  
}
```

Since `signingPropFile` is a `File`, we can call a `canRead()` method to confirm that the file exists and is readable.

```
def Properties signingProps = new Properties()
```

This creates an empty instance of a `java.util.Properties` object and assigns it to the `signingProps` variable.

```
signingProps.load(new FileInputStream(signingPropFile))
```

This creates a standard `java.io.FileInputStream` for the properties file, then passes it to the `load()` method on the `Properties` object, to read in the properties file.

```
keyAlias signingProps['KEY_ALIAS']  
storePassword signingProps['STORE_PASSWORD']  
keyPassword signingProps['KEY_PASSWORD']
```

These statements access properties from the `Properties` object, where Groovy has augmented `Properties` to support square-bracket syntax to access individual properties.

The author would like to thank Gabriele Mariotti for [his blog post](#) that, among other things, depicted this technique.

Environment Variables

Any environment variables with a prefix of `ORG_GRADLE_PROJECT_` will show up as global variables in your Gradle script. So, for example, you can access an environment variable named `ORG_GRADLE_PROJECT_foo` by accessing a `foo` variable in `build.gradle`.

If you would prefer to use environment variables without that prefix, you can call `System.getenv()`, passing in the name of the environment variable, to retrieve its value.

Note, however, that you may or may not have access to the environment variables that you think you should. Android Studio, for example, does not expose environment variables to Gradle for its builds, and so an environment variable that you can access perfectly well from the command line may not be available in the same `build.gradle` script when run from Android Studio.

Automating APK Version Information

Once Gradle for Android started catching on, one of the first things many developers raced to do was automate the `android:versionCode` and `android:versionName` properties from the manifest. Since those can be defined in a Gradle file (overriding values from any `AndroidManifest.xml` files), and since Gradle is backed by Groovy, it is possible to programmatically assign values to those properties.

This section outlines a few approaches to that problem.

Auto-Incrementing the `versionCode`

Since the `android:versionCode` is a monotonically increasing integer, one approach for automating it is to simply increment it on each build. While this may seem wasteful, two billion builds is a *lot* of builds, so a solo developer is unlikely to run out. Synchronizing such `versionCode` values across a team will get a bit more complex, but for an individual case (developer, build server, etc.), it is eminently doable using Groovy.

The [Gradle/HelloVersioning](#) sample project uses a `version.properties` file as the backing store for the version information:

```
if (versionPropsFile.canRead()) {
    def Properties versionProps = new Properties()

    versionProps.load(new FileInputStream(versionPropsFile))

    def code = versionProps['VERSION_CODE'].toInteger() + 1

    versionProps['VERSION_CODE']=code.toString()
    versionProps.store(versionPropsFile.newWriter(), null)

    defaultConfig {
        versionCode code
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }
}
else {
    throw new GradleException("Could not read version.properties!")
}
```

First, we try to open a `version.properties` file and fail if it does not exist, requiring the developer to create a starter file manually:

```
VERSION_CODE=1
```

Of course, a more robust implementation of this script would handle this case and supply a starter value for the developer.

The script then uses the read-the-custom-properties logic illustrated in [the preceding section](#) to read the existing value... but it increments the old value by 1 to get the new code to use. The revised code is then written back to the properties file before it is applied in the `defaultConfig` closure.

In this case, the script throws a `GradleException` to halt the build if the `version.properties` file could not be found or otherwise could not be read.

Synchronizing the `versionName...` with the `versionCode`

If you do not want to automatically increment the `android:versionCode` value, you could use it to also create a matching `android:versionName` value. Jake Wharton illustrated this in [a Google+ post](#), showing how you can build the `versionCode` up from parts representing the major, minor, and patch-level numbers, then use those same numbers to generate a standard dot-notation `versionName`.

Synchronizing the versionName... with the APK File Name

You can also use the `android:versionCode` and `android:versionName` elsewhere in your Gradle build file, to apply to other aspects of your build. For example, Kevin Coppock posted [a snippet of code](#) showing how to embed your `versionName` into your compile APK's filename. The HelloVersioning sample uses a modified version of this same approach as part of its `buildTypes` closure:

```
buildTypes {
    debug {
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
    }

    release {
        signingConfig signingConfigs.release
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        signingConfig signingConfigs.release
    }

    // from http://stackoverflow.com/a/27068573/115145
    applicationVariants.all { variant ->
        variant.outputs.each { output ->
            output.outputFile = new File(
                output.outputFile.parent,
                output.outputFile.name.replace(".apk",
                    "-${variant.versionName}.apk"))
        }
    }
}
```

When defining the build types, we iterate over all application variants (build type/product flavor combinations), over each of the possible variant outputs (courtesy of splits), and modify the `outputFile` property of the variant to embed the `variant.versionName` value.

Adding to BuildConfig

The Android development tools have been code-generating the `BuildConfig` class for some time now. Historically, the sole element of that class was the `DEBUG` flag,

which is true for a debug build and false otherwise. This is useful for doing runtime changes based upon build type, such as only configuring `StrictMode` in debug builds.

Nowadays, the Gradle for Android plugin also defines:

- `BUILD_TYPE`, which is the build type used to build this APK.
- `FLAVOR`, which is the product flavor used to build this APK.
- `PACKAGE_NAME`, which is the name that serves as the application ID (i.e., it includes build type suffixes and product flavor overrides). This is useful for cases where you cannot just call `getPackageName()` on a `Context` because you do not have a handy `Context`.
- `VERSION_CODE`, which is the version code derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.
- `VERSION_NAME`, which is the version name derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.

However, you can add your own data members to `BuildConfig`, by including a `buildConfigField` statement in the `defaultConfig` closure of your `android` closure:

```
android {  
    defaultConfig {  
        buildConfigField "int", "FOO", '5'  
    }  
}
```

You can use this to embed any sort of information you want into `BuildConfig`, so long as it is knowable at compile time.

Moreover, you can also have `buildConfigField` statements in build types. This would be useful if you have custom build types, beyond just debug and release, and you need runtime configuration for those. For example, you could put server URLs in `buildConfigField`, so your debug server is different from your integration test server, which in turn is different than your production server.

You can see this approach used in the [Gradle/HelloBuildConfig](#) sample project. Its `buildTypes` closure defines three different variations of a `SERVER_URL` field on the `BuildConfig` object:

```
buildTypes {  
    debug {  
        applicationIdSuffix ".d"  
        versionNameSuffix "-debug"  
        buildConfigField "String", "SERVER_URL",
```

```
'"http://test.this-is-so-fake.com"'
    }

    release {
        signingConfig signingConfigs.release
        buildConfigField "String", "SERVER_URL",
'"http://prod.this-is-so-fake.com"'
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        buildConfigField "String", "SERVER_URL",
'"http://stage.this-is-so-fake.com"'
    }
}
```

The Java code can refer to `BuildConfig.SERVER_URL` to retrieve this value. Since it is defined for all current build types, there will always be a value at compile time. Note, though, that if you add a build type, you need to ensure that it will have a `SERVER_URL` defined.

As of version 0.8 of the Gradle for Android plugin, if you redefine the same `buildConfigField` name, it replaces the previous value. So, in the `build.gradle` segment shown above, we define the `SERVER_URL` on the `release` build type *before* using `release` as the basis for the `mezzanine` build type. Right after the `mezzanine.initWith(buildTypes.release)` statement, the `mezzanine` build type has the same `buildConfigField` value for `SERVER_URL` as did `release`. But, we then replace that value in the `mezzanine` closure, to have a different server URL for `mezzanine` builds than we use for `release` or `debug` builds.

Down and Dirty with the DSL

What `build.gradle` does is build up an object model that describes a build process, in the form of defining tasks. Many times you can define the object model in a declarative fashion, with closures like `android` and `buildTypes` and `signingConfigs` and so on. However, as seen in this chapter, sometimes you need to get into Groovy scripting, and sometimes that scripting involves working with the Gradle for Android object model directly.

To help you understand what that object model looks like, the [“Android Plug-in for Gradle”](#) page contains a download button for “Plugin Command Reference”. Despite

the button's name, this is really documentation for the domain-specific language (DSL) published by the Gradle for Android plugin, including:

- all of the “configuration blocks”, such as the `defaultConfig` closure
- all of the “DSL types”, or the objects that are built up by those “configuration blocks”, such as `BuildType` and `ProductFlavor`

At the present time, there is no link to an online hosted version of this documentation, just to the ZIP file to download the offline copy.

Trail: Testing

JUnit and Android

Presumably, you will want to test your code, beyond just playing around with it yourself by hand. Android offers several means of testing your app, covered in this next series of chapters.

The first Android SDK testing solution we will examine is the JUnit test framework. This is a standard Java unit testing framework. The Android SDK ships a version of JUnit, along with special test classes that will help you build test cases that exercise Android components, like activities and services.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

This chapter also assumes you have some familiarity with JUnit, though you certainly do not need to be an expert. You can learn more about JUnit at the [JUnit site](#), from various books, and from the [JUnit Yahoo forum](#).

Android Studio and Gradle for Android users may also wish to read [the chapter on Gradle dependencies](#).

JUnit Basics

As a quick terminology refresher, for those who have not used JUnit much or have not used it recently:

- A **test case** is a Java class, inheriting (directly or indirectly) from `junit.framework.TestCase`, that represents a set of tests to run
- A **test method** is a method, in a test case, that begins with the keyword `test`, and contains code that tests something in some production code base
- A **test suite** is a collection of test cases

So, a test **suite** enumerates test **cases**, which in turn implement test **methods**.

A test case can also have `setUp()` and `tearDown()` methods, in addition to test methods. `setUp()` is called before each test method invocation, while `tearDown()` is called after each test method invocation. So, for a test case with `testOne()` and `testTwo()` methods, along with `setUp()` and `tearDown()` methods, the following series of method invocations will occur when that test case is run:

- `setUp()`
- `testOne()`
- `tearDown()`
- `setUp()`
- `testTwo()`
- `tearDown()`

Note that while the above list shows `testOne()` being called before `testTwo()`, developers should not rely upon the exact order in which test methods are invoked. Instead, the `setUp()` and `tearDown()` methods are specifically there to establish the environment for each test method run.

Pondering Gradle for Android

Android Studio uses Gradle for Android for building the APK. It *also* uses Gradle for Android for running JUnit tests.

Testing is one aspect of software development that is often automated. You could use a full-blown continuous integration server like [Jenkins](#). Or, you could use something more casual like a Windows Scheduled Task to run tests daily in the early morning hours. Regardless, there is an above-average chance that you will want to run your tests both inside of and outside of Android Studio.

Hence, the instructions in this chapter will not only explain how to run tests from the IDE (both Android Studio and Eclipse), but also how to run tests from the command line using Gradle.

Where Your Test Code Lives

One common problem with testing is determining where the test code should reside, relative to the production code being tested. Ideally, these are not intermingled, as that would increase the odds that you might accidentally ship the testing code as part of your production app — at best, this increases your APK size; at worst, it could open up security flaws.

The approach that you take with JUnit and Android development depends on the environment in which your tests will run.

Android Studio and Gradle for Android

With Gradle-based projects, including those created for Android Studio, we have a dedicated *sourceset* for our instrumentation tests, named `androidTest`, where the code for those tests would reside.

NOTE: The name `androidTest` is for version 0.9.0 or higher of the Gradle for Android plugin. Older versions used `instrumentTest`.

As with any *sourceset*, `androidTest` can have Java code, resources, etc. It does not need an `AndroidManifest.xml` file, though, as that will be auto-generated.

The [Testing/JUnit-Gradle](#) sample project contains such an `androidTest` *sourceset*, and we will be looking at the Java code in there [later in this chapter](#).

Your Android Studio projects should already start with an empty `androidTest` directory, into which you can add a `java/` subdirectory with your test code.

Your `build.gradle` file needs a couple of additional lines in its `defaultConfig` closure:

```
defaultConfig {  
    testApplicationId "com.commonware.android.gradle.hello.test"  
    testInstrumentationRunner "android.test.InstrumentationTestRunner"  
}
```

Here, we define:

- `testApplicationId` (formerly known as `testPackageName`), which is the name of the package to be used for the instrument test APK. For testing

apps, this needs to be a separate package name from the package name of the app. We will discuss testing Android library projects [later in this chapter](#).

- `testInstrumentationRunner`, is the name of the Java class that implements the JUnit test runner to use for executing your tests. Usually, you will use `android.test.InstrumentationTestRunner`, though third-party libraries may offer alternative test runners.

Eclipse

Eclipse takes a different approach, where your test code resides in a completely separate Android test project.

An Android test project is a complete set of Android project artifacts: manifest, source directories, resources, etc. Much of its structure is identical to a regular project. In fact, the generated test project is all ready to go, other than not having any tests. For example, the [Testing/JUnit](#) project has a `tests/` subdirectory containing a test project.

To create a test project, from the standard Eclipse new-project dialog (File > New > Project), choose “Android Test Project”.

The first page of the wizard will ask for your Eclipse settings, such as the project name:

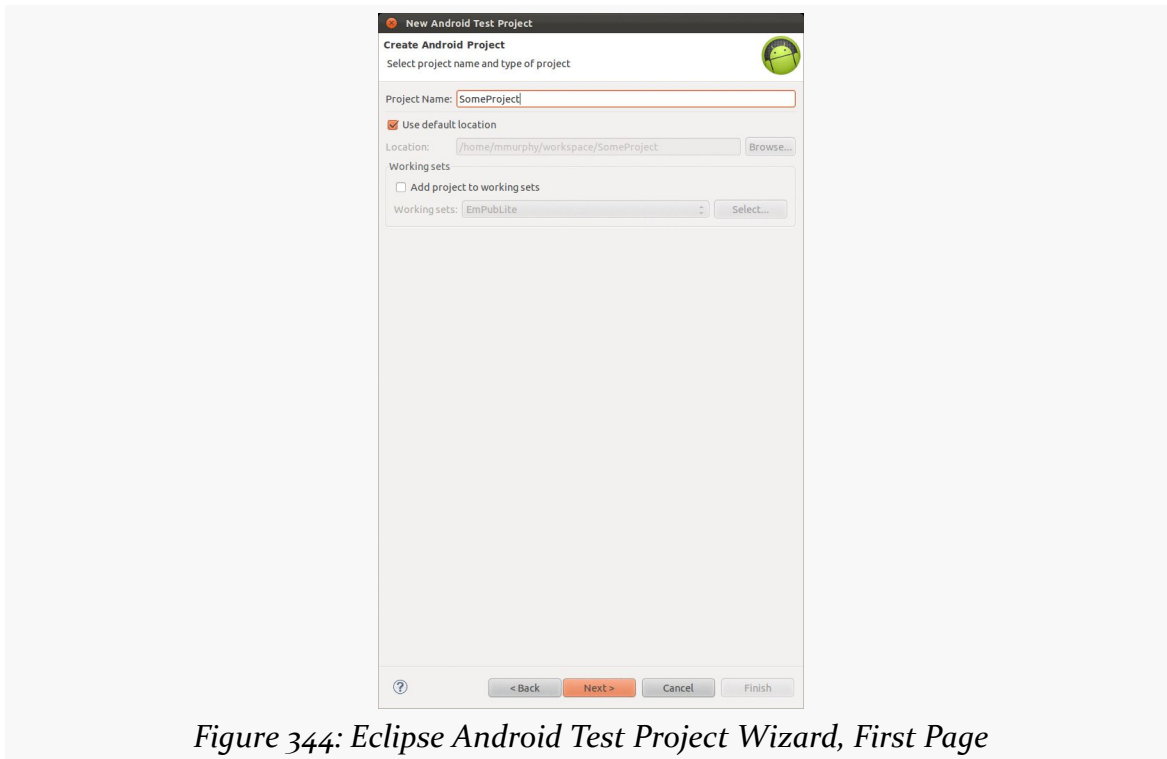

Figure 344: Eclipse Android Test Project Wizard, First Page

The second page of the wizard has you pick from one of your Android projects the one that you wish to test:

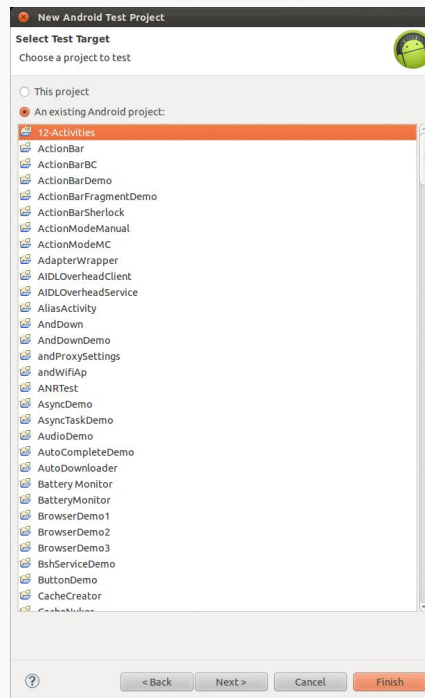

Figure 345: Eclipse Android Test Project Wizard, Second Page

The last page of the wizard lets you specify the build target, which will be based on the build target of the project you specified in the second page:

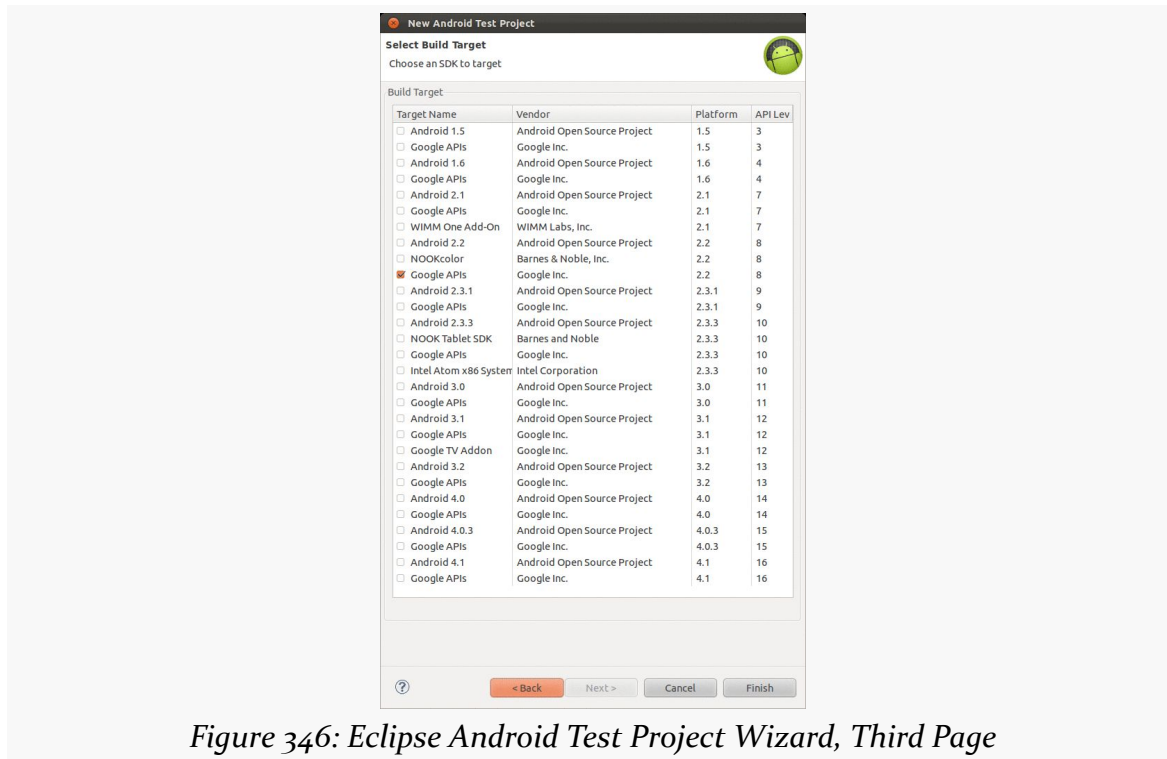

Figure 346: Eclipse Android Test Project Wizard, Third Page

Where Your Test Code Runs

Ordinarily, each code base (e.g., project) is packaged in its own APK and is executed in its own process.

In the case of so-called “instrumentation tests”, like these JUnit tests, your test code and your production code are combined into a single process in a single copy of the virtual machine.

This will allow your JUnit test methods to access objects from your production code, such as your activities and their widgets.

However, this does limit instrumentation testing to be run from a developer’s computer. You cannot package JUnit tests to be initiated from the device itself, except perhaps on rooted devices.

Writing Your Test Cases

A JUnit test project is made up of one (or potentially more) test suites, each comprising one (or usually more) test cases. A test case is a class, containing a series of test methods, designed to test some specific functionality. When a test case is run, JUnit:

- Creates an instance of the test case class
- Calls `setUp()`, where you can do any preparatory work
- Calls one of your test methods
- Calls `tearDown()` for post-test cleanup work
- Repeats the above steps for each test method

Hence, you need to write a series of test cases with test methods, and optionally `setUp()` and `tearDown()` as you see fit.

POJTCs (Plain Old JUnit Test Cases)

For tests that have nothing much to do with Android, you can use the standard JUnit `TestCase` base class. This works the same as JUnit would outside of Android, and is useful for testing business logic on POJOs (plain old Java objects) and the like.

For example, here is a test case that is, well, silly:

```
package com.commonware.android.abf.test;

import junit.framework.TestCase;

public class SillyTest extends TestCase {
    protected void setUp() throws Exception {
        super.setUp();

        // do initialization here, run on every test method
    }

    protected void tearDown() throws Exception {
        // do termination here, run on every test method

        super.tearDown();
    }

    public void testNonsense() {
        assertEquals(1, 1);
    }
}
```

All we have is a single test method — `testNonsense()` that validates that `1` really does equal `1`. Fortunately, this test usually succeeds. Our `TestCase` subclass (`SillyTest`) also implements `setUp()` and `tearDown()` for illustration purposes, as there is little preparation needed for our rigorous and demanding test method.

ActivityInstrumentationTestCase2

While ordinary JUnit tests are certainly helpful, they are still fairly limited, since much of your application logic may be tied up in activities, services, and the like.

To that end, Android has a series of `TestCase` subclasses that you can extend designed specifically to assist in testing these sorts of components.

The one most people focus on is `ActivityInstrumentationTestCase2`. As the name suggests, this class will run your activity for you, giving you access to the `Activity` object itself. You can then:

1. Access your widgets
2. Invoke public and package-private methods (more on this below)
3. Simulate key and touch events

Here are the steps to making use of `ActivityInstrumentationTestCase2`:

- Extend the class to create your own implementation. Since `ActivityInstrumentationTestCase2` is a generic, you need to supply the name of the activity being tested:

```
ActivityInstrumentationTestCase2<ActionBarFragmentActivity>
```

- In the constructor, when you chain to the superclass, supply the activity class itself.
- In `setUp()`, use `getActivity()` to get your hands on your `Activity` object, already typecast to the proper type (e.g., `ActionBarFragmentActivity`) courtesy of our generic. You can also at this time access any widgets, since the activity is up and running by this point.
- If needed, clean up stuff in `tearDown()`, no different than with any other JUnit test case.
- Implement test methods to exercise your activity.

For example, here is a short test case that exercises `ActionBarFragmentActivity`:

```
package com.commonware.android.abf.test;

import android.test.ActivityInstrumentationTestCase2;
import android.test.TouchUtils;
import android.widget.ListView;
import com.commonware.android.abf.ActionBarFragmentActivity;

public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
    private ListView list=null;

    public DemoActivityTest() {
        super(ActionBarFragmentActivity.class);
    }

    @Override
    protected void setUp() throws Exception {
        super.setUp();

        setActivityInitialTouchMode(false);

        ActionBarFragmentActivity activity=getActivity();

        list=(ListView)activity.findViewById(android.R.id.list);
    }

    public void testListCount() {
        assertEquals(25, list.getAdapter().getCount());
    }

    public void testKeyEvents() {
        sendKeys("4*DPAD_DOWN");
        assertEquals(4, list.getSelectedItemPosition());
    }

    public void testTouchEvents() {
        TouchUtils.scrollToBottom(this, getActivity(), list);
        getInstrumentation().waitForIdleSync();
        assertEquals(24, list.getLastVisiblePosition());
    }
}
```

In `setUp()`, we get access to the `ListView` that makes up the bulk of our UI, so we have access to that widget in any test method. We also have three test methods:

- `testListCount()`, where we check our `ListAdapter` in the `ListView` to make sure we have all 25 of our Latin words at the outset
- `testKeyEvents()`, where we simulate pressing the down arrow of a physical keyboard four times, then confirm that the selected row is the proper one

- `testTouchEvents()`, where we use `TouchUtils` and its `scrollToBottom()` method to scroll the `ListView` to the bottom, then confirm that we are actually at the bottom (the last visible row is the 25th row)

The `sendKeys()` method takes both individual key events via their `KeyEvent` constants (e.g., `KeyEvent.KEYCODE_BACK`) or a string containing space-delimited events, where the `KeyEvent.KEYCODE_` prefix is dropped for convenience. Also, a key event can be prefixed by a number and `*` to indicate that the key should be pressed that number of times. So, the `testKeyEvents()` call to `sendKeys("4*DPAD_DOWN")` will simulate four down arrow/D-pad presses in succession.

The `TouchUtils` class has a bunch of low-level methods for performing basic touch events — `scrollToBottom()` is about as sophisticated as they get. In the case of `scrollToBottom()`, the method takes the test case instance, the activity being tested, and the `ViewGroup` to be scrolled. Note that we call `getInstrumentation().waitForIdleSync()` after `scrollToBottom()`, to make sure that our test code blocks waiting for the work to be completed. This was not necessary for `sendKeys()`, as that is documented to have that behavior already.

If you are looking at your emulator or device while this test is running, you will actually see the activity launched on-screen. `ActivityInstrumentationTestCase2` creates a true running copy of the activity. This means you get access to everything you need; on the other hand, it does mean that the test case runs slowly, since the activity needs to be created and destroyed for each test method in the test case. If your activity does a lot on startup and/or shutdown, this may make running your tests a bit sluggish.

Note that our `ActivityInstrumentationTestCase2` resides in a different package than the Activity it is testing. This restricts us to pure black-box testing. If, however, we elected to put the test case in the same package as the activity, we could also call any package-private methods, for a test that is closer to white-box in style.

AndroidTestCase

For tests that only need access to your application resources, you can skip some of the overhead of `ActivityInstrumentationTestCase2` and use `AndroidTestCase`. In `AndroidTestCase`, you are given a `Context` and not much more, so anything you can reach from a `Context` is testable, but individual activities or services are not.

While this may seem somewhat useless, bear in mind that a lot of the static testing of your activities will come in the form of testing the layout: are the widgets

identified properly, are they positioned properly, does the focus work, etc. As it turns out, none of that actually needs an Activity object — so long as you can get the inflated View hierarchy, you can perform those sorts of tests.

Similarly, if you need to test business objects, but because they come from a database you need a Context for use with SQLiteOpenHelper, you could test those with an AndroidTestCase.

Here is a sample AndroidTestCase:

```
package com.commonware.android.abf.test;

import android.test.AndroidTestCase;
import android.view.LayoutInflater;
import android.view.View;
import com.commonware.android.abf.R;

public class DemoContextTest extends AndroidTestCase {
    private View field=null;
    private View root=null;

    @Override
    protected void setUp() throws Exception {
        super.setUp();

        LayoutInflater inflater=LayoutInflater.from(getContext());

        root=inflater.inflate(R.layout.add, null);
        root.measure(800, 480);
        root.layout(0, 0, 800, 480);

        field=root.findViewById(R.id.title);
    }

    public void testExists() {
        assertNotNull(field);
    }

    public void testPosition() {
        assertEquals(0, field.getTop());
        assertEquals(0, field.getLeft());
    }
}
```

Here, we manually inflate the contents of the res/layout/add.xml resource, and lay them out as if they were really in an activity, via calls to `measure()` and `layout()` to simulate a WVGA800 display. At that point, we can start testing the widgets inside of that layout, from simple assertions to confirm that they exist, to testing their size and position.

Other Test Cases

Android also offers various other test case base classes designed to assist in testing Android components, such as:

1. `ServiceTestCase`, used for testing services, as you might expect given the name
2. `ActivityUnitTestCase`, a `TestCase` that creates the Activity (like `ActivityInstrumentationTestCase`), but does not fully connect it to the environment, so you can supply a mock Context, a mock Application, and other mock objects to test out various scenarios
3. `ApplicationTestCase`, for testing custom Application subclasses

Your Test Suite

You will want to organize your test cases into one or more test suites. Many test projects have a single suite. However, elaborate test projects may have different suites for different situations, each representing some subset of the total roster of test cases defined in the project.

The simplest way to set up a test suite is to use Android's built-in `TestSuiteBuilder` class, that pulls in a series of test cases based upon package name, such as the `FullSuite` class in our sample test project:

```
package com.commonware.android.abf.test;

import android.test.suitebuilder.TestSuiteBuilder;
import junit.framework.Test;
import junit.framework.TestSuite;

public class FullSuite extends TestSuite {
    public static Test suite() {
        return(new TestSuiteBuilder(FullSuite.class)
            .includeAllPackagesUnderHere()
            .build());
    }
}
```

Here, we are telling Android to find everything in this package (and sub-packages, if there were any) that implements `TestCase` and include it in the suite. Hence, organizing multiple suites would be a matter of organizing their test cases into separate packages and creating `TestSuite` classes per package.

Running Your Tests

Writing tests is nice. Running tests is nicer. Hence, it would be useful if we could run our JUnit tests. The exact procedure for doing this varies by environment.

Android Studio

At the moment, running tests from Android Studio is a bit of a pain.

First, you must define a new run configuration. To do that, choose Run > “Edit Configurations” from the main menu. That will bring up a dialog showing your current run configurations:

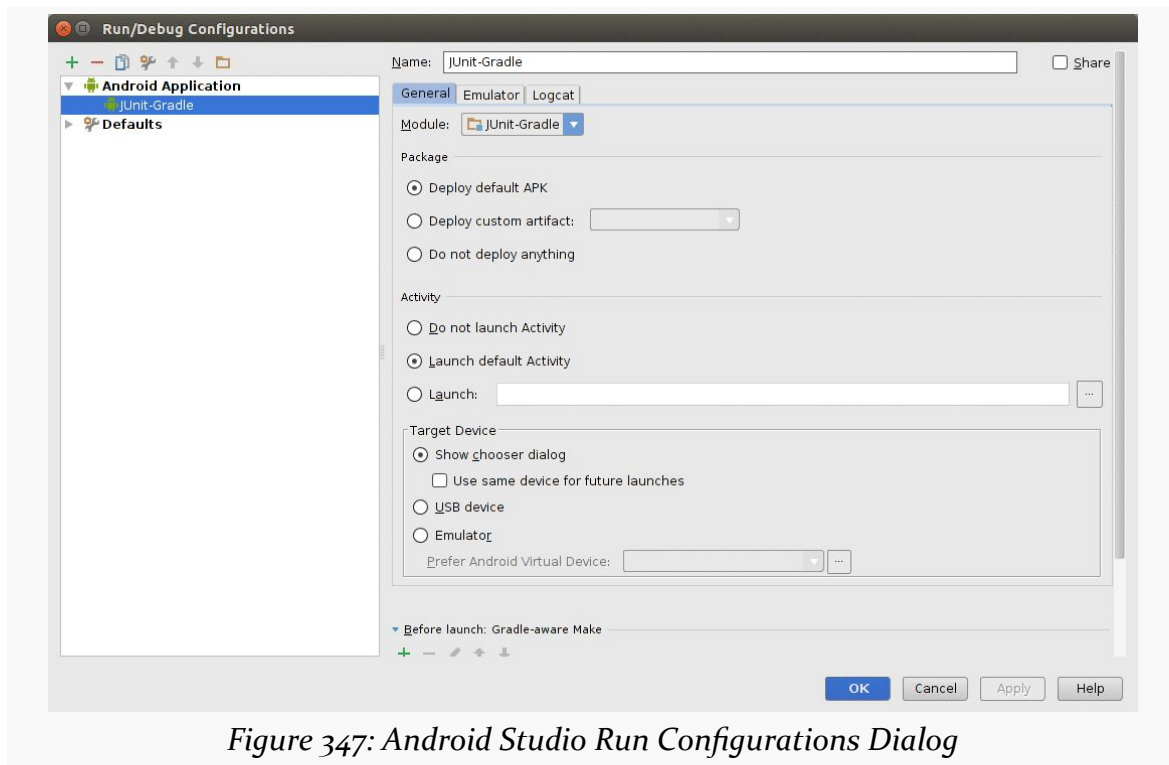

Figure 347: Android Studio Run Configurations Dialog

Towards the upper-left corner of the dialog, you will see a green plus sign. Tapping that will drop down a list of configuration types to choose from:

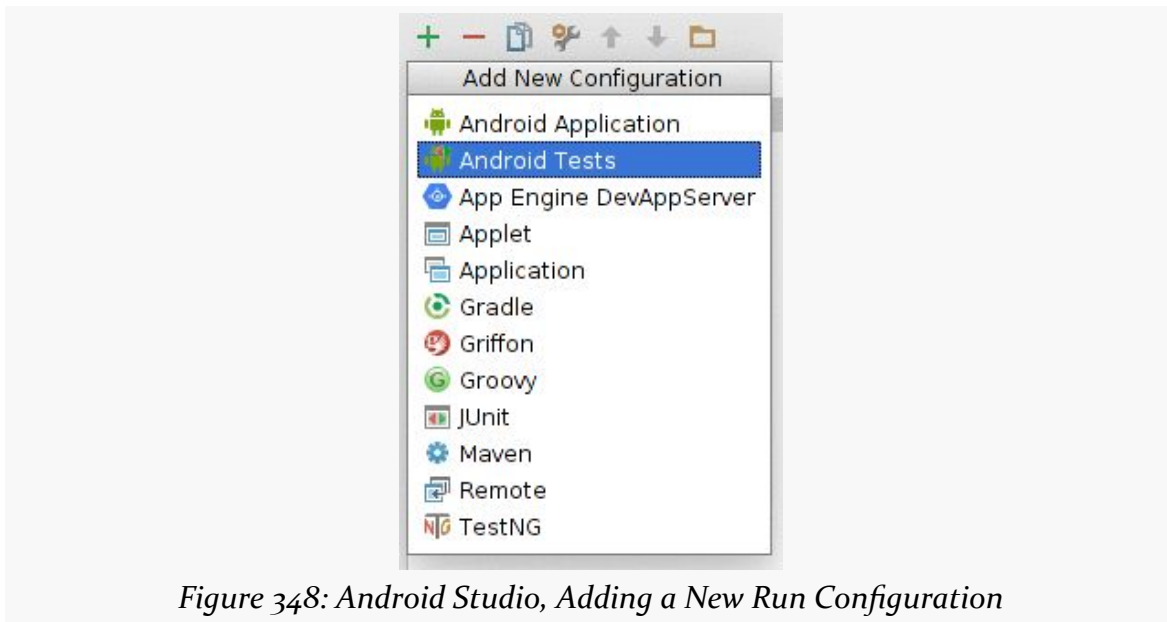

Figure 348: Android Studio, Adding a New Run Configuration

Choose “Android Tests”, and a new empty configuration will be set up for you. You can name it whatever you want via the “Name” field (e.g., “Unit Tests”). Choose your project’s module that you wish to test in the “Module” drop-down (e.g., app). You can also choose the scope of the testing (e.g., “All in Module”), where to run the tests (e.g., “Show chooser dialog”), plus other settings.

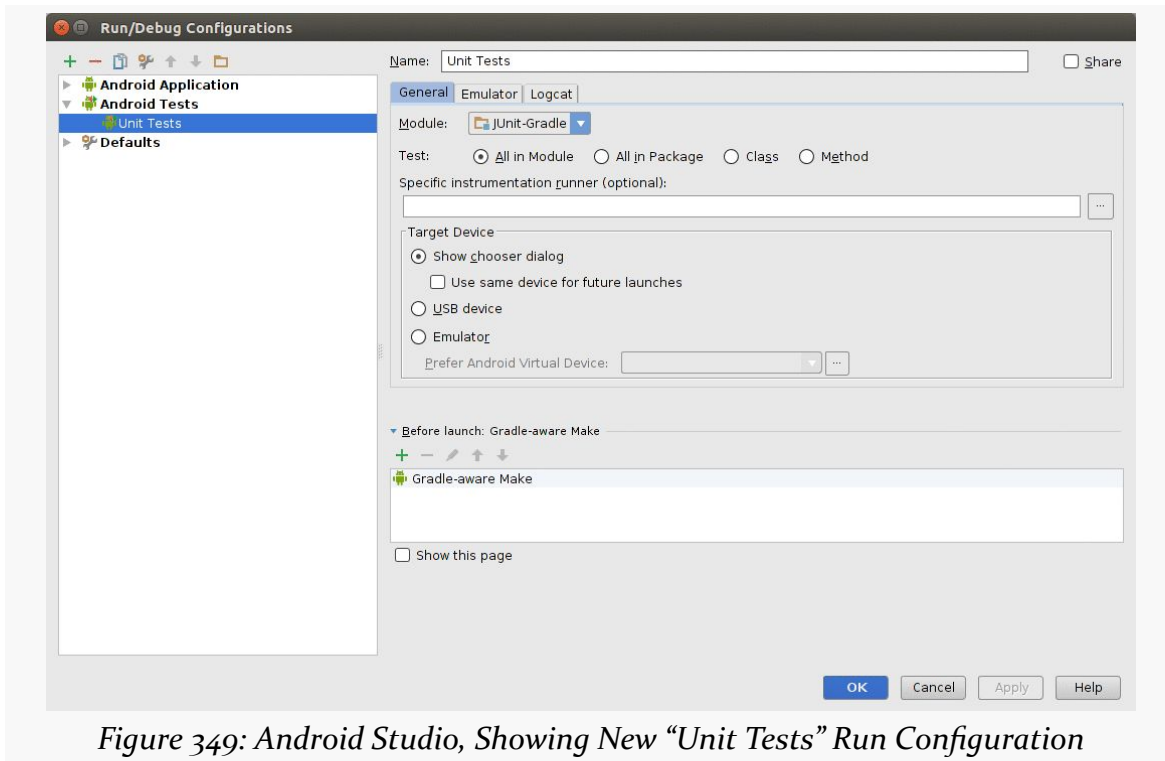

Figure 349: Android Studio, Showing New “Unit Tests” Run Configuration

At that point, you can choose your run configuration from the drop-down to the left of the “play” button in the toolbar:

Figure 350: Android Studio Toolbar, Showing “Unit Tests” Run Configuration

Running that configuration will run your tests. The output will be shown in the Run view, normally docked in the bottom of your IDE window:

JUNIT AND ANDROID

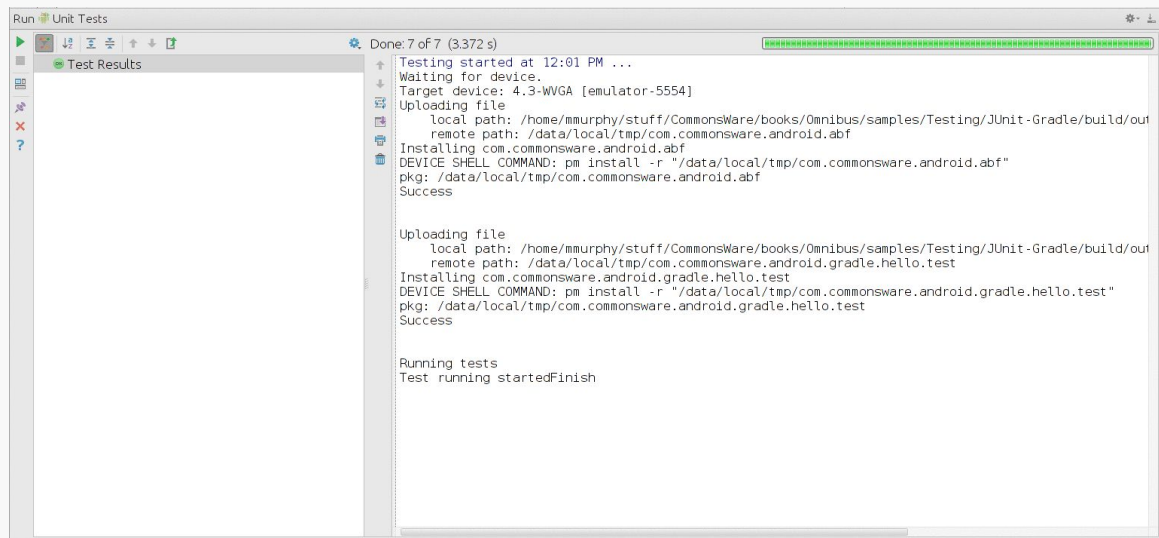

Figure 351: Android Studio, Showing Run Unit Tests Results

If a test fails an assertion or crashes, the test results will show the test case and test method that failed, along with the associated stack trace:

Figure 352: Android Studio, Showing Run Unit Tests Results With a Failure

Gradle for Android

The primary Gradle task that you will use related to testing is `connectedCheck`. This task will build the main app, then, build the test app (using a generated manifest to go along with the code from your `androidTest` sourceset).

At that point, the task will iterate over *all* compatible connected devices and running emulator instances. For each such Android environment, the task will install both apps, run the tests, and uninstall both apps.

Raw test results, in XML format, will be written to `build/outputs/androidTest-results/connected`. These will primarily be of interest to toolsmiths, such as those adding support for Android Gradle-based builds to continuous integration (CI) servers.

For others, the HTML reports will be of greater use. These will be written to `build/outputs/reports/androidTests/connected`, with an `index.html` file serving as your entry point. These will show the results of all of your tests, with hyperlinked pages to be able to “drill down” into the details, such as to investigate failed tests.

Eclipse

You run a test project in Android the same way that you run a regular project. However, when you get the “Run As” dialog, choose “Android JUnit Test”. By default, it will run all of your tests.

However, if you have a single `TestCase` class selected in your Package Explorer, Android can run just that single test case, rather than the full thing — again, choose “Android JUnit Test” in the “Run As” dialog:

JUNIT AND ANDROID

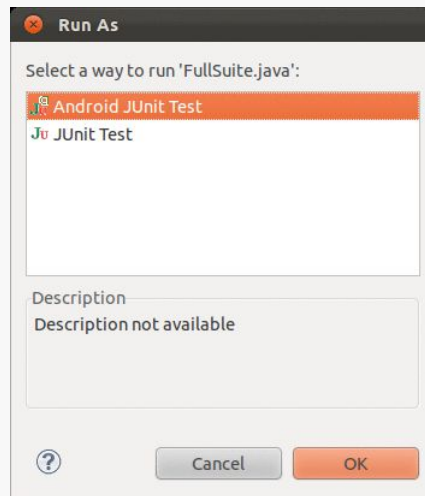

Figure 353: Eclipse “Run As” Dialog for JUnit Test

The results will be displayed in a JUnit view added to your Eclipse workspace, showing the successful and failed tests:

Figure 354: Eclipse Android JUnit Test Results

Testing Android Library Projects

The above procedures are aimed at testing Android application projects. If you are creating an Android library project, you can also use JUnit for testing. However, there will be slight variations in the procedure, once again depending upon environment.

Android Studio and Gradle for Android

A Gradle-built Android library project can have an `androidTest` sourceset, just like a regular app. And, a Gradle-built Android library project can be tested via the `connectedCheck` task. However, that task will create and install a single APK, consisting of the code from the `androidTest` sourceset combined with the library project's own code.

From the standpoint of what you do as a developer, though, it works just like testing an app: add your test cases to the `androidTest` source set and use `connectedCheck` to run the tests.

Eclipse

In Eclipse, to test an Android library project, you create a separate test project and set it up to “this project” (i.e., the package being tested was the test project's own package). This is an option shown on the second page of the new test project wizard:

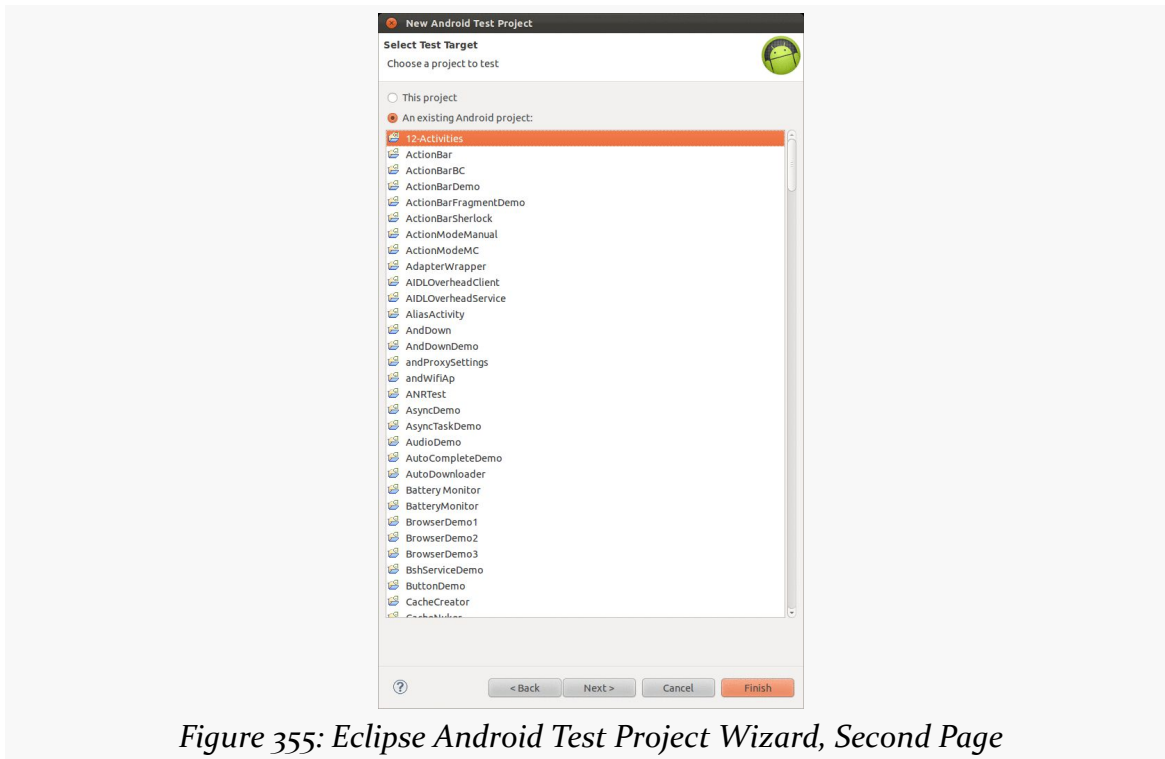

Figure 355: Eclipse Android Test Project Wizard, Second Page

Toggle the radio button at the top to “This project” to set up a test project that tests itself. You then add the Android library project to the test project and write test cases to exercise the library.

Test Dependencies

Sometimes, your test code will have no dependencies, other than the app (or library) being tested.

Sometimes, your test code will have its own dependencies, such as on libraries like [Robotium](#). You need those dependencies for your test code, but you do not want those dependencies to be part of the production app.

To handle this, Gradle for Android (and Android Studio by extension) supports an `androidTestCompile` statement in the dependencies closure. Where `compile` states dependencies for the entire project; `androidTestCompile` states dependencies only for the instrumentation testing:

```
dependencies {  
    // regular dependencies
```

```
compile 'com.android.support:support-v4:19.0.0'
// ...

// test dependencies
androidTestCompile 'com.jayway.android.robotium:robotium-solo:4.3.+'
// ...
}
```

This works similarly to [specifying dependencies for a particular build type](#).

The equivalent in Eclipse would be to add the dependencies to the test project, such as copying a JAR into the test project's `libs/` directory.

Testing Legacy Project Structures with Gradle for Android

Suppose that you have a project that you still need to be buildable using Eclipse, yet you want to start using Gradle. For ordinary projects, using an Eclipse-exported `build.gradle` file will have a setup that supports this. However, your test project will be a standalone Android project, not merely some sourceset, as Eclipse does not know what a “sourceset” even is.

However, just as you can teach the main sourceset where it can find its files, you can do the same thing with the `androidTest` sourceset.

For example, suppose that you have an Android project, one that has a test project located in `tests/`. Both projects follow the legacy project structure. The `android` closure of your `build.gradle` file could look like this:

```
android {
    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        androidTest {
            java.srcDirs = ['tests/src']
            resources.srcDirs = ['tests/src']
            aidl.srcDirs = ['tests/src']
            renderscript.srcDirs = ['tests/src']
        }
    }
}
```

```
        res.srcDirs = ['tests/res']
        assets.srcDirs = ['tests/assets']
    }
}
```

(from [Xavier Ducrohet's answer on Stack Overflow](#))

Here, we teach both the main and the androidTest sourcesets where their respective files are. In the case of the androidTest sourceset, we point it to files in the tests/ subdirectory.

Given this, Gradle can run the tests, just as IDEs can.

Testing with JUnit4

Since the beginning of Android app development, we had unit testing capability via the `AndroidTestRunner`. However, this was based on JUnit3, which nowadays is a bit old.

In late 2014, the `AndroidJUnitRunner` (supporting JUnit4) was added to the Android Support package. This was initially developed outside of the Android tools team, by a separate group in Google devoted to test automation.

In this chapter, we will review how to apply the `AndroidJUnitRunner` to run JUnit4 tests for our Android apps.

Prerequisites

Understanding this chapter requires that you have read [the chapter on JUnit](#) and [the chapter on Gradle dependencies](#).

The AndroidJUnitRunner

JUnit uses test runners to execute our tests. Historically, most developers used `AndroidTestRunner`, as that was what was in the Android SDK and what was officially supported. However, in principle, JUnit test runners do not need to be part of the firmware. `AndroidJUnitRunner` is a great example of this, as it comes as part of the Android Support package, not as part of Android itself.

The primary reason to use `AndroidJUnitRunner` is to be able to use JUnit4 and Espresso tests. That being said, and subject to a few caveats, it is entirely possible for `AndroidJUnitRunner` to run existing JUnit3 tests. This is very useful, given that

rewriting an entire test suite to move *en masse* to JUnit4 may be very time-consuming.

The [Testing/AndroidJUnitRunner](#) sample project is a modified fork of the [Testing/JUnit-Gradle](#) sample project seen in [the chapter on JUnit](#), with the minimum changes needed to get the tests to run successfully with AndroidJUnitRunner.

Note that this sample app only supports Android Studio. There does not appear to be an official recipe for using AndroidJUnitRunner on Eclipse.

Gradle Changes

To use AndroidJUnitRunner, you will need to make a few adjustments to your module's `build.gradle` file.

First, you need to add a test dependency — a dependency that will only be used as part of instrumentation testing. That can be accomplished via an `androidTestCompile` statement in the dependencies closure, instead of a `compile` statement, to limit the scope of the dependency to case where the `androidTest` sourceset is in use.

Specifically, AndroidJUnitRunner resides in the `com.android.support.test:testing-support-lib` artifact in the Android Support Repository, which by now you probably have installed via the SDK Manager.

```
dependencies {  
    androidTestCompile 'com.android.support.test:testing-support-lib:0.1'  
}
```

As of the time of this writing, the latest version of this artifact is 0.1.

However, this artifact also depends upon some other artifacts available in public repositories, like Maven Central or Bintray's JCenter. If you have one of those set up already — and a typical Android Studio project will via the top-level `build.gradle` file — then Gradle will be able to search those repositories for the dependencies. If you do not already have such a repository set up, you will need to do so via the repositories closure, such as is the case in the sample app:

```
repositories {  
    mavenCentral() // required for testing-support-lib dependencies  
}
```

And, because multiple dependencies bundle a `LICENSE.txt` file, and even though we have no use for the `LICENSE.txt` file in the build, the Gradle for Android plugin still complains about duplicate editions of this file. This requires us to filter this out, via a `packagingOptions` closure inside the `android` closure, to exclude the offending file:

```
android {  
    compileSdkVersion 19  
    buildToolsVersion "21.1.2"  
  
    defaultConfig {  
        testApplicationId "com.commonware.android.gradle.hello.test"  
        testInstrumentationRunner  
            "android.support.test.runner.AndroidJUnitRunner"  
    }  
  
    packagingOptions {  
        exclude 'LICENSE.txt' // required for no good reason...  
    }  
}
```

Switching Test Runners

Then, every place where we specify a test runner, we can use `AndroidJUnitRunner` instead of `AndroidTestRunner`. This includes the `testInstrumentationRunner` defined in the `defaultConfig` closure, shown above.

When running tests within Android Studio, the run configuration can specify the instrumentation runner to use:

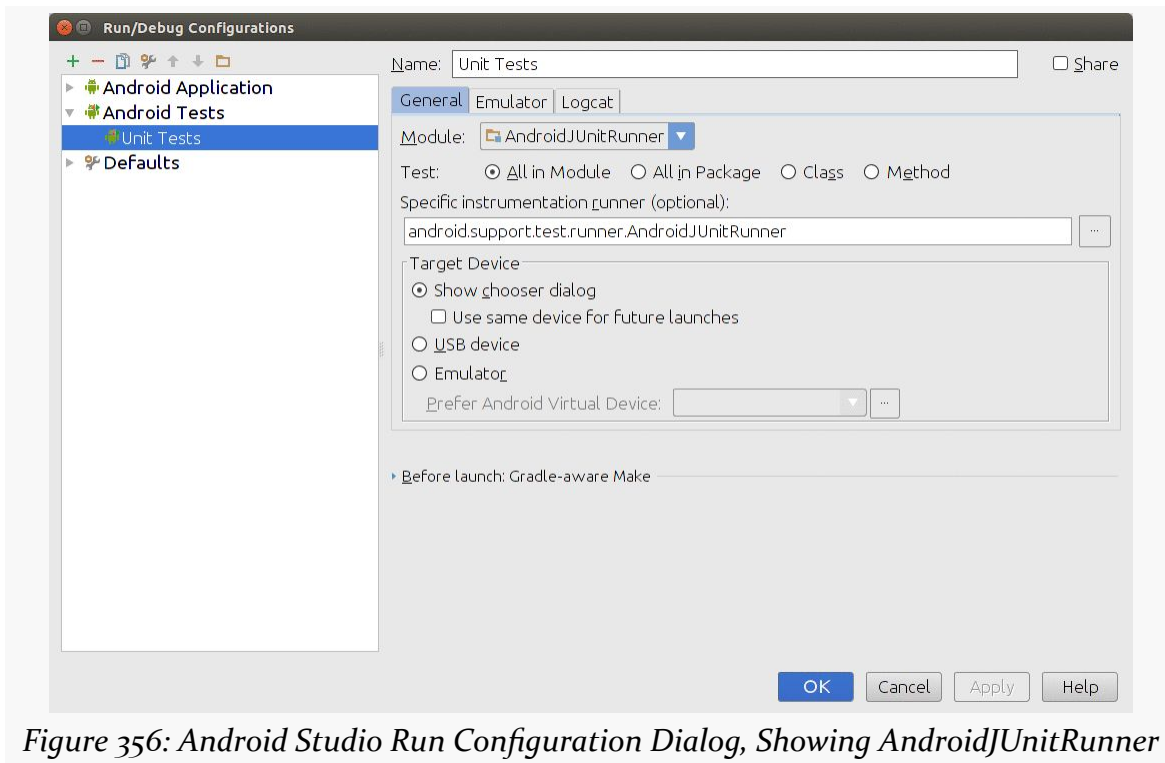

Figure 356: Android Studio Run Configuration Dialog, Showing AndroidJUnitRunner

Removing Your Suites

The JUnit-Gradle sample app from [the chapter on JUnit](#) had a FullSuite implementation of JUnit3's TestSuite. [This does not appear to be supported by AndroidJUnitRunner at present.](#)

Results

The results of running the AndroidJUnitRunner tests — other than the aforementioned suite limitation — should be identical to what you would have with using the classic AndroidTestRunner.

JUnit4

JUnit4, introduced in 2006, is a substantial revision to JUnit3, offering greater flexibility in how you set up your test code. JUnit4 is the current basis for JUnit, and so with AndroidJUnitRunner, Android developers are more up to date with respect to which version of JUnit they can use.

This book does not attempt to cover all aspects of JUnit4. For that, you are encouraged to read [the JUnit documentation](#) or other books on Java testing. This chapter will cover some of the basics of using JUnit4 tests, plus some of the issues with using JUnit4 tests in Android.

The Basics of 4

JUnit4 has the same spirit of testing as does JUnit3, but the actual mechanics are significantly different.

The Class

In JUnit3, we had to inherit from a magic `TestCase` class, supplied by JUnit.

In JUnit4, that is no longer the case (pun lightly intended).

Any Java class can serve as a test case, so long as it has a zero-argument public constructor and is known to the test runner that it contains tests to be run. In the case of `AndroidJUnitRunner`, that comes via a `@RunWith(AndroidJUnit4.class)` annotation on the class, to signal that this class contains tests:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
    // test code goes here
}
```

Identifying Test Methods

In JUnit3, test methods were literally methods whose names began with `test`. That, coupled with the reliance upon `TestCase` as a base class, allowed JUnit3 to use reflection to find the subclasses of `TestCase`, then find all of the test methods within those test cases.

In JUnit4, a test method is any public method that is annotated with the `@Test` annotation:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
    @Test
    public void kThxBye() {
        // do some testing
    }
}
```

While there is nothing stopping you from prefixing the method name with `test`, it is superfluous and usually skipped.

Asserting Results

Since we no longer have access to inherited assertion methods from `TestCase`, JUnit4 supplies an `Assert` class with static assertion methods that we can employ:

```
@RunWith(AndroidJUnit4.class)
public class SillyTest {
    @Test
    public void thisIsReallySilly() {
        Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
    }
}
```

`assertEquals()` takes either two parameters of the same type for comparison (e.g., two `int` values), or three parameters, where the first is a custom assertion failure message.

There are countless other methods on `Assert` (e.g., `assertNotNull()`) for testing objects, collections, etc.

Setup and Teardown

In JUnit3, we could have methods with the magic names of `setUp()` and `tearDown()`. These would be called before (`setUp()`) and after (`tearDown()`) each test method invocation, to set up test “fixtures” (i.e., starter data to be available to all test methods).

In JUnit4, you can name the methods whatever you want, but you need to annotate them with `@Before` (replacing `setUp()`) and `@After` (replacing `tearDown()`). JUnit4 also adds static `@BeforeClass` and `@AfterClass` methods, which are invoked once for the entire test case, designed for setting up immutable starter data for test methods and avoiding the overhead of doing that work on each test method invocation.

The [Testing/JUnit4](#) sample project is a reworking of the `Testing/AndroidJUnitRunner` sample project, this time with all of the test cases set up for JUnit4. Here, `SillyTest` has more flexibility — showing off the implementation of `@BeforeClass` and `@AfterClass`, for example — but is still equally silly:

```
package com.commonware.android.abf.test;

import android.support.test.runner.AndroidJUnit4;
import junit.framework.Assert;
import org.junit.After;
import org.junit.AfterClass;
import org.junit.Before;
import org.junit.BeforeClass;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class SillyTest {
    @BeforeClass
    static public void doThisFirstOnlyOnce() {
        // do initialization here, run once for all SillyTest tests
    }

    @Before
    public void doThisFirst() {
        // do initialization here, run on every test method
    }

    @After
    public void doThisLast() {
        // do termination here, run on every test method
    }

    @AfterClass
    static public void doThisLastOnlyOnce() {
        // do termination here, run once for all SillyTest tests
    }

    @Test
    public void thisIsReallySilly() {
        Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
    }
}
```

Requirements and Backwards Compatibility

One major limitation with AndroidJUnitRunner, with respect to JUnit4, is that while your overall suite of test code can be a mix of JUnit3 and JUnit4, you cannot have a single test *class* mix the approaches. Either the class should extend `TestCase` and follow JUnit3 rules (e.g., test methods prefixed by `test`) or use the JUnit4 annotations, but not both.

Reworking Android-Specific Test Cases

Standard JUnit4 stuff works fine for testing POJOs or other functionality that is not tied to Android constructs like a Context.

The testing-support-lib artifact does not contain equivalents for classes like ActivityInstrumentationTestCase2 (or other classes that inherit from InstrumentationTestCase) or AndroidTestCase. If you wish, you are welcome to stick with JUnit3 syntax for those. If, however, you would prefer to use JUnit4 syntax, you can certainly try.

ActivityInstrumentationTestCase2

The [documentation for AndroidJUnitRunner](#) contains instructions — albeit incomplete ones — for using ActivityInstrumentationTestCase2 with JUnit4 syntax. The same basic approach may work for other subclasses of InstrumentationTestCase. This is illustrated in the revised version of DemoActivityTest in the sample app.

First, as with any JUnit4 test class, you have to add the @RunWith(AndroidJUnit4.class) annotation to the class itself:

```
@RunWith(AndroidJUnit4.class)
public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
```

If you did not have a setUp() method, you need to add one. If you did have a setUp() method, you will need to change it. Specifically:

- It now needs to be public
- It now needs the @Before annotation, as JUnit4 does not pay any attention to the setUp() method name
- It needs to have the
injectInstrumentation(InstrumentationRegistry.getInstrumentation()) statement added, shortly after super.setUp(), to hook in the instrumentation offered via AndroidJUnitRunner

```
@Before
@Override
public void setUp() throws Exception {
    super.setUp();

    injectInstrumentation(InstrumentationRegistry.getInstrumentation());
}
```

TESTING WITH JUNIT4

```
setActivityInitialTouchMode(false);

ActionBarFragmentActivity activity=getActivity();

list=(ListView)activity.findViewById(android.R.id.list);
}
```

If you did not have a `tearDown()` method, you need to add one. If you did have a `tearDown()` method, you will need to change it, with the same basic steps as the first two we did for `setUp()`:

- It now needs to be public
- It now needs the `@After` annotation, as JUnit4 does not pay any attention to the `tearDown()` method name

The required `setUp()` and `tearDown()` is because we can no longer rely upon JUnit4 magically calling those methods, and `ActivityInstrumentationTestCase2` expects them to be called.

You also need to add the `@Test` annotation to any test method, as with any other JUnit4 test class. Plus, you will need to switch to the Assert class' assertions, rather than any inherited ones.

So, the revised `DemoActivityTest` looks like:

```
package com.commonware.android.abf.test;

import android.support.test.InstrumentationRegistry;
import android.support.test.runner.AndroidJUnit4;
import android.test.ActivityInstrumentationTestCase2;
import android.test.TouchUtils;
import android.widget.ListView;
import com.commonware.android.abf.ActionBarFragmentActivity;
import junit.framework.Assert;
import org.junit.After;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
    private ListView list=null;

    public DemoActivityTest() {
        super(ActionBarFragmentActivity.class);
    }
}
```

```
@Before
@Override
public void setUp() throws Exception {
    super.setUp();

    injectInstrumentation(InstrumentationRegistry.getInstrumentation());
    setActivityInitialTouchMode(false);

    ActionBarFragmentActivity activity=getActivity();

    list=(ListView)activity.findViewById(android.R.id.list);
}

@After
public void tearDown() throws Exception {
    super.tearDown();
}

@Test
public void listCount() {
    Assert.assertEquals(25, list.getAdapter().getCount());
}

@Test
public void keyEvents() {
    sendKeys("4*DPAD_DOWN");
    Assert.assertEquals(4, list.getSelectedItemPosition());
}

@Test
public void touchEvents() {
    TouchUtils.scrollToBottom(this, getActivity(), list);
    getInstrumentation().waitForIdleSync();
    Assert.assertEquals(24, list.getLastVisiblePosition());
}
}
```

Note that you will get warnings on each of your @Test methods, complaining about how you are using that annotation on a class that inherits from JUnit3's TestCase. This is intentional behavior on our part. However, [there is no obvious way to suppress this warning](#).

The Wharton Alternative

However, this is not your only option. In fact, Jake Wharton appears to not like this option very much, and he has offered [an alternative solution: ActivityRule](#).

In JUnit4, a Rule is a way of encapsulating setup and teardown work in a way that does not force the use of inheritance from base classes. Mr. Wharton's

TESTING WITH JUNIT4

ActivityRule encapsulates a bit of the logic from ActivityInstrumentationTestCase2 for setting up and finishing an activity for every test method.

This does simplify testing for some cases:

```
@RunWith(AndroidJUnit4.class)
public final class TrivialTest {
    @Rule public final ActivityRule<YourActivityGoesHere> main
        =new ActivityRule(YourActivityGoesHere.class);

    // your test methods go here
}
```

The test methods can refer to main to call the get() method, which returns the Activity instance being tested (already cast to be your activity class). This replaces the getActivity() call you used to inherit from ActivityInstrumentationTestCase2.

However, it would take more code to cover everything that is lost from ActivityInstrumentationTestCase2. There are other methods, like sendKeys(), that we got by inheriting from ActivityInstrumentationTestCase2 that we lack. Also, TouchUtils expects an InstrumentationTestCase, and that would need to be rewritten to work without one.

The sample app has a copy of ActivityRule, plus a DemoActivityRuleTest demonstrating its use. The latter has a copy of sendKeys() from the Android Open Source Project to allow that particular test method to continue to work.

AndroidTestCase

AndroidTestCase and its subclasses are simpler to retrofit. These can be converted into ordinary JUnit4 test classes. Anywhere you used to call getContext() in an AndroidTestCase can be replaced with a call to InstrumentationRegistry.getTargetContext(), which will give you a Context in the app being tested.

The DemoContextTest, therefore, turns into:

```
package com.commonware.android.abf.test;

import android.support.test.InstrumentationRegistry;
import android.support.test.runner.AndroidJUnit4;
import android.test.AndroidTestCase;
```

```
import android.view.LayoutInflater;
import android.view.View;
import com.commonware.android.abf.R;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoContextTest {
    private View field=null;
    private View root=null;

    @Before
    public void init() {
        LayoutInflater inflater=LayoutInflater
            .from(InstrumentationRegistry.getTargetContext());

        root=inflater.inflate(R.layout.add, null);
        root.measure(800, 480);
        root.layout(0, 0, 800, 480);

        field=root.findViewById(R.id.title);
    }

    @Test
    public void exists() {
        Assert.assertNotNull(field);
    }

    @Test
    public void position() {
        Assert.assertEquals(0, field.getTop());
        Assert.assertEquals(0, field.getLeft());
    }
}
```

The `InstrumentationRegistry` also has `getInstrumentation()` (which returns the `Instrumentation` object that we are using for testing) and `getContext()` (which returns the `Context` for our test code's package).

MonkeyRunner and the Test Monkey

Many GUI environments have some means or another of “fuzz” or “bash” testing, where some test driver executes a bunch of random input, in hopes of catching errors (e.g., missing validation logic). Android offers the Test Monkey for this.

Many GUI environments have some means or another of scripting GUI events from outside the application itself, to simulate button clicks or touch events. Android offers MonkeyRunner for this.

As the names suggest, there is a bit of commonality in their implementation. And, as you might expect, there is a bit of commonality in their coverage in this book — we will examine both MonkeyRunner and the Test Monkey in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

MonkeyRunner

MonkeyRunner is a means of creating test suites for Android applications based off of scripted UI input. Rather than write a series of JUnit test cases or the like, you create Jython (JVM implementation of Python) scripts that run commands to install apps, execute GUI events, and take screenshots of results.

Writing a MonkeyRunner Script

The primary object you will work with in a MonkeyRunner script is a `MonkeyDevice`, which represents your connection to the device or emulator that you are testing. You obtain a `MonkeyDevice` by calling `waitForConnection()` on `MonkeyRunner`; this will return once it has established a connection.

From there, `MonkeyDevice` lets you send events to the device or emulator:

- `installPackage()` allows you to install an APK from your development machine, and `removePackage()` allows you to get rid of it
- `startActivity()` and `broadcastIntent()` allow you to start up components of your app
- `press()` to simulate key events, including QWERTY keys, standard device keys like BACK, D-pad/trackball events, and anything else represented by a standard Android `KeyEvent`
- `type()` to simulate entering a whole string, as a simplification over calling `press()` once per letter
- `touch()` and `drag()` let you simulate touch events
- and so on

The biggest limitation is in getting data out of the device, to determine if your test worked successfully. Your options are:

- `takeSnapshot()`, which will capture a screenshot that you can save to disk, compare with other screenshots, etc.
- `shell()` executes `adb shell` commands, returning any results
- ...and that's about it

Unlike [JUnit-based testing](#), you have no visibility into the activity beyond what appears on the screen — you cannot inspect widgets, call methods, or the like.

For example, here is a script that installs an app, runs an activity from it, and presses the down button on the D-pad three times:

```
from com.android.monkeyrunner import MonkeyRunner, MonkeyDevice

device = MonkeyRunner.waitForConnection()
device.installPackage('bin/JUnitDemo.apk')
device.startActivity(component='com.commonware.android.abf/
com.commonware.android.abf.ActionBarFragmentActivity')
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
```

```
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
# result = device.takeSnapshot()
# result.writeToFile('tests/monkey_sample_shots/test1.png', 'png')
```

Executing MonkeyRunner

To execute your MonkeyRunner script, have your device or emulator set up at a likely starting point (e.g., home screen), then execute the `monkeyrunner` command, passing it the path to your script (e.g., `monkeyrunner monkey_sample.py`). You will see the script executing on the screen of your device or emulator, and your console will contain whatever output you might emit from your test script itself. For example, you might take screenshots, compare them against a master copy (using methods on `MonkeyImage` to help with this), and emit warnings if they differ unexpectedly.

Monkeying Around

Independent from the JUnit system and MonkeyRunner is the Test Monkey (referred to here as “the Monkey” for short).

The Monkey is a test program that simulates random user input. It is designed for “bash testing”, confirming that no matter what the user does, the application will not crash. The application may have odd results — random input entered into a Twitter client may, indeed, post that random input to Twitter. The Monkey does not test to make sure that results of random input make sense; it only tests to make sure random input does not blow up the program.

You can run the Monkey by setting up your initial starting point (e.g., the main activity in your application) on your device or emulator, then running a command like this:

```
adb shell monkey -p your.package.here -v --throttle 100 600
```

(substituting the package name of a project on your device or emulator for `your.package.here`)

Working from right to left, we are asking for 600 simulated events, throttled to run every 100 milliseconds. We want to see a list of the invoked events (`-v`) and we want to throw out any event that might cause the Monkey to leave our application, as determined by the application’s package (`-p your.package.here`).

The Monkey will simulate keypresses (both QWERTY and specialized hardware keys, like the volume controls), D-pad/trackball moves, and sliding the keyboard open or closed. Note that the latter may cause your emulator some confusion, as the emulator itself does not itself actually rotate, so you may end up with your screen appearing in landscape while the emulator is still, itself, portrait. Just rotate the emulator a couple of times (e.g., <Ctrl>-<F12>) to clear up the problem.

For playing with a Monkey, the above command works fine. However, if you want to regularly test your application this way, you may need some measure of repeatability. After all, the particular set of input events that trigger your crash may not come up all that often, and without that repeatable scenario, it will be difficult to repair the bug, let alone test that the repair worked.

To deal with this, the Monkey offers the `-s` switch, where you provide a seed for the random number generator. By default, the Monkey creates its own seed, giving totally random results. If you supply the seed, while the sequence of events is random, it is random for that seed — repeatedly using the same seed will give you the same events. If you can arrange to detect a crash and know what seed was used to create that crash, you may well be able to reproduce the crash.

There are many more Monkey options, to control the mix of event types, to generate profiling reports as tests are run, and so on. The [Monkey documentation](#) in the SDK's Developer's Guide covers all of that and more.

Testing with UIAutomator

Yet another approach for testing Android applications is `uiautomator`. This blends JUnit and Test Monkey approaches, offering some unique advantages over either of those individual frameworks.

However, at the present time, it would appear that the Android Studio beta does not have support for `uiautomator` projects. Hence, if you are not comfortable with Eclipse, this is not going to be a viable option for you right now.

Prerequisites

This chapter assumes that you have read [the chapter on JUnit-based testing](#), mostly for comparison purposes. Having read [the chapter on monkeyrunner and the Test Monkey](#) is also a good idea, again for comparison purposes.

What Is UIAutomator?

`uiautomator`, as the name suggests, automates UIs. It simulates user input, in the form of tapping on items and the like. It does so without modifying your process' contents, and so in that respect it behaves like the Test Monkey.

However, unlike the Test Monkey, tests run by `uiautomator` are implemented in JUnit, and those tests have limited access to the widgets inside of a UI. Such access not only allows for directing simulated user input (e.g., “click the OK button”), but also for asserting that various test conditions are true (e.g., “does the list have five rows?”). In this respect, `uiautomator` behaves like traditional Android JUnit testing.

Why Choose UIAutomator Over Alternatives?

In some respects, `uiautomator` represents the worst of both worlds. You have to use JUnit, making test authoring a challenge for those not skilled with Java. Yet you only have fairly generic access to an activity's widgets, versus the complete white-box capability of normal instrumentation-based JUnit testing.

Hence, why would anyone bother?

The big thing that `uiautomator` offers over classic JUnit testing is greater ability to test an *application* versus testing *individual components*. The classic JUnit test cases are organized around testing some specific component, such as using `ActivityInstrumentationTestCase2` to exercise some specific activity. Testing the flow of work between activities is difficult from classic JUnit, but is relatively easy with `uiautomator`. You can also use this for integration testing, as you can exercise and analyze applications other than your own, such as to confirm that you are starting a third-party app correctly.

Similarly, classic JUnit testing cooks up activity instances “out of thin air”. Instead, `uiautomator` executes normal UI operations to create the activities, such as tapping on your app's icon in the home screen launcher. This more accurately simulates what a user will do — users are far more likely to tap on a launcher than to hack into your Dalvik VM and manually instantiate an activity.

Creating Some Tests

As with JUnit, creating test cases for `uiautomator` involves creating a separate project. In this case, though, the project will create just an ordinary Java JAR file, not an APK, let alone one designed to run in the same process as your main app. `uiautomator` can then run that JAR to execute your tests, as we will see [later in this chapter](#).

You can see a set of `uiautomator` tests in a suitable project in the [Testing/JUnit/uiautomator](#) directory. This is where the various code samples shown in this chapter come from.

Using this project straight from the GitHub repo will require some modifications, discussed below.

Setting Up for Command-Line Builds

While some pieces of the process for creating and executing `uiautomator` tests can be done from an IDE, not all can. Hence, you will need to be set up to support command-line builds in addition to any IDE you might already have configured.

Creating the Test Project

First, create an ordinary Java project, *not* an Android application project or an Android test project. You can place this project wherever you want on your development machine's filesystem — it does not have to be in some “magic directory” relative to the application being tested.

In that project, you will need to add two JARs to your classpath: `uiautomator.jar` and `android.jar`. The latter is the standard compile-time edition of the Android SDK, what you normally get in an Android application project by specifying your build target. The former, as the name might suggest, contains classes related to writing `uiautomator` tests.

These two JARs are Android version-specific, insofar as there are different editions of these JARs for each Android API level from API Level 16 on up. Since tests written using these JARs are backwards-compatible, you will typically choose the most recent edition of the JARs for your project. In particular, choosing a JAR that is for API Level 18 or higher is a good idea, to give you access to some newer automation APIs.

In Eclipse, you would add those JARs via right-clicking on the project, choosing Build Path > Configure Build Path from the context menu, switching to the Libraries tab, clicking “Add External JARs...”, navigating to the appropriate platforms/ subdirectory in your SDK installation (e.g., `platforms/android-17/`), and choosing those two JARs. Outside of Eclipse, you would add those two JARs to your compile-time classpath via whatever means are appropriate.

You also need to attach JUnit to the project. In Eclipse, to do this, you would right-click on the project, choose Build Path > Add Libraries..., choose JUnit from the resulting dialog, then choose JUnit3 from the final dialog. You would need to do something similar outside of Eclipse to attach JUnit to your compile-time classpath.

Then, you will need to make the project files necessary to prepare your code for use as a `uiautomator` test JAR. To do that, you will need to run the `android create uitest-project` command:

```
android create uitest-project -n <name> -t android-17 -p <path>
```

where:

- `-n` is the name you wish to give the JAR, minus the `.jar` file extension. Note that the documentation presently claims that this is optional; it is not.
- `-t` to indicate what API level's JARs you are using. This needs to be the name of the directory from which you pulled the JARs (e.g., `android-17`). Note that the documentation presently shows something else (a value of 1), which is incorrect.
- `-p [path>` needs to point to the directory in which your test project will reside (note: *not* your production project!)

If you are trying to use the sample test project from the GitHub repo, you will need to adjust the references to the external JARs (`android.jar` and `uiautomator.jar`) to point to your own SDK installation, as the project configuration files will be pointing elsewhere (unless your development environment is set up exactly the same as that of the author of this book, which would be really surprising).

Creating a Test Case

Your test case classes should inherit from `com.android.uiautomator.core.UiAutomatorTestCase`, supplied by the `uiautomator.jar` library. This will initialize the `uiautomator` connection to your device or emulator and give you access to it via a `UiDevice` object, retrieved by calling `getUiDevice()`. You will use this object as your primary gateway into the device for events and retrieving information about your UI, as will be seen in the next few sections.

Note that `UiAutomatorTestCase` itself inherits from the standard `JUnit TestCase` class, and so you are also welcome to create `setUp()` and `tearDown()` methods as you see fit.

Performing Device-Level Actions

The `UiDevice` you get from `getUiDevice()` has many methods that allow you to perform device-level actions, such as calling `pressHome()` to press the HOME button (and thereby bring up the home screen). Similarly, you can call:

- `pressBack()` and `pressMenu()` for the BACK and MENU buttons
- `pressDPadUp()`, `pressDPadLeft()`, etc. for D-pad events

- `pressRecentApps()` to bring up the recent tasks list
- `pressKeyCode()` to press an arbitrary key based on the keycode from `KeyEvent`

...and so on.

Inspecting and Interacting with the UI

Of course, pressing some buttons is not especially useful on its own, only as a means to an end, such as launching your activity. To do more than this, you will need to get your hands on widgets and containers, to perform operations related to them.

The key is that you can “get your hands on widgets and containers” *from whatever activity is in the foreground*. This is not limited to your own app, but rather works for *any* app, including the home screen itself.

The following sections will work through some common `uiautomator` operations, in the context of the `openActivity()` from the `ListTests` class in the sample project. This method, called from `setUp()`, consolidates the work to bring an instance of our production activity to the foreground, by means of interacting with the home screen:

```
private void openActivity() throws UiObjectNotFoundException {
    getUiDevice().pressHome();

    UiObject allAppsButton=
        new UiObject(new UiSelector().description("Apps"));

    allAppsButton.clickAndWaitForNewWindow();

    UiObject appsTab=new UiObject(new UiSelector().text("Apps"));
    appsTab.click();

    UiScrollable appViews=
        new UiScrollable(new UiSelector().scrollable(true));

    appViews.setAsHorizontalList();

    UiObject ourApp=
        appViews.getChildByText(new
            UiSelector().className("android.widget.TextView"),
                "Action Bar Fragment Demo");

    ourApp.clickAndWaitForNewWindow();

    UiObject appValidation=
```

```
new UiObject(  
    new  
    UiSelector().packageName("com.commonware.android.abf"));  
    assertTrue("Could not open test app", appValidation.exists());  
}
```

Finding and Interaction with Widgets

`openActivity()` starts by calling `pressHome()` on the `UiDevice`, to ensure that the home screen is in the foreground:

```
getUiDevice().pressHome();
```

Next, we want to bring up the home screen's launcher, showing the available launchable activities, so that we can find our app and launch it. What a user would do, on a stock Android environment like an emulator, would be to click on the appropriate button to bring up the launcher. We need to do the same thing, except from our test code. This implies:

- Finding that widget
- Simulating a click of that widget

Web developers are used to finding DOM nodes by CSS queries. Developers using XML are used to using XPath queries to find particular elements. Along the same lines, `uiautomator` gives us a flexible system to find widgets in the foreground activity, by means of a `UiSelector` object, typically created using the public zero-argument constructor (i.e., `new UiSelector()`).

In CSS, a “selector” can identify DOM nodes by class, id, or ones with particular properties. A `UiSelector` can do much the same thing. So, the first `UiSelector` created in `openActivity()` will find a widget in the foreground activity whose “description” is Apps (`new UiSelector().description("Apps")`). Here, “description” will mean either the text of a `TextView` or the `android:contentDescription` of other types of widgets.

How do we know that this particular button has a “description” of Apps? In this case, we found out using `uiautomatorviewer`, which will be discussed [later in this chapter](#).

By passing our `UiSelector` to the constructor of `UiObject`, we get a `UiObject` that, hopefully, knows how to interact with this particular button of the home screen. In

particular, we call `clickAndWaitForNewWindow()` on it, which taps the button and blocks until something else (e.g., a new activity) has taken over the foreground:

```
UiObject allAppsButton=  
    new UiObject(new UiSelector().description("Apps"));  
  
allAppsButton.clickAndWaitForNewWindow();
```

The stock Android launcher has two tabs, one for apps and one for (app) widgets. We need to ensure that the apps tab is selected. So, once again, we create a `UiSelector` and use it to create a `UiObject` to represent the apps tab. This time, we use `text()` instead of `description()`. `text()` will find a widget based solely on its display text (e.g., `android:text` of a `TextView`). In truth, we could have used `description()` here as well, with the same results.

Then, we call `click()` on the `UiObject`, to simulate a tap on this tab, to ensure that is the selected tab.

```
UiObject appsTab=new UiObject(new UiSelector().text("Apps"));  
  
appsTab.click();
```

Dealing with Collections

Finding widgets by text or description is fairly easy when there is only one possible widget that has that text or description. Things get more complicated when you are dealing with a collection of widgets, such as an `AdapterView`.

For example, the Apps tab of the standard Android launcher uses a `GridView` to show up to 20 launchable activities. Then, you need to swipe horizontally, courtesy of a `ViewPager`, to uncover additional `GridView` collections of launchable activities.

A `UiCollection` helps deal with this, in terms of allowing you to inspect a collection of widgets, including performing the necessary swipe operations to access all of the contents.

A `UiSelector` called with `scrollable(true)` will return a widget that is scrollable. Creating a `UiCollection` with that `UiSelector` will create a `UiCollection` around the first scrollable widget. In the case of the Apps tab, that will be the `ViewPager-and-GridView` combination.

In our case, to get to other elements in the collection, you need to swipe horizontally. To configure the `UiCollection` that way, we have to call `setAsHorizontalList()` on the `UiCollection`:

```
UiScrollable appViews=  
    new UiScrollable(new UiSelector().scrollable(true));  
  
appViews.setAsHorizontalList();
```

Finding Widgets By Type

In that collection, we want to find the item that contains our app's caption. This test project is designed to test the same sample app that was tested in [the JUnit chapter](#), a slightly modified version of an early action bar sample. Our launcher entry's name will be "Action Bar Fragment Demo", as that is what we set up in the production project's manifest and string resources. So, we need to find the entry in the `ViewPager-of-GridViews` that has that title.

To do that, we will create yet another `UiSelector`. This time, though, we will find widgets by type, specifying `className("android.widget.TextView")` to only work with `TextView` widgets.

That `UiSelector` is passed into the `getChildByText()` method of `UiCollection`, which will iterate over the children to find the first one that matches the `UiSelector` and where the selected widget contains the supplied text:

```
UiObject ourApp=  
    appViews.getChildByText(new  
        UiSelector().className("android.widget.TextView"),  
            "Action Bar Fragment Demo");
```

Then, we again call `clickAndWaitForNewWindow()`, to tap on our launcher entry, triggering our app's activity to come to the foreground:

```
ourApp.clickAndWaitForNewWindow();
```

Asserting Conditions

`UiSelector` and `UiObject` can also be used for some odd operations that do not fit the normal widgets-and-containers pattern shown above.

For example, now that we have opened a window from our app to be tested, it would be nice to confirm that, indeed, this is our app, and that our `openActivity()` method did not open some other app by mistake.

To do this, we can create a `UiSelector` and apply `packageName()`, to constrain the selection to widgets coming from an app with our desired package name:

```
UiObject appValidation=  
    new UiObject(  
        new  
UiSelector().packageName("com.commonware.android.abf"));
```

The `UiObject` we create always exists (i.e., is not null), as we are creating it via the constructor. However, it is entirely possible that our `UiSelector` cannot match any widget, such as would be the case if we accidentally opened the wrong app and tried to find a widget stemming from our package. The `exists()` method on a `UiObject` returns true if the `UiObject` is pointing at an actual widget, false otherwise. Hence, we can assert that we indeed have a widget coming from our package:

```
assertTrue("Could not open test app", appValidation.exists());
```

The net result is that we open our main activity and confirm that, indeed, that is what we opened.

Two Sample Test Methods

All of that was just to get the activity for testing onto the screen.

Now the *real* testing begins.

The `ListTests` class has two test methods, `testContents()` and `testAdd()`, designed to (lightly) exercise the UI.

testContents()

The objective of the `testContents()` method is to confirm that the 25 words all appear in the `ListView`.

To do that, we:

- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity

- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Iterate over the array of words, finding the `TextView` for each word and confirming that this widget does indeed exist

```
public void testContents() throws UiObjectNotFoundException {
    UiScrollable words=
        new UiScrollable(
            new UiSelector().className("android.widget.ListView"));

    words.setAsVerticalList();

    for (String s : items) {
        assertNotNull("Could not find " + s,
            words.getChildByText(new
                UiSelector().className("android.widget.TextView"),
                    s));
    }
}
```

testAdd()

The objective of the `testAdd()` method is to add a new word to the list, via the `EditText` widget in our action bar, then confirm that the new word was actually added to the list.

To do that, we:

- Retrieve the `EditText` by finding the widget whose text is “Word” (the hint of our `EditText`)
- Call `setText()` to fill in `snicklefritz` into the `EditText` widget, which `UiObject` accomplishes by actually typing in the value
- Call `pressEnter()` on the `UiDevice` to simulate pressing the Enter key of a keyboard, which will trigger our action listener in the test activity and will add the word to the list
- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity
- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Try to find a `TextView` whose text is `snicklefritz` and assert that it was found

```
public void testAdd() throws UiObjectNotFoundException {
    UiObject add=new UiObject(new UiSelector().text("Word"));
```

```
add.setText("snicklefritz");
getUiDevice().pressEnter();

UiScrollable words=
    new UiScrollable(
        new UiSelector().className("android.widget.ListView"));

words.setAsVerticalList();

assertNotNull("Could not find snicklefritz",
    words.getChildByText(new
UiSelector().className("android.widget.TextView"),
        "snicklefritz"));
}
```

Cleaning Up

Our ListTests class also has a tearDown() method, invoked by JUnit after each test method. Here, we press BACK twice, to return us to the main home screen from our activity, setting things back up for the next test method:

```
@Override
public void tearDown() {
    getUiDevice().pressBack();
    getUiDevice().pressBack();
}
```

Running Your Tests

At the present time, running your tests is a fairly manual process, driven from the command line. In the future, with luck, there will be better tooling to assist with this.

Building and Pushing the JAR

Your test project, created via `android create uitest-project`, should contain an Ant build.xml file. Hence, running `ant build` from the root of your test project's directory should create a JAR file in `bin/` containing your compiled test code.

You then need to push that to the device's temporary directory, `/data/local/tmp`, such as via the `adb push` command:

```
adb push bin/NameOfYour.jar /data/local/tmp/
```

Executing uiautomator

To actually run the tests, you will use `adb shell` to run the `uiautomator` command on the connected device or emulator:

```
adb shell uiautomator runtest <jar> -c <tests>
```

where:

- `<jar>` is the name of the test JAR that you pushed to the device in the preceding step.
- `<tests>` is the fully-qualified name of your test class (e.g., `com.commonware.android.abf.uiautomator.ListTests`), optionally with a suffix identifying a single test method to run (e.g., `com.commonware.android.abf.uiautomator.ListTests#testContents`). Without this suffix, all test methods on the class will be run. You can specify two or more classes (or class+methods) using a space as a separator between them.

There are [other command-line switches](#) that you can optionally provide to further customize the behavior of your tests, though the ones listed above are all that are needed.

As with running a classic set of JUnit tests, the output of the test run is dumped to your terminal window, showing you the successes and failures.

Note that the device or emulator will have to be set up with your production app, so that your test code that launches it will succeed. Since the test project and the production project are decoupled, simply running the `uiautomator` does not automatically push a new copy of your app to the device or emulator, though you could augment some build scripts or a wrapper shell script/batch file to do this for you.

Finding Your Widgets

The key to finding your desired widgets stems in large part from the `text()` or `description()` methods on `UiSelector`. Of those two, the latter is more flexible, as it will use the `android:contentDescription` from any widget, while `text()` is limited to `TextView` and its subclasses.

However, this implies that your widgets have `android:contentDescription` defined. This is also important for [accessibility](#), and therefore is a good idea regardless of its use with `uiautomator`.

For testing your own code, you can also find widgets via their resource IDs. `UiSelector` has `resourceId()` and `resourceIdMatches()` methods to configure the resource ID you want. As the `resourceIdMatches()` method name suggests, the resource ID here is a *string representation* of the resource name. It will be of the form `your.app.package:id/resource` (e.g., `com.commonware.android.hotkey:id/editor`). However:

- Note that this requires API Level 18 or higher versions of the two JARs (`uiautomator.jar` and `android.jar`)
- Note that this requires running the tests on an API Level 18+ device or emulator
- Bear in mind that third party apps are welcome to rename their widgets when they wish, so your integration tests may break when third parties do so

Trail: Advanced UI

Introducing GridLayout

In 2011, Google added `GridLayout` to our roster of available container classes (a.k.a., layout managers). `GridLayout` is an attempt to make setting up complex Android layouts a bit easier, particularly with an eye towards working well with IDE graphical layout editors. In this chapter, we will examine why `GridLayout` was added and how we can use it in our projects.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Issues with the Classic Containers

Most layouts are implemented using a combination of `LinearLayout`, `RelativeLayout`, and `TableLayout`. Almost everything you would want to be able to create can be accomplished using one, or sometimes more than one, of those containers.

However, there are issues with the classic containers. The two most prominent might be the over-reliance upon nested containers and issues with drag-and-drop GUI building capability.

Nested Containers

`LinearLayout` and `TableLayout` suffer from a tendency to put too many containers inside of other containers. For example, implementing some sort of 2x2 grid would involve:

- A vertical `LinearLayout` holding onto a pair of horizontal `LinearLayout`s, or
- A `TableLayout` holding onto a pair of `TableRows`

On the surface, this does not seem that bad. And, in many cases, it is not that bad.

However, views and containers are relatively heavyweight items. They consume a fair bit of heap space, and when it comes time to lay them out on the screen, they consume a fair bit of processing power. In particular, the fact that a container can hold onto *any* type of widget or container means that it is difficult to optimize common scenarios (e.g., a 2x2 grid) for faster processing. Instead, a container treats its children more or less as “black boxes”, requiring lots of method invocations up and down the call stack to calculate sizes and complete the layout process.

Moreover, the call stack itself can be an issue. The stack size of the main application thread has historically been rather small (8KB was the last reported value). If you have a complex UI, with more than ~15 nested containers, you are likely to run into a `StackOverflowError`. Android itself will contribute some of these containers, exacerbating this problem.

`RelativeLayout`, by comparison, can implement some UI patterns without any nested containers, simply by positioning widgets relative to the container’s bounds and relative to each other.

Drag-and-Drop

Where `RelativeLayout` falls down is with the drag-and-drop capability of the graphical layout editor in IDEs like Eclipse and Android Studio.

When you release the mouse button when dropping a widget into the preview area, the tools need to determine what that really means in terms of layout rules.

`LinearLayout` works fairly well: it will either insert your widget in between two other widgets or add it to the end of the row or column you dropped into. `TableLayout` behaves similarly.

`RelativeLayout`, though, has a more difficult time guessing what particular combination of rules you really mean by this particular drop target. Are you trying to attach the widget to another widget? If so, which one? Are you trying to attach the widget to the bounds of the `RelativeLayout`? While sometimes it will guess properly, sometimes it will not, with potentially confusing results. It is reasonably

likely that you will need to tweak the layout rules manually, either via the Properties pane or via the raw XML.

The New Contender: GridLayout

GridLayout tries to cull the best of the capabilities of the classic containers and drop as many of their limitations as possible.

GridLayout works a bit like `TableLayout`, insofar as it sets things up in a grid, with rows and columns, where the row and column sizes are computed based upon what is placed into those rows and columns. However, unlike `TableLayout`, which relies upon a separate `TableRow` container to manage the rows, `GridLayout` takes the `RelativeLayout` approach of putting rules on the individual widgets (or containers) in the grid, where those rules steer the layout processing. For example, with `GridLayout`, widgets can declare specifically which row and column they should slot into.

`GridLayout` also goes a bit beyond what `TableLayout` offers in terms of capabilities. Notably, it supports row spans as well as column spans, whereas `TableRow` only supports a column span. This gives you greater flexibility when designing your layout to fit the grid-style positioning rules. You can also:

- Explicitly state how many columns there are, rather than having that value be inferred by row contents
- Allow Android to determine where to place a widget without specifying any row or column, with it finding the next available set of grid cells capable of holding the widget, based upon its requested row span and column span values
- Have control over orientation: whereas `TableLayout` always was a column of rows, you could have a `GridLayout` be a row of columns, if that makes implementing the design easier
- And so on

GridLayout and the Android Support Package

`GridLayout` was natively added to the Android SDK in API Level 14 (Android 4.0). Fortunately, the Android Support package has a backport of `GridLayout`. However, the backport is not in one of the JAR files, such as `support-v4`, as `GridLayout` requires some resources. Hence, it is in an Android library project that you must add to your project, known as `gridlayout-v7`.

Android Studio users can simply add a compile 'com.android.support:gridlayout-v7:...' statement to their top-level dependencies closure, for some version identified by So long as those users have the Android Repository set up in the SDK Manager, Gradle will be able to find and incorporate the artifact.

Eclipse users can copy the library project from \$SDK/extras/android/support/v7/gridlayout (where \$SDK is wherever you installed your copy of the Android SDK) to some other spot on their development machine. Then, they can import the library project and attach it to their app project, as was described in the [chapter on library projects](#).

When using the backported GridLayout, you will need to declare another XML namespace in your layout XML resources. That namespace will be http://schemas.android.com/apk/res-auto. If you use an IDE to add the GridLayout to the layout resource, it will automatically add this namespace, under the prefix of app, such as:

```
<android.support.v7.widget.GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">
</android.support.v7.widget.GridLayout>
```

That namespace is required for GridLayout-specific attributes. For example, we can have a columnCount attribute, indicating how many columns the GridLayout should contain. For the native API Level 14 GridLayout, that attribute would be android:columnCount. For the backport, it will be app:columnCount, assuming that you gave the namespace the prefix of app.

When citing GridLayout-specific attributes, the rest of this chapter will use the app prefix, to clarify which attributes need that prefix for the backport. If you are using the native API Level 14 implementation of GridLayout, and you are manually working with the XML, just remember to use android as a prefix instead of app.

The sample app shows *both* the native and the backport implementations of GridLayout: on API Level 14+ devices/emulators it will use native implementations from res/layout-v14/, and it will use the backport on older environments.

Eclipse and GridLayout

You will find GridLayout in the “Layouts” portion of the palette of available widgets and containers. As with anything else, you can drag it from the palette into the preview area, then use the Outline and Properties views to configure it.

However, this is the native API Level 14 version of GridLayout, not the backport. If you wish to use the backport, you will need to go into the XML and manually adjust the element name, to be `android.support.v7.widget.GridLayout` instead of `GridLayout`. This may, in turn, require restarting Eclipse to make it happy, if you get errors in the preview area when trying to view the resulting GridLayout.

Trying to Have Some Rhythm

One of the things that the Android design guidelines try to emphasize is having everything work in 48dp-high blocks, to give you a reasonable set of touch targets for fingers, while maintaining some uniformity of sizing.

Figure 357: 48dp Rhythm, Depicted (image courtesy of Android Open Source Project)

When working with GridLayout in the Eclipse graphical layout editor, you will be prompted to try to put your widgets in 48dp-based positions. There is even a “snap to grid” toolbar toggle button that, when pressed, will force everything you drag into the GridLayout to reside on a 16dp-based grid.

To accomplish this, it adds a series of Space widgets to your layout (or, if you are working with the backport of GridLayout, you get `android.support.v7.widget.Space` widgets). These will consume the space that gets your widgets to line up in what Eclipse thinks is the proper positioning. We will see examples of that as we examine our sample application.

Our Test App

To look at a series of GridLayout-based layouts, let's turn our attention to the [GridLayout/Sampler](#) sample project. This has the same ViewPager and PagerTabStrip as did the second sample app from [the chapter on ViewPager](#). However, rather than use a list of 10 EditText widgets managed by fragments, in this case, our fragments will manage layouts containing GridLayout. Each page of our pager will contain a TrivialFragment, whose contents are based on a Sample class that is a simple pair of a layout resource ID and a string resource ID for the fragment's title:

```
package com.commonware.android.gridlayout;

class Sample {
    int layoutId;
    int titleId;

    Sample(int layoutId, int titleId) {
        this.layoutId=layoutId;
        this.titleId=titleId;
    }
}
```

Our revised SampleAdapter maintains a static ArrayList of these Sample objects, one per layout we wish to examine, and uses those values to populate our ViewPager title:

```
package com.commonware.android.gridlayout;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;
import java.util.ArrayList;

public class SampleAdapter extends FragmentPagerAdapter {
    static ArrayList<Sample> SAMPLES=new ArrayList<Sample>();
    private Context ctxt=null;

    static {
        SAMPLES.add(new Sample(R.layout.row, R.string.row));
        SAMPLES.add(new Sample(R.layout.column, R.string.column));
        SAMPLES.add(new Sample(R.layout.table, R.string.table));
        SAMPLES.add(new Sample(R.layout.table_flex, R.string.flexible_table));
        SAMPLES.add(new Sample(R.layout.implicit, R.string.implicit));
        SAMPLES.add(new Sample(R.layout.spans, R.string.spans));
    }
}
```

INTRODUCING GRIDLAYOUT

```
public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
}

@Override
public int getCount() {
    return(SAMPLES.size());
}

@Override
public Fragment getItem(int position) {
    return(TrivialFragment.newInstance(getSample(position).layoutId));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(getSample(position).titleId));
}

private Sample getSample(int position) {
    return(SAMPLES.get(position));
}
}
```

TrivialFragment just inflates our desired layout, having received the layout resource ID as a parameter to its factory method:

```
package com.commonware.android.gridlayout;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class TrivialFragment extends Fragment {
    private static final String KEY_LAYOUT_ID="layoutId";

    static TrivialFragment newInstance(int layoutId) {
        TrivialFragment frag=new TrivialFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_LAYOUT_ID, layoutId);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
```

```
return(inflater.inflate(getArguments().getInt(KEY_LAYOUT_ID, -1),
    container, false));
}
```

Note that if you load this project from the GitHub repository, you will need to update it for your copy of the GridLayout library project.

Replacing the Classics

Let's first examine the behavior of GridLayout by seeing how it can replace some of the classic layouts we would get from LinearLayout and TableLayout. Each of the following sub-sections will examine one GridLayout-based layout XML resource, how it can be constructed, and what the result looks like when viewed in the sample project.

Horizontal LinearLayout

The classic way to create a row of widgets is to use a horizontal LinearLayout. The LinearLayout will put each of its children, one after the next, within the row.

The GridLayout equivalent is to specify one that has an `app:columnCount` equal to the number of widgets in the row. Then, each widget will have `app:layout_column` set to its specific column index (starting at 0) and `app:layout_row` set to 0, as seen in `res/layout/row.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <Button
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/button"/>

    <Button
        app:layout_column="1"
        app:layout_row="0"
        android:text="@string/button"/>

</android.support.v7.widget.GridLayout>
```

INTRODUCING GRIDLAYOUT

Unlike `LinearLayout`, though, we do not specify sizes of the children, in terms of `android:layout_width` and `android:layout_height`. `GridLayout` works a bit like `TableLayout` in this regard, supplying default values for these attributes. In the case of `GridLayout`, the defaults are `wrap_content`, and this cannot be overridden (akin to the behavior of immediate children of a `TableRow`). Instead, you will control size via row and column spans, as will be illustrated later in this chapter.

Given the above layout, we get:

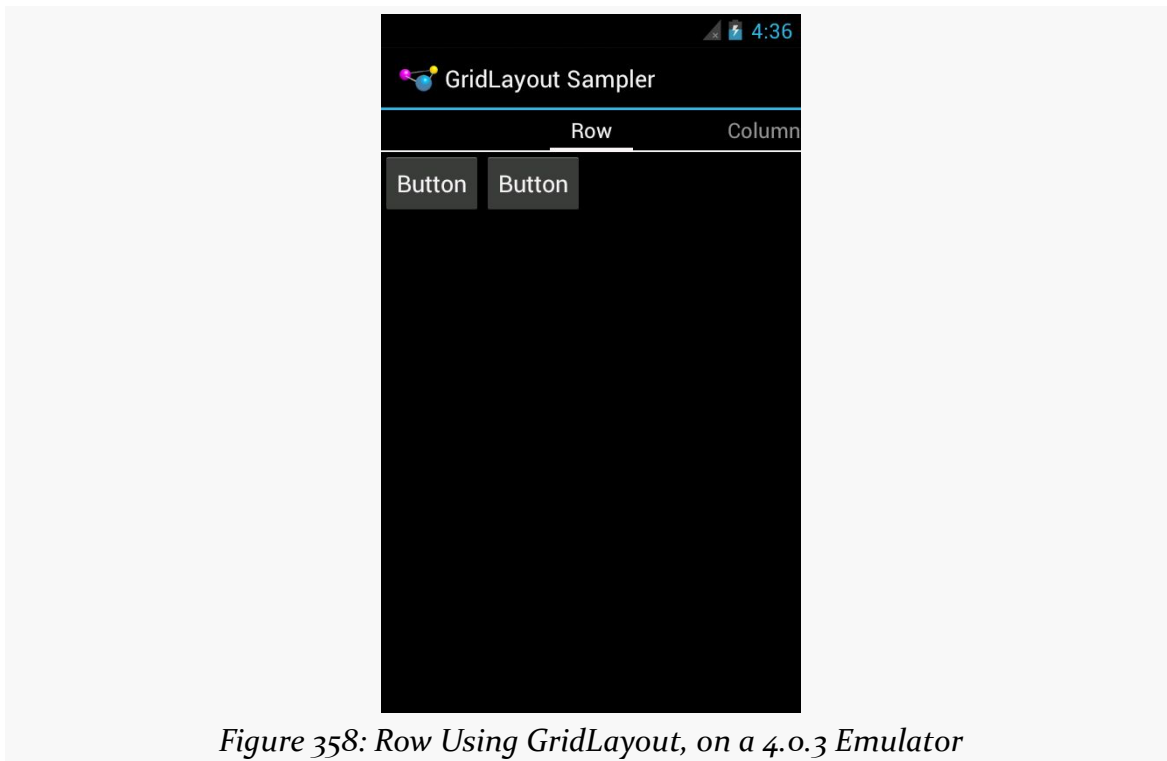

Figure 358: Row Using GridLayout, on a 4.0.3 Emulator

Vertical LinearLayout

Similarly, the conventional way you would specify a column is to use a vertical `LinearLayout`, which would position its children one after the next. The `GridLayout` equivalent would be to have `app:columnCount` set to 1, and to place the widgets in each required row via `app:layout_row` attributes, as seen in `res/layout/column.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
```

INTRODUCING GRIDLAYOUT

```
android:layout_height="match_parent"
app:columnCount="1">

<Button
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/button"/>

<Button
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/button"/>

</android.support.v7.widget.GridLayout>
```

Figure 359: Column Using GridLayout, on a 4.0.3 Emulator

All that being said, it is still probably better to use `LinearLayout` in these cases, rather than mess with `GridLayout`.

TableLayout

The big key to a `TableLayout` is column width, where columns expand to fill their contents, assuming there is sufficient room in the table. `GridLayout` also expands its columns to address the sizes of its contents.

INTRODUCING GRIDLAYOUT

For example, here is a simple 2x2 table, with TextView widgets in the left column and EditText widgets in the right column, as seen in res/layout/table.xml:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <TextView
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/name"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

    <EditText
        app:layout_column="1"
        app:layout_row="0"
        android:inputType="textPersonName">

        <requestFocus/>
    </EditText>

    <TextView
        app:layout_column="0"
        app:layout_row="1"
        android:text="@string/address"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

    <EditText
        app:layout_column="1"
        app:layout_row="1"
        android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

One feature of the Eclipse graphical layout editor is that we can toggle on a series of lines showing the sizing of the rows and columns, by clicking the “Show Structure” toolbar button:

Figure 360: “Show Structure” Toolbar Icon

This helps illustrate that our right column actually takes up all remaining room on the screen, by showing green gridlines denoting the transitions between rows and columns:

Figure 361: “Show Structure” Output for GridLayout Table Layout

However, our EditText widgets are small, because nothing is causing them to fill the available space. To do that, we can use `android:layout_gravity`, to ask the GridLayout to let the widgets fill the available horizontal space, as seen in `res/layout/table_flex.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <TextView
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/name"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

    <EditText
```

INTRODUCING GRIDLAYOUT

```
app:layout_column="1"
app:layout_row="0"
app:layout_gravity="fill_horizontal"
android:inputType="textPersonName">

    <requestFocus/>
</EditText>

<TextView
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

<EditText
    app:layout_column="1"
    app:layout_row="1"
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress" />

</android.support.v7.widget.GridLayout>
```

This allows the EditText widgets to fill the width of the column:

Figure 362: Table Using GridLayout, on a 4.0.3 Emulator

That holds true regardless of how wide that column is:

Figure 363: Table Using GridLayout, in Landscape, on a 4.0.3 Emulator

Implicit Rows and Columns

While all the previous samples showed the row and column of each widget being defined explicitly via `app:layout_row` and `app:layout_column` attributes, that is not your only option.

If you have `app:columnCount` on the `GridLayout` element itself, you can allow `GridLayout` to assign rows and columns. In this respect, `GridLayout` behaves a bit like a “flow layout”: it assigns widgets to cells in the first row, starting from the first column and working its way across, wrapping to the next row when it runs out of room. This makes for a more terse layout file, at the cost of perhaps introducing a bit of confusion when you add or remove a widget and everything after it in the layout file shifts location.

For example, `res/layout/implicit.xml` is the same as `res/layout/table_flex.xml`, except that it skips the `app:layout_row` and `app:layout_column` attributes, allowing `GridLayout` to assign the positions:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2"
```

INTRODUCING GRIDLAYOUT

```
app:orientation="horizontal">

<TextView
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

<EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPersonName">

    <requestFocus/>
</EditText>

<TextView
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

<EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

Visually, this sample is identical to the last one:

Figure 364: Table Using GridLayout and Implicit Positions, on a 4.0.3 Emulator

The “across columns, then down rows” model holds for GridLayout in the default orientation: horizontal. You can add an `app:orientation` attribute to the GridLayout, setting it to vertical. Then, based on an `app:rowCount` value, GridLayout will automatically assign positions, working down the first column, then across to the next column when it runs out of rows.

Row and Column Spans

Like TableLayout, GridLayout supports the notion of column spans. You can use `app:layout_columnSpan` to indicate how many columns a particular widget should span in the resulting grid.

However, GridLayout also supports row spans, in the form of `app:layout_rowSpan` attributes. A widget can span rows, columns, or both, as needed.

If you are using implicit positions, per the previous section, GridLayout will seek the next available space that has sufficient rows and columns for a widget’s set of spans.

For example, the following diagram depicts five buttons placed in a GridLayout with various spans, and an attempt to add a sixth button that should span two columns:

Figure 365: Span Sample (image courtesy of Android Open Source Project)

Assuming the first five buttons were added in sequence and with implicit positioning, GridLayout ordinarily would drop the sixth button into the fourth column of the third row. However, there is only a one-column-wide space available there, given that the third button intrudes into the third row. Hence, GridLayout will skip over the smaller space and put the sixth button into the sixth column in the third row.

A GridLayout-based layout that implements the above diagram can be found in `res/layout/spans.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="9"
    app:orientation="horizontal"
    app:rowCount="5">

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="2"
        android:text="@string/string_1"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_2"/>

    <Button
        app:layout_gravity="fill_vertical"
        app:layout_rowSpan="4"
        android:text="@string/string_3"/>

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="3"
        app:layout_rowSpan="2"
        android:text="@string/string_4"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="3"
        android:text="@string/string_5"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_6"/>

    <android.support.v7.widget.Space
        android:layout_width="36dp"
        app:layout_column="0"
        app:layout_row="4"/>

    <android.support.v7.widget.Space
        android:layout_width="36dp"
        app:layout_column="1"
        app:layout_row="4"/>
```

```
<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="2"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="3"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="4"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="5"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="6"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="7"
    app:layout_row="4"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="0"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="1"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="2"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="3"/>

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
```

INTRODUCING GridLayout

```
app:layout_row="4"/>  
</android.support.v7.widget.GridLayout>
```

This layout shows one of the limitations of GridLayout: its columns and rows will have a size of 0 by default. Hence, to ensure that each row and column has a minimum size, this layout uses Space elements (in an eighth column and fifth row) to establish those minimums. This makes the layout file fairly verbose, but it gives the desired results:

Figure 366: GridLayout Spans, on a 4.0.3 Emulator

However, the fixed-sized Space elements break the fluidity of the layout:

Figure 367: GridLayout Spans, in Landscape, on a 4.0.3 Emulator

Perhaps someday someone will create a PercentSpace widget, occupying a percentage of the parent's size, that could be used instead.

The author would like to give thanks to [those on Stack Overflow who assisted in getting the span layout to work](#).

Dialogs and DialogFragments

Generally speaking, modal dialogs are considered to offer poor UX, particularly on mobile devices. You want to give the user more choices, not fewer, and so locking them into “deal with this dialog right now, or else” is not especially friendly. That being said, from time to time, there will be cases where that sort of modal interface is necessary, and to help with that, Android does have a dialog framework that you can use.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

DatePickerDialog and TimePickerDialog

Android has a pair of built-in dialogs that handle the common operations of allowing the user to select a date (`DatePickerDialog`) or a time (`TimePickerDialog`). These are simply dialog wrappers around the [DatePicker](#) and [TimePicker](#) widgets, as are described in this book’s Widget Catalog.

The `DatePickerDialog` allows you to set the starting date for the selection, in the form of a year, month, and day of month value. Note that the month runs from 0 for January through 11 for December. Most importantly, both let you provide a callback object (`OnDateChangeListener` or `OnDateSetListener`) where you are informed of a new date selected by the user. It is up to you to store that date someplace, particularly if you are using the dialog, since there is no other way for you to get at the chosen date later on.

Similarly, `TimePickerDialog` lets you:

- Set the initial time the user can adjust, in the form of an hour (0 through 23) and a minute (0 through 59)
- Indicate if the selection should be in 12-hour mode with an AM/PM toggle, or in 24-hour mode (what in the US is thought of as “military time” and what in much of the rest of the world is thought of as “the way times are supposed to be”)
- Provide a callback object (`OnTimeChangeListener` or `OnTimeSetListener`) to be notified of when the user has chosen a new time, which is supplied to you in the form of an hour and minute

For example, from the [Dialogs/Chrono](#) sample project, here’s a trivial layout containing a label and two buttons — the buttons will pop up the dialog flavors of the date and time pickers:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView android:id="@+id/dateAndTime"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
    <Button android:id="@+id/dateBtn"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="Set the Date"
        android:onClick="chooseDate"
        />
    <Button android:id="@+id/timeBtn"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="Set the Time"
        android:onClick="chooseTime"
        />
</LinearLayout>
```

The more interesting stuff comes in the Java source:

```
package com.commonware.android.chrono;

import android.app.Activity;
import android.app.DatePickerDialog;
import android.app.TimePickerDialog;
```

```
import android.os.Bundle;
import android.text.format.DateUtils;
import android.view.View;
import android.widget.DatePicker;
import android.widget.TextView;
import android.widget.TimePicker;
import java.util.Calendar;

public class ChronoDemo extends Activity {
    TextView dateAndTimeLabel;
    Calendar dateAndTime=Calendar.getInstance();

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        dateAndTimeLabel=(TextView)findViewById(R.id.dateAndTime);

        updateLabel();
    }

    public void chooseDate(View v) {
        new DatePickerDialog(this, d,
            dateAndTime.get(Calendar.YEAR),
            dateAndTime.get(Calendar.MONTH),
            dateAndTime.get(Calendar.DAY_OF_MONTH))

            .show();
    }

    public void chooseTime(View v) {
        new TimePickerDialog(this, t,
            dateAndTime.get(Calendar.HOUR_OF_DAY),
            dateAndTime.get(Calendar.MINUTE),
            true)

            .show();
    }

    private void updateLabel() {
        dateAndTimeLabel
            .setText(DateUtils
                .formatDateTime(this,
                    dateAndTime.getTimeInMillis(),
                    DateUtils.FORMAT_SHOW_DATE|DateUtils.FORMAT_SHOW_TIME));
    }

    DatePickerDialog.OnDateSetListener d=new DatePickerDialog.OnDateSetListener() {
        public void onDateSet(DatePicker view, int year, int monthOfYear,
            int dayOfMonth) {
            dateAndTime.set(Calendar.YEAR, year);
            dateAndTime.set(Calendar.MONTH, monthOfYear);
            dateAndTime.set(Calendar.DAY_OF_MONTH, dayOfMonth);
            updateLabel();
        }
    }
```

```
    }  
};  
  
TimePickerDialog.OnTimeSetListener t=new TimePickerDialog.OnTimeSetListener() {  
    public void onTimeSet(TimePicker view, int hourOfDay,  
                           int minute) {  
        dateAndTime.set(Calendar.HOUR_OF_DAY, hourOfDay);  
        dateAndTime.set(Calendar.MINUTE, minute);  
        updateLabel();  
    }  
};  
}
```

The “model” for this activity is just a `Calendar` instance, initially set to be the current date and time. In the `updateLabel()` method, we take the current `Calendar`, format it using `DateUtils` and `formatDateTime()`, and put it in the `TextView`. The nice thing about using Android’s `DateUtils` class is that it will format dates and times using the user’s choice of date formatting, determined through the `Settings` application.

Each button has a corresponding method that will get control when the user clicks it (`chooseDate()` and `chooseTime()`). When the button is clicked, either a `DatePickerDialog` or a `TimePickerDialog` is shown. In the case of the `DatePickerDialog`, we give it an `OnDateSetListener` callback that updates the `Calendar` with the new date (year, month, day of month). We also give the dialog the last-selected date, getting the values out of the `Calendar`. In the case of the `TimePickerDialog`, it gets an `OnTimeSetListener` callback to update the time portion of the `Calendar`, the last-selected time, and a `true` indicating we want 24-hour mode on the time selector

With all this wired together, the resulting activity looks like this:

Figure 368: ChronoDemo, As Initially Launched, on Android 4.0.3

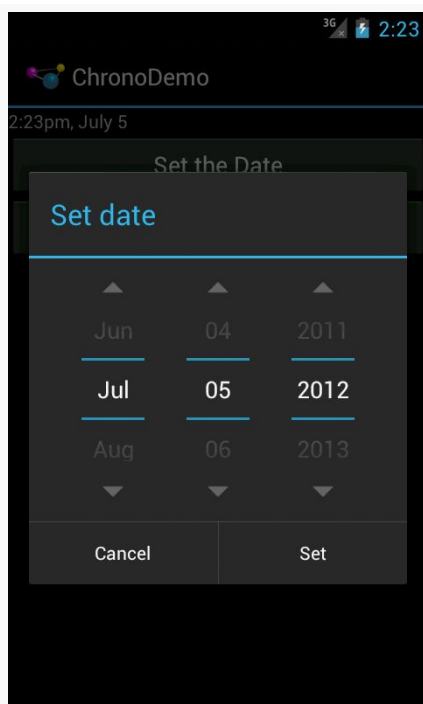

Figure 369: ChronoDemo, Showing DatePickerDialog

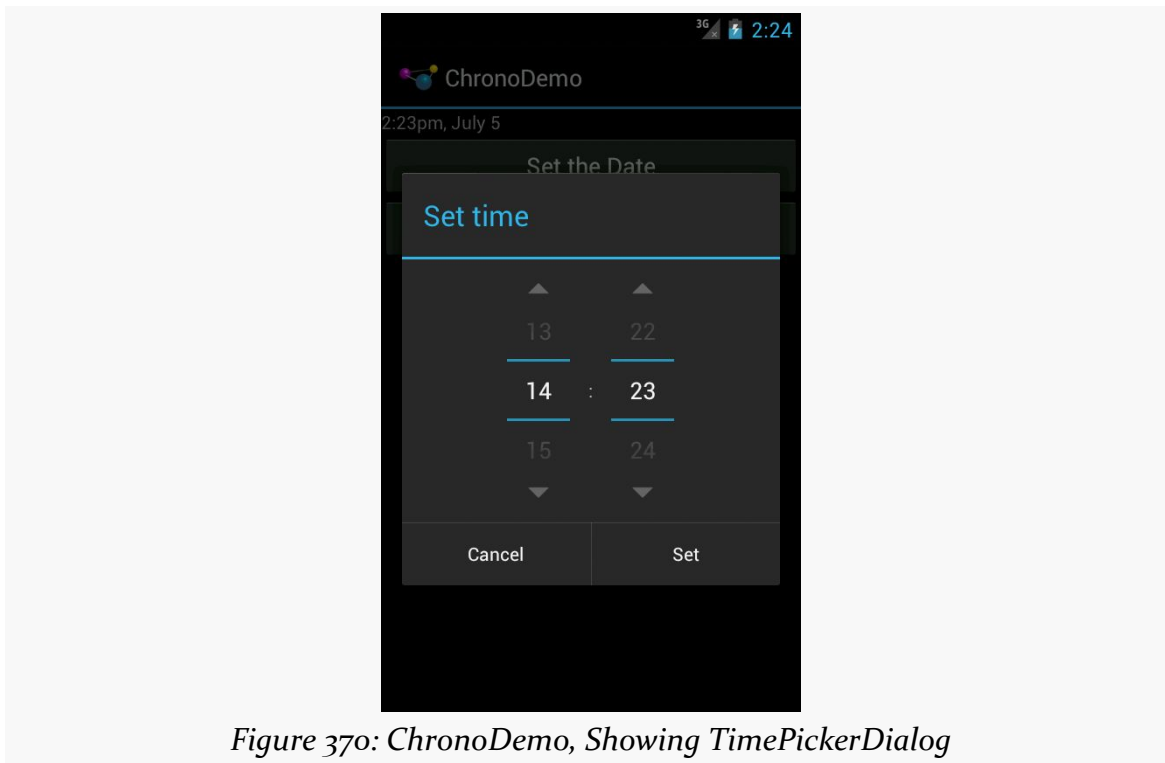

Figure 370: ChronoDemo, Showing TimePickerDialog

Changes (and Bugs) in Jelly Bean

DatePickerDialog and TimePickerDialog were modified in Android 4.1, and not necessarily for the better.

First, the “Cancel” button has been removed, unless you specifically add a negative button listener to the underlying DatePicker or TimePicker widget:

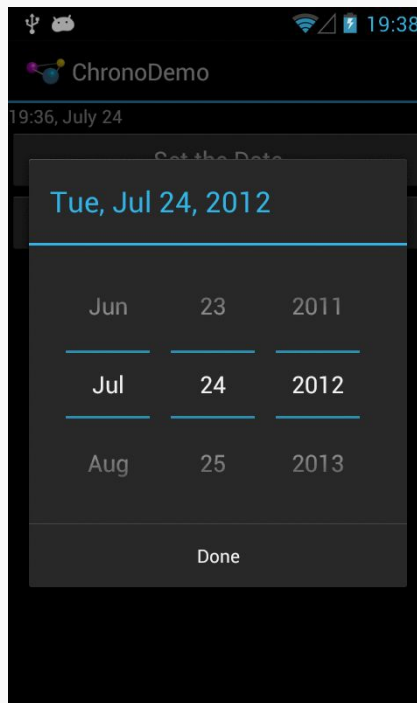

Figure 371: ChronoDemo, Showing DatePickerDialog, on a Jelly Bean Nexus S

The user can press BACK to exit the dialog, so all functionality is still there, but you may need to craft your documentation to accommodate this difference.

Then, your `OnDateSetListener` or `OnTimeSetListener` will be called an extra time. If the user presses BACK to leave the dialog, your `onDateSet()` or `onTimeSet()` will be called. If the user clicks the positive button of the dialog, you are called *twice*. There is a workaround [documented on Stack Overflow](#), and [the bug report can be found on the Android issue tracker](#).

AlertDialog

For your own custom dialogs, you could extend the `Dialog` base class, as do `DatePickerDialog` and `TimePickerDialog`. More commonly, though, developers create custom dialogs via `AlertDialog`, in large part due to the existence of `AlertDialog.Builder`. This builder class allows you to construct a custom dialog using a single (albeit long) Java statement, rather than having to create your own custom subclass. Builder offers a series of methods to configure an `AlertDialog`, each method returning the Builder for easy chaining.

Commonly-used configuration methods on Builder include:

- `setMessage()` if you want the “body” of the dialog to be a simple textual message, from either a supplied String or a supplied string resource ID.
- `setTitle()` and `setIcon()`, to configure the text and/or icon to appear in the title bar of the dialog box.
- `setPositiveButton()`, `setNeutralButton()`, and `setNegativeButton()`, to indicate which button(s) should appear across the bottom of the dialog, where they should be positioned (left, center, or right, respectively), what their captions should be, and what logic should be invoked when the button is clicked (besides dismissing the dialog).

Calling `create()` on the Builder will give you the `AlertDialog`, built according to your specifications. You can use additional methods on `AlertDialog` itself to perhaps configure things beyond what Builder happens to support.

Note, though, that calling `create()` does not actually display the dialog. The modern way to display the dialog is to tie it to a `DialogFragment`, as will be discussed in the next section.

DialogFragments

One challenge with dialogs comes with configuration changes, notably screen rotations. If they pivot the device from portrait to landscape (or vice versa), presumably the dialog should remain on the screen after the change. However, since Android wants to destroy and recreate the activity, that would have dire impacts on your dialog.

Pre-fragments, Android had a “managed dialog” facility that would attempt to help with this. However, with the introduction of fragments came the `DialogFragment`, which handles the configuration change process.

You have two ways of supplying the dialog to the `DialogFragment`:

1. You can override `onCreateDialog()` and return a `Dialog`, such as `AlertDialog` created via an `AlertDialog.Builder`
2. You can override `onCreateView()`, as you would with an ordinary fragment, and the `View` that you return will be placed inside of a dialog

DIALOGS AND DIALOGFRAGMENTS

The [Dialogs/DialogFragment](#) sample project demonstrates the use of a DialogFragment in conjunction with an AlertDialog in this fashion.

Here is our DialogFragment, named SampleDialogFragment:

```
package com.commonware.android.dlgfrag;

import android.app.AlertDialog;
import android.app.Dialog;
import android.app.DialogFragment;
import android.content.DialogInterface;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.EditText;
import android.widget.Toast;

public class SampleDialogFragment extends DialogFragment implements
    DialogInterface.OnClickListener {
    private View form=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        form=
            getActivity().getLayoutInflater()
                .inflate(R.layout.dialog, null);

        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

        return(builder.setTitle(R.string.dlg_title).setView(form)
            .setPositiveButton(android.R.string.ok, this)
            .setNegativeButton(android.R.string.cancel, null).create());
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        String template=getActivity().getString(R.string.toast);
        EditText name=(EditText)form.findViewById(R.id.title);
        EditText value=(EditText)form.findViewById(R.id.value);
        String msg=
            String.format(template, name.getText().toString(),
                value.getText().toString());

        Toast.makeText(getActivity(), msg, Toast.LENGTH_LONG).show();
    }

    @Override
    public void onDismiss(DialogInterface unused) {
        super.onDismiss(unused);

        Log.d(getClass().getSimpleName(), "Goodbye!");
    }
}
```

```
@Override
public void onCancel(DialogInterface unused) {
    super.onCancel(unused);

    Toast.makeText(getActivity(), R.string.back, Toast.LENGTH_LONG).show();
}
```

In `onCreateDialog()`, we inflate a custom layout (`R.layout.dialog`) that consists of some `TextView` labels and `EditText` fields:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_name"/>

        <EditText
            android:id="@+id/title"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:inputType="text"/>
    </LinearLayout>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/value"/>

        <EditText
            android:id="@+id/value"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:inputType="number"/>
    </LinearLayout>
```

```
</LinearLayout>
```

We then create an instance of `AlertDialog.Builder`, then start configuring the dialog by calling a series of methods on the Builder:

- `setTitle()` to supply the text to appear in the title bar of the dialog
- `setView()` to define the contents of the dialog, in the form of our inflated View
- `setPositiveButton()` to define the caption of one button (set here to the Android-supplied “OK” string resource) and to arrange to get control when that button is clicked (via this as the second parameter and our activity implementing `DialogInterface.OnClickListener`)
- `setNegativeButton()` to define the caption of the other button (set here to the Android-supplied “Cancel” resource)

We do not supply a listener to `setNegativeButton()`, because we do not need one in this case. Whenever the user clicks on *any* of the buttons, the dialog will be dismissed automatically. Hence, you only need a listener if you intend to do something special beyond dismissing the dialog when a button is clicked.

At that point, we call `create()` to construct the actual `AlertDialog` instance and hand that back to Android.

If the user taps our positive button, we are called with `onClick()` and can collect information from our form and do something with it, in this case displaying a Toast.

We also override:

- `onCancel()`, which is called if the user presses the BACK button to exit the dialog
- `onDismiss()`, which is called whenever the dialog goes away for any reason (BACK or a button click)

Our activity (`MainActivity`), has a big button tied to a `showMe()` method, which calls `show()` on a newly-created instance of our `SampleDialogFragment`:

```
public void showMe(View v) {  
    new SampleDialogFragment().show(getFragmentManager(), "sample");  
}
```

The second parameter to `show()` is a tag that can be used to retrieve this fragment again later from the `FragmentManager` via `findFragmentByTag()`.

When you click the big button in the activity, our dialog is displayed:

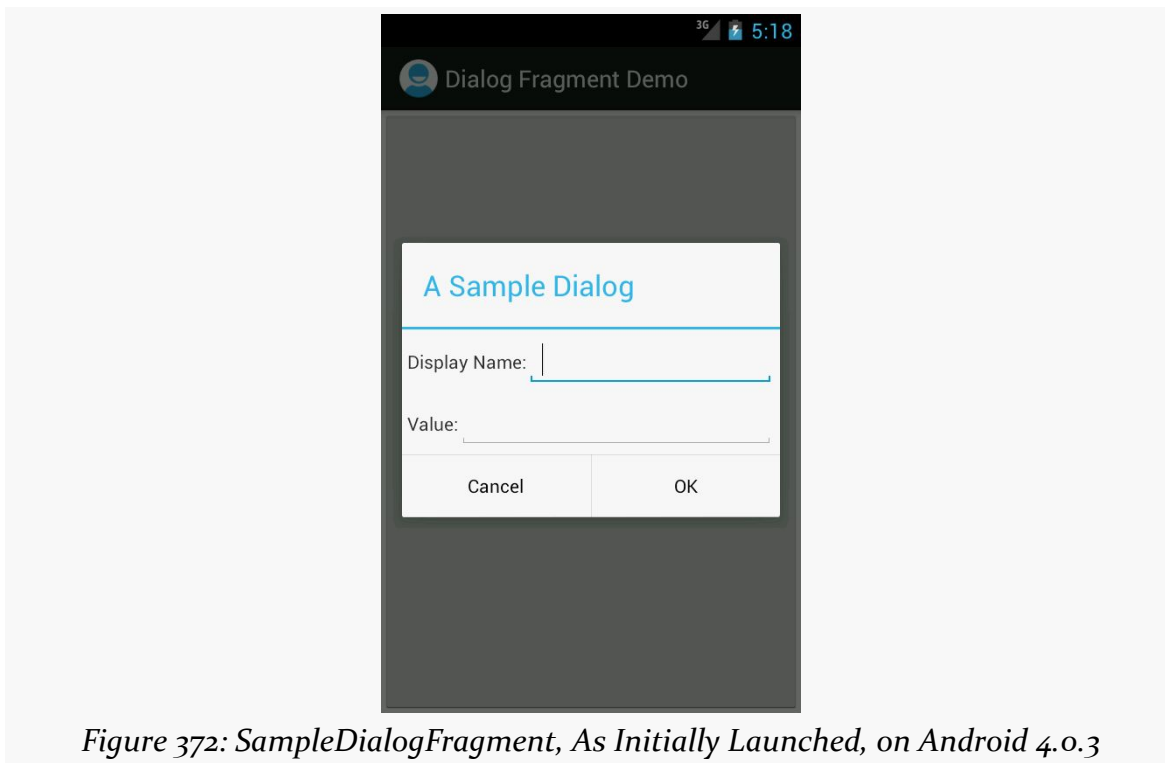

Figure 372: SampleDialogFragment, As Initially Launched, on Android 4.0.3

Android will handle the configuration change, and so long as our dialog uses typical widgets like `EditText`, the standard configuration change logic will carry our data forward from the old activity's dialog to the new activity's dialog.

DialogFragment: The Other Flavor

If you do not override `onCreateDialog()`, Android will assume that you want the `View` returned by `onCreateView()` to be poured into an ordinary `Dialog`, which `DialogFragment` will create for you automatically.

One advantage of this approach is that you can selectively show the fragment as a dialog *or* show it as a regular fragment as part of your main UI.

To show the fragment as a dialog, use the same `show()` technique as was outlined in the previous section. To display the fragment as part of the main UI, use a `FragmentManager` to `add()` it, the way you would for any other dynamic fragment.

This is one alternative to the normal fragment approach of having dedicated activities for each fragment on smaller screen sizes.

We will also see this approach used when we try to apply fragments to display content on a secondary screen using Android 4.2's `Presentation` class, covered [elsewhere in this book](#).

Dialogs: Modal, Not Blocking

Dialogs in Android are modal in terms of UI. The user cannot proceed in your activity until they complete or dismiss the dialog.

Dialogs in Android are not blocking in terms of the programming model. When you call `show()` to display a dialog — either directly or by means of adding a `DialogFragment` to the screen — this is not a blocking call. The dialog will be displayed sometime after the call to `show()`, asynchronously. You use callbacks, such as the button event listeners, to find out about events going on with respect to the dialog that you care about.

This runs counter to a couple of GUI toolkits, where displaying the dialog blocks the thread that does the displaying. In those toolkits, the call to `show()` would not return until the dialog had been displayed and dealt with by the user. That being said, most modern GUI toolkits take the approach Android does and have dialogs be non-blocking. Some developers try to figure out some way of hacking a blocking approach on top of Android's non-blocking dialogs — their time would be far better spent learning modern event-driven programming.

Advanced ListViews

The humble `ListView` is the backbone of many an Android application. On phone-sized screens, the screen may be dominated by a single `ListView`, to allow the user to choose something to examine in more detail (e.g., pick a contact). On larger screens, the `ListView` may be shown side-by-side with the details of the selected item, to minimize the “pogo stick” effect seen on phones as users bounce back and forth between the list and the details.

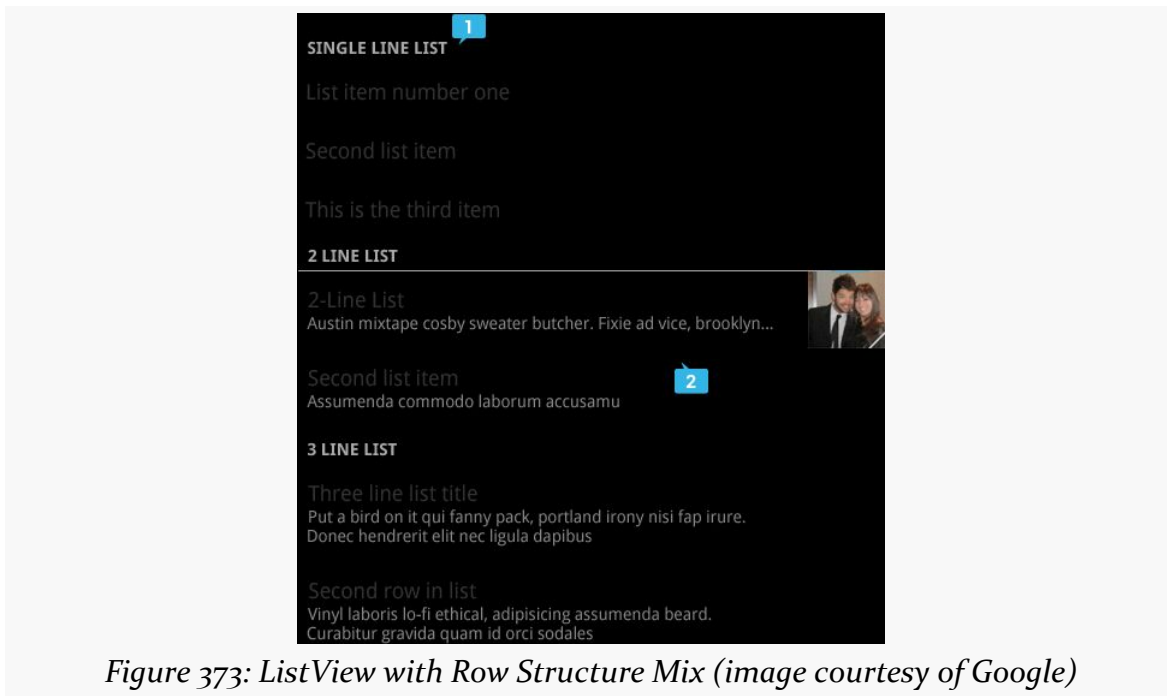

While we have covered the basics of `ListView` in the core chapters of this book, there is a lot more that you can do if you so choose, to make your lists that much more interesting — this chapter will cover some of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on `Adapter` and `AdapterView`](#).

Multiple Row Types, and Self Inflation

When we originally looked at `ListView`, we had all of our rows come from a common layout. Hence, while the data in each row would vary, the row structure itself would be consistent for all rows. This is very easy to set up, but it is not always what you want. Sometimes, you want a mix of row structures, such as header rows versus detail rows, or detail rows that vary a bit in structure based on the data:

Here, we see some header rows (e.g., “SINGLE LINE LIST”) along with detail rows. While the detail rows visually vary a bit, they might still be all inflated from the same layout, simply making some pieces (second line of text, thumbnail, etc.) visible or invisible as needed. However, the header rows are sufficiently visually distinct that they really ought to come from separate layouts.

The good news is that Android supports multiple row types. However, this comes at a cost: you will need to handle the row creation yourself, rather than chaining to the superclass.

Our sample project, [Selection/HeaderDetailList](#) will demonstrate this, along with showing how you can create your own custom adapter straight from `BaseAdapter`, for data models that do not quite line up with what Android supports natively.

Our Data Model and Planned UI

The `HeaderDetailList` project is based on the `ViewHolderDemo` project from [the chapter on ListView](#). However, this time, we have our list of 25 Latin words broken down into five groups of five, as seen in the `HeaderDetailList` activity:

```
private static final String[][] items= {  
    { "lorem", "ipsum", "dolor", "sit", "amet" },
```

ADVANCED LISTVIEWS

```
{ "consectetuer", "adipiscing", "elit", "morbi", "vel" },  
{ "ligula", "vitae", "arcu", "aliquet", "mollis" },  
{ "etiam", "vel", "erat", "placerat", "ante" },  
{ "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

We want to display a header row for each batch:

Figure 374: HeaderDetailList, on Android 4.0.3

The Basic BaseAdapter

Once again, we have a custom ListAdapter named IconicAdapter. However, this time, instead of inheriting from ArrayAdapter, or even CursorAdapter, we are inheriting from BaseAdapter. As the name suggests, BaseAdapter is a basic implementation of the ListAdapter interface, with stock implementations of many of the ListAdapter methods. However, BaseAdapter is abstract, and so there are a few methods that we need to implement:

- `getCount()` returns the total number of rows that would be in the list. In our case, we total up the sizes of each of the batches, plus add one for each batch for our header rows:

```
@Override
public int getCount() {
    int count=0;

    for (String[] batch : items) {
        count+=1 + batch.length;
    }

    return(count);
}
```

- getItem() needs to return the data model for a given position, passed in as the typical int index. An ArrayAdapter would return the value out of the array at that index; a CursorAdapter would return the Cursor positioned at that row. In our case, we will return one of two objects: either the String for rows that are to display a Latin word, or an Integer containing our batch's index for rows that are to be a header:

```
@Override
public Object getItem(int position) {
    int offset=position;
    int batchIndex=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }

        offset--;

        if (offset < batch.length) {
            return(batch[offset]);
        }

        offset-=batch.length;
        batchIndex++;
    }

    throw new IllegalArgumentException("Invalid position: "
        + String.valueOf(position));
}
```

- getItemId() needs to return a unique long value for a given position. A CursorAdapter would find the _id value in the Cursor for that position and return it. In our case, lacking anything else, we simply return the position itself:

```
@Override
public long getItemId(int position) {
```

```
return(position);  
}
```

- `getView()`, which returns the View to use for a given row. This is the method that we overrode on our `IconicAdapter` in some previous incarnations to tailor the way the rows were populated. Our `getView()` implementation will be a bit more complex in this case, due to our multiple-row-type requirement, so we will examine it a bit later in this section.

Requesting Multiple Row Types

The methods listed above are the abstract ones that you have no choice but to implement yourself. Anything else on the `ListAdapter` interface that you wish to override you can, to replace the stub implementation supplied by `BaseAdapter`.

If you wish to have more than one type of row, there are two such methods that you will wish to override:

- `getViewTypeCount()` needs to return the number of distinct row types you will use. In our case, there are just two:

```
@Override  
public int getViewTypeCount() {  
    return(2);  
}
```

- `getItemViewType()` needs to return a value from 0 to `getViewTypeCount()-1`, indicating the index of the particular row type to use for a particular row position. In our case, we need to return different values for headers (0) and detail rows (1). To determine which is which, we use `getItem()` — if we get an `Integer` back, we need to use a header row for that position:

```
@Override  
public int getItemViewType(int position) {  
    if (getItem(position) instanceof Integer) {  
        return(0);  
    }  
  
    return(1);  
}
```

The reason for supplying this information is for row recycling. The View that is passed into `getView()` is either null or a row that we had previously created that has scrolled off the screen. By passing us this now-unused View, Android is asking us to

reuse it if possible. By specifying the row type for each position, Android will ensure that it hands us the right type of row for recycling — we will not be passed in a header row to recycle when we need to be returning a detail row, for example.

Creating and Recycling the Rows

Our `getView()` implementation, then, needs to have two key enhancements over previous versions:

1. We need to create the rows ourselves, particularly using the appropriate layout for the required row type (header or detail)
2. We need to recycle the rows when they are provided, as this has a **major** impact on the scrolling speed of our `ListView`

To help simplify the logic, we will have `getView()` focus on the detail rows, with a separate `getHeaderView()` to create/recycle and populate the header rows. Our `getView()` determines up front whether the row required is a header and, if so, delegates the work to `getHeaderView()`:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    if (getItemViewType(position) == 0) {
        return(getHeaderView(position, convertView, parent));
    }

    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.row, parent, false);
    }

    ViewHolder holder=(ViewHolder)row.getTag();

    if (holder == null) {
        holder=new ViewHolder(row);
        row.setTag(holder);
    }

    String word=(String)getItem(position);

    if (word.length() > 4) {
        holder.icon.setImageResource(R.drawable.delete);
    }
    else {
        holder.icon.setImageResource(R.drawable.ok);
    }

    holder.label.setText(word);
}
```

```
holder.size.setText(String.format(getString(R.string.size_template),
                                word.length()));

return(row);
}
```

Assuming that we are to create a detail row, we then check to see if we were passed in a non-null View. If we were passed in null, we cannot recycle that row, so we have to inflate a new one via a call to `inflate()` on a `LayoutInflater` we get via `getLayoutInflater()`. But, if we were passed in an actual View to recycle, we can skip this step.

From here, the `getView()` implementation is largely the way it was before, including dealing with the `ViewHolder`. The only change of significance is that we have to manage the label `TextView` ourselves — before, we chained to the superclass and let `ArrayAdapter` handle that. So our `ViewHolder` now has a label data member with our label `TextView`, and we fill it in along with the size and icon. Also, we use `getItem()` to retrieve our Latin word, so it can find the right word for the given position out of our various word batches.

Our `getHeaderView()` does much the same thing, except it uses `getItem()` to retrieve our batch index, and we use that for constructing our header:

```
private View getHeaderView(int position, View convertView,
                           ViewGroup parent) {
    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.header, parent, false);
    }

    Integer batchIndex=(Integer)getItem(position);
    TextView label=(TextView)row.findViewById(R.id.label);

    label.setText(String.format(getString(R.string.batch),
                                1 + batchIndex.intValue()));

    return(row);
}
```

Choice Modes and the Activated Style

In [the chapter on large-screen strategies](#), we saw the EU4You sample application, and we mentioned that the `ListView` formatted its rows as “activated” to represent the current selection, when the `ListView` was side-by-side with the details.

In [the chapter on styles](#), we saw an example of an “activated” style that referred to a device-specific color to use for an activated background. It just so happens that this is the same style that we used in EU4You.

Hence, the recipe for using activated notation for a `ListView` adjacent to details on the last-clicked-upon `ListView` row is:

- Use `CHOICE_MODE_SINGLE` (or `android:choiceMode="singleChoice"`) on the `ListView`.
- Have a style resource, in `res/values-v11/`, that references the device-specific activated background:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/
activatedBackgroundIndicator</item>
  </style>
</resources>
```

- Have the same style resource also defined in `res/values` if you are supporting pre-Honeycomb devices, where you skip the parent and the background color override, as neither of those specific values existed before API Level 11:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated">
  </style>
</resources>
```

- Use that style as the background of your `ListView` row (e.g., `style="@style/activated"`)

Android will automatically color the row background based upon the last row clicked, instead of checking a `RadioButton` as you might ordinarily see with `CHOICE_MODE_SINGLE` lists.

Custom Mutable Row Contents

Lists with pretty icons next to them are all fine and well. But, can we create `ListView` widgets whose rows contain interactive child widgets instead of just passive widgets like `TextView` and `ImageView`? For example, there is a `RatingBar` widget that allows users to assign a rating by clicking on a set of star icons. Could we combine the

RatingBar with text in order to allow people to scroll a list of, say, songs and rate them right inside the list?

There is good news and bad news.

The good news is that interactive widgets in rows work just fine. The bad news is that it is a little tricky, specifically when it comes to taking action when the interactive widget's state changes (e.g., a value is typed into a field). We need to store that state somewhere, since our RatingBar widget will be recycled when the ListView is scrolled. We need to be able to set the RatingBar state based upon the actual word we are viewing as the RatingBar is recycled, and we need to save the state when it changes so it can be restored when this particular row is scrolled back into view.

What makes this interesting is that, by default, the RatingBar has absolutely no idea what item in the ArrayAdapter it represents. After all, the RatingBar is just a widget, used in a row of a ListView. We need to teach the rows which item in the ArrayAdapter they are currently displaying, so when their RatingBar is checked, they know which item's state to modify.

So, let's see how this is done, using the activity in the [Selection/RateList](#) sample project. We will use the same basic classes as in most of our ListView samples, where we are showing a list of Latin words. In this case, you can rate the words on a three-star rating. Words given a top rating are put in all caps:

```
package com.commonware.android.ratelist;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.LinearLayout;
import android.widget.RatingBar;
import android.widget.TextView;
import java.util.ArrayList;

public class RateListDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
```

```
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    ArrayList<RowModel> list=new ArrayList<RowModel>();

    for (String s : items) {
        list.add(new RowModel(s));
    }

    setListAdapter(new RatingAdapter(list));
}

private RowModel getModel(int position) {
    return(((RatingAdapter)getListAdapter()).getItem(position));
}

class RatingAdapter extends ArrayAdapter<RowModel> {
    RatingAdapter(ArrayList<RowModel> list) {
        super(RateListDemo.this, R.layout.row, R.id.label, list);
    }

    public View getView(int position, View convertView,
                        ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        RatingBar bar=(RatingBar)row.getTag();

        if (bar==null) {
            bar=(RatingBar)row.findViewById(R.id.rate);
            row.setTag(bar);

            RatingBar.OnRatingBarChangeListener l=
                new RatingBar.OnRatingBarChangeListener() {
                    public void onRatingChanged(RatingBar ratingBar,
                                                float rating,
                                                boolean fromTouch) {
                        Integer myPosition=(Integer)ratingBar.getTag();
                        RowModel model=getModel(myPosition);

                        model.rating=rating;

                        LinearLayout parent=(LinearLayout)ratingBar.getParent();
                        TextView label=(TextView)parent.findViewById(R.id.label);

                        label.setText(model.toString());
                    }
                };

            bar.setOnRatingBarChangeListener(l);
        }

        RowModel model=getModel(position);

        bar.setTag(Integer.valueOf(position));
        bar.setRating(model.rating);
    }
}
```

```
        return(row);
    }
}

class RowModel {
    String label;
    float rating=2.0f;

    RowModel(String label) {
        this.label=label;
    }

    public String toString() {
        if (rating>=3.0) {
            return(label.toUpperCase());
        }

        return(label);
    }
}
```

Here is what is different in this activity and `getView()` implementation than in earlier, simpler samples:

1. While we are still using `String` array items as the list of Latin words, rather than pour that `String` array straight into an `ArrayAdapter`, we turn it into a list of `RowModel` objects. `RowModel` is the mutable model: it holds the Latin word plus the current rating. In a real system, these might be objects populated from a database, and the properties would have more business meaning.
2. Utility methods like `onListItemClick()` had to be updated to reflect the change from a pure-`String` model to use a `RowModel`.
3. The `ArrayAdapter` subclass (`RatingAdapter`), in `getView()`, lets `ArrayAdapter` inflate and recycle the row, then checks to see if we have a `ViewHolder` in the row's tag. If not, we create a new `ViewHolder` and associate it with the row. For the row's `RatingBar`, we add an anonymous `onRatingChanged()` listener that looks at the row's tag (`getTag()`) and converts that into an `Integer`, representing the position within the `ArrayAdapter` that this row is displaying. Using that, the rating bar can get the actual `RowModel` for the row and update the model based upon the new state of the rating bar. It also updates the text adjacent to the `RatingBar` when checked to match the rating bar state.

4. We always make sure that the RatingBar has the proper contents and has a tag (via `setTag()`) pointing to the position in the adapter the row is displaying.

The row layout is very simple: just a RatingBar and a TextView inside a LinearLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
>
    <RatingBar
        android:id="@+id/rate"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:numStars="3"
        android:stepSize="1"
        android:rating="2" />
    <TextView
        android:id="@+id/label"
        android:padding="2dip"
        android:textSize="18sp"
        android:layout_gravity="left|center_vertical"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>
</LinearLayout>
```

And the result is what you would expect, visually:

ADVANCED LISTVIEWS

Figure 375: RateList, As Initially Shown

This includes the toggled rating bars turning their words into all caps:

Figure 376: RateList, With a Three-Star Word

From Head To Toe

Perhaps you do not need section headers scattered throughout your list. If you only need extra “fake rows” at the beginning or end of your list, you can use header and footer views.

ListView supports `addHeaderView()` and `addFooterView()` methods that allow you to add View objects to the beginning and end of the list, respectively. These View objects otherwise behave like regular rows, in that they are part of the scrolled area and will scroll off the screen if the list is long enough. If you want fixed headers or footers, rather than put them in the ListView itself, put them outside the ListView, perhaps using a `LinearLayout`.

To demonstrate header and footer views, take a peek at the [Selection/HeaderFooter](#) sample project, particularly the `HeaderFooterDemo` class:

```
package com.commonware.android.header;

import java.util.Arrays;
import java.util.Collections;
import java.util.List;
import android.app.ListActivity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.Button;
import android.widget.TextView;

public class HeaderFooterDemo extends ListActivity {
    private static String[] items={"lorem", "ipsum", "dolor",
                                   "sit", "amet", "consectetuer",
                                   "adipiscing", "elit", "morbi",
                                   "vel", "ligula", "vitae",
                                   "arcu", "aliquet", "mollis",
                                   "etiam", "vel", "erat",
                                   "placerat", "ante",
                                   "porttitor", "sodales",
                                   "pellentesque", "augue",
                                   "purus"};

    private long startTime=SystemClock.uptimeMillis();
    private boolean areWeDeadYet=false;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        getListView().addHeaderView(buildHeader());
    }
}
```

ADVANCED LISTVIEWS

```
        getListView().addFooterView(buildFooter());
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            items));
    }

    @Override
    public void onDestroy() {
        super.onDestroy();

        areWeDeadYet=true;
    }

    private View buildHeader() {
        Button btn=new Button(this);

        btn.setText("Randomize!");
        btn.setOnClickListener(new View.OnClickListener() {
            public void onClick(View v) {
                List<String> list=Arrays.asList(items);

                Collections.shuffle(list);

                setListAdapter(new ArrayAdapter<String>(HeaderFooterDemo.this,
                    android.R.layout.simple_list_item_1,
                    list));
            }
        });

        return(btn);
    }

    private View buildFooter() {
        TextView txt=new TextView(this);

        updateFooter(txt);

        return(txt);
    }

    private void updateFooter(final TextView txt) {
        long runtime=(SystemClock.uptimeMillis()-startTime)/1000;

        txt.setText(String.valueOf(runtime)+" seconds since activity launched");

        if (!areWeDeadYet) {
            getListView().postDelayed(new Runnable() {
                public void run() {
                    updateFooter(txt);
                }
            }, 1000);
        }
    }
}
```

ADVANCED LISTVIEWS

Here, we add a header View built via `buildHeader()`, returning a Button that, when clicked, will shuffle the contents of the list. We also add a footer View built via `buildFooter()`, returning a TextView that shows how long the activity has been running, updated every second. The list itself is the ever-popular list of *lorem ipsum* words.

When initially displayed, the header is visible but the footer is not, because the list is too long:

Figure 377: A ListView with a header view shown

If you scroll downward, the header will slide off the top, and eventually the footer will scroll into view:

ADVANCED LISTVIEWS

Figure 378: A ListView with a footer view shown

Action Bar Navigation

Beyond the app icon (a.k.a., icon on the left), action bar toolbar items, and the overflow menu, the action bar also supports a navigation area. This resides to the right of the app icon and to the left of the toolbar items/overflow menu. You can:

- Put tabs in here, to allow users to switch between portions of your app
- Use “list navigation”, which effectively puts a Spinner in here, also to allow users to switch from place to place
- Put in some other custom form of navigation, such as a search field

This chapter will review how to do these things, and how they tie into other constructs in Android, notably the ViewPager.

NOTE: The tab and list navigation forms outlined in this chapter have been marked as deprecated in Android 5.0. Developers are encouraged to use other techniques for in-activity navigation.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

List Navigation

Android’s action bar supports a “list navigation” option. Despite the name, the “list” is really a Spinner, hosted in the action bar. You get to populate the Spinner via your own SpinnerAdapter, and you get control when the user changes the selected item, so that you can update your UI as you see fit.

To set this up:

1. Call `setNavigationMode(ActionBar.NAVIGATION_MODE_LIST)` on the `ActionBar` to enable the list navigation mode, which you get via `getActionBar()`
2. Call `setListNavigationCallbacks()` on the `ActionBar`, simultaneously supplying the `SpinnerAdapter` to use to populate the `Spinner` and an `ActionBar.OnNavigationListener` object to be notified when there is a selection change in the `Spinner`

The [ActionBar/ListNavNative](#) sample project demonstrates this, using a variation on the “whole lot of editors” UI first seen in [the ViewPager chapter](#).

We want to display a full-screen `EditText` widget whose contents will be driven by the list navigation selection. The fragment for this — `EditorFragment` — is a slightly revised version of the same class from the `ViewPager` samples. Here, though, state management will be handled completely by the activity, so we simply expose getters and setters as needed for working with the text in the editor, along with its hint:

```
package com.commonware.android.listnav;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private EditText editor=null;

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.editor, container, false);

        editor=(EditText)result.findViewById(R.id.editor);

        return(result);
    }

    CharSequence getText() {
        return(editor.getText());
    }

    void setText(CharSequence text) {
        editor.setText(text);
    }
}
```

ACTION BAR NAVIGATION

```
}  
  
void setHint(CharSequence hint) {  
    editor.setHint(hint);  
}  
}
```

Setting up the list navigation mode is part of the work we do in `onCreate()`:

```
ArrayAdapter<String> nav=null;  
ActionBar bar=getActionBar();  
  
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH) {  
    nav=  
        new ArrayAdapter<String>(  
            bar.getThemedContext(),  
            android.R.layout.simple_spinner_item,  
            labels);  
}  
else {  
    nav=  
        new ArrayAdapter<String>(  
            this,  
            android.R.layout.simple_spinner_item,  
            labels);  
}  
  
nav.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);  
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_LIST);  
bar.setListNavigationCallbacks(nav, this);
```

Android 4.0 added a `getThemedContext()` method on `ActionBar`. Use the `Context` returned by this method when working with resources that relate to the `ActionBar`. In this case, we use it when creating our `ArrayAdapter` to use with the `Spinner`. However, since this is only available on API Level 14 and higher, you need to check for that and fall back to using the `Activity` as your `Context` for earlier versions of Android.

We then use `setNavigationMode()` to indicate that we want list navigation, then use `setListNavigationCallbacks()` to supply our `ArrayAdapter`, plus our implementation of `OnNavigationListener` — in this case, we are implementing this interface on the activity itself.

Because we are implementing `OnNavigationListener`, we need to override the `onNavigationItemSelected()` method. This will get called when the `Spinner` selection changes (including when it is initially set), and it is up to us to affect our UI. That requires a bit of additional preparation work:

- We set up our EditorFragment in onCreate(), if it does not already exist:

```
frag=
(EditorFragment)getFragmentManager().findFragmentById(android.R.id.content);

if (frag==null) {
    frag=new EditorFragment();
    getFragmentManager().beginTransaction()
                        .add(android.R.id.content, frag)
                        .commit();
}
```

- We track the last known position of the Spinner selection, by means of a lastPosition data member
- We store our data model (the text held by the editor) in a models CharSequence array

Our objective is to have 10 total “editors”, accessible via the list navigation. Our labels array in our ArrayAdapter has 10 entries, and models is a 10-item array to match.

That allows us to implement onNavigationItemSelected():

```
@Override
public boolean onNavigationItemSelected(int itemPosition, long itemId) {
    if (lastPosition > -1) {
        models[lastPosition]=frag.getText();
    }

    lastPosition=itemPosition;
    frag.setText(models[itemPosition]);
    frag.setHint(labels[itemPosition]);

    return(true);
}
```

In the ViewPager sample, we actually had 10 instances of EditorFragment. Here, we have just one. We will use it for all 10 positions. Hence, all we do is grab the current contents of the editor and save them in models (except when we are first starting and have no prior position). Then, we populate the editor with the next model and a suitable hint.

Now, we *could* have 10 instances of EditorFragment and swap between them with FragmentTransactions. Or, we could have a variety of distinct fragment instances, from different classes, and swap between them using FragmentTransactions. What you do to update your UI based upon the list navigation change is up to you.

ACTION BAR NAVIGATION

One limitation of list navigation, compared to `ViewPager`, is state management on configuration changes. `ViewPager` handled keeping track of what page we were on, and if we retained all our fragments, our model data (the editors' contents) were retained as well. With list navigation and a single non-retained fragment, we have to do all of that ourselves.

So, we implement `onSaveInstanceState()` to persist both the `models` array and our current position:

```
@Override
public void onSaveInstanceState(Bundle state) {
    if (lastPosition > -1) {
        models[lastPosition]=frag.getText();
    }

    state.putCharSequenceArray(KEY_MODELS, models);
    state.putInt(KEY_POSITION,
        getActionBar().getSelectedNavigationIndex());
}
```

In `onCreate()`, we restore our `models` array:

```
if (state != null) {
    models=state.getCharSequenceArray(KEY_MODELS);
}
```

And, later in `onCreate()`, we tell the action bar which position to select:

```
if (state != null) {
    bar.setSelectedNavigationItem(state.getInt(KEY_POSITION));
}
```

The result is a Spinner in the action bar, allowing the user to choose which of the 10 “editors” to work with:

Figure 379: ListNavDemo, Showing the List, on Android 4.0.3

Tabs (And Sometimes List) Navigation

Similarly, you can set up tab navigation, where you present a roster of tabs the user can tap on.

Maybe.

(We'll get to the explanation of “maybe” in a bit)

Setting up tabs is fairly straightforward, once you know the recipe:

1. Call `setNavigationMode(ActionBar.NAVIGATION_MODE_TABS)` on the `ActionBar`, which you get via `getActionBar()`
2. Call `addTab()` on `ActionBar` for each tab you want, supplying at minimum the text caption of the tab and a `TabListener` implementation that will be notified of state changes in that tab

The [ActionBar/TabFragmentDemoNative](#) sample project is very similar to the one for list navigation described above, except that it uses tabs instead of list navigation. We

have the same 10 editors, the same data model (models), and the same basic logic for saving and restoring our instance state. What differs is in how we set up the UI.

As with list navigation, you can do whatever you want when tabs are selected or unselected. You could:

- Add and remove fragments
- Attach and detach fragments (which remove them from the UI but keep them in the `FragmentManager` for later reuse)
- Flip pages of a `ViewPager`
- Update a simple UI in place (akin to what we did in the list navigation sample above)

In our case, we will take the “caveman” approach of replacing our entire fragment on each tab click.

Our `EditorFragment` is a bit closer to the original from the `ViewPager` samples, except that this time we pass in the initial text to display, along with the position, in the factory method:

```
package com.commonsware.android.tabfrag;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private static final String KEY_POSITION="position";
    private static final String KEY_TEXT="text";
    private EditText editor=null;

    static EditorFragment newInstance(int position,
                                     CharSequence text) {
        EditorFragment frag=new EditorFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_POSITION, position);
        args.putCharSequence(KEY_TEXT, text);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
```

ACTION BAR NAVIGATION

```
        ViewGroup container,
        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(String.format(getString(R.string.hint), position + 1));
    editor.setText(getArguments().getCharSequence(KEY_TEXT));

    return(result);
}

CharSequence getText() {
    return(editor.getText());
}
}
```

In `onCreate()`, we tell the `ActionBar` that we want tab navigation, then we add 10 tabs to the bar:

```
ActionBar bar=getActionBar();
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

for (int i=0; i < 10; i++) {
    bar.addTab(bar.newTab().setText("Tab #" + String.valueOf(i + 1))
        .setTabListener(this).setTag(i));
}
```

Calling `newTab()` on the `ActionBar` gives us an `ActionBar.Tab` object, which we can use builder-style to configure the tab. In our case, we are setting the caption (`setText()`), the listener (`setTabListener()`), and a tag to use to identify this tab (`setTag()`). The tag is akin to the tags on `Views` — it can be any object you want. In our case, we just use the index of the tab.

Our activity needs to implement the `TabListener` interface, since we are passing it into the `setTabListener()` method. There are three methods you must implement on that interface:

1. `onTabSelected()` is called when the tab is selected by the user
2. `onTabUnselected()` is called when some other tab is selected by the user
3. `onTabReselected()` is called, presumably, when the user taps on an already-selected tab (e.g., to refresh the tab's contents)

Our implementation ignores the latter and focuses on the first two:

ACTION BAR NAVIGATION

```
@Override
public void onTabSelected(Tab tab, FragmentTransaction ft) {
    int i=((Integer)tab.getTag()).intValue();

    ft.replace(android.R.id.content,
               EditorFragment.newInstance(i, models[i]));
}

@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    int i=((Integer)tab.getTag()).intValue();
    EditorFragment frag=
(EditorFragment)getFragmentManager().findFragmentById(android.R.id.content);

    if (frag != null) {
        models[i]=frag.getText();
    }
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // unused
}
```

In `onTabSelected()`, we get our tab's position via its tag, then call `replace()` on the supplied `FragmentTransaction` to replace the current contents of the activity with a new `EditorFragment`, set up with the proper position and model data.

In `onTabUnselected()`, we get our tab's position and the `EditorFragment`, then save the updated text (if any) from the editor in `models` for later reuse.

Running this on a phone-sized screen gives you your tabs, in a row beneath the main action bar itself:

Figure 380: TabFragmentDemo, on Android 4.0.3, Phone-Sized Screen

Those tabs are “swipey”, meaning that the user can fling the row of tabs to get to all 10 of them.

This UI makes perfect sense for something described as “tab navigation”. Where things get a bit odd is in any configuration, such as a normal-sized screen in landscape:

ACTION BAR NAVIGATION

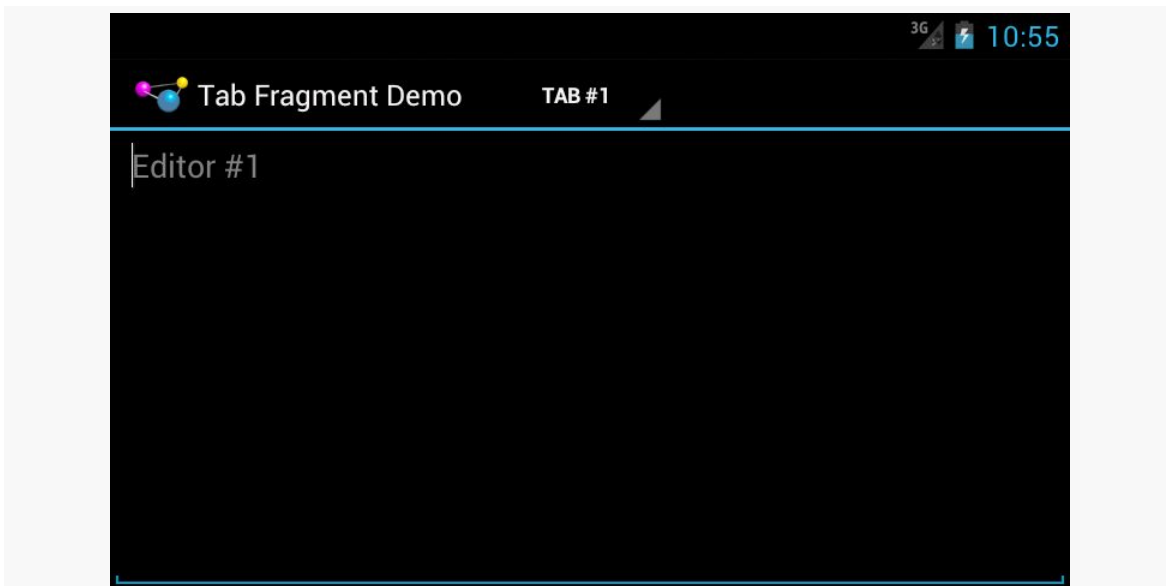

Figure 381: TabFragmentDemo, on Android 4.0.3, Phone-Sized Screen in Landscape

or on a large-sized screen in portrait:

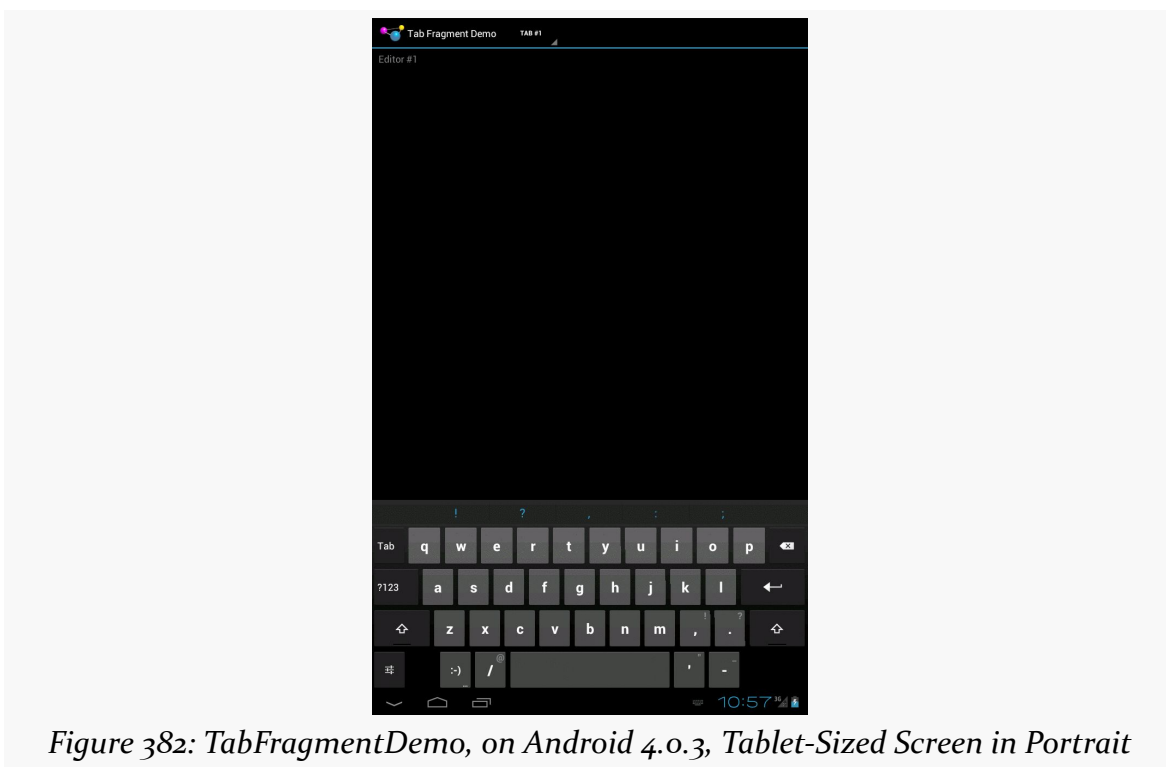

Figure 382: TabFragmentDemo, on Android 4.0.3, Tablet-Sized Screen in Portrait

Android will automatically convert your tab navigation to list navigation if and when it wishes to. You do not have control over this behavior, and it will vary by Android release:

The system will apply the correct UX policy for the device. As the exact policy of presentation may change on different devices or in future releases, it is intentionally not specified in documentation.

(from [the issue filed by the author of this book over this behavior](#))

Custom Navigation

You could also elect to use one of the various flavors of `setCustomView()` on `ActionBar`. These allow you to completely control what goes in the navigation area of the bar, by supplying either a `View` or a layout resource ID that should get inflated into the bar. Particularly in the latter case, you would call `getCustomView()` later on to retrieve the inflated layout, so you can access the widgets, configure listeners, and so forth.

While Google definitely steers you in the direction of using the tabs or list navigation, plenty of apps will use a custom navigation option, for things like:

- a search field
- an `AutoCompleteTextView` (e.g., a browser's address bar)
- etc.

Action Modes and Context Menus

If you have spent much time on an Android 3.0+ device, then you probably have run into a curious phenomenon. Sometimes, when you select an item in a list or other widget, the action bar magically transforms from its normal look:

to one designed to perform operations on what you have selected:

The good news is that this is not some sort of magic limited only to firmware applications like Gmail. You too can have this effect in your application, by triggering an “action mode”.

Action modes — sometimes called the “contextual action bar” — is the replacement for the “context menu”, whereby a menu would appear when you long-tap on some widget. Context menus were most commonly used with `AdapterViews`, particularly with `ListView`, to perform an operation on the specific long-tapped-upon item.

In this chapter, we will explore action modes, with context menus being relegated to the dustbin of history.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Another Wee Spot O' History

Most desktop operating systems have had the notion of a “context menu” for some time, typically triggered by a click of the right mouse button. In particular, a right-click over some selected item might bring up a context menu of operations to perform on that item:

- Selecting text in a text editor, then right-clicking, might bring up a context menu for cut/copy/paste of the text
- Right-clicking over a file in some sort of file explorer might bring up a context menu for cut/copy/paste of the file
- Etc.

Android supports context menus, driven by a long-tap on a widget rather than a right-click. You will find many applications that offer such menus, particularly on lists of things.

Context menus are certainly useful. Power users can save screen taps if they know where context menus reside and what features they offer. For example, rather than tapping on a list item, then opening an options menu, then tapping a menu item to delete something, a power user could long-tap to open a context menu, then tap on a context menu item — saving one tap and switching back and forth between activities.

The problem is that context menus are invisible and are triggered by an action not used elsewhere very much (long tap).

In theory, users would find out about context menus in your application from reading your documentation. That would imply that we were in some alternate universe where all users read documentation, all people live in peace and harmony, and all book authors have great heads of hair. In this universe, power users will find your context menus, but ordinary users may be completely oblivious to them. Also, the hair of book authors remains stubbornly variable.

The action bar itself is designed to help raise the visibility of what had been the options menu (e.g., turning menu items into toolbar buttons) and standardizing the location of navigation elements (e.g., tabs, search fields). The action mode is designed to perform a similar bit of magic for context menus. Rather than have context menus be buried under a long-tap, action modes let the contextual actions take over the action bar, putting them front-and-center in the user experience.

Manual Action Modes

A common pattern will be to activate an action mode when the user checks off something in a multiple-choice `ListView`, as is the case with applications like Gmail. If you want to go that route, there is some built-in scaffolding to make that work, described [later in this chapter](#).

You can, if you wish, move the action bar into an action mode whenever you want. This would be particularly important if your UI is not based on a `ListView`. For example, tapping on an image in a `GridView` might activate it and move you into an action mode for operations upon that particular image.

In this section, we will examine the [ActionMode/ManualNative](#) sample project. This is another variation on the “show a list of Latin words in a list” sample used elsewhere in this book.

Choosing Your Trigger

As noted above, Gmail switches into an action mode when the user checks off one or more conversations in the conversations list. Selecting a word or passage in an `EditText` (e.g., via a long-tap) brings up an action mode for cut/copy/paste operations. And so on.

You will need to choose, for your own UI, what trigger mechanism will bring up an action mode. It should be some trigger that makes it obvious to the user what the action mode will be acting upon. For example:

- If the user long-taps on an item in a `GridView`, bring up an action mode, and treat future taps on `GridView` items as adding or removing items from the “selection” while that action mode is visible
- If the user “rubber-bands” some figures in your vector art drawing `View`, bring up an action mode for operations on those figures (e.g., rotate, resize)
- And so on

In the case of the sample project, we stick with the classic long-tap on a `ListView` row to bring up an action mode that replaces the context menu when run on a API Level 11+ device:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    initAdapter();
    getListView().setLongClickable(true);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    getListView().setOnItemLongClickListener(new ActionModeHelper(
                                                                    this,
getListView()));
}
```

Starting the Action Mode

Starting an action mode is trivially easy: just call `startActionMode()` on your Activity, passing in an implementation of `ActionMode.Callback`, which will be called with various lifecycle methods for the action mode itself.

In the case of the `ActionMode` sample project, `ActionModeHelper` – our `OnItemLongClickListener` from the preceding section – also is our `ActionMode.Callback` implementation. Hence, when the user long-clicks on an item in the `ListView`, the `ActionModeHelper` establishes itself as the action mode:

```
@Override
public boolean onItemLongClick(AdapterView<?> view, View row,
                                int position, long id) {
    modeView.clearChoices();
    modeView.setItemChecked(position, true);

    if (activeMode == null) {
        activeMode=host.startActionMode(this);
    }

    return(true);
}
```

Note that `startActionMode()` returns an `ActionMode` object, which we can use later on to configure the mode's behavior, by stashing it in an `actionMode` data member.

Also, we make the long-clicked-upon item be “checked”, to show which item the action mode will act upon. Our row layout will make a checked row show up with

the “activated” style, courtesy of Android’s `simple_list_item_activated_1` stock layout.

Also note that we only start the action mode if it is not already started.

Implementing the Action Mode

The real logic behind the action mode lies in your `ActionMode.Callback` implementation. It is in these four lifecycle methods where you define what the action mode should look like and what should happen when choices are made in it.

`onCreateActionMode()`

The `onCreateActionMode()` method will be called shortly after you call `startActionMode()`. Here, you get to define what goes in the action mode. You get the `ActionMode` object itself (in case you do not already have a reference to it). More importantly, you are passed a `Menu` object, just as you get in `onCreateOptionsMenu()`. And, just like with `onCreateOptionsMenu()`, you can inflate a menu resource into the `Menu` object to define the contents of the action mode:

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);

    return(true);
}
```

In addition to inflating our context menu resource into the action mode’s menu, we also set the title of the `ActionMode`, which shows up to the right of the Done button:

Figure 385: The ActionMode sample application’s action bar on a Honeycomb tablet, showing the active action mode

onPrepareActionMode()

If you determine that you need to change the contents of your action mode, you can call `invalidate()` on the `ActionMode` object. That, in turn, will trigger a call to `onPrepareActionMode()`, where you once again have an opportunity to configure the `Menu` object. If you do make changes, return `true` — otherwise, return `false`. In the case of `ActionModeHelper`, we take the latter approach:

```
@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}
```

onActionItemClicked()

Just as `onCreateActionMode()` is the action mode analogue to `onCreateOptionsMenu()`, `onActionItemClicked()` is the action mode analogue to `onOptionsItemSelected()`. This will be called if the user clicks on something related to your action mode. You are passed in the corresponding `MenuItem` object (plus the `ActionMode` itself), and you can take whatever steps are necessary to do whatever the work is.

On the `ActionModeDemo` class, we have the business logic for handling the data-change operations in a `performAction()` method:

```
public boolean performAction(int itemId, int position) {
    switch (itemId) {
        case R.id.cap:
            String word=words.get(position);

            word=word.toUpperCase();

            adapter.remove(words.get(position));
            adapter.insert(word, position);

            return(true);

        case R.id.remove:
            adapter.remove(words.get(position));

            return(true);
    }

    return(false);
}
```

And, the `onActionItemClicked()` method calls `performAction()`:

```
@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=
        host.performAction(item.getItemId(),
                           modeView.getCheckedItemPosition());

    if (item.getItemId() == R.id.remove) {
        activeMode.finish();
    }

    return(result);
}
```

`onActionItemClicked()` also dismisses the action mode if the user chose the “remove” item, since the action mode is no longer needed. You get rid of an active action mode by calling `finish()` on it.

onDestroyActionMode()

The `onDestroyActionMode()` callback will be invoked when the action mode goes away, for any reason, such as:

1. The user clicks the Done button on the left
2. The user clicks the BACK button
3. You call `finish()` on the `ActionMode`

Here, you can do any necessary cleanup. `ActionModeHelper` tries to clean things up, notably the “checked” state of the last item long-tapped-upon:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
    modeView.clearChoices();
    modeView.requestLayout();
}
```

However, for reasons that are not yet clear, `clearChoices()` does not update the UI when called from `onDestroyActionMode()` unless you also call `requestLayout()`.

Multiple-Choice-Modal Action Modes

For many cases, the best user experience will be for you to have a multiple-choice `ListView`, where checking items in that list enables an action mode for performing

operations on the checked items. For this scenario, API Level 11+ has a built-in ListView choice mode, `CHOICE_MODE_MULTIPLE_MODAL`, that automatically sets up an `ActionMode` for you as the user checks and unchecks items.

To see how this works, let's examine the [ActionMode/ActionModeMC](#) sample project. This is the same project as in the preceding section, but altered to have a multiple-choice ListView, utilizing an action mode on API Level 11+.

Once again, in `onCreate()`, we need to set up the smarts for our ListView. This time, though, we will use `CHOICE_MODE_MULTIPLE_MODAL`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    initAdapter();

    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setMultiChoiceModeListener(new HCMultiChoiceModeListener(
        this, getListView()));
}
```

We enable `CHOICE_MODE_MULTIPLE_MODAL` for the ListView, and register an instance of an `HCMultiChoiceModeListener` object via `setMultiChoiceModeListener()`. This object is an implementation of the `MultiChoiceModeListener` interface that we will examine shortly.

Since we now may have multiple checked items, our `performAction()` method must take this into account, capitalizing or removing all checked words:

```
public boolean performActions(MenuItem item) {
    SparseBooleanArray checked=getListView().getCheckedItemPositions();

    switch (item.getItemId()) {
        case R.id.cap:
            for (int i=0; i < checked.size(); i++) {
                if (checked.valueAt(i)) {
                    int position=checked.keyAt(i);
                    String word=words.get(position);

                    word=word.toUpperCase(Locale.ENGLISH);

                    adapter.remove(words.get(position));
                    adapter.insert(word, position);
                }
            }

            return(true);
    }
}
```

```
case R.id.remove:
    ArrayList<Integer> positions=new ArrayList<Integer>();

    for (int i=0; i < checked.size(); i++) {
        if (checked.valueAt(i)) {
            positions.add(checked.keyAt(i));
        }
    }

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        adapter.remove(words.get(position));
    }

    getListView().clearChoices();

    return(true);
}

return(false);
}
```

MultiChoiceModeListener extends the ActionMode.Callback interface we used with our manual action mode earlier in this book. Hence, we need to implement all the standard ActionMode.Callback methods, plus a new onItemCheckedStateChanged() method introduced by MultiChoiceModeListener:

```
package com.commonware.android.actionmodemc;

import android.annotation.TargetApi;
import android.os.Build;
import android.view.ActionMode;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.widget.AbsListView;
import android.widget.ListView;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
public class HCMultiChoiceModeListener implements
    AbsListView.MultiChoiceModeListener {
    ActionModeDemo host;
    ActionMode activeMode;
    ListView lv;

    HCMultiChoiceModeListener(ActionModeDemo host, ListView lv) {
        this.host=host;
        this.lv=lv;
    }
}
```

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);
    mode.setSubtitle("(1)");
    activeMode=mode;

    return(true);
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=host.performActions(item);

    updateSubtitle(activeMode);

    return(result);
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
}

@Override
public void onItemCheckedStateChanged(ActionMode mode, int position,
                                       long id, boolean checked) {
    updateSubtitle(mode);
}

private void updateSubtitle(ActionMode mode) {
    mode.setSubtitle("(" + lv.getCheckedItemCount() + ")");
}
}
```

Android will automatically start our action mode for us when the user checks the first item in the list, using our `MultiChoiceModeListener` as the callback. Android will also automatically finish the action mode if the user unchecks all previously-checked items.

In `onCreateActionMode()`, we populate the menu, plus set up a title and subtitle on the `ActionMode`. The subtitle appears below the title, as you might expect. In this case, we are indicating how many words are checked and therefore will be affected by the actions the user chooses in the action mode:

Figure 386: The ActionModeMC sample application's action bar on a Honeycomb tablet, showing the active action mode

Then, in `onActionItemClicked()`, we both call `performActions()` to affect the desired changes, plus update the subtitle in case the user removed words (which means they are no longer checked).

The new `onItemCheckedStateChanged()` will be called whenever the user checks or unchecks an item, up until the last item is unchecked. `HCMultiChoiceModeListener` simply updates the subtitle to reflect the new count of checked items.

On the whole, using `CHOICE_MODE_MULTIPLE_MODAL` is simpler than setting up your own trigger mechanism and managing the action mode yourself. That being said, both are completely valid options, which is particularly important for situations where a multiple-choice `ListView` is not the desired user interface.

Long-Click To Initiate an Action Mode

However, rather than having checkboxes or the like always in the `ListView`, a more modern approach is to move into multiple-selection mode based on a long-click. Before then, clicks on rows behave like with any other `ListView`, but after a long-click, the action mode appears and the user can tap on rows to select which of them to operate upon.

The [ActionMode/LongPress](#) sample project is a variation on the preceding project, with some slight simplifications, and adopting the long-click as the means to enter the action mode.

Setting Up the Listeners

In `onCreate()`, we set up listeners for both a long click (via `setOnItemLongClickListener()`) and for multiple-choice mode (via `setMultiChoiceModeListener()`). Both times, we supply the activity as the listener, as it implements the appropriate interfaces:

```
getListView().setOnItemLongClickListener(this);  
getListView().setMultiChoiceModeListener(this);
```

Handling the Long Click

By default, the `ListView` is in no-choice mode, where clicks on rows simply trigger `onItemClickListener()` or the equivalent. However, if the user long-clicks on a row, our `onItemLongClick()` method will be called, and we can both switch into multiple-choice mode and mark the long-clicked row as being checked:

```
@Override  
public boolean onItemLongClick(AdapterView<?> parent, View view,  
                                int position, long id) {  
    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);  
    getListView().setItemChecked(position, true);  
  
    return(true);  
}
```

At this point, the action mode will also start up, courtesy of having called `setMultiChoiceModeListener()`.

Addressing Configuration Changes

If we undergo a configuration change, we want:

1. To keep the current set of words, including any that were added
2. To keep the action mode going, if the user had long-clicked to enter the action mode
3. To keep our checked item states, if the action mode is active

Keeping the checked item states will be handled for us by the built-in instance-state management of `ListView` and `ListActivity`. However, the rest we need to handle ourselves. So, we have an `onSaveInstanceState()` implementation in the activity, which saves the current choice mode, plus the current word list:

```
@Override  
public void onSaveInstanceState(Bundle state) {  
    super.onSaveInstanceState(state);  
    state.putInt(STATE_CHOICE_MODE, getListView().getChoiceMode());  
    state.putStringArrayList(STATE_MODEL, words);  
}
```

Plus, in `onCreate()`, after setting up the listeners, we set up the choice mode of the `ListView` based upon the passed in instance state `Bundle`, if there is one:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    if (state == null) {
        initAdapter(null);
    }
    else {
        initAdapter(state.getStringArrayListList(STATE_MODEL));
    }

    getListView().setOnItemLongClickListener(this);
    getListView().setMultiChoiceModeListener(this);

    int choiceMode=
        (state == null ? ListView.CHOICE_MODE_NONE
         : state.getInt(STATE_CHOICE_MODE));

    getListView().setChoiceMode(choiceMode);
}
```

Once we call `setChoiceMode()` with the previous activity instance's choice mode, if that was `CHOICE_MODE_MULTIPLE_MODAL`, Android will automatically open up the action mode again and restore our checked items.

Resetting the Choice Mode

Where things get a bit interesting is when the user dismisses the action mode, at which point we need to move back to no-choice mode.

You might think that this would merely be a matter of calling `setChoiceMode()` on the `ListView`, asking for `CHOICE_MODE_NONE`. Indeed, that is part of the solution. However, there are two problems:

1. If you call that in `onDestroyActionMode()` directly, you wind up with infinite recursion and a `StackOverflowError`, as changing the choice mode while the action mode is still technically active will cause it to destroy the action mode again.
2. Switching the choice mode back to “none” enables some optimizations within `ListView` that ignore the checked state of our rows. However, those rows still already checked will show up as activated, even after calling `setChoiceMode()` to return to the normal “none” mode. `clearChoices()` also does not have a worthwhile effect, for whatever reason.

Hence, in `onDestroyActionMode()`, not only do we need to call `setChoiceMode()`, but we need to “smack around” the `ListView` enough to get it to clear our checked

rows, and the easiest way to do that is to call `setAdapter()` on it, passing in its existing adapter:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        getListView().setChoiceMode(ListView.CHOICE_MODE_NONE);
        getListView().setAdapter(getListView().getAdapter());
    }
}
```

And, we only do that while our action mode is active (i.e., `activeMode` is not null), to avoid the infinite recursion.

This is a bit clunky, but it works.

The Results

When initially launched, the activity looks like a simple `ListActivity`:

Figure 387: Action Mode Long Press Demo, As Initially Launched

Tapping on a row provides the normal momentary highlight.

ACTION MODES AND CONTEXT MENUS

However, if the user long-clicks a row, we move into the action mode and a multiple-choice `ListView`:

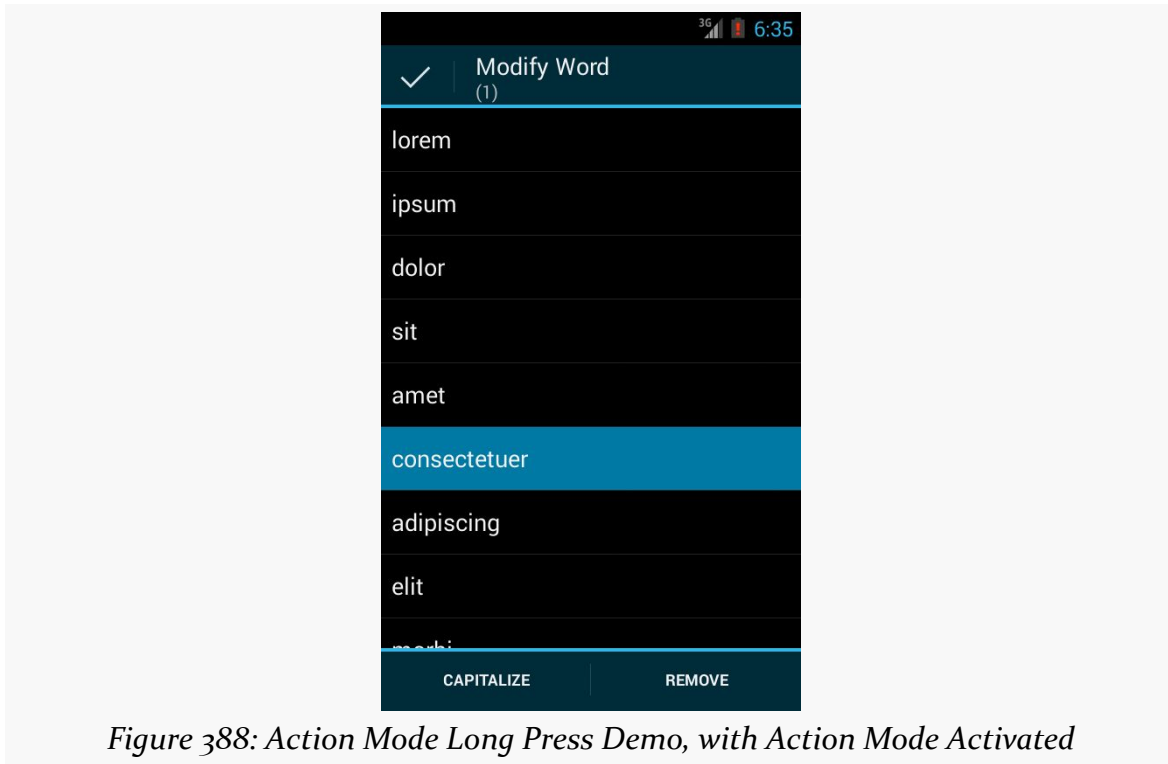

Figure 388: Action Mode Long Press Demo, with Action Mode Activated

Figure 389: Action Mode Long Press Demo, with Multiple Selections

Dismissing the action mode returns the `ListView` to normal operation.

Split Action Modes

Android 4.0 brought action modes to phone-sized devices. Small screens in the portrait orientation have problems with the action bar in general being too small. Action modes inherit the same problem.

For example, here is the `ActionMode/ActionModeMC` project as seen on a Nexus S running Android 4.0.3:

ACTION MODES AND CONTEXT MENUS

Figure 390: The ActionModeMC sample on a phone

You will notice that our mode's title gets ellipsized due to the lack of room, and this is just with two action items. Admittedly, using icons rather than text labels would help, but even that can only get us so far.

If you use a split action bar, by adding `android:uiOptions="splitActionBarWhenNarrow"` to the `<activity>` element in the manifest, the action mode will also split, with the action items moving to the bottom:

ACTION MODES AND CONTEXT MENUS

Figure 391: The ActionModeMC sample on a phone, using a split action bar

If there is more horizontal room (i.e., it is not “narrow”), then the action mode will display as normal:

ACTION MODES AND CONTEXT MENUS

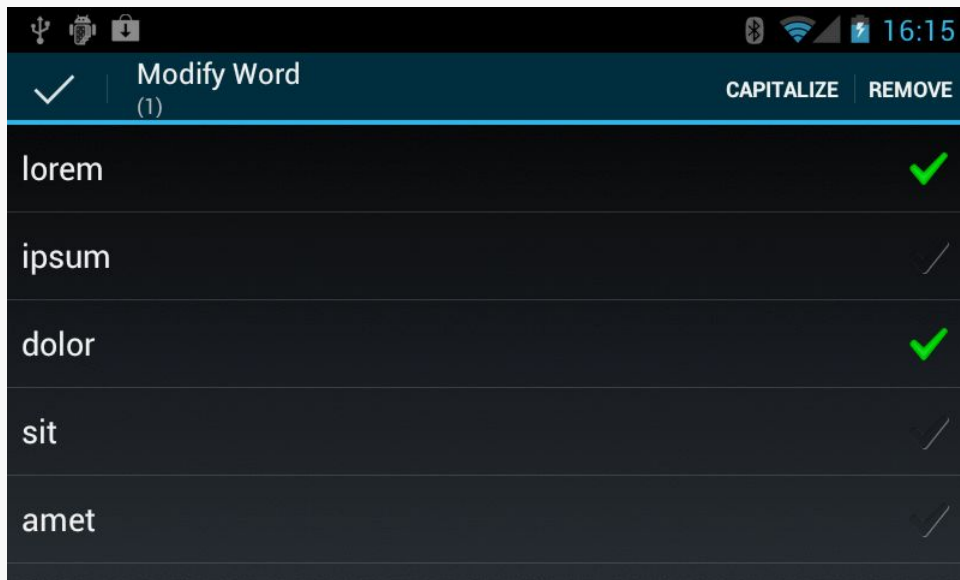

Figure 392: The ActionModeMC sample on a phone, using a split action bar, in landscape orientation

Other Advanced Action Bar Techniques

The action bar offers a number of other features that developers can take advantage of, ones that do not necessarily fit into the other chapters. Hence, this chapter is a “catch all” for other things you may wish to do with your action bar.

Note that this chapter is focused on the native action bar, not the [ActionBarSherlock](#) or [AppCompat](#) backports.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Splitting the Bar

The native action bar debuted with Honeycomb, which was only available for tablets. Here, we had lots of room, even with the device in portrait mode.

Once Ice Cream Sandwich (Android 4.0) rolled around, and the native action bar became available for phones, it was readily apparent that it was too small in portrait mode to do very much.

To help with this, you can enable a mode for your application (or specific activities) that gives you a “split” action bar: one at the top of your activity, and another at the bottom. Your toolbar buttons and the action overflow area will appear at the bottom,

OTHER ADVANCED ACTION BAR TECHNIQUES

leaving the top available for your icon, application name, and other stuff that we have not talked about just yet.

To enable this feature, add `android:uiOptions="splitActionBarWhenNarrow"` to your `<application>` or a specific `<activity>` in the manifest. In the sample application manifest shown above, you will see this in the `<application>` element, which means the split action bar is used on *all* activities, by default.

However, this feature is not supported on Android 5.0 and higher, if you are using `Theme.Material` on those devices. The option is simply ignored, and all of your action bar items will go on the main (top) action bar, or into the overflow if there is insufficient room.

For example, the [ActionBar/SplitBarDemo](#) sample project is a clone of the `ActionBarDemoNative` application with just one change: adding `android:uiOptions="splitActionBarWhenNarrow"` to the `<application>` element in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.splitbar"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="15"
        android:targetSdkVersion="19"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:uiOptions="splitActionBarWhenNarrow">
        <activity
            android:name="ActionBarDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
```

OTHER ADVANCED ACTION BAR TECHNIQUES

```
</manifest>
```

When using the default Theme.Holo on Android 4.x, you get a split action bar, with the action items on the bottom of a “narrow” screen configuration:

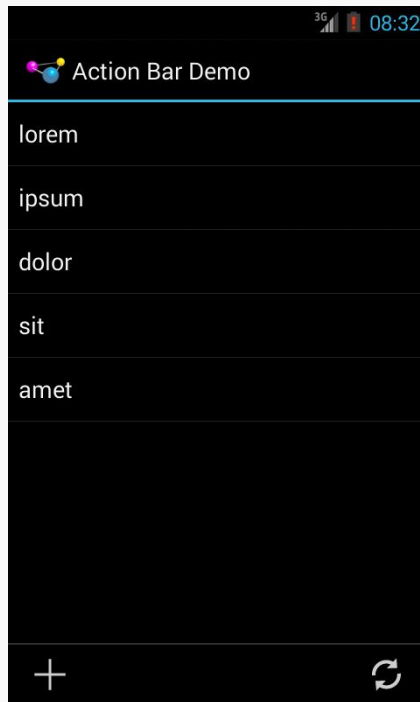

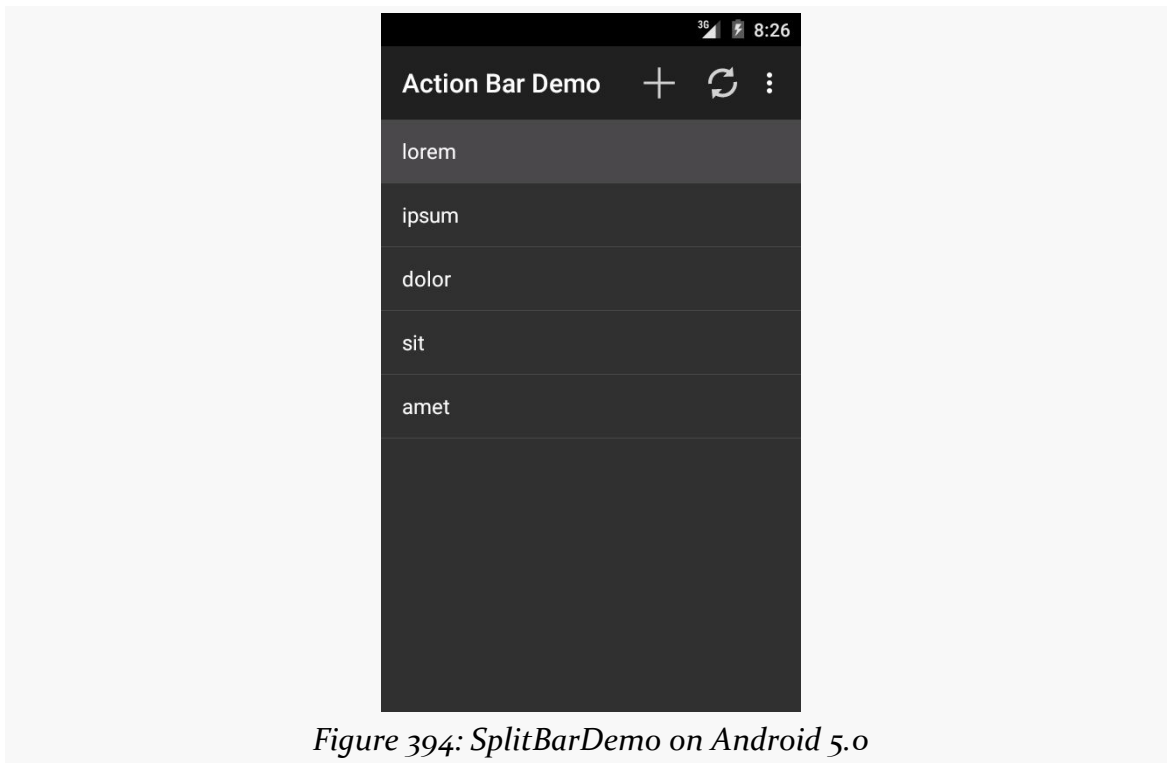

Figure 393: SplitBarDemo on Android 4.3

However, the same sample app, using the default Theme.Material on Android 5.0+, will not get the split bar:

In this particular sample, everything still fits. However, for apps with more action bar items, we might “lose” some, having them fall into the overflow, whereas they would be directly visible using the split action bar on Android 4.x.

Action Layouts

What happens if you want something other than a button to appear as an action bar item? Suppose you want a field instead?

Fortunately, this is supported. Otherwise, this would be a completely pointless section of the book.

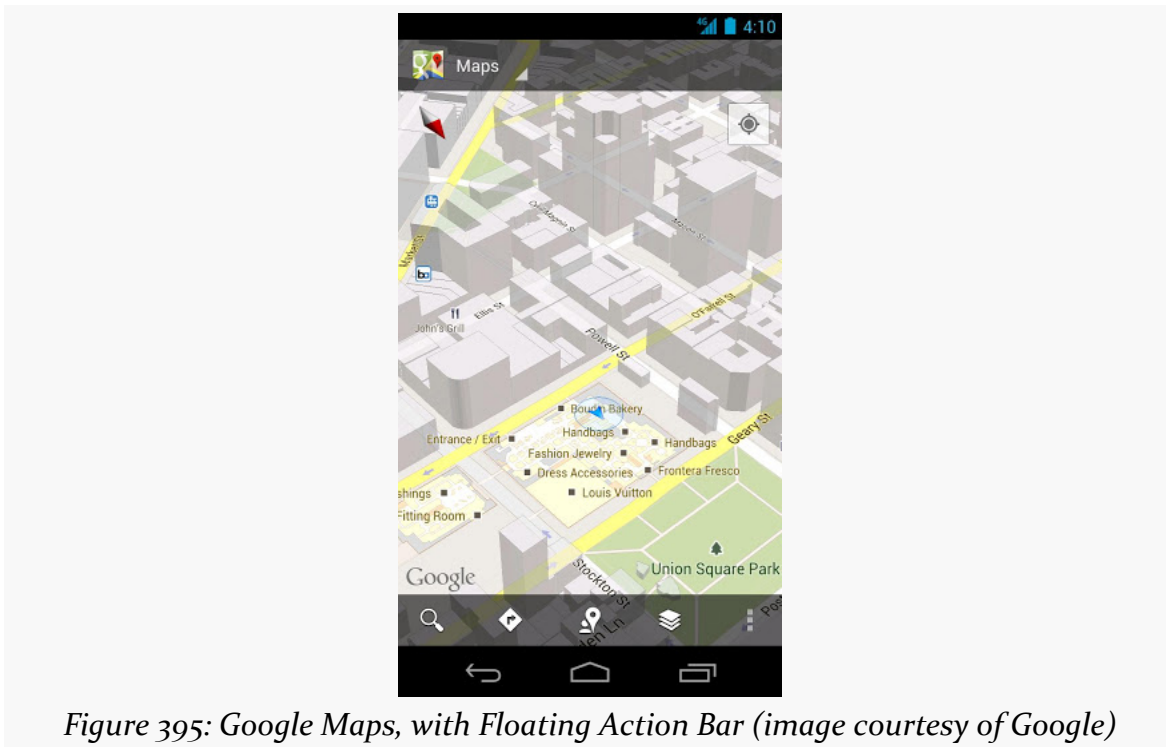

You can specify `android:actionLayout` on an `<item>` element in a menu resource. This will point to a reference to a layout XML resource that you want to have inflated into the action bar instead of a toolbar button. Then, in `onCreateOptionsMenu()`, you can call `findMenuItem()` on the `Menu` to retrieve the `MenuItem` associated with this `<item>` element, then call `getActionView()` to retrieve the root of your inflated layout. At that point, you can hook up event listeners to the widgets in that layout, as needed.

Obviously, since the action bar is only so big, you will need to be judicious about your use of space. This is particularly true on Android 5.0+, when a split action bar is no longer an available option. In practice, you will probably rarely use `android:actionLayout`, if ever.

Floating Action Bars

By default, your action bar (or action bars, if you are using `splitActionBarWhenNarrow`) will be separate from the main content area of your activity. Normally, that is what you want.

But, sometimes, you may want to have the action bar(s) float over the top of your activity, as can be seen in Google Maps:

To accomplish this, you can use `FEATURE_ACTION_BAR_OVERLAY`, as is illustrated in the [ActionBar/OverlayNative](#) sample project.

This is nearly identical to the `ActionBar/ActionBarDemoNative` sample project, with just a few changes, mostly in the `onCreate()` method of our activity:

OTHER ADVANCED ACTION BAR TECHNIQUES

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    getWindow().requestFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getActionBar().setBackgroundDrawable(d);
    getActionBar().setSplitBackgroundDrawable(d);
}
```

In addition to the original logic, we:

- Call `requestFeature()` on our `Window` (obtained via a call to `getWindow()`), asking for `FEATURE_ACTION_BAR_OVERLAY`
- Call `setBackgroundDrawable()` on our `ActionBar` (obtained via a call to `getSupportActionBar()`, since we are using `ActionBarSherlock`, supplying a reference to a drawable resource to use for the background of the floating action bar
- Call `setSplitBackgroundDrawable()` on our `ActionBar` to set the same drawable resource for the background of the bottom action bar, if and when one is used

The drawable resource is a `ShapeDrawable`, defined in XML:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <solid android:color="#AAFFFFFF"/>

</shape>
```

We will discuss `ShapeDrawable` in much greater detail [later in this book](#) . For the moment, take it on faith that our resource is defining a rectangle, with a translucent white fill. The alpha channel (AA) for our translucence is important, so the user can see a bit of our activity underneath the floating action bar.

The result is that our action bars float over the top of the list:

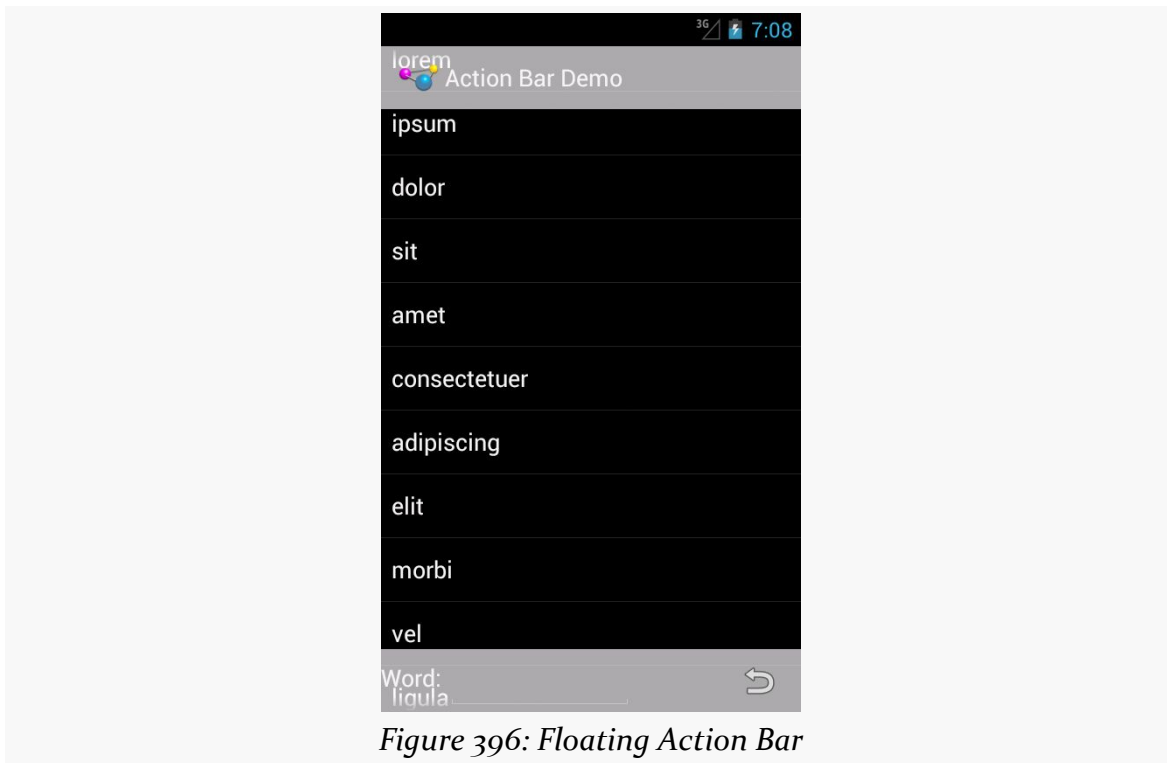

Figure 396: Floating Action Bar

In this case, the effect is not very good, as the words will blend in too strongly with the overlaid action bars. However, that is a question of organizing the screen content and using this overlay feature only in cases where you will see good results, such as in the Google Maps example shown above.

Action Layouts, Action Views, and Action Providers

There are many options for replacing the stock toolbar-style button used for an action item with something else. In [the original chapter on the action bar](#), we saw how to use `android:actionLayout` and `getActionView()` to replace the toolbar button with the contents of a layout resource, which we could then configure at runtime.

If all you need is a single widget to replace the toolbar button, rather than a whole layout resource, you can use `android:actionViewClass` instead of `android:actionLayout`. In `android:actionViewClass`, you provide the fully-qualified class name of the widget that you wish to use to replace the toolbar button. You still use `getActionView()` to retrieve a reference to this at runtime.

If the widget you use implements the `CollapsibleActionView` interface, then it has an additional behavior: the ability to collapse into a standard toolbar button or expand into its normal mode. The only example of this in the current Android SDK is `SearchView`, which can expand into a field for searching or collapse into a simple search icon (magnifying glass) as needed. We will see more about `SearchView`, and how it behaves as a `CollapsibleActionView`, [later in this chapter](#).

Yet another possible toolbar button replacement is an action provider. Whereas an action view or action layout provide the UI, and your code provides the handling of touch events, an action provider is an “all-in-one” solution. It is designed to be configured, then used by the user without any required additional intervention by the developer. That being said, an action provider can have its own listener interfaces to let developers know about various events that have occurred. The two primary implementations of the `ActionProvider` base class are:

- `MediaRouteActionProvider`, used to allow users to control the destination for media, such as routing audio to Bluetooth headphones instead of the device speaker
- `ShareActionProvider`, to simplify sharing content via `ACTION_SEND`, as is covered [elsewhere in the book](#)

To use an `ActionProvider`, you add the `android:actionProviderClass` attribute to an `<item>` in the `<menu>` resource, providing the fully-qualified class name of the `ActionProvider` implementation. You can call `getActionProvider()` on the `MenuItem` to retrieve the `ActionProvider` instance, for configuration at runtime.

Searching with SearchView

Many apps employ a `SearchView` in their action bar. The user typically sees the search icon as a regular toolbar button:

Figure 397: SearchView Demo, Showing Collapsed Action View

Tapping that opens a search field, taking over more of the action bar:

Figure 398: SearchView Demo, Showing Expanded Action View

Typing something in initiates some sort of search, as defined by the activity that is using the SearchView. BACK or the app icon in the action bar will “collapse” the SearchView back into its iconified state.

While you are welcome to use SearchView in conjunction with Android’s [overall search framework](#), you can also use it standalone within your app, as is seen in the [ActionBar/SearchView](#) sample project, profiled in this section. This sample is a clone of one of the previous action bar samples, where we have the list of 25 words, hosted in a ListFragment, with action bar items to add a word and reset the word list. In this section, we will augment the sample with a SearchView and a filtered ListView.

SearchView... in the Menu Resource

The project’s menu resource (res/menu/actions.xml) contains a regular action item (reset), an action item employing an action layout (add), and an action item containing our SearchView (search):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/search"
        android:actionViewClass="android.widget.SearchView"
        android:icon="@drawable/ic_action_search"
        android:showAsAction="ifRoom|collapseActionView"
        android:title="@string/filter">
    </item>

</menu>
```

Note that the search item not only has `android:actionViewClass="android.widget.SearchView"` to tie in our action view, but it also has `android:showAsAction="ifRoom|collapseActionView"`, to indicate that this action view should support collapsing and expanding.

SearchView... in the Action Bar Configuration

In `onCreateOptionsMenu()` of our `ActionBarFragment`, in addition to inflating the menu resource and calling a `configureActionItem()` method to configure the add action layout, we now also call a `configureSearchView()` method to configure the `SearchView`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    configureSearchView(menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

In `configureSearchView()`, surprisingly enough, we configure the `SearchView`:

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

Specifically, we:

- Register our fragment as the `QueryTextListener` and the `OnCloseListener`, which will be covered in greater detail [later in this chapter](#)
- Disable the submit button, as we will be using the `SearchView` for filtering rather than querying
- Indicate that the `SearchView` should be collapsed (“iconified”) as the default state

Also, our fragment has an `initialQuery` data member, and if that is not null, we expand the `SearchView` and fill in `initialQuery` as the query to be shown in the `SearchView`, also submitting it.

`initialQuery` comes from our configuration change logic, as if the user fills in something in the `SearchView` in one configuration (e.g., portrait), we do not want to lose it on a configuration change (e.g., to landscape). In our `onSaveInstanceState()` method, we save both the query from the `SearchView` and the words currently in our list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (!sv.isIconified()) {
        state.putCharSequence(STATE_QUERY, sv.getQuery());
    }

    state.putStringArrayList(STATE_MODEL, words);
}
```

In `onActivityCreated()`, we use the `savedInstanceState` `Bundle` to populate the adapter with the previous set of words, plus store the old `SearchView`'s query in `initialQuery`:

```
@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    if (savedInstanceState == null) {
        initAdapter(null);
    }
    else {
        initAdapter(savedInstanceState.getStringArrayList(STATE_MODEL));
        initialQuery=savedInstanceState.getCharSequence(STATE_QUERY);
    }

    setHasOptionsMenu(true);
}
```

Hence, on a configuration change, by the time `configureSearchView()` is called, we will have our `initialQuery`, if there is one, and we can set up the UI to be the same as it was in the old configuration.

SearchView... And Filtering a ListView

The `ActionBarFragment` implements the `SearchView.OnQueryTextListener` and `SearchView.OnCloseListener` interfaces, which is why we can pass this to `setOnQueryTextListener()` and `setOnCloseListener()` in `configureSearchView()`.

Those two interfaces require a total of three methods, described below.

onQueryTextChanged()

The `onQueryTextChanged()` method — required by `SearchView.OnQueryTextListener` — will be called whenever the user has changed the contents of the expanded `SearchView`, such as by typing a character. This is used when you want to employ the `SearchView` for filtering, updating the filter as the user types, rather than for searching, in which case you would wait until the user “submits” the search request.

Our implementation takes advantage of `ArrayAdapter`’s built-in filtering capability:

```
@Override
public boolean onQueryTextChanged(String newText) {
    if (TextUtils.isEmpty(newText)) {
        adapter.getFilter().filter("");
    }
    else {
        adapter.getFilter().filter(newText.toString());
    }

    return(true);
}
```

Adapters that implement the `Filterable` interface can be filtered, automatically restricting the displayed items to ones that match the filter. Calling `getFilter()` on a `Filterable` returns a `Filter`. The default implementation of a `Filter` filters on the leading characters of `toString()` of `getItem()` from the Adapter. Hence, filtering an `ArrayAdapter` on our roster of 25 words, where the filter string is 'm', would show `morbi` and `molllis` but skip `amet`, let alone other words not beginning with `m`.

So, our `onQueryTextChanged()` method simply updates the `Filter` with whatever the user has typed into the `SearchView`, setting the filter to the empty string if the `SearchView` is either empty or has null contents.

onQueryTextSubmit()

The `onQueryTextSubmit()` method — required by `SearchView.OnQueryTextListener` — would be called if the user tapped on the submit button within the expanded `SearchView`, to ask us to perform the search. In this sample, we have disabled that button, as we are filtering our list on the fly, rather than performing a query once the `SearchView` is filled out. Hence,

ActionBarFragment has a do-nothing implementation of `onQueryTextSubmit()`, simply returning `false` to indicate that we have not consumed the event:

```
@Override
public boolean onQueryTextSubmit(String query) {
    return(false);
}
```

The chapter on advanced database techniques has [a section on full-text indexing](#), and the sample app in that chapter demonstrates the use of the submit button in a `SearchView` and `onQueryTextSubmit()`.

onClose()

The `onClose()` method — required by `SearchView.OnCloseListener` — in theory will be called when the `SearchView` is collapsed. Here, we simply clear out the filter that we are using to limit the contents of the `ListView`, plus return `true` to say that we have handled the event:

```
@Override
public boolean onClose() {
    adapter.getFilter().filter("");

    return(true);
}
```

According to the `SearchView` source code, it will only be called if:

- The query text is empty, and
- The `SearchView` is iconified by default (`setIconifiedByDefault(true)`)

In practice, [not even that works](#).

Hence, if you really need to find out when the `SearchView` is collapsed, you will probably need to use the more generic `OnActionExpandListener` interface, attached to the `SearchView` via `setOnActionExpandListener()`. `onMenuItemActionCollapse()` should be called when the `SearchView` is collapsed. This also works for other types of collapsible action views, not just `SearchView`.

SearchView... From the User's Perspective

If the user taps on the search icon, then starts typing into the `SearchView`'s editing area, the `ListView` is filtered based upon the typed-in prefix:

Figure 399: SearchView Demo, Showing Filtered Results

AppCompat: The Official Action Bar Backport

Approximately 30 months after Google added the action bar to Android 3.0, Google released a backport for previous devices. Referred to here as AppCompat, this fills much the same niche as does [ActionBarSherlock](#), adding action bar support to Android apps, going all the way back to API Level 7.

The `appcompat-v7` Android Support Package artifact houses AppCompat. Version 21 and higher of this artifact change the way that AppCompat looks, to try to not only backport the action bar, but to backport a bit of the Material Design aesthetic.

This chapter will outline why you might want to use AppCompat and how to employ it in your Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Ummmm... Why?

You might wonder why we would bother with any of it. AppCompat is not required, and apps can work fine without it. And, in truth, most apps will be just fine using the native action bar implementation.

That being said, you may find some pressures nudging you towards using an action bar backport, and AppCompat specifically.

Why an Action Bar Backport?

If your `minSdkVersion` is 11 or higher, you have an action bar on all Android versions that your app supports.

If, however, your `minSdkVersion` is below 11, by default you will get the old-style options menu on Android 1.x/2.x devices. That is not a crime. However, the action bar design pattern had been used in various Android apps prior to Android 3.0's formalization of the pattern. Many apps that users will see on older devices will have an action bar, courtesy of one of the backports. By adopting a backport, you will gain a measure of consistency in your UX across Android versions that you would otherwise miss by falling back to the options menu.

You might also adopt a backport because something else is steering you to use AppCompat, and therefore you elect to use it for those reasons.

Why AppCompat?

AppCompat is a somewhat controversial library nowadays. It did not start that way when it was released in the Summer of 2013, other than being the target of “why didn't Google just endorse ActionBarSherlock?” inquiries. But Google has been rather aggressive about trying to get developers to use AppCompat, and that aggressiveness has had its downsides.

Supported

The #1 reason for using AppCompat is because you decided, for other reasons, that you wanted an action bar backport, and AppCompat right now is the primary supported option. ActionBarSherlock is officially deprecated by its author (Jake Wharton), who is steering you towards the native action bar or AppCompat as alternatives. While this does not prevent you from using ActionBarSherlock, it is probably not a great choice today given that Google is supporting AppCompat.

Materialistic

The current version of AppCompat does not only give you an action bar. It gives you an action bar that looks like the one that you get from `Theme.Material`. It also will attempt to apply your accent color to select widgets, the way Android 5.0 and `Theme.Material` do, to make your app abide a bit more by the Material Design aesthetic.

[Whether or not this is a good thing is up to you.](#)

Consistent

One hidden advantage of using AppCompat, particularly in concert with the fragments backport, is consistency across Android versions. By using the native action bar and fragments, you are at some risk of inconsistent behavior based upon:

- Android OS version, due to bug fixes, deprecations, and the like
- Manufacturer or ROM modder tweaks to the native implementations, which you do not control

Having your action bar and fragments be in a library in your app isolates you from those changes. In particular, while ActionBarSherlock will defer to the native action bar implementation on API Level 14+ devices, AppCompat always uses its own implementation, so any changes in the native implementation will not affect your app.

This comes at a cost of additional complexity and APK size. Also, while AppCompat is supported, it is not nearly as supported as the native implementations. While it isolates you from inconsistency bugs, it has [its own bugs and other issues](#).

Forced

Some things in the Android development ecosystem, like official support for the `MediaRouteActionProvider`, only work with the AppCompat action bar, as Google has either not shipped or has deprecated their native alternatives.

You may find some “cross-ports” of those things that work with the native action bar, but those are unlikely to be as well-supported as Google’s own editions.

While it is theoretically possible that Google itself will eventually offer native action bar implementations of those things, it is unlikely. Hence, if you determine that you need one of those, you may be more inclined to use AppCompat, even if you do not need it for any other reason.

The Basics of Using AppCompat

The recipe for using the AppCompat action bar requires no new skills beyond what you have learned so far in this book. However, there are some subtle and not-so-

subtle differences in the approaches AppCompat takes when compared to the native action bar, let alone other backports like ActionBarSherlock.

To see the basic differences, we will take a look at the [AppCompat/ActionBar](#) sample project. This is a port of the fragments-and-action-bar sample from [earlier in the book](#), where we have replaced the native action bar with AppCompat.

The Library Project

AppCompat is provided by the `appcompat-v7` Android library project, part of the Android Support Package. How you get that depends upon your build environment.

Android Studio and Gradle for Android

Just add the compile `'com.android.support:appcompat-v7:...'` line to your dependencies closure, replacing `...` with a suitable version number of the library. That will take care of downloading the library and adding it to your project.

To get the material effects described in this chapter, you will want to use version 21 or higher of `appcompat-v7` (e.g., `com.android.support:appcompat-v7:21.0.3`).

Eclipse

Your SDK's copy of the AppCompat library project can be found in your Android SDK installation, inside the `extras/android/support/v7/appcompat/` directory.

You will want to import that project into your workspace. Ideally, you should make a copy of the project, so that way when the project gets updated by Google (and you install the update via the SDK Manager), your existing copy is not immediately affected. This will allow *you* to decide when to upgrade to the new AppCompat version.

Your Build Settings

If you are using version 21 or higher of AppCompat, your build target must be API Level 21 or higher. In Android Studio and Gradle for Android, this would be the `compileSdkVersion` found in your `build.gradle` file. In Eclipse, this would be the API level chosen in `Project > Properties > Android`.

Your Theme

Rather than using `Theme.Holo` or `Theme.Material`, when using `AppCompatActivity` you will use `Theme.AppCompat`, whether you use that theme directly or create your own custom theme inheriting from it. There is also `Theme.AppCompat.Light` and `Theme.AppCompat.Light.DarkActionBar`, mirroring their native counterparts.

```
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.AppCompat">
```

Your Menu Resources

Where things start to get a bit strange with `AppCompatActivity` comes with our menu resources. `AppCompatActivity` forces you to use a *different namespace* for any action bar-related attributes, those added in API Level 11 or higher.

So, we started with:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/add"
        android:icon="@drawable/ic_action_new"
        android:showAsAction="always"
        android:title="@string/add"/>
    <item
        android:id="@+id/reset"
        android:icon="@drawable/ic_action_refresh"
        android:showAsAction="always|withText"
        android:title="@string/reset"/>

</menu>
```

and we had to change it to:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <item
        android:id="@+id/add"
        android:icon="@drawable/ic_action_new"
        app:showAsAction="always">
```

```
        android:title="@string/add"/>
    <item
        android:id="@+id/reset"
        android:icon="@drawable/ic_action_refresh"
        app:showAsAction="always|withText"
        android:title="@string/reset"/>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        app:showAsAction="never"
        android:title="@string/about">
    </item>
</menu>
```

Note that we have a new `xmlns:app="http://schemas.android.com/apk/res-auto"` namespace declaration in the root `<menu>` element, and that namespace is used for the `app:showAsAction` attribute. The actual prefix name, here shown as `app`, can be whatever you want. It just has to be unique within the document and a valid XML namespace prefix (e.g., no whitespace).

Your Activity and Fragments

We have to inherit from an `ActionBarActivity` class to use AppCompat. `ActionBarActivity` itself inherits from `FragmentActivity`, and so we can use the Android Support Package's backport of fragments without issue, so you have access to backported versions of `Fragment`, `ListFragment`, etc.

However, note that there are no other analogues of `ActionBarActivity` for other scenarios, such as `ListActivity`. In principle, you should be able to make your own mash-ups of `ActionBarActivity` and other base activity classes, though the proof of this is left as an exercise for the reader. The sample app just uses `ActionBarActivity` directly for showing a `ListView`:

```
package com.commonware.android.inflation;

import android.os.Bundle;
import android.support.v7.app.ActionBarActivity;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.ArrayAdapter;
import android.widget.ListAdapter;
import android.widget.ListView;
import android.widget.Toast;
import java.util.ArrayList;

public class ActionBarDemoActivity extends ActionBarActivity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
```

```
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",  
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",  
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",  
        "pellentesque", "augue", "purus" };  
private ArrayList<String> words=null;  
private ArrayAdapter<String> adapter=null;  
  
@Override  
public void onCreate(Bundle icle) {  
    super.onCreate(icle);  
  
    setContentView(R.layout.list_content_simple);  
    initAdapter();  
}  
  
@Override  
public boolean onCreateOptionsMenu(Menu menu) {  
    getMenuInflater().inflate(R.menu.actions, menu);  
  
    return(super.onCreateOptionsMenu(menu));  
}  
  
@Override  
public boolean onOptionsItemSelected(MenuItem item) {  
    switch(item.getItemId()) {  
        case R.id.add:  
            addWord();  
  
            return(true);  
  
        case R.id.reset:  
            initAdapter();  
  
            return(true);  
  
        case R.id.about:  
            Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)  
                .show();  
  
            return(true);  
    }  
  
    return(super.onOptionsItemSelected(item));  
}  
  
private void initAdapter() {  
    words=new ArrayList<String>();  
  
    for (int i=0;i<5;i++) {  
        words.add(items[i]);  
    }  
  
    adapter=  
        new ArrayAdapter<String>(this,
```

```
        android.R.layout.simple_list_item_1,
        words);

    setListAdapter(adapter);
}

private void addWord() {
    if (adapter.getCount() < items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}

private void setListAdapter(ListAdapter la) {
    ((ListView) findViewById(android.R.id.list)).setAdapter(la);
}
}
```

The layout, `res/layout/list_content_simple.xml`, is cloned from the one used by `ListActivity` itself:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/assets/res/layout/list_content.xml
**

*/
-->
<ListView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"
    />
```

Your Callback Methods

In many cases, your `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods will be the same for AppCompat as they would be for a regular Android app.

However, if you do need to manipulate action bar-specific attributes of your inflated menu resources, you will be unable to do so directly. The workaround is to use `MenuCompat` and `MenuItemCompat`, from the Android Support package, to give you access to newer `Menu` and `MenuItem` features in a backwards-compatible fashion.

Your Results

Visually, the results are very similar to what we get from `Theme.Material`, whether we run on Android 5.0 itself:

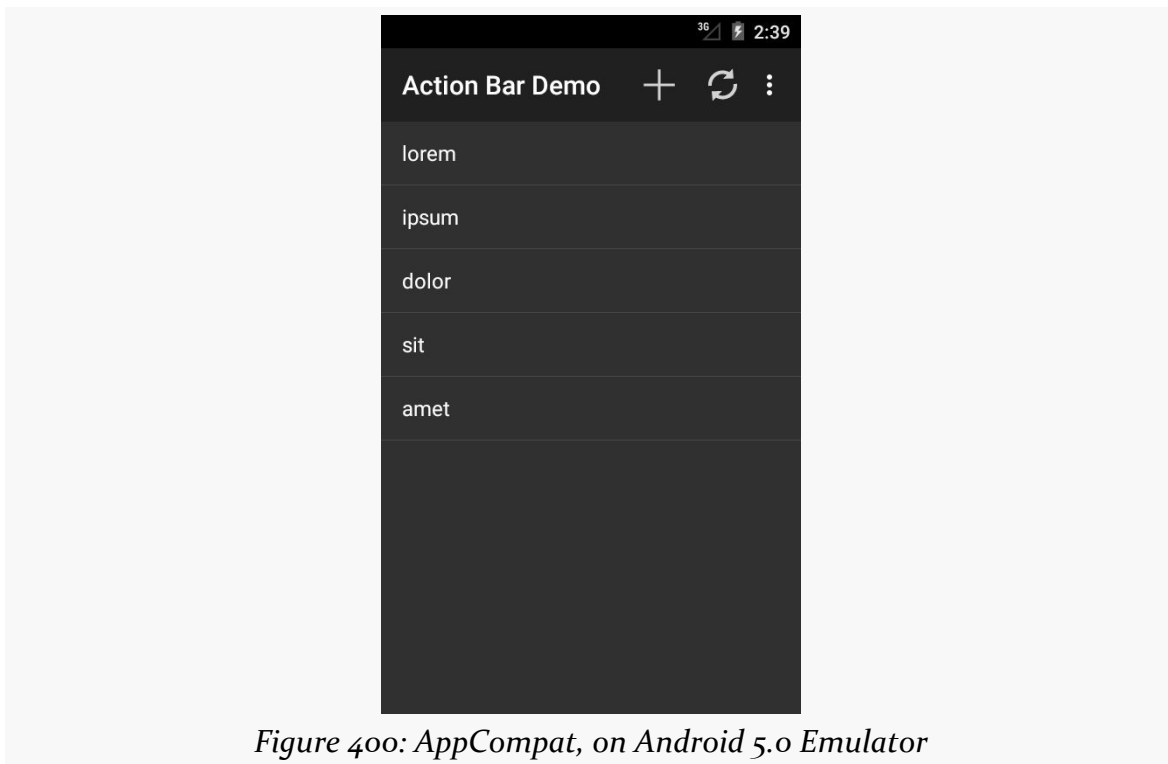

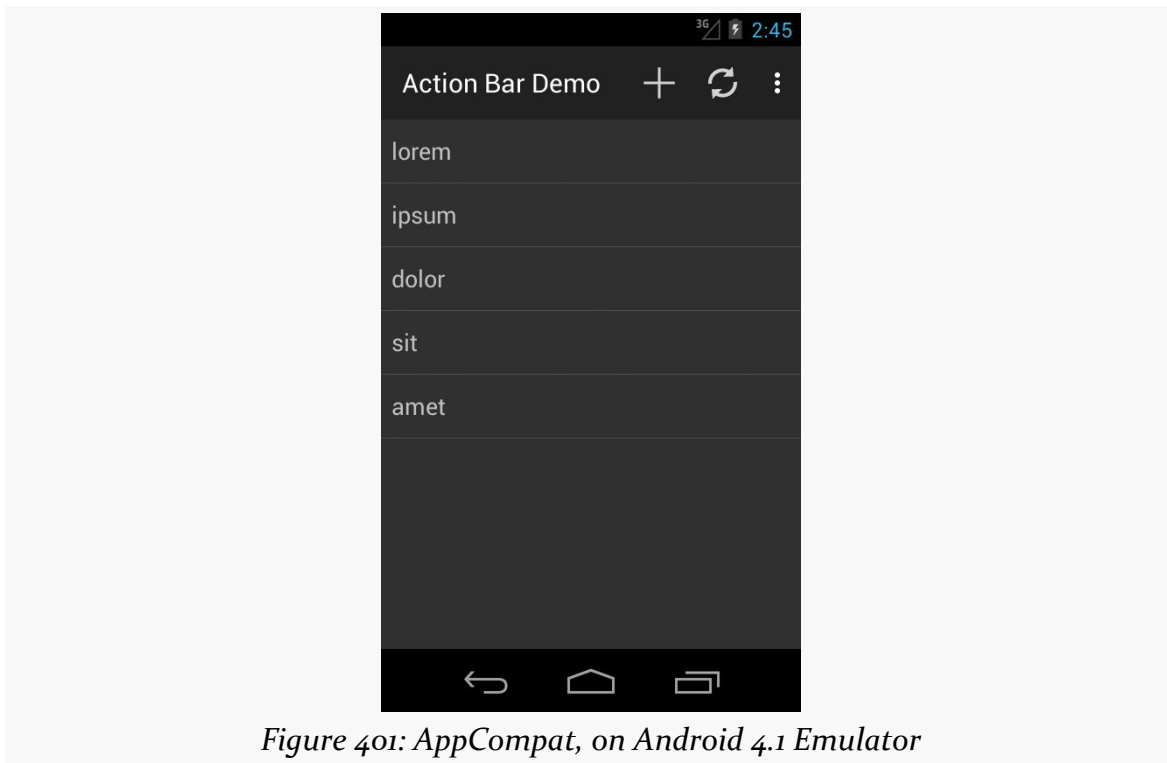

Figure 400: AppCompatActivity, on Android 5.0 Emulator

...or on something older, like an Android 4.1 emulator:

Other AppCompatActivity Effects

While the above recipe will give you the basics, you can go a lot further with AppCompatActivity, just as you can with the native action bar. Generally speaking, AppCompatActivity's backport includes all of the capabilities of the native action bar.

The biggest key is that when working with AppCompatActivity, if you need to access your ActionBar instance, call `getSupportActionBar()`, not `getActionBar()`. The latter will compile, but it will return null at runtime, as you are disabling the native action bar and using AppCompatActivity's instead.

Tinting

The same basic tinting rules that apply for `Theme.Material` apply for `Theme.AppCompat` and AppCompatActivity, with two noteworthy differences.

First, the theme attributes do not have the android prefix, but instead are just the bare names (e.g., `colorPrimary`). So, in the [AppCompatActivity/ActionBarColor](#) sample project, the style resource becomes:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="Theme.AppCompat">
    <item name="colorPrimary">@color/primary</item>
    <item name="colorPrimaryDark">@color/primary_dark</item>
    <item name="colorAccent">@color/accent</item>
  </style>
</resources>
```

Second, not all widgets will have their colors affected by the theme. At the present time, the roster is limited to:

- CheckBox
- CheckedTextView
- EditText
- RadioButton
- Spinner

Also, Switch adopts the colors, if you use the SwitchCompat backport discussed in the next section.

In the [AppCompat/Basic](#) directory you will find projects mirroring those from the BasicMaterial directory. In BasicMaterial, we saw how widgets were tinted based on a Theme.Material-based theme; in AppCompat/Basic, you will see how widgets are tinted based upon a Theme.AppCompat-based theme.

Note that AppCompat does not affect the status bar. You can use [the Android 5.0 APIs for changing the status bar color](#) on such devices from an ActionBarActivity. However, you cannot tint the status bar on older devices, despite using AppCompat.

Switch Backport

As mentioned above, there is an official backport of the Switch widget, known as SwitchCompat, added to the appcompat-v7 library. This works back to API Level 7, as does everything in appcompat-v7. And, for better or worse, it provides a backport of the Material Design implementation of a Switch. So, rather than the Theme.Holo ON/OFF toggle, we get the unlabeled “looks like a really tiny SeekBar” widget:

Figure 402: SwitchCompat, on an Android 4.3 Emulator

The above screenshot comes from the [AppCompat/Basic/Switch](#) sample project, which uses a layout specifying the SwitchCompat widget:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.SwitchCompat
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

Also note that SwitchCompat only works inside an ActionBarActivity. It is not a general backport of Switch that can be used in any activity.

Overlay

AppCompat supports the same basic sort of [floating action bar](#) that is supported by the native action bar implementation. There are two slight changes in the recipe:

- Use `supportRequestWindowFeature()`, rather than `requestWindowFeature()`, to request `Window.FEATURE_ACTION_BAR_OVERLAY`

- Use `getSupportActionBar()`, rather than `getActionBar()`, to set the background

This is illustrated in `onCreate()` of the `ActionBarDemoActivity` version found in the [AppCompat/Overlay](#) sample project:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    supportRequestWindowFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    setContentView(R.layout.list_content_simple);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getSupportActionBar().setBackgroundDrawable(d);
    getSupportActionBar().setSplitBackgroundDrawable(d);
}
```

And, you get the same basic results as with the native action bar:

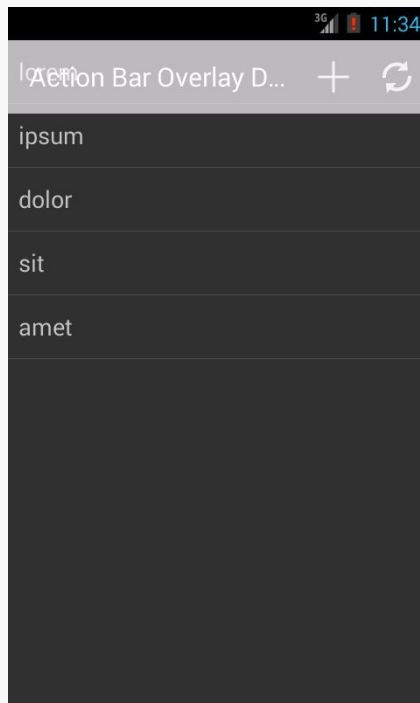

Figure 403: AppCompatActivity with FEATURE_ACTION_BAR_OVERLAY on an Android 4.3 Emulator

SearchView

AppCompatActivity has its own implementation of SearchView, as `android.support.v7.widget.SearchView`. To use it, switch to that class in your menu resource, then use `MenuItemCompat.getActionView()` to retrieve the instance after your menu resource has been inflated.

For example, the [AppCompatActivity/SearchView](#) sample project uses the AppCompatActivity implementation of SearchView in its `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <item
        android:id="@+id/search"
        app:actionViewClass="android.support.v7.widget.SearchView"
        android:icon="@drawable/ic_action_search"
        app:showAsAction="ifRoom|collapseActionView"
        android:title="@string/filter">
    </item>
```

```
</menu>
```

Then, in `onCreateOptionsMenu()`, `ActionBarFragment` calls out to a private `configureSearchView()` method that retrieves the `SearchView` and sets it up, much as you saw with the native implementation of `SearchView` from [earlier in this book](#):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)MenuItemCompat.getActionView(search);
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

The resulting `SearchView` is tied into `AppCompat` and offers a Material Design-esque look, applying your tints when opened:

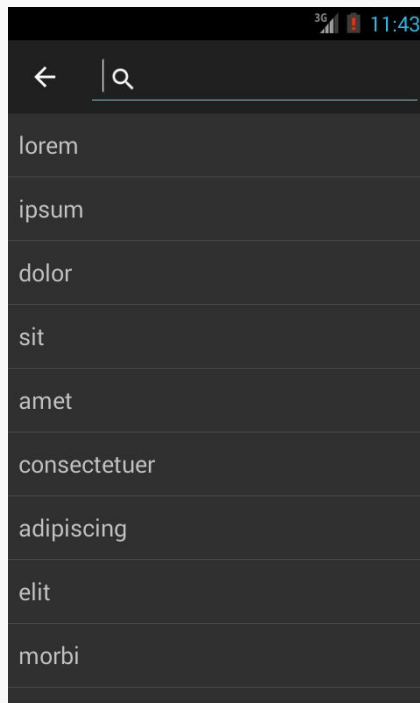

Figure 404: AppCompat with SearchView on an Android 4.3 Emulator

ShareActionProvider

Similarly, AppCompat has its own implementation of `ShareActionProvider`, as `android.support.v7.widget.ShareActionProvider`. The recipe for using it resembles that of using `SearchView`:

- Refer to the AppCompat edition of the class in your menu resource
- Use `MenuItemCompat.getActionProvider()` to retrieve your `ShareActionProvider` instance after inflating the menu resource, to configure and use it

The [AppCompat/Share](#) sample project is a clone of the `ShareActionProvider` project described [elsewhere in the book](#), converted to use AppCompat and its edition of `ShareActionProvider`.

And Then, There Are the Bugs

Unfortunately, AppCompat is not immune to bugs, such as:

- Some Samsung devices running Android 4.2 [baked in an older AppCompat into their firmware's copy of the zygote](#), causing class mismatches with apps using the newer AppCompat
- On some HTC devices, some of the ways that AppCompat handles applying its theme [break text colors in dialogs](#)

To Material, or Not to Material

(the following is adapted from [one of the author's blog posts](#))

There has been a lot of discussion regarding the adoption of Material Design aesthetics in Android apps. Newcomers to Android might conclude that Material Design must be The Most Important Thing in Android Development and therefore should be pursued immediately at all costs.

[Not everybody shares this opinion](#)

With that in mind, here is the author's recommendations on what to consider with Material Design:

DO start considering the effects of Material Design upon your Android app. Theme.Material is the dominant theme on Android 5.0 devices, and it should remain the dominant theme on future Android versions, at least for a while. There will be hundreds of millions of these devices in use, eventually, and you will want your app to look like "it belongs" on those devices. On those devices, not only will Google's apps be employing Theme.Material, but manufacturer-supplied apps should do so as well. While not everything on the device may necessarily adopt this theme, more than enough will that your app may stand out somewhat if your app does not and the user thinks that it should.

DON'T worry about this right away. Android 4.4 reached 30% of the Android device ecosystem after one year, and we have not seen that rate of adoption since Android 1.0. Odds are that it will be mid-2015 before Android 5.0 crosses the 10% threshold. As such, there just are not that many Android 5.0 devices out there, so worrying about those devices over the next several weeks is serious overkill.

DO plan on including Material Design impacts in your next UI refresh, and you should probably try to budget time for that refresh by the end of 2015 (by which time Android 5.0 might be 20-30% of the ecosystem).

DON'T blindly assume that you should be using a Material-ish look on all versions of Android. Your objective should be having an app that looks like it belongs on the device. Material-themed apps are highly unlikely to achieve majority status, let alone dominance, on pre-Android 5.0 releases. After all, device manufacturers are not going to be shipping Material-themed updates to built-in apps *en masse*, and there are plenty of apps out there that are still using pre-Holo themes. This is all on top of app that have no identifiable Android theme (e.g., most games). Certainly, there will be Material-themed apps running on Android 4.x devices, courtesy of Google and some other developers. But there will be enough Holo-themed apps that your app will not look out of place on Android 4.x any time soon, if ever. Hence, you have your choice of adopting Material Design across the board or not — user pressure is unlikely to be a major criterion any time soon.

DON'T fall victim to the “our app must look the same across all devices” mindset. Again, your app should look like it belongs on the device, which is why trying to ape an iOS look-and-feel on Android is rarely a good move. Most people do not have two Android devices, and only a small subset of those will have an Android 5.x device and an Android 4.x (or older) device. Hence, most of the people who will care about your app appearing identical on those devices will be in your meeting room discussing the issue. Few of your users will notice — they want an app that works, does what the user wants, and looks like it belongs on their device.

DO consider whether adopting Material Design across the board may offer *engineering* benefits. For example, if you have been heavily customizing widget colors in a Holo-based theme, the tinting options provided by `appcompat-v7` may simplify your app a fair bit, reducing APK size, maintenance costs after the Material conversion, etc. Since your users are unlikely to be terribly concerned one way or the other, engineering considerations may help to “tip the scales” in one direction or another.

DON'T blindly assume that `appcompat-v7` will result in a simpler app, or that it should be the basis for all new apps. While the original `appcompat-v7` has now been around for 16 months or so, the new Material `appcompat-v7` is very young, and hence it has bugs. Not all of those bugs are Google's fault (e.g., the Samsung device issue was really caused by a screwy decision on Samsung's part), but that comes as cold comfort to developers trying to distribute `appcompat-v7` apps. And, if you are comfortable with using themes based on `Theme.Holo` for pre-Android 5.0 devices, `appcompat-v7` may be much more of an impediment than an advance. `appcompat-v7` is a tool, not a religion — use it where it clearly adds value *to you and your app*.

DO start planning for Google's next major theme overhaul. Google, of course, is portraying Material Design as being The One True UI Design. Google will probably get irritated when people point out that `Theme.Material` is the third major theme in the six-year production history of Android, and so assuming that `Theme.Material` is "the be-all and end-all" of themes is unrealistic. Whether the next-generation theme is a refinement on Material Design or a larger overhaul remains to be seen. But you should be taking into account that we may well wind up going through this same process in, say, early 2018. The more you can isolate the theme-related changes from the rest of your app, the more likely it is that you will be able to accommodate future theme changes with less work.

ActionBarSherlock

As noted in [the chapter on AppCompat](#), there was a ~2.5 year gap where older devices had no official backport of the action bar. Various third-party projects implemented action bars to try to fill this gap, and none did that nearly as well as did [ActionBarSherlock](#).

ActionBarSherlock, in effect, extends the support-v4 library, adding a backported action bar for apps running on devices prior to API Level 14. While native action bars became available with API Level 11, there were enough differences that ActionBarSherlock uses its own implementation from API Level 13 on down to API Level 7 (Android 2.1).

Today, ActionBarSherlock is considered to be deprecated, with Jake Wharton (the author of ActionBarSherlock) steering developers towards the native action bar or AppCompat. That being said, many existing projects still use ActionBarSherlock successfully today.

To use ActionBarSherlock, you need to do a few things, above and beyond what you would ordinarily need to do to use the native action bar implementation. This chapter reviews what is required and how to use this library.

NOTE: This chapter is scheduled to be removed from this book in one of the 2015 updates.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Installation

Android Studio users can add a dependency for `com.actionbarsherlock:actionbarsherlock:4.4.0@aar` to their dependencies closure. The `@aar` suffix is to help distinguish the AAR artifact from others for this group ID/artifact ID combination.

Eclipse users will need to download ActionBarSherlock, such as by downloading a ZIP file or by cloning [the project's GitHub repository](#). Inside of the ActionBarSherlock distribution is an `actionbarsherlock/` directory, containing an Android library project that you will need to add to your application's project as described [in a previous chapter](#).

Code Changes

There are some changes to your code needed to use ActionBarSherlock, compared with the code you might use with the native API Level 11+ action bar. These changes are fairly minor in scope, to make it easy for you to move back to the native action bar implementation at some time in the future.

Base Activity Class

You will need to adjust your activities to inherit from `SherlockActivity` or one of its kin (e.g., `SherlockListActivity`). This is mostly a matter of adding the Sherlock prefix and adjusting your imports to refer to the `com.actionbarsherlock.app` package instead of `android.app`.

This, in turn, will require some changes to the code in the activities themselves:

- References to `Menu` and `MenuItem` need to be changed from the `android.view` package to the `com.actionbarsherlock.view` package
- Calls to `getActionBar()` need to be replaced with `getSupportActionBar()`
- Calls to `getMenuInflater()` need to be replaced with `getSupportMenuInflater()`

Similarly, if you are using fragments, they need to inherit from `SherlockFragment` or some other Sherlock-flavored class (e.g., `SherlockListFragment`). This too will require the aforementioned changes to imports and methods. Also, bear in mind that ActionBarSherlock is using the fragments backport from the Android Support package, and so calls to `getFragmentManager()` need to be replaced by calls to

`getSupportFragmentManager()`, references to classes like `FragmentTransaction` need to be replaced with their Android Support backport equivalents, etc.

Theme

You will also need to apply an `ActionBarSherlock`-flavored theme to your activities, either on a per-activity basis, or for the application as a whole. The Sherlock theme that most closely resembles the default theme is `Theme.Sherlock`.

The [ActionBar/ActionBarDemo](#) sample project applies `Theme.Sherlock` to the whole application, via an `android:theme` attribute on the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.inflation"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="14"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/Theme.Sherlock"
        android:uiOptions="splitActionBarWhenNarrow">
        <activity
            android:name=".ActionBarDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

NOTE: If you use this sample app, or any other one that uses `ActionBarSherlock`, on Eclipse, you will need to update its configuration to point to your own copy of `ActionBarSherlock`'s Android library project.

Menu Resources

Your menu resources for use with ActionBarSherlock are largely identical to their native action bar counterparts. In fact, most menu resources will not need to change at all.

The only significant difference is if you are using `ShareActionProvider`. You will need to use a backport of `ShareActionProvider` supplied by the ActionBarSherlock library, `com.actionbarsherlock.widget.ShareActionProvider`. You will need to reference this class in the menu resource, plus use this class in your Java code when you configure the `ShareActionProvider`. By and large, though, the API exposed by the ActionBarSherlock edition of `ShareActionProvider` is the same as the API exposed by the native `ShareActionProvider`.

Implementing a Navigation Drawer

Each year brings a new design pattern in Android that takes the development community by storm. In 2011, it was the [action bar](#). In 2012, it was [ViewPager](#). In 2013, it was the navigation drawer.

This chapter covers that navigation drawer pattern: what it is, where you use it, and how you implement it, using a `DrawerLayout` class supplied by the Android Support package.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, one section ties into [the chapter on action modes](#).

What is a Navigation Drawer?

Complex apps often require complex navigation, to get to all of the different areas of the app. And, in many cases, that navigation is tied to nouns, reflecting different types of content, more so than verbs, reflecting operations to be performed against a particular piece of content. Verbs are actions, and can usually go in the action bar as action bar items (e.g., toolbar-style buttons). Nouns *could* be put in the action bar as well as items, though having a mixed bunch of nouns and verbs makes the action bar item roster inconsistent.

Back before the action bar, the “go-to” design pattern for navigation was the so-called “dashboard”:

Figure 405: Google IO 2010 Conference App, with Dashboard

But this took up the whole screen and was therefore only available as the “home” activity of an app.

The navigation drawer, or “sliding menu”, pattern has the same sort of content navigation options available in a drawer that slides out from the side of the screen:

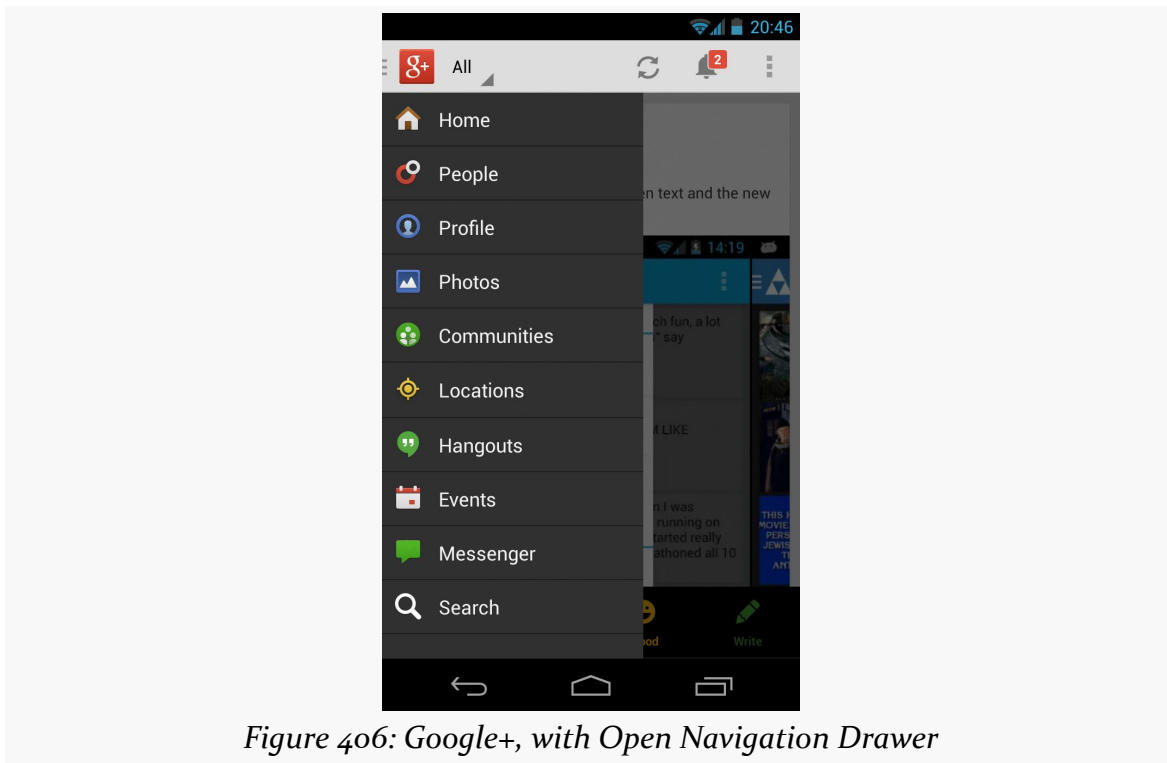

Figure 406: Google+, with Open Navigation Drawer

The drawer can be accessed from many, if not all, activities in the app, to allow the user to get wherever they need to from wherever they happen to be.

A Simple Navigation Drawer

The good news is that Google released an implementation of the navigation drawer pattern, called `DrawerLayout`, in the Android Support package (`support-v4` and `support-v13`).

The bad news is that it still takes a bit of work to get this integrated with your app.

This section will review the [NavDrawer/Simple](#) sample project, that shows a fairly simplistic integration of a `DrawerLayout` into an activity.

The Activity Layout

The root element of your activity layout, for an activity using `DrawerLayout`, is `DrawerLayout` itself:

IMPLEMENTING A NAVIGATION DRAWER

```
<android.support.v4.widget.DrawerLayout
xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/content"
        android:layout_width="match_parent"
        android:layout_height="match_parent"/>

    <ListView
        android:id="@+id/drawer"
        android:layout_width="240dp"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:background="#111"
        android:choiceMode="singleChoice"
        android:divider="@android:color/transparent"
        android:dividerHeight="0dp"/>

</android.support.v4.widget.DrawerLayout>
```

DrawerLayout itself is rather unremarkable in the layout resource: you size and position it, usually to fill the screen. It needs to have precisely two child elements:

1. The first child represents the “real” activity content
2. The second child represents the contents of the drawer that can be opened and closed

If you are adapting an existing activity to use the DrawerLayout, that first child could well be an `<include>` element pointing to your existing activity layout resource, so that you can leave it undisturbed and just point your activity to start with this new DrawerLayout resource.

There are a couple of attributes in the children that are important for proper DrawerLayout operation:

- The second child — often a `ListView` — needs to have its `android:layout_gravity` set to indicate what side of the screen the drawer will slide out from. Typically this will be `left` (or `start` if you are on API Level 17+ and are taking advantage of the RTL layout support).
- The second child also specifies its `android:layout_width` to indicate the size of the drawer when opened. This should *not* be the full width of the screen, and the [Android design guidelines](#) suggest a width between 240dp and 320dp.

The ActionBarDrawerToggle

The `onCreate()` method of `MainActivity` is responsible for setting up the drawer, as well as the activity's main content:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }

    ListView drawer=(ListView)findViewById(R.id.drawer);

    drawer.setAdapter(new ArrayAdapter<String>(
        this,
        R.layout.drawer_row,
        getResources().getStringArray(R.array.drawer_rows)));
    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
            R.drawable.ic_drawer,
            R.string.drawer_open,
            R.string.drawer_close);
    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);
}
```

In terms of the content, if the `FrameLayout` placed in the layout resource is empty, we call `showLorem()` to lazy-create a `LoremFragment` (a `ListFragment` with 25 Latin words) and run a `FragmentManager` transaction to display it:

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
        getFragmentManager().beginTransaction()
            .replace(R.id.content, lorem).commit();
    }
}
```

`onCreate()` then retrieves the `ListView`, sets the contents of the list to be a `<string-array>` resource named `drawer_rows`, and sets up the activity itself to respond to clicks on the list.

`onCreate()` then sets up an `ActionBarDrawerToggle`. This allows the app icon on the left of the action bar to open and close the navigation drawer. The `ActionBarDrawerToggle` constructor takes five parameters:

- The Activity as a Context
- The `DrawerLayout` widget to be managed by this toggle
- The icon to superimpose on the app icon to indicate that there is a toggle
- String resources for the open and close operations, for accessibility

Google's ["Action Bar Icon Pack"](#) contains stock icons to use for the third parameter, for light and dark action bar themes. In addition, the [Android Asset Studio](#) offers a way for you to customize the navigation drawer indicator artwork for other themes.

In addition to creating the toggle instance, we need to:

- Associate it with the `DrawerLayout`, by calling `setDrawerListener()` on it
- Enable the app icon via `setHomeButtonEnabled()` and enable it for "up" navigation via `setDisplayHomeAsUpEnabled()`
- Forward the `onPostCreate()`, `onConfigurationChanged()`, and `onOptionsItemSelected()` activity callback methods on to the toggle:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    toggle.syncState();
}

@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    toggle.onConfigurationChanged(newConfig);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (toggle.onOptionsItemSelected(item)) {
        return(true);
    }
}
```

IMPLEMENTING A NAVIGATION DRAWER

```
return(super.onOptionsItemSelected(item));  
}
```

Without any additional work, launching the app will show the “mini hamburger” navigation drawer icon in the action bar:

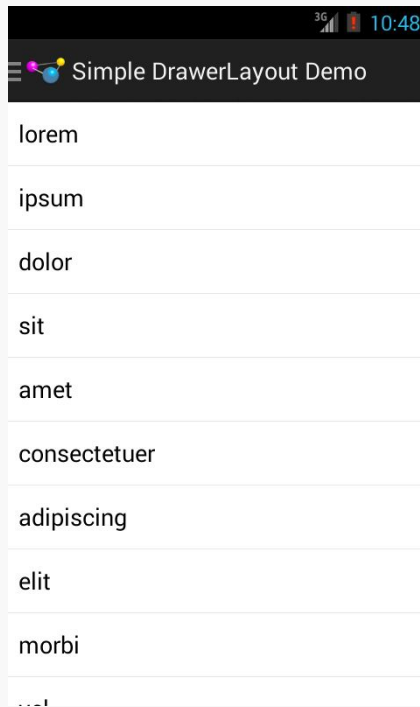

Figure 407: Nav Drawer Sample App, Showing the Mini Hamburger

Tapping the app icon will open the drawer:

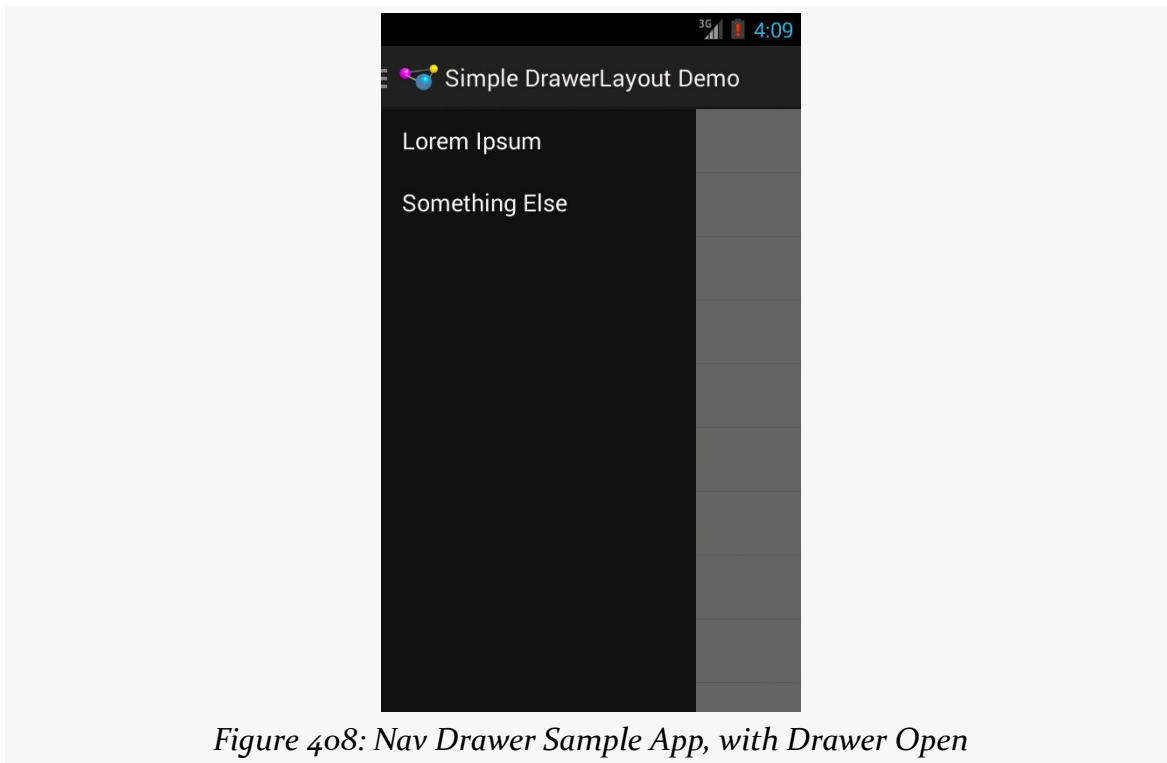

Figure 408: Nav Drawer Sample App, with Drawer Open

The drawer slides over the content, rather than pushing the content away, which is why we do not see the words peeking out on the right side of the screen.

Tapping the app icon again will close the drawer.

The user can also open the drawer via gestures. A bezel swipe from the left side will open the drawer, and swiping the open drawer right to left will close it. In addition, tapping and holding on the left edge of the content will cause the drawer to “peek” open by a handful of pixels, to hint to the user that there may be something that they can access by swiping from the left.

NOTE: This implementation of `ActionBarDrawerToggle` is officially deprecated as of the 21.0.0 version of the Android Support library. However, it is still necessary, at this time, for using `DrawerLayout` with the native action bar.

The Actions on Navigation Clicks

Of course, a navigation drawer is useless unless we do something when the user interacts with it, clicking on list rows in this case.

Our list is very simple, with just two elements. The app simply toggles between two fragments based upon the list item click:

```
@Override
public void onItemClick(AdapterView<?> listView, View row,
                        int position, long id) {
    if (position == 0) {
        showLorem();
    }
    else {
        showContent();
    }

    drawerLayout.closeDrawers();
}
```

We also close the drawer, using `closeDrawers()`, as otherwise the `DrawerLayout` is unaware that the user chose something and that we should return to the content.

Alternative Row Layouts

The rows in the sample app's `ListView` were fairly conventional. Rows in a nav drawer should be fairly simple, as you are merely trying to lead the users to pieces of content, not present content itself.

That being said, the navigation options can have a bit more to them than what the sample app showed. The [Android design guidelines](#) will steer you in the direction of how best to style:

- Rows with leading icons
- Rows with trailing badges (e.g., unread message counts)
- Expandable sections (e.g., less-important items but still worth having in the drawer)
- Dividers, to help organize groups of related rows

IMPLEMENTING A NAVIGATION DRAWER

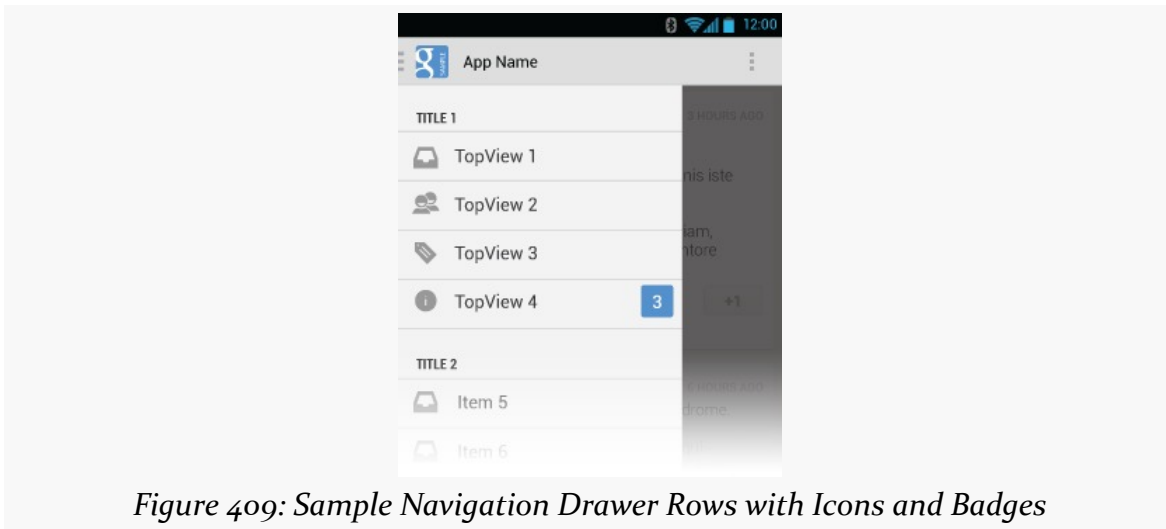

Figure 409: Sample Navigation Drawer Rows with Icons and Badges

You will see other apps experiment with other capabilities. For example, Gmail uses `RadioButton` widgets for the accounts:

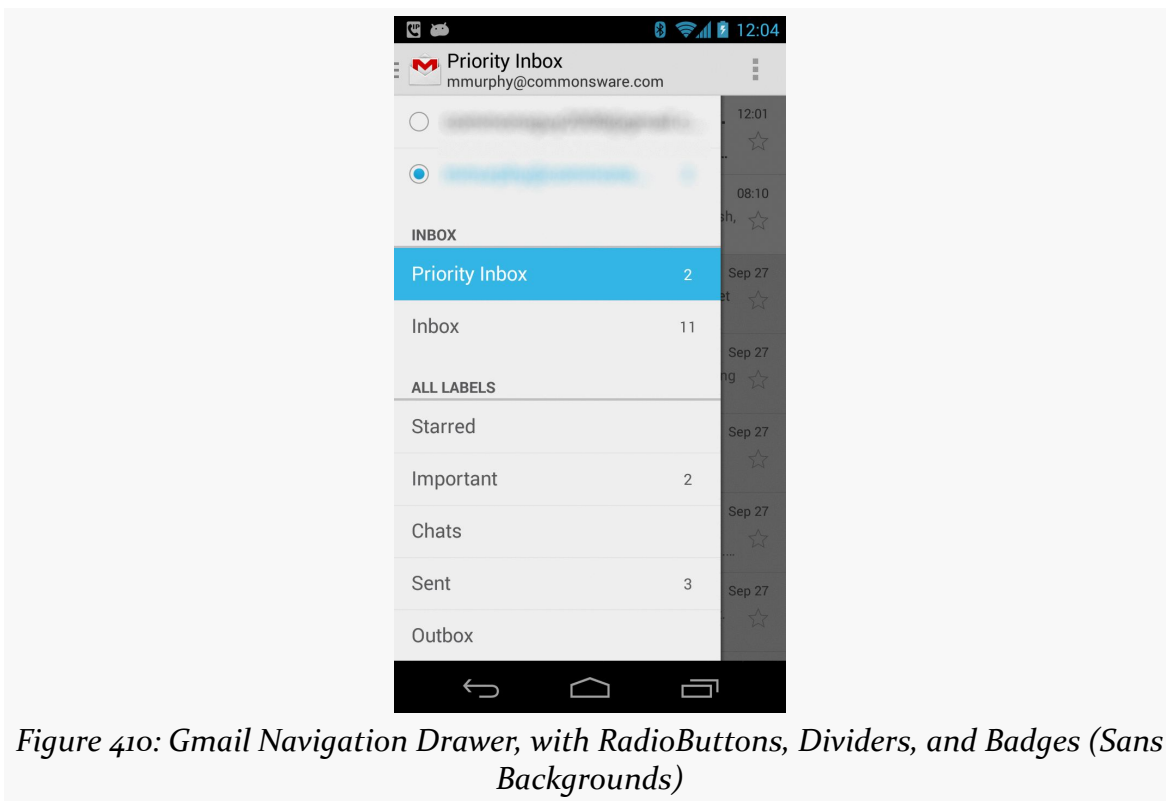

Figure 410: Gmail Navigation Drawer, with RadioButtons, Dividers, and Badges (Sans Backgrounds)

That being said, the closer you can stick with the official design guidelines, the better off you will tend to be, in terms of meeting user expectations and not encountering rendering or click event oddities with `DrawerLayout`.

Additional Considerations

Beyond putting the right things into the navigation drawer, there are some other things that you will need to take into account, particularly as your navigation drawer interacts with the rest of the activity and overall application.

Highlighting the Current Location

If the user opens the navigation drawer, and they are already at one of the navigation destinations shown in the drawer, that destination should show up with the activated state, to indicate to the user that she is already there. Conversely, if the user has drilled down into some part of your application that does *not* have a corresponding entry in the navigation drawer, the navigation drawer should show no activated entry.

One way to handle this is to keep the `ListView` updated as the user navigates (whether through the navigation drawer or by other means), selecting and de-selecting items as needed.

The row layout used in the original sample, culled from [Google's DrawerLayout sample code](#), already has the activated background:

```
<android.support.v4.widget.DrawerLayout
xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/drawer_layout"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/content"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>

  <ListView
    android:id="@+id/drawer"
    android:layout_width="240dp"
    android:layout_height="match_parent"
    android:layout_gravity="start"
    android:background="#111"
    android:choiceMode="singleChoice"
    android:divider="@android:color/transparent"
```

```
        android:dividerHeight="0dp"/>
</android.support.v4.widget.DrawerLayout>
```

However, we were not using it in that sample, so the drawer `ListView` did not give the user any indication that they had already navigated to a navigable destination. But, we have the [NavDrawer/Activated](#) sample project, a clone of the original sample, that adds this activation capability, and demonstrates the headaches it causes.

First, as part of our `onCreate()` work in `MainActivity`, we need to configure the `ListView` to work in single-choice mode (the `ListView` engine behind the activated state), along with the rest of the `ListView` setup:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    drawer=(ListView)findViewById(R.id.drawer);
    drawer.setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    String[] rows=getResources().getStringArray(R.array.drawer_rows);

    drawer.setAdapter(new ArrayAdapter<String>(this,
                                                R.layout.drawer_row,
                                                rows));

    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
                                   R.drawable.ic_drawer,
                                   R.string.drawer_open,
                                   R.string.drawer_close);

    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);

    getFragmentManager().addOnBackStackChangedListener(this);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }
}
```

Our `showLorem()` method now will `post()` a `Runnable`, named `onNavChange`, after it calls `commit()` on its `FragmentManager`:

IMPLEMENTING A NAVIGATION DRAWER

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
        getFragmentManager().popBackStack();
        getFragmentManager().beginTransaction()
            .replace(R.id.content, lorem).commit();
        drawer.post(onNavChange);
    }
}
```

That magic onNavChange Runnable simply sees what fragment is presently visible and updates the checked item in the nav drawer's ListView to match:

```
private Runnable onNavChange=new Runnable() {
    @Override
    public void run() {
        if (lorem != null && lorem.isVisible()) {
            drawer.setItemChecked(0, true);
        }
        else if (content != null && content.isVisible()) {
            drawer.setItemChecked(1, true);
        }
        else {
            int toClear=drawer.getCheckedItemPosition();

            if (toClear >= 0) {
                drawer.setItemChecked(toClear, false);
            }
        }
    }
};
```

By using post(), we schedule the Runnable to be executed after the fragment change has occurred. Ideally, we would somehow more explicitly attach the Runnable to the FragmentTransaction, but [that does not appear to be an option](#).

Since we call showLorem() in onCreate(), this causes our navigation drawer to show that we are in LoremFragment when the activity first starts up:

Figure 411: Activated Navigation Drawer Demo, As Initially Launched

The natural behavior of a single-choice `ListView` will check the row that we tap upon, and so when the user taps on an entry in the navigation drawer, it automatically becomes activated. This means we do not have to do our own work for that.

If *everything* in your app is represented by an entry in the navigation drawer, your work is done. However, most likely, there are parts of your app that do not directly map to entries in the navigation drawer... and that is where things get a wee bit complex.

To demonstrate this, we need a bit more to our UI. So, we make `LoremFragment` use the contract pattern, seen elsewhere in the book. We override `onListItemClick()` to call a `wordClicked()` method on the contract, to let the hosting activity know about that UI operation:

```
package com.commonsware.android.drawer.activated;

import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ListView;
```

IMPLEMENTING A NAVIGATION DRAWER

```
public class LoremFragment extends ContractListFragment<LoremFragment.Contract> {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        setListAdapter(new ArrayAdapter<String>(
            getActivity(),
            android.R.layout.simple_list_item_1,
            items));
    }

    @Override
    public void onListItemClick(ListView l, View v, int position, long id) {
        getContract().wordClicked();
    }

    interface Contract {
        void wordClicked();
    }
}
```

We also create a StuffFragment that displays a simple message:

The idea is that clicking on a word in the LoremFragment should bring up the StuffFragment, as if this were a master/detail implementation.

The implementation of `wordClicked()` in `MainActivity` does indeed show a `StuffFragment` (while also adding it to the back stack), but it also needs to make the drawer `ListView` have no checked items, reflecting the fact that the UI state does not reflect one of the navigation destinations:

```
@Override
public void wordClicked() {
    if (stuff == null) {
        stuff=new StuffFragment();
    }

    getFragmentManager().beginTransaction()
        .replace(R.id.content, stuff)
        .addToBackStack(null).commit();
    drawer.post(onNavChange);
}
```

Note that we also `post()` the `onNavChange` `Runnable` here as well.

IMPLEMENTING A NAVIGATION DRAWER

The result is that when we do tap on a word in the list, the `StuffFragment` appears, but the navigation drawer shows no activated row:

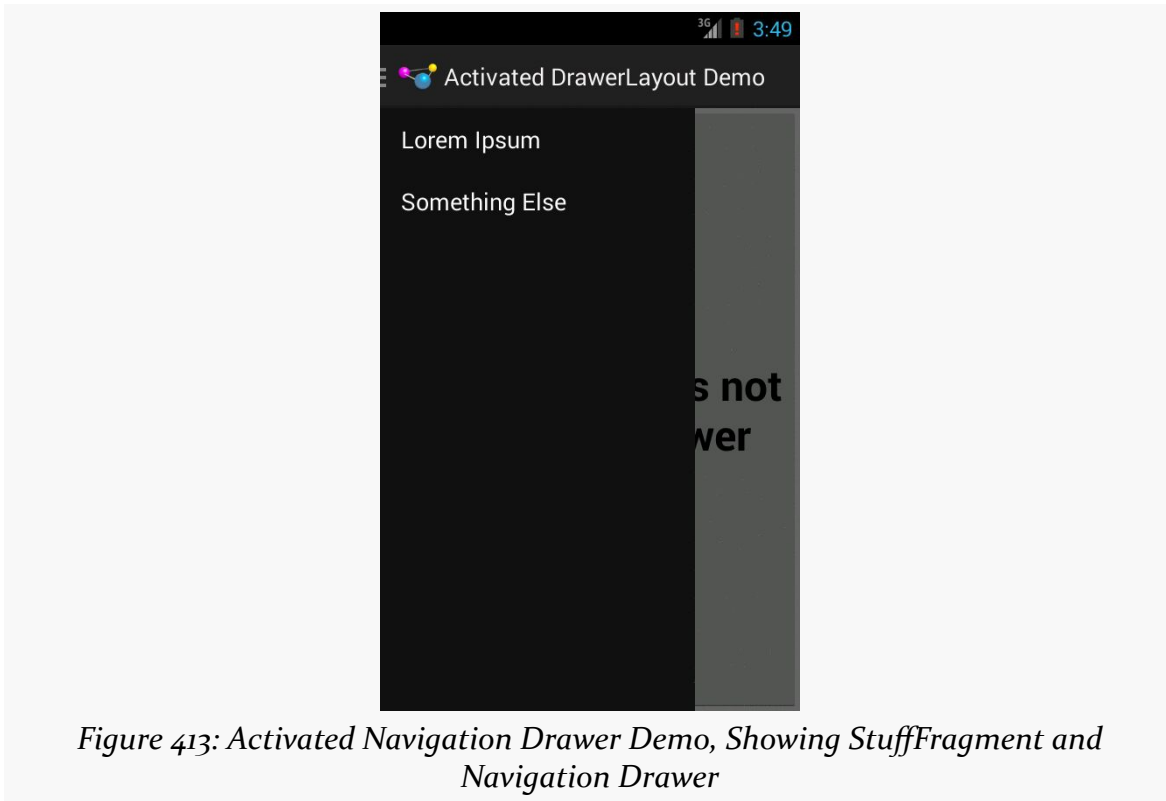

Figure 413: Activated Navigation Drawer Demo, Showing StuffFragment and Navigation Drawer

However, since we manually cleared the checked state, we now need to re-check a row if the user navigates back to one of the other fragments. There are two ways the user could return to one of those other fragments: via the navigation drawer, or via the BACK button (popping our transaction off the back stack).

If they navigate to one of the other fragments via the navigation drawer, the appropriate row will be activated automatically by the user's click event. However, we need to consider what to do about that transaction hanging around the back stack from before. One option is to remove it, so the other fragments behave as they do normally, where BACK exits the activity. That is a matter of calling `popBackStack()` on the `FragmentManager` as part of showing one of the fragments, such as the `showContent()` method that shows the `ContentFragment`:

```
private void showContent() {  
    if (content == null) {  
        content=new ContentFragment();  
    }  
}
```

```
if (!content.isVisible()) {  
    getFragmentManager().popBackStack();  
    getFragmentManager().beginTransaction()  
        .replace(R.id.content, content).commit();  
    drawer.post(onNavChange);  
}  
}
```

If the user presses the BACK button, having the earlier fragment reappear happens automatically. However, we need to fix up the navigation drawer to show the proper row as being activated. To do that, we implement `OnBackStackChangeListener` on `MainActivity` and call `addOnBackStackChangeListener()` on the `FragmentManager` in the `onCreate()` initialization work. That way, `onBackStackChanged()` will be called when there is a change in the state of the back stack. Then, it is merely a matter of calling `post()` for `onNavChange` again, to update the nav drawer:

```
@Override  
public void onBackStackChanged() {  
    drawer.post(onNavChange);  
}
```

Hiding Context-Specific Action Bar Items

Another Google design guideline that makes sense, but adds complexity, is to only show action bar items that pertain to the entire application while the navigation drawer is visible. So, for example, a “Help” action bar item should remain visible, to allow users to switch over to that. But an “Edit” action bar item, to edit something in the main activity, should be hidden while the navigation drawer is visible.

The navigation drawer is effectively an application-level construct, even if we wind up implementing it on a per-activity basis due to the way Android user interfaces are constructed. Hence, the action bar items with the drawer open should pertain to the same scope that the drawer itself does: the application, not a particular activity or fragment inside of it.

Also, on phone-sized screens, the user may not be able to see much of the underlying UI, as the drawer itself will occlude most of it. They may not remember exactly what was showing, and therefore may forget what that “Delete” action bar item would actually delete. Hiding such a context-specific item, while the drawer is open, is safer.

The converse, of course, is that when the drawer closes, you will need to show once again the items that you hid when the drawer opened.

`DrawerLayout` supports a `DrawerListener`, an instance of which you can attach to the drawer itself, to be notified of when the drawer opens and closes, so you can adjust your action bar items to match.

Interacting with an Action Mode

You may be using your own custom [action modes](#) (a.k.a., contextual action bars), such as allowing the user to perform operations on multiple selections in a `ListView`.

Since the navigation drawer is tied to the application as a whole, not necessarily just the current activity or the selections in it, Google's recommendation is for you to temporarily dismiss the action mode when the navigation drawer is opened. This will allow the action bar to show items of relevance to the app, not to the selection. If the user navigates elsewhere using the navigation drawer, you would leave the action mode dismissed. If the user slides the navigation drawer closed, though, you could re-enable the action mode, tied back into the multiple selections the user has already made.

Advertising Your Drawer

Users who have spent some time with Android will have a decent shot at recognizing that tapping the action bar item adorned with the nav drawer artwork will open a drawer. However, not all users will necessarily make that connection, particularly users relatively new to Android.

As noted earlier in this chapter, `DrawerLayout` implements the “peek” pattern, where a long-tap on the edge of the screen will cause the drawer to open just a bit, to hint that there is something that can be opened with a swipe gesture. This is nice and subtle, but perhaps too subtle, as users are not necessarily likely to tap-and-hold on the screen edge just to see if something interesting happens.

Another possibility is to have the drawer open automatically, either the first time that your app is launched, or every time your app is launched until you detect that the user has manually opened the drawer (e.g., by adding a `DrawerListener` and watching for `onDrawerSlide()` and `onDrawerOpened()` events not triggered by you). On the plus side, this puts the drawer “front and center”, so the user cannot miss it. Once the user taps in your activity (inside or outside of the drawer), the drawer will close with the animated slide to the edge. The hope is that the user will either eventually realize that they can bezel-swipe to get that drawer open, or they will

learn about the action bar option (where you have it). This works if the drawer is fairly useful, relative to what the activity would be displaying by default. If, however, the drawer pales in comparison to the main activity view, forcing the drawer open may reduce, not improve, usability.

What Should Not Be in the Drawer

Your navigation drawer should only provide access to the major areas of content in your app. If you do not have many “major areas of content in your app”, reconsider having a navigation drawer, and use something else (e.g., ViewPager with a tabbed indicator) to get to what content you have.

Also, there are certain things that should not go into a navigation drawer:

- Actions (verbs) generally do not belong in the navigation drawer. “Edit”, “Save”, and so forth belong as action bar items, or perhaps as part of an action mode, not in the navigation drawer.
- Content itself does not belong in the navigation drawer. Bits of metadata, in the form of badges and similar sorts of indicators, are fine, to hint to the user about the content that is available in that area of your app. But the navigation drawer is not meant to be the “master” in the master/detail pattern, nor is it some sort of “sidebar” of additional content that you just want to have hidden away.
- Low-priority areas of your app, particularly those that are traditionally in the action bar, should not be in the navigation drawer. “Help” and “About” are classic examples. “Settings” is another, though the line starts to get a bit fuzzy (while “Settings” might be something traditional for the action bar, “Accounts” is not). The overflow menu of an action bar is a fine place to have those sorts of areas be available to the user without cluttering up the primary action bar or the navigation drawer.

Independent Implementations

The navigation drawer pattern did not begin with the introduction of DrawerLayout. There have been many independent implementations of such a “sliding menu” that pre-dated DrawerLayout and the Android design guidelines for navigation drawers. Examples include:

- Jeremy Feinstein’s [SlidingMenu](#)
- 6Wunderkinder’s [Sliding Layer](#)

- David Scott's [RibbonMenu](#)

Just bear in mind that these implementations do not necessarily adhere to everything in the design guidelines, requiring you to perhaps make modifications or simply ignore those guidelines as needed.

Advanced Uses of WebView

Android uses the WebKit browser engine as the foundation for both its Browser application and the WebView embeddable browsing widget. The Browser application, of course, is something Android users can interact with directly; the WebView widget is something you can integrate into your own applications for places where an HTML interface might be useful.

[Earlier in this book](#), we saw a simple integration of a WebView into an Android activity, with the activity dictating what the browsing widget displayed and how it responded to links.

Here, we will expand on this theme, and show how to more tightly integrate the Java environment of an Android application with the JavaScript environment of WebKit.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one [covering WebView](#).

Friends with Benefits

When you integrate a WebView into your activity, you can control what Web pages are displayed, whether they are from a local provider or come from over the Internet, what should happen when a link is clicked, and so forth. And between WebView, WebViewClient, and WebSettings, you can control a fair bit about how the embedded browser behaves. Yet, by default, the browser itself is just a browser, capable of showing Web pages and interacting with Web sites, but otherwise gaining nothing from being hosted by an Android application.

Except for one thing: `addJavascriptInterface()`.

The `addJavascriptInterface()` method on `WebView` allows you to inject a Java object into the `WebView`, exposing its methods, so they can be called by JavaScript loaded by the Web content in the `WebView` itself.

Now you have the power to provide access to a wide range of Android features and capabilities to your `WebView`-hosted content. If you can access it from your activity, and if you can wrap it in something convenient for use by JavaScript, your Web pages can access it as well.

For example, HTML5 offers geolocation, whereby the Web page can find out where the device resides, by browser-supplied means. We can do much of the same thing ourselves via `addJavascriptInterface()`.

In the [WebKit/GeoWeb1](#) project, you will find a fairly simple layout (`main.xml`):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <WebView android:id="@+id/webkit"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

All this does is host a full-screen `WebView` widget.

Next, take a look at the `GeoWebOne` activity class:

```
package com.commonware.android.geoweb;

import android.annotation.SuppressLint;
import android.app.Activity;
import android.content.Context;
import android.location.Location;
import android.location.LocationListener;
import android.location.LocationManager;
import android.os.Bundle;
import android.webkit.JavascriptInterface;
import android.webkit.WebView;
import org.json.JSONException;
import org.json.JSONObject;

public class GeoWebOne extends Activity {
```

ADVANCED USES OF WEBVIEW

```
private static String PROVIDER=LocationManager.GPS_PROVIDER;
private WebView browser;
private LocationManager myLocationManager=null;

@SuppressLint("SetJavaScriptEnabled")
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);

myLocationManager=(LocationManager)getSystemService(Context.LOCATION_SERVICE);

    browser.getSettings().setJavaScriptEnabled(true);
    browser.addJavascriptInterface(new Locater(), "locater");
    browser.loadUrl("file:///android_asset/geoweb1.html");
}

@Override
public void onResume() {
    super.onResume();
    myLocationManager.requestLocationUpdates(PROVIDER, 10000,
                                              100.0f,
                                              onLocation);
}

@Override
public void onPause() {
    super.onPause();
    myLocationManager.removeUpdates(onLocation);
}

LocationListener onLocation=new LocationListener() {
    public void onLocationChanged(Location location) {
        // ignore...for now
    }

    public void onProviderDisabled(String provider) {
        // required for interface, not used
    }

    public void onProviderEnabled(String provider) {
        // required for interface, not used
    }

    public void onStatusChanged(String provider, int status,
                                Bundle extras) {
        // required for interface, not used
    }
};

public class Locater {
```

```
@JavascriptInterface
public String getLocation() throws JSONException {
    Location loc=myLocationManager.getLastKnownLocation(PROVIDER);

    if (loc==null) {
        return(null);
    }

    JSONObject json=new JSONObject();

    json.put("lat", loc.getLatitude());
    json.put("lon", loc.getLongitude());

    return(json.toString());
}
}
```

This looks a bit like some of the WebView examples from earlier in this book. However, it adds three key bits of code:

- It sets up the LocationManager to provide updates when the device position changes, routing those updates to a do-nothing LocationListener callback object
- It has a Locator inner class that provides a convenient API for accessing the current location, in the form of latitude and longitude values encoded in JSON
- It uses addJavascriptInterface() to expose a Locator instance under the name locator to the Web content loaded in the WebView

The Locator API uses JSON to return both a latitude and a longitude at the same time. We are limited to using data types that are in common between JavaScript and Java, so we cannot pass back the Location object we get from the LocationManager. Hence, we convert the key Location data into a simple JSON structure that the JavaScript on the Web page can parse.

Note that the getLocation() method on Locator has the @JavascriptInterface annotation. This is required of apps with android:targetSdkVersion set to 17 or higher, though it is a good idea to start using it anyway. With such an android:targetSdkVersion, in an app running on an Android 4.2 or higher device, *only* public methods with the @JavascriptInterface annotation will be accessible by JavaScript code. On earlier devices, or with an earlier android:targetSdkVersion, *all* public methods on the Locator object would be accessible by JavaScript, including those inherited from superclasses like Object. Note that your build target

will need to be Android 4.2 or higher in order to reference the `@JavascriptInterface` annotation.

Also note that `onCreate()` has the `@SuppressWarnings("SetJavaScriptEnabled")` annotation. This overrides a Lint warning about the use of `setJavaScriptEnabled(true)`, where Lint wants to make sure that you understand the risks of allowing arbitrary JavaScript to execute inside your app. In this case, the JavaScript is code that we wrote, and so we can ensure that it is safe and sane.

[Later in this chapter](#), we will cover security issues with WebView and put those annotations into context.

The Web page itself is referenced in the source code as `file:///android_asset/geoweb1.html`, so the GeoWeb1 project has a corresponding `assets/` directory containing `geoweb1.html`:

```
<html>
<head>
<title>Android GeoWebOne Demo</title>
<script language="javascript">
  function whereami() {
    var location=JSON.parse(locater.getLocation());

    document.getElementById("lat").innerHTML=location.lat;
    document.getElementById("lon").innerHTML=location.lon;
  }
</script>
</head>
<body>
<p>
You are at: <br/> <span id="lat">(unknown)</span> latitude and <br/>
<span id="lon">(unknown)</span> longitude.
</p>
<p><a onClick="whereami()">Update Location</a></p>
</body>
</html>
```

When you click the “Update Location” link, the page calls a `whereami()` JavaScript function, which in turn uses the `locater` object to update the latitude and longitude, initially shown as “(unknown)” on the page.

If you run the application, initially, the page is pretty boring:

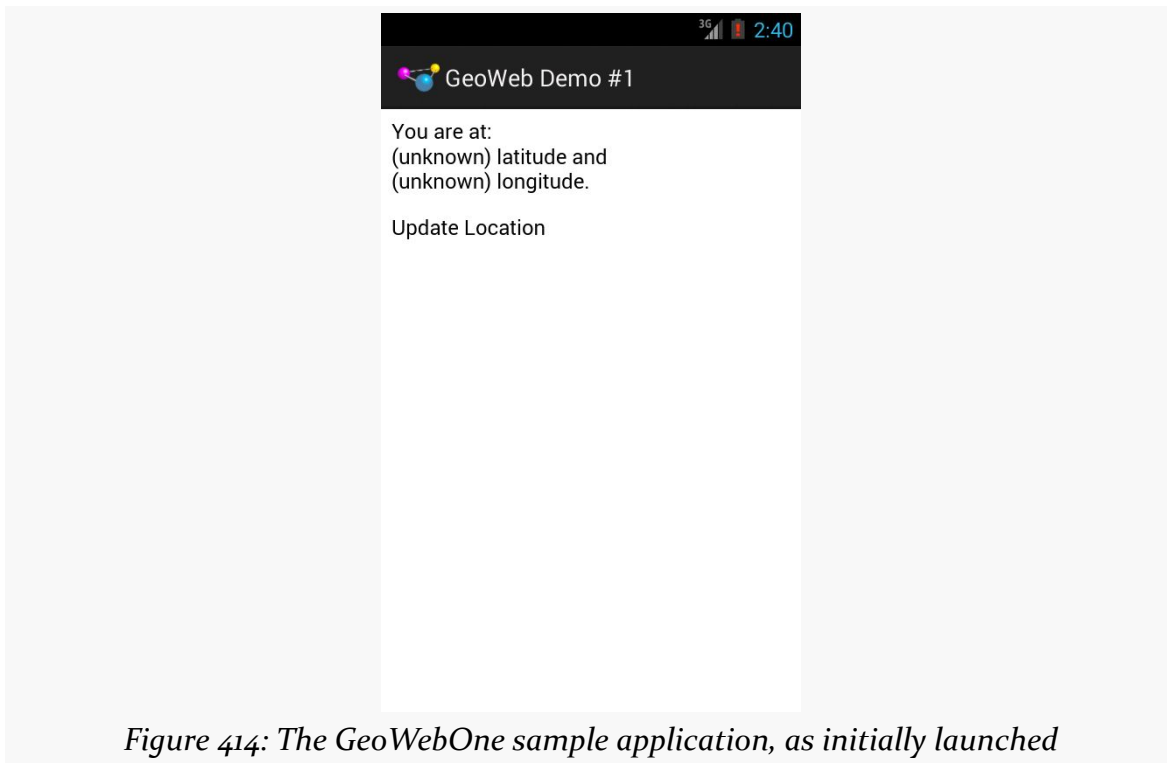

Figure 414: The GeoWebOne sample application, as initially launched

However, if you wait a bit for a GPS fix, and click the “Update Location” link... the page is still pretty boring, but it at least knows where you are:

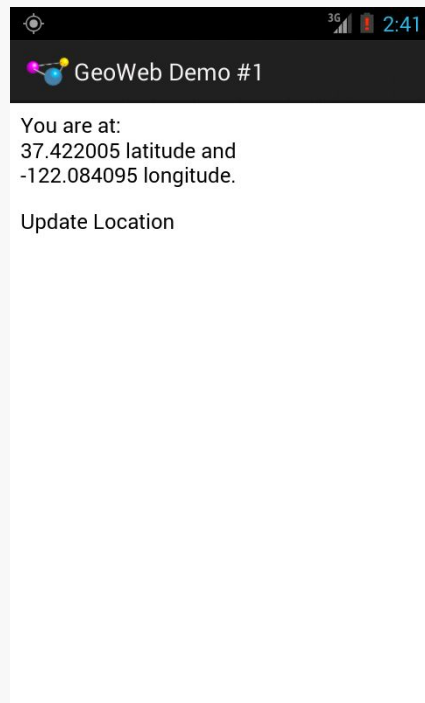

Figure 415: The GeoWebOne sample application, after clicking the Update Location link

Turnabout is Fair Play

Now that we have seen how JavaScript can call into Java, it would be nice if Java could somehow call out to JavaScript. In our example, it would be helpful if we could expose automatic location updates to the Web page, so it could proactively update the position as the user moves, rather than wait for a click on the “Update Location” link.

Well, as luck would have it, we can do that too. This is a good thing, otherwise, this would be a really weak section of the book.

What is unusual is how you call out to JavaScript. One might imagine there would be an `evaluateJavaScript()` counterpart to `addJavascriptInterface()`, where you could supply some JavaScript source and have it executed within the context of the currently-loaded Web page.

Actually, there *is* such a method on Android 4.4. However, earlier versions of Android lacked that method. Instead, on older versions of Android, given your

snippet of JavaScript source to execute, you call `loadUrl()` on your `WebView`, as if you were going to load a Web page, but you put `javascript:` in front of your code and use that as the “address” to load.

If you have ever created a “bookmarklet” for a desktop Web browser, you will recognize this technique as being the Android analogue – the `javascript:` prefix tells the browser to treat the rest of the address as JavaScript source, injected into the currently-viewed Web page.

So, armed with this capability, let us modify the previous example to continuously update our position on the Web page.

The layout for the [WebKit/GeoWeb2](#) sample project is the same as before. The Java source for our activity changes a bit:

```
package com.commonware.android.geoweb2;

import android.annotation.SuppressLint;
import android.annotation.TargetApi;
import android.app.Activity;
import android.content.Context;
import android.location.Location;
import android.location.LocationListener;
import android.location.LocationManager;
import android.os.Build;
import android.os.Bundle;
import android.webkit.JavascriptInterface;
import android.webkit.WebView;
import org.json.JSONException;
import org.json.JSONObject;

public class GeoWebTwo extends Activity {
    private static String PROVIDER="gps";
    private WebView browser;
    private LocationManager myLocationManager=null;

    @SuppressLint("SetJavaScriptEnabled")
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);

        myLocationManager=
            (LocationManager) getSystemService(Context.LOCATION_SERVICE);

        browser.getSettings().setJavaScriptEnabled(true);
        browser.addJavascriptInterface(new Locater(), "locater");
        browser.loadUrl("file:///android_asset/geoweb2.html");
    }
}
```

```
@Override
public void onResume() {
    super.onResume();
    myLocationManager.requestLocationUpdates(PROVIDER, 0, 0, onLocation);
}

@Override
public void onPause() {
    super.onPause();
    myLocationManager.removeUpdates(onLocation);
}

LocationListener onLocation=new LocationListener() {
    @TargetApi(Build.VERSION_CODES.KITKAT)
    public void onLocationChanged(Location location) {
        StringBuilder buf=new StringBuilder("whereami(");

        buf.append(String.valueOf(location.getLatitude()));
        buf.append(",");
        buf.append(String.valueOf(location.getLongitude()));
        buf.append(")");

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
            browser.evaluateJavascript(buf.toString(), null);
        }
        else {
            browser.loadUrl("javascript:" + buf.toString());
        }
    }
}

public void onProviderDisabled(String provider) {
    // required for interface, not used
}

public void onProviderEnabled(String provider) {
    // required for interface, not used
}

public void onStatusChanged(String provider, int status,
    Bundle extras) {
    // required for interface, not used
}
};

public class Locater {
    @JavascriptInterface
    public String getLocation() throws JSONException {
        Location loc=myLocationManager.getLastKnownLocation(PROVIDER);

        if (loc == null) {
            return(null);
        }
    }
}
```

```
JSONObject json=new JSONObject();

json.put("lat", loc.getLatitude());
json.put("lon", loc.getLongitude());

return(json.toString());
}
}
```

Before, the `onLocationChanged()` method of our `LocationListener` callback did nothing. Now, it builds up a call to a `whereami()` JavaScript function, providing the latitude and longitude as parameters to that call. So, for example, if our location were 40 degrees latitude and -75 degrees longitude, the call would be `whereami(40,-75)`.

What happens then depends upon the version of Android the device is running.

- For devices running Android 4.4+, it calls `evaluateJavascript()`. This takes the JavaScript source code, plus an optional callback, and executes it in the context of the currently-loaded Web page.
- For devices running older versions of Android, it puts `javascript:` in front of the Javascript source and calls `loadUrl()` on the `WebView`. This is the same syntax used for “bookmarklets” in desktop Web browsers.

The result is that a `whereami()` function in the Web page gets called with the new location.

That Web page, of course, also needed a slight revision, to accommodate the option of having the position be passed in:

```
<html>
<head>
<title>Android GeoWebTwo Demo</title>
<script language="javascript">
  function whereami(lat, lon) {
    document.getElementById("lat").innerHTML=lat;
    document.getElementById("lon").innerHTML=lon;
  }

  function pull() {
    var location=JSON.parse(locater.getLocation());

    whereami(location.lat, location.lon);
  }
</script>
</head>
```

```
<body>
<p>
You are at: <br/> <span id="lat">(unknown)</span> latitude and <br/>
<span id="lon">(unknown)</span> longitude.
</p>
<p><a onClick="pull()">Update Location</a></p>
</body>
</html>
```

The basics are the same, and we can even keep our “Update Location” link, albeit with a slightly different onClick attribute.

If you build, install, and run this revised sample on a GPS-equipped Android device, the page will initially display with “(unknown)” for the current position. After a fix is ready, though, the page will automatically update to reflect your actual position. And, as before, you can always click “Update Location” if you wish.

Navigating the Waters

There is no navigation toolbar with the WebView widget. This allows you to use it in places where such a toolbar would be pointless and a waste of screen real estate. That being said, if you want to offer navigational capabilities, you can, but you have to supply the UI. WebView offers ways to perform garden-variety browser navigation, including:

- reload() to refresh the currently-viewed Web page
- goBack() to go back one step in the browser history, and canGoBack() to determine if there is any history to go back to
- goForward() to go forward one step in the browser history, and canGoForward() to determine if there is any history to go forward to
- goBackOrForward() to go backwards or forwards in the browser history, where negative numbers represent a count of steps to go backwards, and positive numbers represent how many steps to go forwards
- canGoBackOrForward() to see if the browser can go backwards or forwards the stated number of steps (following the same positive/negative convention as goBackOrForward())
- clearCache() to clear the browser resource cache and clearHistory() to clear the browsing history

Settings, Preferences, and Options (Oh, My!)

With your favorite desktop Web browser, you have some sort of “settings” or “preferences” or “options” window. Between that and the toolbar controls, you can tweak and twiddle the behavior of your browser, from preferred fonts to the behavior of JavaScript.

Similarly, you can adjust the settings of your WebView widget as you see fit, via the `WebSettings` instance returned from calling the widget’s `getSettings()` method.

There are lots of options on `WebSettings` to play with. Most appear fairly esoteric (e.g., `setFantasyFontFamily()`). However, here are some that you may find more useful:

- Control the font sizing via `setDefaultFontSize()` (to use a point size) or `setTextSize()` (to use constants indicating relative sizes like `LARGER` and `SMALLEST`)
- Control Web site rendering via `setUserAgent()`, so you can supply your own user agent string to make the Web server think you are a desktop browser, another mobile device (e.g., iPhone), or whatever. The settings you change are not persistent, so you should store them somewhere (such as via the Android preferences engine) if you are allowing your users to determine the settings, versus hard-wiring the settings in your application.

Security and Your WebView

More so than normal widgets, `WebView` opens up potential security issues, just as a Web browser could. If all you are doing is displaying your own content, the risks are minimal. If, on the other hand, you are displaying content from third parties, it is possible that their content is malicious in a way that can compromise your app’s security, to your users’ detriment.

Rogue JavaScript Risks

If you call `setJavaScriptEnabled(true)` on your `WebSettings`, you are allowing JavaScript code to be loaded and executed by `WebView`. In many cases, this is essential to get your content to render properly (e.g., the JavaScript is issuing AJAX calls). However, if you did not write the scripts, you do not know what they might be

doing. If there are flaws in `WebView` — such as those discussed in the next sections — then your users may be at risk.

Even in the absence of such bugs, JavaScript can always:

- Consume so much CPU that it represents an attempt at a denial-of-service attack on the user's device
- Access anything the user enters into the Web page
- Access anything you enter into the Web page, using approaches as `javascript: URLs` or `evaluateJavaScript()`

The `addJavaScriptInterface()` Bugs

Another way that rogue JavaScript can attack users is if you use `addJavaScriptInterface()` to allow JavaScript code to call out to a Java object that you supply.

As was noted [earlier in this chapter](#), when `addJavaScriptInterface()` was introduced, there is this `@JavascriptInterface` annotation that we should apply to the methods we want JavaScript to be able to call on the object we supply via `addJavaScriptInterface()`. This is because of a bug in the `addJavaScriptInterface()` implementation, whereby on 4.1 and below *any* method on the Java object could be called by JavaScript. This includes methods like `getClass()`... which in turn would allow JavaScript to use `Class.forName()` to get at arbitrary stuff. This was used by various bits of malware.

Hence, using `addJavaScriptInterface()` on Android 4.1 and below is rather risky, if you are loading arbitrary third-party JavaScript. If you have the means of examining that JavaScript (e.g., you are loading the scripts yourself), you might perform some simple scans of it to see if they appear to be doing anything unfortunate with your Java object that you injected into JavaScript via `addJavaScriptInterface()`.

Worse, Android sometimes also injects its *own* objects, without our requesting them.

In particular, [this security bug](#) points out that, through Android 4.3, if users have enabled an accessibility service, Android automatically injects objects into `WebView`, using `addJavaScriptInterface()`, named `accessibility` and `accessibilityTraversal`. So, even if you do not inject any objects yourself via `addJavaScriptInterface()`, your `WebView` may be at risk. The security researchers

who uncovered this attack vector suggest using `removeJavascriptInterface()` to specifically get rid of those objects.

The Same-Origin Policy Bug

Due to a bizarre bug in the parsing of URLs, it is possible for JavaScript code to violate the “same-origin policy” of a WebView on Android 4.3 and earlier.

Quoting [Wikipedia](#) from September 2014:

the same-origin policy is an important concept in the web application security model. The policy permits scripts running on pages originating from the same site -- a combination of scheme, hostname, and port number -- to access each other's DOM with no specific restrictions, but prevents access to DOM on different sites... This mechanism bears a particular significance for modern web applications that extensively depend on HTTP cookies to maintain authenticated user sessions, as servers act based on the HTTP cookie information to reveal sensitive information or take state-changing actions. A strict separation between content provided by unrelated sites must be maintained on the client side to prevent the loss of data confidentiality or integrity.

All modern Web browsers implement the same-origin policy (SOP)... but there can be bugs. A security researcher disclosed that the original AOSP Browser application [failed to implement the SOP properly](#), when a `javascript:` URL has a null byte before the `j` in `javascript`. And while the report was focused on the AOSP Browser app, the problem really lies with WebView.

To see this in action, load `http://commonsware.com/misc/sop-demo.html` in the AOSP Browser app on Android 4.3 or lower. This Web page consists of:

```
<html>
<head>
<title>WebView SOP Test</title>
</head>
<body>
<h1>WebView SOP Test</h1>
<iframe name="test" src="http://developer.android.com"></iframe>
<input type="button" value="test"
onclick="window.open('\u0000javascript:alert(document.domain)','test')">
</body>
</html>
```

It is derived from a similar example found in [the blog post outlining the security flaw](#).

In an SOP-compliant browser, clicking the button will have no effect. In the AOSP Browser app, clicking the button shows the domain name of the document in the iframe. And, loading this HTML into a WebView has the same effect.

Part of the WebView overhaul in Android 4.4 — replacing the original implementation with a new one backed by Chromium — had the effect of fixing this bug, whether intentionally or inadvertently.

There is no obvious mitigation approach for this bug, insofar as for the attack shown above, none of the callbacks on `WebViewClient` or `WebChromeClient` seem to allow us to intercept this URL before its JavaScript is executed. If you are loading HTML yourself from a third party, you might consider scanning that HTML for obvious signs of the attack (e.g., regular expression check for `\u0000javascript`), but that will be limited at best. Beyond that, try to limit the content in a `WebView` to be from only one origin, so that there is nothing for attackers to obtain via this bug.

Also note that the security researcher who found this bug has also found [another SOP violation](#), suggesting that mitigation strategies may be impractical.

The Input Method Framework

Android 1.5 introduced the input method framework (IMF), which is commonly referred to as “soft keyboards”. However, the “soft keyboard” term is not necessarily accurate, as IMF could be used for handwriting recognition or other means of accepting text input via the screen.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [section covering the `EditText` widget](#).

Keyboards, Hard and Soft

Some Android devices have a hardware keyboard that is visible some of the time (when it is slid out). A few Android devices have a hardware keyboard that is always visible (so-called “bar” or “slab” phones). Most Android devices, though, have no hardware keyboard at all.

The IMF handles all of these scenarios. In short, if there is no hardware keyboard, an input method editor (IME) will be available to the user when they tap on an enabled `EditText`.

This requires no code changes to your application... if the default functionality of the IME is what you want. Fortunately, Android is fairly smart about guessing what you want, so it may be you can just test with the IME but otherwise make no specific code changes.

Of course, the keyboard may not quite behave how you would like. For example, in the Basic/Field sample project, the `FieldDemo` activity has the IME overlaying the multiple-line `EditText`:

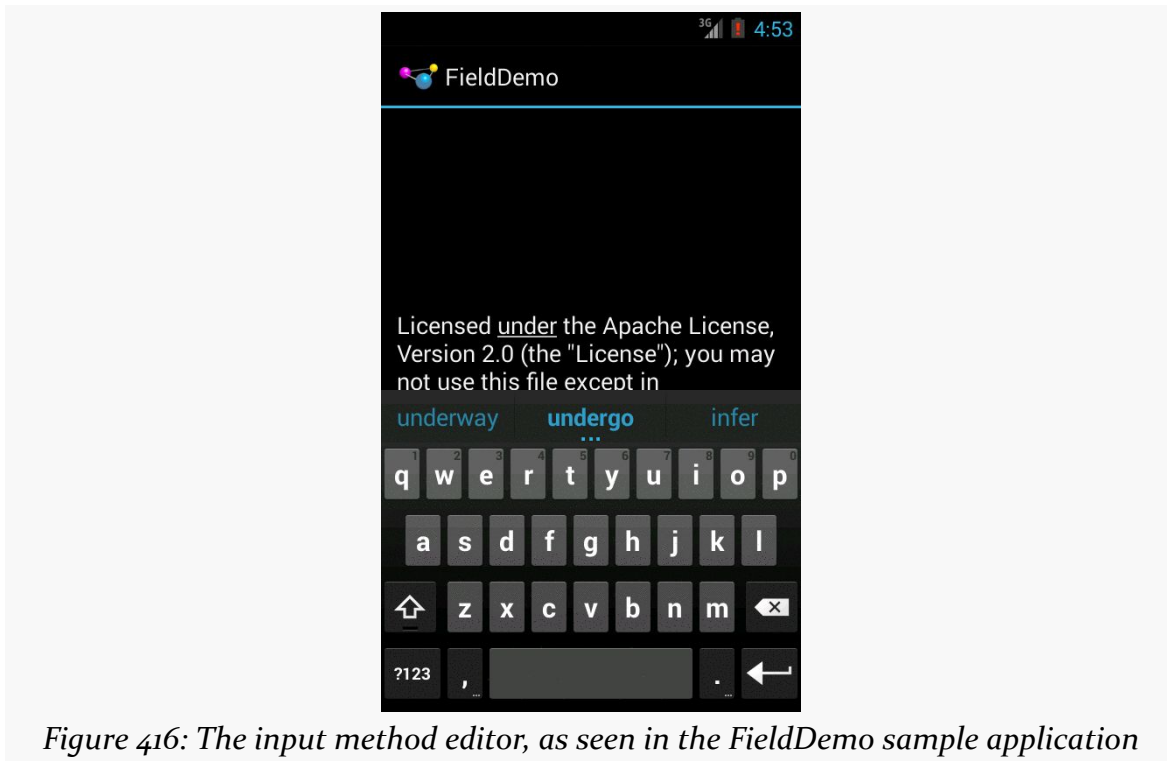

Figure 416: The input method editor, as seen in the FieldDemo sample application

It would be nice to have more control over how this appears, and for other behavior of the IME. Fortunately, the framework as a whole gives you many options for this, as is described over the bulk of this chapter.

Tailored To Your Needs

Android 1.1 and earlier offered many attributes on `EditText` widgets to control their style of input, such as `android:password` to indicate a field should be for password entry (shrouding the password keystrokes from prying eyes). Starting in Android 1.5, with the IMF, many of these have been combined into a single `android:inputType` attribute.

The `android:inputType` attribute takes a class plus modifiers, in a pipe-delimited list (where `|` is the pipe character). The class generally describes what the user is

allowed to input, and this determines the basic set of keys available on the soft keyboard. The available classes are:

1. text (the default)
2. number
3. phone
4. datetime
5. date
6. time

Many of these classes offer one or more modifiers, to further refine what the user will be entering. To help explain those, take a look at the `res/layout/main.xml` file from the [InputMethod/IMEDemo1](#) project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="No special rules:"
            />
        <EditText
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Email address:"
            />
        <EditText
            android:inputType="text|textEmailAddress"
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Signed decimal number:"
            />
        <EditText
            android:inputType="number|numberSigned|numberDecimal"
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Date:"
            />
        <EditText
            android:inputType="date"
            />
    </TableRow>
</TableLayout>
```

```
</TableRow>
<TableRow>
  <TextView
    android:text="Multi-line text:"
  />
  <EditText
    android:inputType="text|textMultiLine|textAutoCorrect"
    android:minLines="3"
    android:gravity="top"
  />
</TableRow>
</TableLayout>
```

Here, you will see a `TableLayout` containing five rows, each demonstrating a slightly different flavor of `EditText`:

- One has no attributes at all on the `EditText`, meaning you get a plain text entry field
- One has `android:inputType = "text|textEmailAddress"`, meaning it is text entry, but specifically seeks an email address
- One allows for signed decimal numeric input, via `android:inputType = "number|numberSigned|numberDecimal"`
- One is set up to allow for data entry of a date (`android:inputType = "date"`)
- The last allows for multi-line input with auto-correction of probable spelling errors (`android:inputType = "text|textMultiLine|textAutoCorrect"`)

The class and modifiers tailor the keyboard. So, a plain text entry field results in a plain soft keyboard:

Figure 417: A standard input method editor (a.k.a., soft keyboard)

An email address field might put the @ symbol on the soft keyboard, at the cost of a smaller spacebar:

Figure 418: The input method editor for email addresses

Note, though, that this behavior is specific to the input method editor. Some editors might put an @ sign on the primary keyboard for an email field. Some might put a “.com” button on the primary keyboard. Some might not react at all. It is up to the implementation of the input method editor — all you can do is supply the hint.

Numbers and dates restrict the keys to numeric keys, plus a set of symbols that may or may not be valid on a given field:

Figure 419: The input method editor for signed decimal numbers

And so on.

By choosing the appropriate `android:inputType`, you can give the user a soft keyboard that best suits what it is they should be entering.

Tell Android Where It Can Go

You may have noticed a subtle difference between the first and second input method editors, beyond the addition of the @ key. If you look in the lower-right corner of the soft keyboard, the second field's editor has a "Next" button, while the first field's editor has a newline button.

This points out two things:

- `EditText` widgets are multi-line by default if you do not specify `android:inputType`
- You can control what goes on with that lower-right-hand button, called the action key

By default, on an `EditText` where you have specified `android:inputType`, the action key will be “Next”, moving you to the next `EditText` in sequence, or “Done”, if you are on the last `EditText` on the screen. You can manually stipulate what the action key will be labeled via the `android:imeOptions` attribute. For example, in the `res/layout/main.xml` from the [InputMethod/IMEDemo2](#) sample project, you will see an augmented version of the previous example, where two input fields specify what their action key should look like:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:stretchColumns="1"
    >
        <TableRow>
            <TextView
                android:text="No special rules:"
            />
            <EditText
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Email address:"
            />
            <EditText
                android:inputType="text|textEmailAddress"
                android:imeOptions="actionSend"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Signed decimal number:"
            />
            <EditText
                android:inputType="number|numberSigned|numberDecimal"
                android:imeOptions="actionDone"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Date:"
            />
            <EditText
                android:inputType="date"
            />
        </TableRow>
    </TableLayout>
</ScrollView>
```

```
<TextView
    android:text="Multi-line text:"
/>
<EditText
    android:inputType="text|textMultiLine|textAutoCorrect"
    android:minLines="3"
    android:gravity="top"
/>
</TableRow>
</TableLayout>
</ScrollView>
```

Here, we attach a “Send” action to the action key for the email address (`android:imeOptions = "actionSend"`), and the “Done” action on the middle field (`android:imeOptions = "actionDone"`).

By default, “Next” will move the focus to the next `EditText` and “Done” will close up the input method editor. However, for those, or for any other ones like “Send”, you can use `setOnEditorActionListener()` on `EditText` (technically, on the `TextView` superclass) to get control when the action key is clicked or the user presses the `<Enter>` key. You are provided with a flag indicating the desired action (e.g., `IME_ACTION_SEND`), and you can then do something to handle that request (e.g., send an email to the supplied email address).

If you need more control over the action button, you can set:

- `android:imeActionId`, which provides a custom value for the `actionId` that is passed to `onEditorAction()` of your `OnEditorActionListener`
- `android:imeActionLabel`, where you provide your own caption for the button (bearing in mind that your desired caption may or may not fit)

Fitting In

You will notice that the `IMEDemo2` layout shown above has another difference from its `IMEDemo1` predecessor: the use of a `ScrollView` container wrapping the `TableLayout`. This ties into another level of control you have over the input method editors: what happens to your activity’s own layout when the input method editor appears?

There are three possibilities, depending on circumstances:

1. Android can “pan” your activity, effectively sliding the whole layout up to accommodate the input method editor, or overlaying your layout, depending

- on whether the EditText being edited is at the top or bottom. This has the effect of hiding some portion of your UI.
2. Android can resize your activity, effectively causing it to shrink to a smaller screen dimension, allowing the input method editor to sit below the activity itself. This is great when the layout can readily be shrunk (e.g., it is dominated by a list or multi-line input field that does not need the whole screen to be functional).
 3. In landscape mode, Android may display the input method editor full-screen, obscuring your entire activity. This allows for a bigger keyboard and generally easier data entry.

Android controls the full-screen option purely on its own. And, by default, Android will choose between pan and resize modes depending on what your layout looks like. If you want to specifically choose between pan and resize, you can do so via an `android:windowSoftInputMode` attribute on the `<activity>` element in your `AndroidManifest.xml` file. For example, here is the manifest from `IMEDemo2`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.imf.two"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name=".IMEDemo2"
            android:label="@string/app_name"
            android:windowSoftInputMode="adjustResize">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

Because we specified `resize`, Android will shrink our layout to accommodate the input method editor. With the `ScrollView` in place, this means the scroll bar will appear as needed:

Figure 420: The shrunk, scrollable layout

Jane, Stop This Crazy Thing!

Sometimes, you need the input method editor to just go away. For example, if you make the action button be “Search”, the user tapping that button will not automatically hide the editor.

To hide the editor, you will need to make a call to the `InputMethodManager`, a system service that controls these input method editors:

```
InputMethodManager  
mgr=(InputMethodManager) getSystemService(INPUT_METHOD_SERVICE);  
mgr.hideSoftInputFromWindow(fld.getWindowToken(), 0);
```

(where `fld` is the `EditText` whose input method editor you want to hide)

Inevitably, you'll get the question "hey, can we change this font?" when doing application development. The answer depends on what fonts come with the platform, whether you can add other fonts, and how to apply them to the widget or whatever needs the font change.

Android is no different. It comes with some fonts plus a means for adding new fonts. Though, as with any new environment, there are a few idiosyncrasies to deal with.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [files](#).

Love The One You're With

Android natively knows three fonts, by the shorthand names of "sans", "serif", and "monospace". For Android 1.x, 2.x, and 3.x, these fonts are actually the Droid series of fonts, created for the Open Handset Alliance by [Ascender](#). A new font set, Roboto, is used in Android 4.x and beyond.

For those fonts, you can just reference them in your layout XML, if you choose, such as the following layout from the [Fonts/FontSampler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">
```

```
<TableRow>
  <TextView
    android:text="sans:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/sans"
    android:text="Hello, world!"
    android:typeface="sans"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="serif:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/serif"
    android:text="Hello, world!"
    android:typeface="serif"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="monospace:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/monospace"
    android:text="Hello, world!"
    android:typeface="monospace"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="Custom:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/custom"
    android:text="Hello, world!"
    android:textSize="20sp"
  />
</TableRow>
<TableRow android:id="@+id/filerow">
  <TextView
    android:text="Custom from File:"
```

```
        android:layout_marginRight="4dip"
        android:textSize="20sp"
    />
    <TextView
        android:id="@+id/file"
        android:text="Hello, world!"
        android:textSize="20sp"
    />
</TableRow>
</TableLayout>
```

This layout builds a table showing short samples of five fonts. Notice how the first three have the `android:typeface` attribute, whose value is one of the three built-in font faces (e.g., “sans”).

The three built-in fonts are very nice. However, it may be that a designer, or a manager, or a customer wants a different font than one of those three. Or perhaps you want to use a font for specialized purposes, such as a “dingbats” font instead of a series of PNG graphics.

The easiest way to accomplish this is to package the desired font(s) with your application. To do this, simply create an `assets/` folder in the project root, and put your TrueType (TTF) fonts in the assets. You might, for example, create `assets/fonts/` and put your TTF files in there.

Then, you need to tell your widgets to use that font. Unfortunately, you can no longer use layout XML for this, since the XML does not know about any fonts you may have tucked away as an application asset. Instead, you need to make the change in Java code:

```
package com.commonware.android.fonts;

import android.app.Activity;
import android.graphics.Typeface;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.TextView;
import java.io.File;

public class FontSampler extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        TextView tv=(TextView)findViewById(R.id.custom);
        Typeface face=Typeface.createFromAsset(getAssets(),
```

FONTS

```
                                "fonts/HandmadeTypewriter.ttf");

    tv.setTypeface(face);

    File font=new File(Environment.getExternalStorageDirectory(),
                        "MgOpenCosmeticaBold.ttf");

    if (font.exists()) {
        tv=(TextView)findViewById(R.id.file);
        face=Typeface.createFromFile(font);

        tv.setTypeface(face);
    }
    else {
        findViewById(R.id.filerow).setVisibility(View.GONE);
    }
}
}
```

Here we grab the `TextView` for our “custom” sample, then create a `Typeface` object via the static `createFromAsset()` builder method. This takes the application’s `AssetManager` (from `getAssets()`) and a path within your `assets/` directory to the font you want.

Then, it is just a matter of telling the `TextView` to `setTypeface()`, providing the `Typeface` you just created. In this case, we are using the [Handmade Typewriter](#) font.

You can also load a font out of a local file and use it. The benefit is that you can customize your fonts after your application has been distributed. On the other hand, you have to somehow arrange to get the font onto the device. But just as you can get a `Typeface` via `createFromAsset()`, you can get a `Typeface` via `createFromFile()`. In our `FontSampler`, we look in the root of “external storage” (typically the SD card) for the `MgOpenCosmeticaBold` TrueType font file, and if it is found, we use it for the fifth row of the table. Otherwise, we hide that row.

The results?

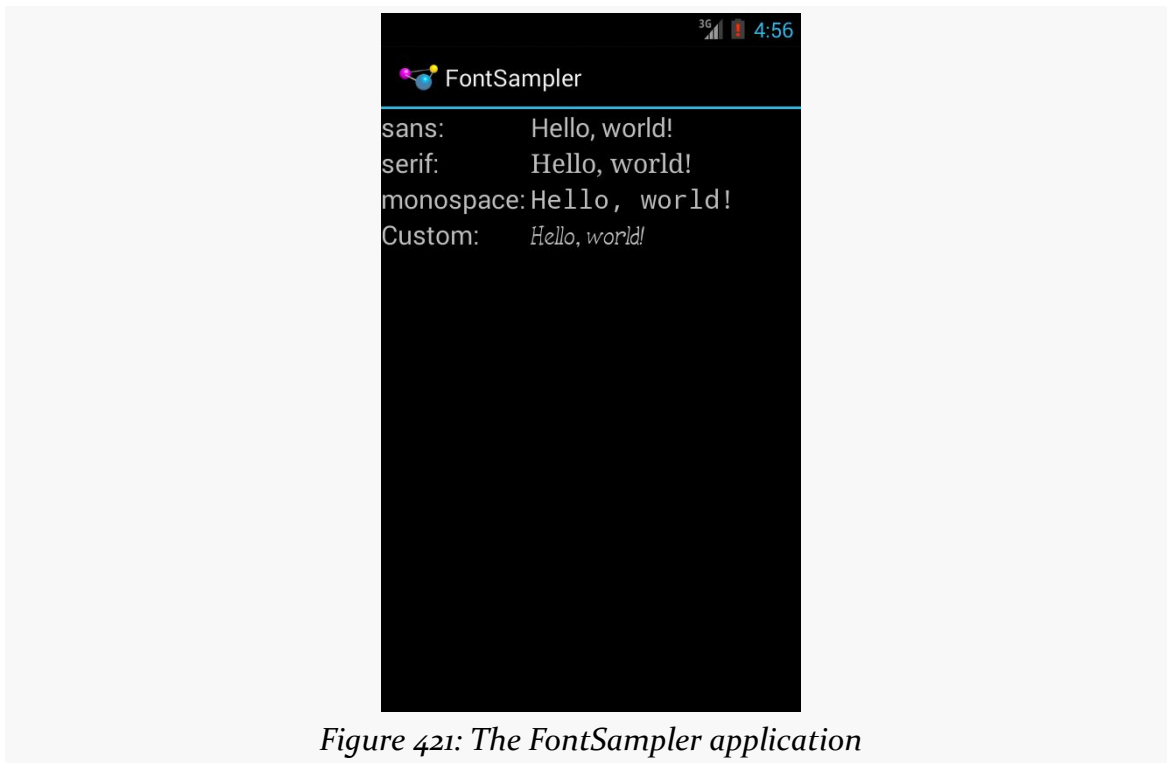

Figure 421: The FontSampler application

Note that Android does not seem to like all TrueType fonts. When Android dislikes a custom font, rather than raise an Exception, it seems to substitute Droid Sans (“sans”) quietly. So, if you try to use a different font and it does not seem to be working, it may be that the font in question is incompatible with Android, for whatever reason.

Yeah, But Do We Really Have To Do This in Java?

One common complaint with font handling in Android is that you have to apply a custom font on a per-widget basis in Java code.

This gets old quickly.

It is not too bad with just a single TextView. But for a whole activity, or a whole application, changing all of the relevant TextView widgets (and descendents, like Button) gets to be a bit tedious.

While there are “traverse the widget hierarchy and fix up the fonts” code snippets available, you are probably better served using a third-party library, like Christopher

Jenkins' [Calligraphy](#), which lets you define custom fonts in layout XML files or style resources.

Here a Glyph, There a Glyph

TrueType fonts can be rather pudgy, particularly if they support an extensive subset of the available Unicode characters. The Handmade Typewriter font used above runs over 70KB; the DejaVu free fonts can run upwards of 500KB apiece. Even compressed, these add bulk to your application, so be careful not to go overboard with custom fonts, lest your application take up too much room on your users' phones.

Conversely, bear in mind that fonts may not have all of the glyphs that you need. As an example, let us talk about the ellipsis.

Android's `TextView` class has the built-in ability to “ellipsize” text, truncating it and adding an ellipsis if the text is longer than the available space. You can use this via the `android:ellipsize` attribute, for example. This works fairly well, at least for single-line text.

The ellipsis that Android uses is not three periods. Rather it uses an actual ellipsis character, where the three dots are contained in a single glyph. Hence, any font that you use in a `TextView` where you also use the “ellipsizing” feature will need the ellipsis glyph.

Beyond that, though, Android pads out the string that gets rendered on-screen, such that the length (in characters) is the same before and after “ellipsizing”. To make this work, Android replaces one character with the ellipsis, and replaces all other removed characters with the Unicode character ‘ZERO WIDTH NO-BREAK SPACE’ (U+FEFF). This means the “extra” characters after the ellipsis do not take up any visible space on screen, yet they can be part of the string.

However, this means any custom fonts you use for `TextView` widgets that you use with `android:ellipsize` must also support this special Unicode character. Not all fonts do, and you will get artifacts in the on-screen representation of your shortened strings if your font lacks this character (e.g., rogue X's appear at the end of the line).

And, of course, Android's international deployment means your font must handle any language your users might be looking to enter, perhaps through a language-specific input method editor.

Fonts

Hence, while using custom fonts in Android is very possible, there are many potential problems, and so you must weigh carefully the benefits of the custom fonts versus their potential costs.

Plain text is so, well, plain.

Fortunately, Android has fairly extensive support for formatted text, before you need to break out something as heavy-weight as `WebView`. However, some of this rich text support has been shrouded in mystery, particularly how you would allow users to edit formatted text.

This chapter will explain how the rich text support in Android works and how you can take advantage of it, with particular emphasis on some open source projects to help you do just that.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic widgets](#) and the [input method framework](#).

The Span Concept

You may have noticed that many methods in Android accept or return a `CharSequence`. The `CharSequence` interface is little used in traditional Java, if for no other reason than there are relatively few implementations of it outside of `String`. However, in Android, `CharSequence` becomes much more important, because of a sub-interface named `Spanned`.

`Spanned` defines sequences of characters (`CharSequence`) that contain *inline markup rules*. These rules — instances of `CharacterStyle` — indicate whether the “spanned”

portion of the characters should be rendered in an alternate font, or be turned into a hyperlink, or have other effects applied to them.

Methods that take a `CharSequence` as a parameter, therefore, can work equally well with `String` objects as well as objects that implement `Spanned`.

Implementations

The base interface for rich-text `CharSequence` objects is `Spanned`. This is used for any `CharSequence` that has inline markup rules, and it defines methods for retrieving markup rules applied to portions of the underlying text.

The primary concrete implementation of `Spanned` is `SpannedString`. `SpannedString`, like `String`, is immutable — you cannot change either the text or the formatting of a `SpannedString`.

There is also the `Spannable` sub-interface of `Spanned`. `Spannable` is used for any `CharSequence` with inline markup rules that can be modified, and it defines the methods for modifying the formatting. There is a corresponding `SpannableString` implementation.

Finally, there is a related `Editable` interface, which is for a `CharSequence` that can have its *text* modified in-place. `SpannableStringBuilder` implements both `Editable` and `Spannable`, for modifying text and formatting at the same time.

TextView and Spanned

One of the most important uses of `Spanned` objects is with `TextView`. `TextView` is capable of rendering a `Spanned`, complete with all of the specified formatting. So, if you have a `Spanned` that indicates that the third word should be rendered in italics, `TextView` will faithfully italicize that word.

`TextView`, of course, is an ancestor of many other widgets, from `EditText` to `Button` to `CheckBox`. Each of those, therefore, can use and render `Spannable` objects. The fact that `EditText` has the ability to render `Spanned` objects — and even allow them to be edited — is key for allowing users to enter rich text themselves as part of your UI.

Available Spans

As noted above, the markup rules come in the form of instances of a base class known as `CharacterStyle`. Despite that name, all of the SDK-supplied subclasses of `CharacterStyle` end in `Span` (not `Style`), and so you will likely see references to these as “spans” as often as “styles”. That also helps minimize confusion between character styles and style resources.

There are well over a dozen supplied `CharacterStyle` subclasses, including:

1. `ForegroundColorSpan` and `BackgroundColorSpan` for coloring text
2. `StyleSpan`, `TextAppearanceSpan`, `TypefaceSpan`, `UnderlineSpan`, and `StrikethroughSpan` for affecting the true “style” of text
3. `AbsoluteSizeSpan`, `RelativeSizeSpan`, `SuperscriptSpan`, and `SubscriptSpan` for affecting the size (and, in some cases, vertical position) of the text

And so on.

In principle, you could implement your own custom subclasses of `CharacterStyle`, though coverage of this is well outside the scope of this book.

Loading Rich Text

Spanned objects do not appear by magic. Plenty of things in Java will give you ordinary strings, from XML and JSON parsers to loading data out of a database to simply hard-coding string constants. However, there are only a few ways that you as a developer will get a `Spanned` complete with formatting, and that includes you creating such a `Spanned` yourself by hand.

String Resource

The primary way most developers get a `Spanned` object into their application is via a string resource. String resources support inline markup in the form of HTML tags. Bold (``), italics (`<i>`), and underline (`<u>`) are officially supported, such as:

```
<string name="welcome">Welcome to <b>Android</b>!</string>
```

When you retrieve the string resource via `getText()`, you get back a `CharSequence` that represents a `Spanned` object with the markup rules in place.

HTML

The next-most common way to get a Spanned object is to use `Html.fromHtml()`. This parses an HTML string and returns a Spanned object, with all recognized tags converted into corresponding spans. You might use this for text loaded from a database, retrieved from a Web service call, extracted from an RSS feed, etc.

Unfortunately, the list of tags that `fromHtml()` understands is undocumented. Based upon the source code to `fromHtml()`, the following seem safe:

- ``
- ``
- `<big>`
- `<blockquote>`
- `
`
- `<cite>`
- `<dfn>`
- `<div align="...">`
- ``
- ``
- `<h1>`
- `<h2>`
- `<h3>`
- `<h4>`
- `<h5>`
- `<h6>`
- `<i>`
- ``
- `<p>`
- `<small>`
- `<strike>`
- ``
- `<sub>`
- `<sup>`
- `<tt>`
- `<u>`

However, do bear in mind that these are undocumented and therefore are subject to change. Also note that `fromHtml()` is perhaps slower than you might think, particularly for longer strings.

You might also wind up using some other support code to get your HTML. For example, some data sources might publish text formatted as [Markdown](#) — Stack Overflow, GitHub, etc. use this extensively. Markdown can be converted to HTML, through any number of available Java libraries or via [CWAC-AndDown](#), which wraps the native [hoedown](#) Markdown-to-HTML converter for maximum speed. CWAC-AndDown will be explored in a bit more detail in [the chapter on the NDK](#).

From EditText

The reason why so much sample code calls `getText()` followed by `toString()` on an `EditText` widget is because `EditText` is going to return an `Editable` object from `getText()`, not a simple string. That's because, in theory, `EditText` could be returning something with formatting applied. The call to `toString()` simply strips out any potential formatting as part of giving you back a `String`.

However, you could elect to use the `Editable` object (presumably a `SpannableStringBuilder`) if you wanted, such as for pouring the entered text into a `TextView`, complete with any formatting that might have wound up on the entered text.

Actually getting formatting applied to the contents of an `EditText` is covered [later in this chapter](#).

Manually

You are welcome to create a `SpannableString` via its constructor, supplying the text that you wish to display, then calling various methods on `SpannableString` to format it. We will see an example of this [later in this chapter](#).

Or, you are welcome to create a `SpannableStringBuilder` via its constructor. In some respects, `SpannableStringBuilder` works like the classic `StringBuilder` — you call `append()` to add more text. However, `SpannableStringBuilder` also offers `delete()`, `insert()`, and `replace()` methods to modify portions of the existing content. It also supports the same methods that `SpannableString` does, via the `Spannable` interface, for applying formatting rules to portions of text.

Editing Rich Text

If the `Spannable` you wound up with is a `SpannedString`, it is what it is — you cannot change it. If, however, you have a `SpannableString`, that can be modified by

you, or by the user. Of course, allowing the user to modify a Spannable gets a wee bit tricky, and is why the RichEditText project was born.

RichEditText

If you load a Spannable into an EditText, the formatting will not only be displayed, but it will be part of the editing experience. For example, if the phrase “**the fox jumped**” is in bold, and the user adds in more words to make it “**the quick brown fox jumped**”, the additional words will also be in boldface. That is because the user is modifying text in the middle of a defined span, and so therefore the adjusted text is rendered according to that span.

The biggest problem is that EditText alone has no mechanism to allow users to *change* formatting. Perhaps someday it will have options for that. In the meantime, though, RichEditText is designed to fill that gap.

[RichEditText is a CWAC project](#) that offers a reasonably convenient API for applying, toggling, or removing effects applied to the current selected text. You have your choice of creating your own UI for this (e.g., implementing a toolbar) or enabling an extension to the EditText action modes to allow the users to format the text.

More information on using RichEditText can be found on [the project site](#), and a future version of this chapter will go into details not only of its use, but also its construction, once the project has matured a little more.

Manually

Spannable offers two methods for modifying its formatting: `setSpan()` to apply formatting, and `removeSpan()` to get rid of an existing span. And, since Spannable extends Spanned, a Spannable also has `getSpans()`, to return existing spans of a current type within a certain range of characters in the text. These methods, along with others on Spanned, allow you to get and set whatever formatting you wish to apply on a Spannable object, such as a SpannableString.

For example, let’s take a look at the [RichText/Search](#) sample project. Here, we are going to load some text into a TextView, then allow the user to enter a search string in an EditText, and we will use the Spannable methods to highlight the search string occurrences inside the text in the TextView.

Our layout is simply an EditText atop a TextView (wrapped in a ScrollView):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/search"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:singleLine="true">

        <requestFocus/>
    </EditText>

    <ScrollView
        android:id="@+id/scroll"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <TextView
            android:id="@+id/prose"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/address"
            android:textAppearance="?android:attr/textAppearanceMedium"/>
    </ScrollView>
</LinearLayout>
```

We pre-fill the `TextView` with a string resource (`@string/address`), which in this project is the text of Lincoln's Gettysburg Address, with a bit of inline markup (e.g., "Four score and seven years ago" italicized). So, when we fire up the project at the outset, we see the formatted prose from the string resource:

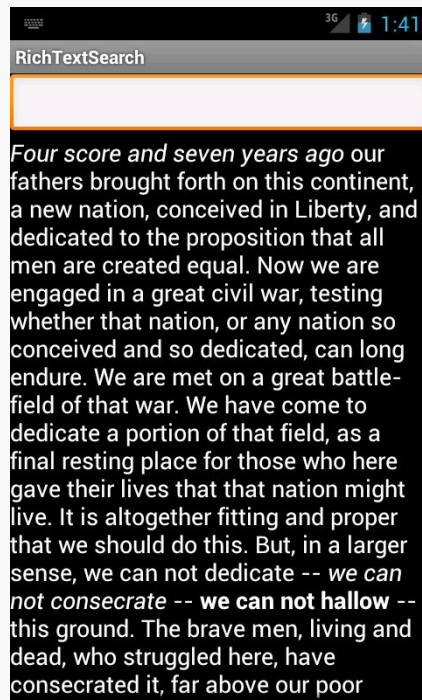

Figure 422: The RichTextSearch sample, as initially launched

In `onCreate()` of our activity, we find the `EditText` widget and designate the activity itself as being an `OnEditorActionListener` for the `EditText`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    search=(EditText)findViewById(R.id.search);
    search.setOnEditorActionListener(this);
}
```

That means when the user presses <Enter>, we will get control in an `onEditorAction()` method. There, we pass the search text to a private `searchFor()` method, plus ensure that the input method editor is hidden (if one was used to fill in the search text):

```
@Override
public boolean onEditorAction(TextView v, int actionId, KeyEvent event) {
    if (event == null || event.getAction() == KeyEvent.ACTION_UP) {
        searchFor(search.getText().toString());

        InputMethodManager imm=
            (InputMethodManager)getSystemService(INPUT_METHOD_SERVICE);
```

```
        imm.hideSoftInputFromWindow(v.getWindowToken(), 0);
    }

    return(true);
}
```

The `searchFor()` method is where the formatting is applied to our search text:

```
private void searchFor(String text) {
    TextView prose=(TextView)findViewById(R.id.prose);
    Spannable raw=new SpannableString(prose.getText());
    BackgroundColorSpan[] spans=raw.getSpans(0,
                                           raw.length(),
                                           BackgroundColorSpan.class);

    for (BackgroundColorSpan span : spans) {
        raw.removeSpan(span);
    }

    int index=TextUtils.indexOf(raw, text);

    while (index >= 0) {
        raw.setSpan(new BackgroundColorSpan(0xFF8B008B), index, index
            + text.length(), Spanned.SPAN_EXCLUSIVE_EXCLUSIVE);
        index=TextUtils.indexOf(raw, text, index + text.length());
    }

    prose.setText(raw);
}
```

First, we get a `Spannable` object out of the `TextView`. While an `EditText` returns an `Editable` from `getText()`, `getText()` on a `TextView` returns a `CharSequence`. In particular, the first time we execute `searchFor()`, `getText()` will return a `SpannedString`, as that is what a string resource turns into. However, that is not modifiable, so we convert it into a `SpannableString` so we can apply formatting to it. An optimization would be to see if `getText()` returns something implementing `Spannable` and then just using it directly.

We want to highlight the search terms using a `BackgroundColorSpan`. However, that means we first need to get rid of any existing `BackgroundColorSpan` objects applied to the prose from a previous search — otherwise, we would keep highlighting more and more of the prose. So, we use `getSpans()` to find all `BackgroundColorSpan` objects anywhere in the prose (from index 0 through the length of the text). For each that we find, we call `removeSpan()` to get rid of it from our `Spannable`.

Then, we use `indexOf()` on `TextUtils` to find the first occurrence of whatever the user typed into the `EditText`. If we find it, we create a new `BackgroundColorSpan`

and apply it to the matching portion of the prose using `setSpan()`. The last parameter to `setSpan()` is a flag, indicating what should happen if text is inserted at either the starting or ending point. In our case, the text itself is remaining constant, so the flag does not matter much – here, we use `SPAN_EXCLUSIVE_EXCLUSIVE`, which would mean that the span would not cover any text inserted at the starting or ending point of the span.

We then continue using `indexOf()` to find any remaining occurrences of the search text. Once we are done modifying our `Spannable`, we put it into the `TextView` via `setText()`.

The result is that all matching substrings are highlighted in a purple/magenta shade:

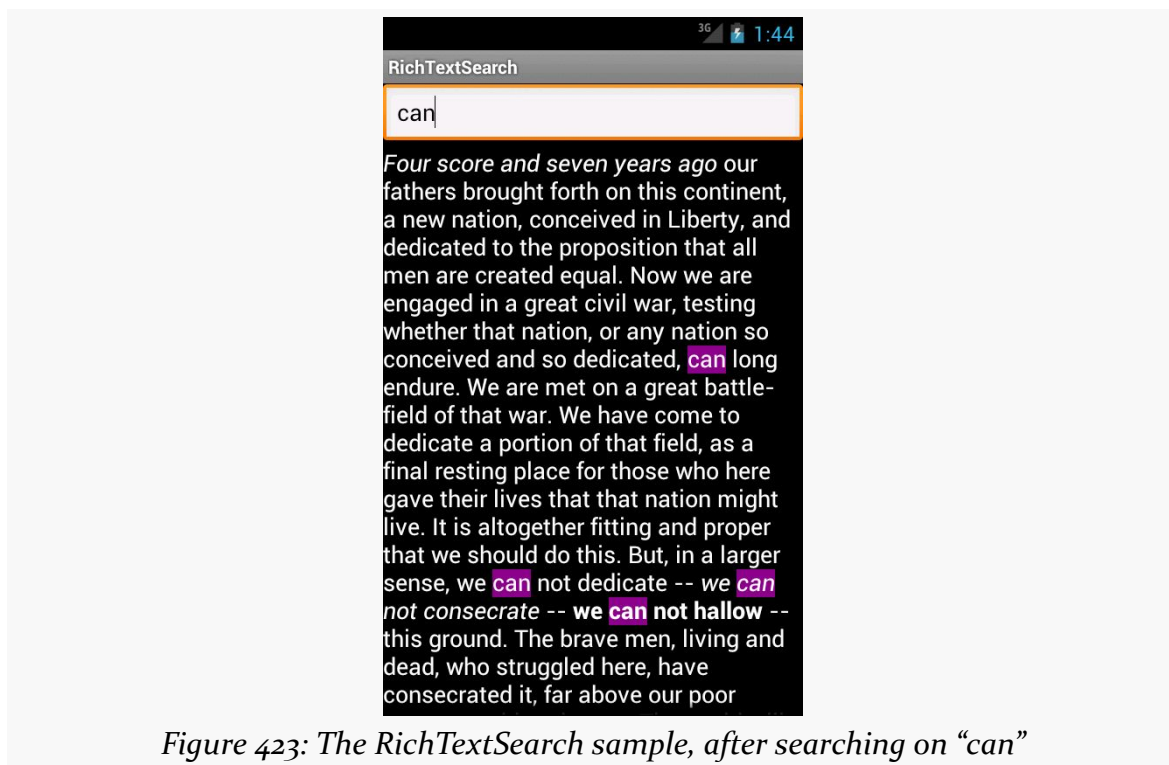

Figure 423: The `RichTextSearch` sample, after searching on “can”

Saving Rich Text

`SpannableString` and `SpannedString` are not `Serializable`. There is no built-in way to persist them directly.

However, `Html.toHtml()` will convert a `Spanned` object into corresponding HTML, for all `CharacterStyle` objects that can be readily converted into HTML. You can then persist the resulting HTML any place you would persist a `String` (e.g., database column).

In principle, you could create other similar conversion code, such as something to take a `Spanned` and return the corresponding Markdown source.

Manipulating Rich Text

The `TextUtils` class has many utility methods that manipulate a `CharSequence`, to allow you to do things that you might ordinarily have done just with methods on `String`. These utility methods will work with any `CharSequence`, including `SpannedString` and `SpannableString`.

Some are specifically aimed at `Spanned` objects, such as `copySpansFrom()` (to apply formatting from one `CharSequence` onto another). Some are clones of `String` equivalents, such as `split()`, `join()`, and `substring()`. Yet others are designed for developers using the Canvas 2D drawing API, such as `ellipsize()` and `commaEllipsize()` for intelligently truncating messages.

Animators

Users like things that move. Or fade, spin, or otherwise offer a dynamic experience.

Much of the time, such animations are handled for us by the framework. We do not have to worry about sliding rows in a `ListView` when the user scrolls, or as the user pans around a `ViewPager`, and so forth.

However, sometimes, we will need to add our own animations, where we want effects that either are not provided by the framework innately or are simply different (e.g., want something to slide off the bottom of the screen, rather than off the left edge).

Android had an [animation framework](#) back in the beginning, one that is still available for you today. However, Android 3.0 introduced a new *animator* framework that is going to be Android's primary focus for animated effects going forward. Many, but not all, of the animator framework capabilities are available to us as developers via a backport.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on [custom views](#), to be able to make sense of one of the samples.

ViewPropertyAnimator

Let's say that you want to fade out a widget, instead of simply setting its visibility to `INVISIBLE` or `GONE`.

For a widget whose name is `v`, on API Level 11 or higher, that is as simple as:

```
v.animate().alpha(0);
```

Here, “alpha” refers to the “alpha channel”. An alpha of 1 is normal opacity, while an alpha of 0 is completely transparent, with values in between representing various levels of translucence.

That may seem rather simple. The good news is, it *really* is that easy. Of course, there is a lot more you can do here, and you might have to worry about supporting older Android versions, and we need to think about things other than fading widgets in and out, and so forth.

First, though, let’s consider what is really going on when we call `animate()` on a widget on API Level 11+.

Native Implementation

The call to `animate()` returns an instance of `ViewPropertyAnimator`. This object allows us to build up a description of an animation to be performed, such as calling `alpha()` to change the alpha channel value. `ViewPropertyAnimator` uses a so-called [fluent interface](#), much like the various builder classes (e.g., `Notification.Builder`) — calling a method on a `ViewPropertyAnimator()` usually returns the `ViewPropertyAnimator` itself. This allows you to build up an animation via a chained series of method calls, starting with that call to `animate()` on the widget.

You will note that we do not end the chain of method calls with something like a `start()` method. `ViewPropertyAnimator` will automatically arrange to start the animation once we return control of the main application thread back to the framework. Hence, we do not have to explicitly start the animation.

You will also notice that we did not indicate any particulars about how the animation should be accomplished, beyond stating the ending alpha channel value of 0. `ViewPropertyAnimator` will use some standard defaults for the animation, such as a default duration, to determine how quickly Android changes the alpha value from its starting point to 0. Most of those particulars can be overridden from their defaults via additional methods called on our `ViewPropertyAnimator`, such as `setDuration()` to provide a duration in milliseconds.

There are four standard animations that `ViewPropertyAnimator` can perform:

ANIMATORS

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

We will see an example of changing a widget's position, using the `translationXBy()` method, [later in this chapter](#).

You are welcome to use more than one animation effect simultaneously, such as using both `alpha()` and `translationXBy()` to slide a widget horizontally and have it fade in or out.

There are other aspects of the animation that you can control. By default, the animation happens linearly — if we are sliding 500 pixels in 500ms, the widget will move evenly at 1 pixel/ms. However, you can specify a different “interpolator” to override that default linear behavior (e.g., start slow and accelerate as the animation proceeds). You can attach a listener object to find out about when the animation starts and ends. And, you can specify `withLayer()` to indicate that Android should try to more aggressively use hardware acceleration for an animation, a concept that we will get into in greater detail [later in this chapter](#).

To see this in action, take a look at the [Animation/AnimatorFade](#) sample app.

The app consists of a single activity (MainActivity). It uses a layout that is dominated by a single TextView widget, whose ID is `fadee`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/fadee"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:text="@string/fading_out"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>

</RelativeLayout>
```

ANIMATORS

In `onCreate()`, we load up the layout and get our hands on the `fadee` widget:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    fadee=(TextView)findViewById(R.id.fadee);
}
```

`MainActivity` itself implements `Runnable`, and our `run()` method will perform some animated effects:

```
@Override
public void run() {
    if (fadingOut) {
        fadee.animate().alpha(0).setDuration(PERIOD);
        fadee.setText(R.string.fading_out);
    }
    else {
        fadee.animate().alpha(1).setDuration(PERIOD);
        fadee.setText(R.string.coming_back);
    }

    fadingOut=!fadingOut;

    fadee.postDelayed(this, PERIOD);
}
```

Specifically, if we are to fade out the `TextView` (as we are at the outset, we use `ViewPropertyAnimator` to fade out the widget over a certain period (`fadee.animate().alpha(0).setDuration(PERIOD);`) and set the caption of the `TextView` to a value indicating that we are fading out. If we are to be fading back in, we perform the opposite animation and set the caption to a different value. We then flip the `fadingOut` boolean for the next pass and use `postDelayed()` to reschedule ourselves to run after the period has elapsed.

To complete the process, we run() our code initially in `onResume()` and cancel the `postDelayed()` loop in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    run();
}

@Override
public void onPause() {
```

```
fadee.removeCallbacks(this);  
  
super.onPause();  
}
```

The result is that the TextView smoothly fades out and in, alternating captions as it goes.

However, it would be really unpleasant if all this animator goodness worked only on API Level 11+. Fortunately for us, somebody wrote a backport... somebody with whom you are already familiar.

Backport Via NineOldAndroids

Jake Wharton, author of ActionBarSherlock, ViewPagerIndicator, and other libraries, also wrote [NineOldAndroids](#). This is, in effect, a backport of ViewPropertyAnimator and its underpinnings. There are some slight changes in how you use it, because NineOldAndroids is simply a library. It cannot add methods to existing classes (like adding `animate()` to `View`), nor can it add capabilities that the underlying firmware simply lacks. But, it may cover many of your animator needs, even if the name is somewhat inexplicable, and it works going all the way back to API Level 1, ensuring that it will cover any Android release that you care about.

As with ActionBarSherlock, NineOldAndroids is an Android library project.

Eclipse users will need to download that project (look in the `library/` directory of the ZIP archive) and import the project. Android Studio users can add a compile statement to their dependencies closure in `build.gradle` to pull in `com.nineoldandroids:library:...` (for some version indicated by ...) from `mavenCentral()`.

Since NineOldAndroids cannot add `animate()` to `View`, the recommended approach is to use a somewhat obscure feature of Java: imported static methods. An `import static` statement, referencing a particular static method of a class, makes that method available as if it were a static method on the class that you are writing, or as some sort of global function. NineOldAndroids has an `animate()` method that you can import this way, so instead of `v.animate()`, you use `animate(v)` to accomplish the same end. Everything else is the same, except perhaps some imports, to reference NineOldAndroids instead of the native classes.

You can see this in the [Animation/AnimatorFadeBC](#) sample app.

In addition to having the NineOldAndroids JAR in `libs/`, the only difference between this edition and the previous sample is in how the animation is set up. Instead of lines like:

```
fadee.animate().alpha(0).setDuration(PERIOD);
```

we have:

```
animate(fadee).alpha(0).setDuration(PERIOD);
```

This takes advantage of our static import:

```
import static com.nineoldandroids.view.ViewPropertyAnimator.animate;
```

If the static import makes you queasy, you are welcome to simply import the `com.nineoldandroids.view.ViewPropertyAnimator` class, rather than the static method, and call the `animate()` method on `ViewPropertyAnimator`:

```
ViewPropertyAnimator.animate(fadee).alpha(0).setDuration(PERIOD);
```

The Foundation: Value and Object Animators

`ViewPropertyAnimator` itself is a layer atop of a more primitive set of animators, known as value and object animators.

A `ValueAnimator` handles the core logic of transitioning some value, from an old to a new value, over a period of time. `ValueAnimator` offers replaceable “interpolators”, which will determine how the values change from start to finish over the animation period (e.g., start slowly, accelerate, then end slowly). `ValueAnimator` also handles the concept of a “repeat mode”, to indicate if the animation should simply happen once, a fixed number of times, or should infinitely repeat (and, in the latter cases, whether it does so always transitioning from start to finish or if it reverses direction on alternate passes, going from finish back to start).

What `ValueAnimator` does *not* do is actually change anything. It is merely computing the different values based on time. You can call `getAnimatedValue()` to find out the value at any point in time, or you can call `addUpdateListener()` to register a listener object that will be notified of each change in the value, so that change can be applied somewhere.

Hence, what tends to be a bit more popular is `ObjectAnimator`, a subclass of `ValueAnimator` that automatically applies the new values. `ObjectAnimator` does this

by calling a setter method on some object, where you supply the object and the “property name” used to derive the getter and setter method names. For example, if you request a property name of `foo`, `ObjectAnimator` will try to call `getFoo()` and `setFoo()` methods on your supplied object.

As with `ViewPropertyAnimator`, `ValueAnimator` and `ObjectAnimator` are implemented natively in API Level 11 and are available via the `NineOldAndroids` backport as well.

To see what `ObjectAnimator` looks like in practice, let us examine the [Animation/ObjectAnimator](#) sample app.

Once again, our activity’s layout is pretty much just a centered `TextView`, here named `word`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/word"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>

</RelativeLayout>
```

The objective of our activity is to iterate through 25 words, showing one at a time in the `TextView`:

```
package com.commonware.android animator.obj;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
import com.nineoldandroids.animation.ObjectAnimator;
import com.nineoldandroids.animation.ValueAnimator;

public class MainActivity extends Activity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
}
```

```
private TextView word=null;
int position=0;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    word=(TextView)findViewById(R.id.word);

    ValueAnimator positionAnim = ObjectAnimator.ofInt(this, "wordPosition", 0,
24);
    positionAnim.setDuration(12500);
    positionAnim.setRepeatCount(ValueAnimator.INFINITE);
    positionAnim.setRepeatMode(ValueAnimator.RESTART);
    positionAnim.start();
}

public void setWordPosition(int position) {
    this.position=position;
    word.setText(items[position]);
}

public int getWordPosition() {
    return(position);
}
}
```

To accomplish this, we use NineOldAndroids version of `ObjectAnimator`, saying that we wish to “animate” the `wordPosition` property of the activity itself, from 0 to 24. We configure the animation to run for 12.5 seconds (i.e., 500ms per word) and to repeat indefinitely by restarting the animation from the beginning on each pass. We then call `start()` to kick off the animation.

For this to work, though, we need `getWordPosition()` and `setWordPosition()` accessor methods for the theoretical `wordPosition` property. In our case, the “word position” is simply an integer data member of the activity, which we return in `getWordPosition()` and update in `setWordPosition()`. However, we also update the `TextView` in `setWordPosition()`, to display the word at that position.

The net effect is that words appear in our `TextView`, changing on average every 500ms.

Animating Custom Types

In the previous section, we animated an `int` property of an `Activity`. That works, because Android knows how to compute `int` values between the start and end position, through simple math.

But, what if we wanted to animate something that is not a simple number? For example, what if we want to animate a `Color`, or a `LatLng` from [Maps V2](#), or a `TastyTreat` class of our own design?

So long as we can perform the calculations, we can animate a type of anything we want, using `TypeEvaluator` and `ofObject()` on `ObjectAnimator`.

A `TypeEvaluator` is a simple interface, containing a single method that we need to override: `evaluate()`. However, `TypeEvaluator` uses generics, and so our implementation will actually be of some concrete class (e.g., a `TypeEvaluator` of `TastyTreat`). Our job in `evaluate()` is to return a value of our designated type (e.g., `TastyTreat`) given three inputs:

1. The initial value for our animation range, in the form of our designated type
2. The end value for our animation range, in the form of our designated type
3. The fraction along that range that represents how much we have moved from the initial value to the end value

Note that the fraction is not limited to being between 0 and 1, as certain interpolators (e.g., an overshoot interpolator) might result in a fraction being negative (e.g., we overshoot past the initial value) or greater than one (e.g., we overshoot past the end value).

For example, to have a `TypeEvaluator` of `Color`, we might have `evaluate()` generate a new `Color` instance based upon applying the fraction to the initial and end red, green, blue, and alpha channels.

To use a `TypeEvaluator`, instead of `ofInt()`, `ofFloat()`, or similar simple factory methods on `ObjectAnimator`, we use `ofObject()`. `ofObject()` takes the object to be animated, the property to be animated, the `TypeEvaluator` to assist in the actual animation, and the final value of the animation (or, optionally, a series of waypoints to be animated along).

A flavor of `ofObject()` that takes the property name — akin to the `wordPosition` of `Int()` used in the previous section — has been around since API Level 11. API Level 14 added an `ofObject()` method that takes a `Property` value instead of the name of the property. This version has the added benefit of type-safety, as it can ensure that your object to be animated, `TypeEvaluator`, and final position are all of the same type.

You can see an example of using `TypeEvaluator` this way in [the chapter on Maps V2](#), as we animate the movement of a map marker from a starting point to an ending point.

Hardware Acceleration

Animated effects operate much more smoothly with hardware acceleration. There are two facets to employing hardware acceleration for animations: enabling it overall and directing its use for the animations themselves.

Hardware acceleration is enabled overall on Android devices running Android 4.0 or higher (API Level 14). On Android 3.x, hardware acceleration is available but is disabled by default — use `android:hardwareAccelerated="true"` in your `<application>` or `<activity>` element in the manifest to enable it on those versions. Hardware acceleration for 2D graphics operations like widget animations is not available on older versions of Android.

While this will provide some benefit across the board, you may also wish to consider rendering animated widgets or containers in an off-screen buffer, or “hardware layer”, that then gets applied to the screen via the GPU. In particular, the GPU can apply certain animated transformations to a hardware layer without forcing software to redraw the widgets or containers (e.g., what happens when you `invalidate()` them). As it turns out, these GPU-enhanced transformations match the ones supported by `ViewPropertyAnimator`:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget’s rotation, around any of the three axes
4. Changes in the widget’s size, where Android can scale the widget by some percentage to expand or shrink it

By having the widget be rendered in a hardware layer, these `ViewPropertyAnimator` operations are significantly more efficient than before.

However, since hardware layers take up video memory, generally you do not want to keep a widget or container in a hardware layer indefinitely. Instead, the recommended approach is to have the widget or container be rendered in a hardware layer only while the animation is ongoing, by calling `setLayerType()` for `LAYER_TYPE_HARDWARE` before the animation begins, then calling `setLayerType()` for `LAYER_TYPE_NONE` (i.e., return to default behavior) when the animation completes. Or, for `ViewPropertyAnimator` on API Level 16 and higher, use `withLayer()` in the fluent interface to have it apply the hardware layer automatically just for the animation duration.

We will see examples of using hardware acceleration this way in the next section.

The Three-Fragment Problem

If you have used an Android tablet, there is a decent chance that you have used the Gmail app on that tablet. Gmail organizes its landscape main activity into two panes, one on the left taking up ~30% of the screen, and one on the right taking up the remainder:

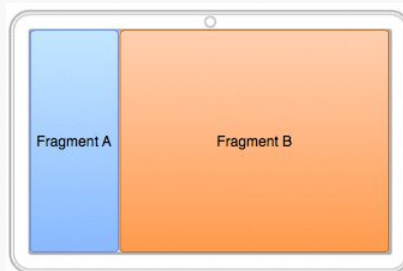

Figure 424: Gmail Fragments (image courtesy of Google and AOSP)

Gmail has a very specific navigation mode in its main activity when viewed in landscape on a tablet, where upon some UI event (e.g., tapping on something in the right-hand area):

- The original left-hand fragment (Fragment A) slides off the screen to the left
- The original right-hand fragment (Fragment B) slides to the left edge of the screen and shrinks to take up the spot vacated by Fragment A

- Another fragment (Fragment C) slides in from the right side of the screen and takes up the spot vacated by Fragment B

And a BACK button press reverses this operation.

This is a bit tricky to set up, leading to the author of this book posting [a question on Stack Overflow to get input](#). Here, we will examine one of the results of that discussion, based in large part on the implementation of the AOSP Email app, which has a similar navigation flow. The other answers on that question may have merit in other scenarios as well.

You can see one approach for implementing the three-pane solution in the [Animation/ThreePane](#) sample app.

The ThreePaneLayout

The logic to handle the animated effects is encapsulated in a ThreePaneLayout class. It is designed to be used in a layout XML resource where you supply the contents of the three panes, sizing the first two as you want, with the third “pane” having zero width at the outset:

```
<com.commonware.android.anim.threepane.ThreePaneLayout
xmlns:android="http://schemas.android.com/apk/res/android"
xmlns:tools="http://schemas.android.com/tools"
android:id="@+id/root"
android:layout_width="match_parent"
android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/left"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="3"/>

  <FrameLayout
    android:id="@+id/middle"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="7"/>

  <Button
    android:layout_width="0dp"
    android:layout_height="match_parent"/>

</com.commonware.android.anim.threepane.ThreePaneLayout>
```

ThreePanelLayout itself is a subclass of LinearLayout, set up to always be horizontal, regardless of what might be set in the layout XML resource.

```
public ThreePanelLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    initSelf();
}

void initSelf() {
    setOrientation(HORIZONTAL);
}
```

When the layout finishes inflating, we grab the three panes (defined as the first three children of the container) and stash them in data members named left, middle, and right, with matching getter methods:

```
@Override
public void onFinishInflate() {
    super.onFinishInflate();

    left=getChildAt(0);
    middle=getChildAt(1);
    right=getChildAt(2);
}

public View getLeftView() {
    return(left);
}

public View getMiddleView() {
    return(middle);
}

public View getRightView() {
    return(right);
}
```

The major operational API, from the standpoint of an activity using ThreePanelLayout, is hideLeft() and showLeft(). hideLeft() will switch from showing the left and middle widgets in their original size and position to showing the middle and right widgets wherever left and middle had been originally. showLeft() reverses the operation.

The problem is that, initially, we do not know where the widgets are or how big they are, as that should be able to be set from the layout XML resource and are not known until the ThreePanelLayout is actually applied to the screen. Hence, we lazy-retrieve those values in hideLeft(), plus remove any weights that had been originally defined, setting the actual pixel widths on the widgets instead:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", middleWidthNormal,
                        leftWidth).setDuration(ANIM_DURATION).start();
}
```

The work to change the weights into widths is handled in `resetWidget()`:

```
private void resetWidget(View v, int width) {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)v.getLayoutParams();

    p.width=width;
    p.weight=0;
}
```

After the lazy-initialization and widget cleanup, we perform the two animations. `translateWidgets()` will slide each of our three widgets to the left by the width of the left widget, using a `ViewPropertyAnimator` and a hardware layer:

```
private void translateWidgets(int deltaX, View... views) {
    for (final View v : views) {
        v.setLayerType(View.LAYER_TYPE_HARDWARE, null);

        v.animate().translationXBy(deltaX).setDuration(ANIM_DURATION)
            .setListener(new AnimatorListenerAdapter() {
                @Override
                public void onAnimationEnd(Animator animation) {
                    v.setLayerType(View.LAYER_TYPE_NONE, null);
                }
            });
    }
}
```

The resize animation — to set the middle size to be what left had been – is handled via an `ObjectAnimator`, for a theoretical property of `middleWidth` on `ThreePaneLayout`. That is backed by a `setMiddleWidth()` method that adjusts the width property of the middle widget's `LayoutParams` and triggers a redraw:

```
@SuppressWarnings("unused")
private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
```

The `showLeft()` method simply performs those two animations in reverse:

```
public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", leftWidth,
                        middleWidthNormal).setDuration(ANIM_DURATION)
                .start();
}
```

Using the ThreePaneLayout

The sample app uses one activity (`MainActivity`) and one fragment (`SimpleListFragment`) to set up and use the `ThreePaneLayout`. The objective is a UI that roughly mirrors that of Gmail and the AOSP Email app: a list on the left, a list in the middle (whose contents are based on the item chosen in the left list), and something else on the right (whose contents are based on the item chosen in the middle list).

`SimpleListFragment` is used for both lists. Its `newInstance()` factory method is handed the list of strings to display. `SimpleListFragment` just loads those into its `ListView`, also setting up `CHOICE_MODE_SINGLE` for use with the activated style, and routing all clicks on the list to the `MainActivity` that hosts the fragment:

```
package com.commonware.android.anim.threepane;

import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ListView;
import java.util.ArrayList;
import java.util.Arrays;

public class SimpleListFragment extends ListFragment {
    private static final String KEY_CONTENTS="contents";

    public static SimpleListFragment newInstance(String[] contents) {
        return(new SimpleListFragment(new ArrayList<String>(Arrays.asList(contents))));
    }

    public static SimpleListFragment newInstance(ArrayList<String> contents) {
```

```
SimpleListFragment result=new SimpleListFragment();
Bundle args=new Bundle();

args.putStringArrayList(KEY_CONTENTS, contents);
result.setArguments(args);

return(result);
}

@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    setContents(getArguments().getStringArrayList(KEY_CONTENTS));
}

@Override
public void onItemClick(ListView l, View v, int position, long id) {
    ((MainActivity) getActivity()).onItemClick(this, position);
}

void setContents(ArrayList<String> contents) {
    setListAdapter(new ArrayAdapter<String>(
        getActivity(),
        R.layout.simple_list_item_1,
        contents));
}
}
```

MainActivity populates the left FrameLayout with a SimpleListFragment in onCreate(), if the fragment does not already exist (e.g., from a configuration change). When an item in the left list is clicked, MainActivity populates the middle FrameLayout. When an item in the middle list is clicked, it sets the caption of the right Button and uses hideLeft() to animate that Button onto the screen, hiding the left list. If the user presses BACK, and our left list is not showing, MainActivity calls showLeft() to reverse the animation:

```
package com.commonware.android.anim.threepane;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;
import java.util.ArrayList;

public class MainActivity extends Activity {
    private static final String KEY_MIDDLE_CONTENTS="middleContents";
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
```

```
        "pellentesque", "augue", "purus" };
private boolean isLeftShowing=true;
private SimpleListFragment middleFragment=null;
private ArrayList<String> middleContents=null;
private ThreePanelLayout root=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    root=(ThreePanelLayout)findViewById(R.id.root);

    if (getFragmentManager().findFragmentById(R.id.left) == null) {
        getFragmentManager().beginTransaction()
            .add(R.id.left,
                SimpleListFragment.newInstance(items))
            .commit();
    }

    middleFragment=
        (SimpleListFragment)getFragmentManager().findFragmentById(R.id.middle);
}

@Override
public void onBackPressed() {
    if (!isLeftShowing) {
        root.showLeft();
        isLeftShowing=true;
    }
    else {
        super.onBackPressed();
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putStringArrayList(KEY_MIDDLE_CONTENTS, middleContents);
}

@Override
protected void onRestoreInstanceState(Bundle inState) {
    middleContents=inState.getStringArrayList(KEY_MIDDLE_CONTENTS);
}

void onListItemClick(SimpleListFragment fragment, int position) {
    if (fragment == middleFragment) {
        ((Button)root.getRightView()).setText(middleContents.get(position));

        if (isLeftShowing) {
            root.hideLeft();
            isLeftShowing=false;
        }
    }
}
```

```
    }  
  }  
  else {  
    middleContents=new ArrayList<String>();  
  
    for (int i=0; i < 20; i++) {  
      middleContents.add(items[position] + " #" + i);  
    }  
  
    if (getFragmentManager().findFragmentById(R.id.middle) == null) {  
      middleFragment=SimpleListFragment.newInstance(middleContents);  
      getFragmentManager().beginTransaction()  
          .add(R.id.middle, middleFragment).commit();  
    }  
    else {  
      middleFragment.setContents(middleContents);  
    }  
  }  
}  
}
```

The Results

If you run this app on a landscape tablet running API Level 11 or higher, you start off with a single list of words on the left:

ANIMATORS

Clicking on a word brings up a second list, taking up the rest of the screen, with numbered entries based upon the clicked-upon word:

Figure 426: ThreePane, After Clicking a Word

Clicking on an entry in the second list starts the animation, sliding the first list off to the left, sliding the second list into the space vacated by the first list, and sliding in a “detail view” into the right portion of the screen:

Figure 427: ThreePane, After Clicking a Numbered Word

Pressing BACK once will reverse the animation, restoring you to the two-list perspective.

The Backport

The ThreePane sample described above uses the native API Level 11 version of the animator framework and the native implementation of fragments. However, the same approach can work using the Android Support package's version of fragments and NineOldAndroids. You can see this in the [Animation/ThreePaneBC](#) sample app.

Besides changing the import statements and adding the NineOldAndroids JAR file, the only other changes of substance were:

- Using `ViewPropertyAnimator.animate(v)` instead of `v.animate()` in `translateWidgets()`
- Conditionally setting the hardware acceleration layers via `setLayerType()` in `translateWidgets()` based upon API level, as that method was only added in API Level 11

The smoothness of animations, though, will vary by hardware capabilities. For example, on a first-generation Kindle Fire, running Android 2.3, the backport works but is not especially smooth, while the animations are very smooth on more modern hardware where hardware acceleration can be applied.

The Problems

As we will see in [the chapter on “jank”](#), there is some stutter in the rendering of this app. Fixing it requires removing the animated change in the width of the middle pane, which in turn makes the animation itself look worse. More details on the analysis can be found in [the “jank” chapter](#).

Legacy Animations

Before `ViewPropertyAnimator` and the rest of [the animator framework](#) were added in API Level 11, we had the original `Animation` base class and specialized animations based upon it, like `TranslateAnimation` for movement and `AlphaAnimation` for fades. On the whole, you will want to try to use the animator framework where possible, as the new system is more powerful and efficient than the legacy `Animation` approach. However, particularly for apps where the `NineOldAndroids` backport is insufficient, you may wish to use the legacy framework.

After an overview of the role of the [animation](#) framework, we go in-depth to animate the [movement](#) of a widget across the screen. We then look at [alpha animations](#), for fading widgets in and out. We then see how you can get control during the [lifecycle](#) of an animation, how to control the [acceleration](#) of animations, and how to [group](#) animations together for parallel execution. Finally, we see how the same framework can now be used to control the animation for the switching of [activities](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#) and [basic widgets](#). Also, you should read the chapter on [custom views](#).

It's Not Just For Toons Anymore

Android has a package of classes (`android.view.animation`) dedicated to animating the movement and behavior of widgets.

They center around an `Animation` base class that describes what is to be done. Built-in animations exist to move a widget (`TranslateAnimation`), change the transparency of a widget (`AlphaAnimation`), revolve a widget (`RotateAnimation`), and resize a widget (`ScaleAnimation`). There is even a way to aggregate animations together into a composite `Animation` called an `AnimationSet`. Later sections in this chapter will examine the use of several of these animations.

Given that you have an animation, to apply it, you have two main options:

1. You may be using a container that supports animating its contents, such as a `ViewFlipper` or `TextSwitcher`. These are typically subclasses of `ViewAnimator` and let you define the “in” and “out” animations to apply. For example, with a `ViewFlipper`, you can specify how it flips between `Views` in terms of what animation is used to animate “out” the currently-visible `View` and what animation is used to animate “in” the replacement `View`.
2. You can simply tell any `View` to `startAnimation()`, given the `Animation` to apply to itself. This is the technique we will be seeing used in the examples in this chapter.

A Quirky Translation

`Animation` takes some getting used to. Frequently, it takes a fair bit of experimentation to get it all working as you wish. This is particularly true of `TranslateAnimation`, as not everything about it is intuitive, even to authors of Android books.

Mechanics of Translation

The simple constructor for `TranslateAnimation` takes four parameters describing how the widget should move: the before and after `X` offsets from the current position, and the before and after `Y` offsets from the current position. The Android documentation refers to these as `fromXDelta`, `toXDelta`, `fromYDelta`, and `toYDelta`.

In Android’s pixel-space, an (X, Y) coordinate of $(0, 0)$ represents the upper-left corner of the screen. Hence, if `toXDelta` is greater than `fromXDelta`, the widget will move to the right, if `toYDelta` is greater than `fromYDelta`, the widget will move down, and so on.

Imagining a Sliding Panel

Some Android applications employ a sliding panel, one that is off-screen most of the time but can be called up by the user (e.g., via a menu) when desired. When anchored at the bottom of the screen, you get a container that slides up from the bottom and slides down and out when being removed.

One way to implement such a panel is to have a container (e.g., a `LinearLayout`) whose contents are absent (`INVISIBLE`) when the panel is closed and is present (`VISIBLE`) when the drawer is open. If we simply toggled `setVisibility()` using the aforementioned values, though, the panel would wink open and closed immediately, without any sort of animation. So, instead, we want to:

1. Make the panel visible and animate it up from the bottom of the screen when we open the panel
2. Animate it down to the bottom of the screen and make the panel invisible when we close the panel

The Aftermath

This brings up a key point with respect to `TranslateAnimation`: the animation temporarily moves the widget, but if you want the widget to stay where it is when the animation is over, you have to handle that yourself. Otherwise, the widget will snap back to its original position when the animation completes.

In the case of the panel opening, we handle that via the transition from `INVISIBLE` to `VISIBLE`. Technically speaking, the panel is always “open”, in that we are not, in the end, changing its position. But when the body of the panel is `INVISIBLE`, it takes up no space on the screen; when we make it `VISIBLE`, it takes up whatever space it is supposed to.

Later in this chapter, we will cover how to use animation listeners to accomplish this end for closing the panel.

Introducing `SlidingPanel`

With all that said, turn your attention to the [Animation/SlidingPanel](#) sample project and, in particular, the `SlidingPanel` class.

LEGACY ANIMATIONS

This class implements a layout that works as a panel, anchored to the bottom of the screen. A `toggle()` method can be called by the activity to hide or show the panel. The panel itself is a `LinearLayout`, so you can put whatever contents you want in there.

We use two flavors of `TranslateAnimation`, one for opening the panel and one for closing it.

Here is the opening animation:

```
anim=new TranslateAnimation(0.0f, 0.0f,  
                           getHeight(),  
                           0.0f);
```

Our `fromXDelta` and `toXDelta` are both 0, since we are not shifting the panel's position along the horizontal axis. Our `fromYDelta` is the panel's height according to its layout parameters (representing how big we want the panel to be), because we want the panel to start the animation at the bottom of the screen; our `toYDelta` is 0 because we want the panel to be at its “natural” open position at the end of the animation.

Conversely, here is the closing animation:

```
anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,  
                           getHeight());
```

It has the same basic structure, except the Y values are reversed, since we want the panel to start open and animate to a closed position.

The result is a container that can be closed:

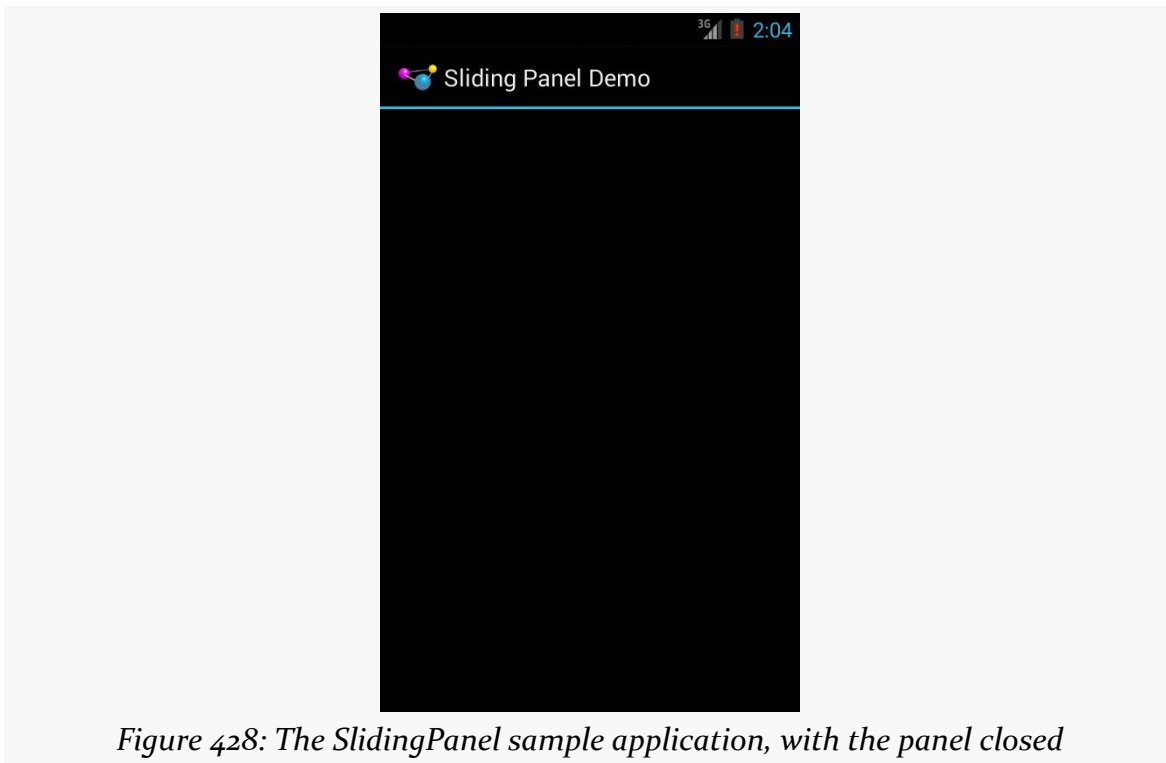

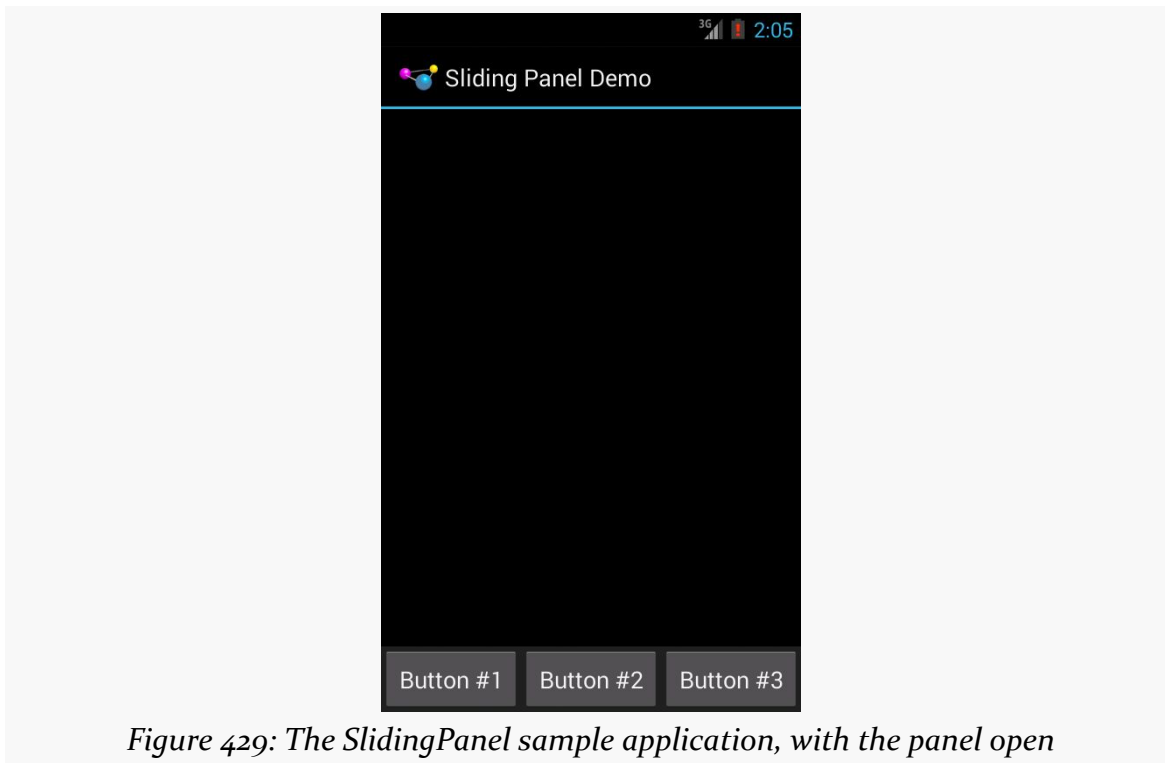

Figure 428: The SlidingPanel sample application, with the panel closed

... or open, in this case toggled via a menu choice in the SlidingPanelDemo activity:

Using the Animation

When setting up an animation, you also need to indicate how long the animation should take. This is done by calling `setDuration()` on the animation, providing the desired length of time in milliseconds.

When we are ready with the animation, we simply call `startAnimation()` on the `SlidingPanel` itself, causing it to move as specified by the `TranslateAnimation` instance.

Fading To Black. Or Some Other Color.

`AlphaAnimation` allows you to fade a widget in or out by making it less or more transparent. The greater the transparency, the more the widget appears to be “fading”.

Alpha Numbers

You may be used to alpha channels, when used in #AARRGGBB color notation, or perhaps when working with alpha-capable image formats like PNG.

Similarly, `AlphaAnimation` allows you to change the alpha channel for an entire widget, from fully-solid to fully-transparent.

In Android, a float value of 1.0 indicates a fully-solid widget, while a value of 0.0 indicates a fully-transparent widget. Values in between, of course, represent various amounts of transparency.

Hence, it is common for an `AlphaAnimation` to either start at 1.0 and smoothly change the alpha to 0.0 (a fade) or vice versa.

Animations in XML

With `TranslateAnimation`, we showed how to construct the animation in Java source code. One can also create animation resources, which define the animations using XML. This is similar to the process for defining layouts, albeit much simpler.

For example, there is a second animation project, [Animation/SlidingPanelEx](#), which demonstrates a panel that fades out as it is closed. In there, you will find a `res/anim/` directory, which is where animation resources should reside. In there, you will find `fade.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<alpha xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromAlpha="1.0"
    android:toAlpha="0.0" />
```

The name of the root element indicates the type of animation (in this case, alpha for an `AlphaAnimation`). The attributes specify the characteristics of the animation, in this case a fade from 1.0 to 0.0 on the alpha channel.

This XML is the same as calling `new AlphaAnimation(1.0f, 0.0f)` in Java.

Using XML Animations

To make use of XML-defined animations, you need to inflate them, much as you might inflate a `View` or `Menu` resource. This is accomplished by using the

`loadAnimation()` static method on the `AnimationUtils` class, seen here in our `SlidingPanel` constructor:

```
public SlidingPanel(final Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    TypedArray a=ctxt.obtainStyledAttributes(attrs,
                                              R.styleable.SlidingPanel,
                                              0, 0);

    speed=a.getInt(R.styleable.SlidingPanel_speed, 300);
    a.recycle();

    fadeOut=AnimationUtils.loadAnimation(ctxt, R.anim.fade);
}
```

Here, we are loading our fade animation, given a `Context`. This is being put into an `Animation` variable, so we neither know nor care that this particular XML that we are loading defines an `AlphaAnimation` instead of, say, a `RotateAnimation`.

When It's All Said And Done

Sometimes, you need to take action when an animation completes.

For example, when we close the panel, we want to use a `TranslationAnimation` to slide it down from the open position to closed... then *keep* it closed. With the system used in `SlidingPanel`, keeping the panel closed is a matter of calling `setVisibility()` on the contents with `INVISIBLE`.

However, you cannot do that when the animation begins; otherwise, the panel is gone by the time you try to animate its motion.

Instead, you need to arrange to have it become invisible when the animation ends. To do that, you use an animation listener.

An animation listener is simply an instance of the `AnimationListener` interface, provided to an animation via `setAnimationListener()`. The listener will be invoked when the animation starts, ends, or repeats (the latter courtesy of `CycleInterpolator`, discussed later in this chapter). You can put logic in the `onAnimationEnd()` callback in the listener to take action when the animation finishes.

For example, here is the `AnimationListener` for `SlidingPanel`:

```
Animation.AnimationListener collapseListener=new Animation.AnimationListener()
{
    public void onAnimationEnd(Animation animation) {
        setVisibility(View.INVISIBLE);
    }

    public void onAnimationRepeat(Animation animation) {
        // not needed
    }

    public void onAnimationStart(Animation animation) {
        // not needed
    }
};
```

All we do is set our content's visibility to be INVISIBLE, thereby closing the panel.

Loose Fill

You will see attributes, available on Animation, named `android:fillEnabled` and `android:fillAfter`. Reading those, you may think that you can dispense with the `AnimationListener` and just use those to arrange to have your widget wind up being “permanently” in the state represented by the end of the animation. All you would have to do is set each of those to true in your animation XML (or the equivalent in Java), and you would be set.

At least for `TranslateAnimation`, you would be mistaken.

It actually will look like it works — the animated widgets will be drawn in their new location. However, if those widgets are clickable, they will not be clicked in their new location, but rather in their old one. This, of course, is not terribly useful.

Hence, even though it is annoying, you will want to use the `AnimationListener` techniques described in this chapter.

Hit The Accelerator

In addition to the Animation classes themselves, Android also provides a set of `Interpolator` classes. These provide instructions for how an animation is supposed to behave during its operating period.

For example, the `AccelerateInterpolator` indicates that, during the duration of an animation, the rate of change of the animation should begin slowly and accelerate

until the end. When applied to a `TranslateAnimation`, for example, the sliding movement will start out slowly and pick up speed until the movement is complete.

There are several implementations of the `Interpolator` interface besides `AccelerateInterpolator`, including:

1. `AccelerateDecelerateInterpolator`, which starts slowly, picks up speed in the middle, and slows down again at the end
2. `DecelerateInterpolator`, which starts quickly and slows down towards the end
3. `LinearInterpolator`, the default, which indicates the animation should proceed smoothly from start to finish
4. `CycleInterpolator`, which repeats an animation for a number of cycles, following the `AccelerateDecelerateInterpolator` pattern (slow, then fast, then slow)

To apply an interpolator to an animation, simply call `setInterpolator()` on the animation with the `Interpolator` instance, such as the following line from `SlidingPanel`:

```
anim.setInterpolator(new AccelerateInterpolator(1.0f));
```

You can also specify one of the stock interpolators via the `android:interpolator` attribute in your animation XML file.

Animate. Set. Match.

For the `Animation/SlidingPanelEx` project, though, we want the panel to slide open, but also fade when it slides closed. This implies two animations working at the same time (a fade and a slide). Android supports this via the `AnimationSet` class.

An `AnimationSet` is itself an `Animation` implementation. Following the composite design pattern, it simply cascades the major `Animation` events to each of the animations in the set.

To create a set, just create an `AnimationSet` instance, add the animations, and configure the set. For example, here is the logic from the `SlidingPanel` implementation in `Animation/SlidingPanelEx`:

```
public void toggle() {  
    TranslateAnimation anim=null;
```

```
AnimationSet set=new AnimationSet(true);

isOpen=!isOpen;

if (isOpen) {
    setVisibility(View.VISIBLE);
    anim=new TranslateAnimation(0.0f, 0.0f,
                                getHeight(),
                                0.0f);
}
else {
    anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                getHeight());
    anim.setAnimationListener(collapseListener);
    set.addAnimation(fadeOut);
}

set.addAnimation(anim);
set.setDuration(speed);
set.setInterpolator(new AccelerateInterpolator(1.0f));
startAnimation(set);
}
```

If the panel is to be opened, we make the contents visible (so we can animate the motion upwards), and create a `TranslateAnimation` for the upward movement. If the panel is to be closed, we create a `TranslateAnimation` for the downward movement, but also add a pre-defined `AlphaAnimation` (`fadeOut`) to an `AnimationSet`. In either case, we add the `TranslateAnimation` to the set, give the set a duration and interpolator, and run the animation.

Active Animations

Starting with Android 1.5, users could indicate if they wanted to have inter-activity animations: a slide-in/slide-out effect as they switched from activity to activity. However, at that time, they could merely toggle this setting on or off, and applications had no control over these animations whatsoever.

Starting in Android 2.0, though, developers have a bit more control. Specifically:

1. Developers can call `overridePendingTransition()` on an Activity, typically after calling `startActivity()` to launch another activity or `finish()` to close up the current activity. The `overridePendingTransition()` indicates an in/out animation pair that should be applied as control passes from this activity to the next one, whether that one is being started (`startActivity()`) or is the one previous on the stack (`finish()`).

LEGACY ANIMATIONS

2. Developers can start an activity via an Intent containing the `FLAG_ACTIVITY_NO_ANIMATION` flag. As the name suggests, this flag requests that animations on the transitions involving this activity be suppressed.

These are prioritized as follows:

- Any call to `overridePendingTransition()` is always taken into account
- Lacking that, `FLAG_ACTIVITY_NO_ANIMATION` will be taken into account
- In the normal case, where neither of the two are used, whatever the user's preference, via the Settings application, is applied

Custom Drawables

Many times, our artwork can simply be some PNG or JPEG files, perhaps with different variations in different resource directories by density.

Sometimes, though, we need something more.

In addition to supporting standard PNG and JPEG files, Android has a number of custom drawable resource formats — mostly written in XML — that handle specific scenarios.

For example, you may wish to customize “the background” of a `Button`, but a `Button` really has several different background images for different circumstances (normal, pressed, focused, disabled, etc.). Android has a certain type of drawable resource that aggregates other drawable resources, indicating which of those other resources should be used in different circumstances (e.g., for a normal button use X, for a disabled button use Y).

In this chapter, we will explore these non-traditional types of “drawables” and how you can use them within your apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#) and [basic widgets](#).

Having read the chapters on [animators](#) and [legacy animations](#) would be useful.

ColorDrawable

The simplest XML drawable format, by far, is for ColorDrawable. Not surprisingly, this defines a Drawable that is a solid color.

So, you can have a `res/drawable/thing.xml` file, containing something like this:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="#80FF00FF"/>
```

From there, you can use `@drawable/thing` or `R.drawable.thing` in the same places that you would use any other drawable resource.

AnimationDrawable

The original way of doing animation on the Web was via the animated GIF. An individual GIF file could contain many frames, and the browser would switch between those frames to display a basic animated effect. This was used by Web designers for things both good (animated progress “spinners”) and bad (“hit the monkey” ad banners).

Android, on the whole, does not support animated GIF files, certainly not as regular images for use with widgets like `ImageView`.

However, there are times where having this sort of frame-by-frame animation would be useful. For example, in [another chapter](#), we will look at `ProgressBar`, which is Android’s primary way of demonstrating progress of background work. You may wish to customize the “spinning wheel” image that Android uses by default, to match your app’s color scheme, or to spin your company logo, or whatever. On the Web, particularly on older browsers, you might use an animated GIF for that — on Android, that is not an option.

An `AnimationDrawable`, though, is an option.

`AnimationDrawable` has the net effect of an animated GIF:

- You define a series of images that serve as the frames of the animation
- You define how long each of those images should be on the screen
- You define whether the animation should loop back to the beginning after it reaches the end or not

However, rather than encoding all of this in an animated GIF, you instead encode this information in an XML file, stored as a drawable resource.

XML-encoded drawable resources are typically stored in a drawable directory that does *not* contain density information, such as `res/drawable/`. That is because the XML-encoded drawable resources are density-invariant: they behave the same regardless of density. Those, like the `AnimationDrawable`, that refer to other images might well refer to other images that are stored in density-dependent resource directories, but the XML-encoded drawable itself is independent of density.

An `AnimationDrawable` is defined as in XML with a root `<animation-list>` element, containing a series of `<item>` elements for each frame:

```
<animation-list xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="true">
    <item android:drawable="@drawable/frame1" android:duration="250" />
    <item android:drawable="@drawable/frame2" android:duration="250" />
    <item android:drawable="@drawable/frame3" android:duration="250" />
    <item android:drawable="@drawable/frame4" android:duration="250" />
</animation-list>
```

The root `<animation-list>` element can have an `android:oneshot` attribute, indicating whether the animation should repeat after displaying the last frame (false) or stop (true).

The `<item>` elements have `android:drawable` attributes pointing to the individual images for the individual frames. Usually these frames are PNG or JPEG files, but you refer to them as drawable resources, using `@drawable` syntax, so Android can find the right image based upon the density (or other characteristics) of the current device. The `<item>` elements also need an `android:duration` attribute, specifying the time in milliseconds that this frame should be on the screen. While the above example has all durations the same, that is not required.

For example, the Android OS uses `AnimationDrawable` resources in a few places. One is for the download icon used in a Notification for use with `DownloadManager` and similar situations. That drawable resource – `stat_sys_download.xml` — looks like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/status_icon_background.xml
**
** Copyright 2008, The Android Open Source Project
**
```

```
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**      http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/stat_sys_download_anim0"
android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim1"
android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim2"
android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim3"
android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim4"
android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim5"
android:duration="200" />
</animation-list>
```

Here, we have a repeating animation (`android:oneshot="false"`), consisting of six frames, each on the screen for 200 milliseconds.

By specifying an `AnimationDrawable` in your `Notification` for its icon, you too can have this sort of animated effect. Of course, the animation is “fire and forget”: other than by removing or replacing the `Notification`, you cannot affect the animation in any other way.

Animated GIF Conversion

It may be that you have an animated GIF that you would like to use as the basis for your `AnimationDrawable`. If you have passing familiarity with Ruby, the author of this book has published [a Ruby script, named `gif2animdraw`](#), that automates the conversion.

To use `gif2animdraw`, in addition to the script itself and a Ruby interpreter, you will need the `RMagick`, `slop`, and `builder` gems. Note that `RMagick`, in turn, will require

ImageMagick libraries and therefore is a bit more complicated to install than is your ordinary gem.

On Linux environments, you can also `chmod` the script to run it directly; otherwise, you would run it via the `ruby` command.

The script takes four command-line switches:

- `-i` should point to the GIF file to be converted
- `-o` should point to the root output directory, which typically would be a project's `res/` directory
- `-d` should have, as a value, one of the Android density bucket names (e.g., `hdpi`); this will be used as the density for the frames of the GIF
- Optionally, include `--oneshot` to indicate that this should be a one-shot animation, not a repeating one

The results will be:

- A `drawable/` directory underneath your supplied root, containing a file with the same name as the GIF file, but with a `.xml` extension, representing the `AnimationDrawable` itself
- A `drawable-XXXX/` directory, where `XXXX` is your stated density, containing each frame of the animated GIF, as a PNG file, with a sequentially numbered filename based on the GIF's filename

StateListDrawable

Another XML-defined drawable resource, the `StateListDrawable`, is key if you want to have different images when widgets are in different states.

As outlined in the introduction to this chapter, what makes a `Button` visually be a `Button` is its background. To handle different looks for the `Button` background for different states (normal, pressed, disabled, etc.), the standard `Button` background is a `StateListDrawable`, one that looks something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
```

<http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

-->

```
<selector xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:state_window_focused="false" android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
  <item android:state_window_focused="false" android:state_enabled="false"
        android:drawable="@drawable/btn_default_normal_disable" />
  <item android:state_pressed="true"
        android:drawable="@drawable/btn_default_pressed" />
  <item android:state_focused="true" android:state_enabled="true"
        android:drawable="@drawable/btn_default_selected" />
  <item android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
  <item android:state_focused="true"
        android:drawable="@drawable/btn_default_normal_disable_focused" />
  <item
        android:drawable="@drawable/btn_default_normal_disable" />
</selector>
```

The XML has a `<selector>` root element, indicating this is a `StateListDrawable`. The `<item>` elements inside the root describe what Drawable resource should be used if the `StateListDrawable` is being used in some state. For example, if the “window” (think activity or dialog) does not have the focus (`android:state_window_focused="false"`) and the Button is enabled (`android:state_enabled="true"`), then we use the `@drawable/btn_default_normal` Drawable resource. That resource, as it turns out, is a nine-patch PNG file, described [later in this chapter](#).

Android applies each rule in turn, top-down, to find the Drawable to use for a given state of the `StateListDrawable`. The last rule has no `android:state_*` attributes, meaning it is the overall default image to use if none of the other rules match.

So, if you want to change the background of a Button, you need to:

- Copy the above resource, found in your Android SDK as `res/drawable/btn_default.xml` inside any of the `platforms/` directories, into your project
- Copy each of the Button state nine-patch images into your project
- Modify whichever of those nine-patch images you want, to affect the visual change you seek

- If need be, tweak the states and images defined in the `StateListDrawable` XML you copied
- Reference the local `StateListDrawable` as the background for your `Button`

The backgrounds of most widgets that have backgrounds by default will use a `StateListDrawable`. Searching a platform version's `res/drawable/` directory for XML files containing `<selector>` elements comes up with a rather long list.

ColorStateList

A `ColorStateList` is analogous to a `StateListDrawable`, in that it defines states and identifies what should be used for a given state. Whereas `StateListDrawable` ties states to drawables, `ColorStateList` ties states to colors. This allows you to, say, change the color of some text based upon whether that text is drawn in a widget that is being pressed, or has the focus, or is disabled. If you tailor the background of a text-based widget using a `StateListDrawable`, you may well wind up tailoring the foreground text using a `ColorStateList`.

While this chapter mentions `ColorStateList`, technically a `ColorStateList` is not a `Drawable`. You do not use it in methods that take drawables or in widget XML attributes that take drawables. Rather, there are other methods and other attributes that take a `ColorStateList`, such as `android:textColor`.

Similarly, while you can define a `ColorStateList` in XML, you do not do so in a `res/drawable/` resource directory, but rather a `res/color/` resource directory. Beyond that, though, a `ColorStateList` XML resource looks a lot like a `StateListDrawable` XML resource, such as this definition of `@android:color/primary_text_dark` from Android 4.4:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

    Licensed under the Apache License, Version 2.0 (the "License");
    you may not use this file except in compliance with the License.
    You may obtain a copy of the License at

        http://www.apache.org/licenses/LICENSE-2.0

    Unless required by applicable law or agreed to in writing, software
    distributed under the License is distributed on an "AS IS" BASIS,
    WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    See the License for the specific language governing permissions and
    limitations under the License.
-->
```

```
<selector xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:state_enabled="false" android:color="@android:color/
bright_foreground_dark_disabled"/>
  <item android:state_window_focused="false" android:color="@android:color/
bright_foreground_dark"/>
  <item android:state_pressed="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_selected="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_activated="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:color="@android:color/bright_foreground_dark"/> <!-- not
selected -->
</selector>
```

Based upon the state, the ColorStateList pulls in a separate resource to define the actual color. Those colors, in turn, are defined via <color> elements in res/values/colors.xml as color resources:

```
<color name="background_dark">#ff000000</color>
<color name="background_light">#ffffffff</color>
<color name="bright_foreground_dark">@android:color/background_light</color>
<color name="bright_foreground_light">@android:color/background_dark</color>
<color name="bright_foreground_dark_disabled">#80ffffff</color>
<color name="bright_foreground_light_disabled">#80000000</color>
<color name="bright_foreground_dark_inverse">@android:color/
bright_foreground_light</color>
<color name="bright_foreground_light_inverse">@android:color/
bright_foreground_dark</color>
```

LayerDrawable

A LayerDrawable basically stacks a bunch of other drawables on top of each other. Later drawables are drawn on top of earlier drawables, much as later children of a RelativeLayout are drawn on top of earlier children.

Typically, you will create a LayerDrawable via a <layer-list> XML drawable resource.

For example, a ToggleButton widget has a LayerDrawable as its background:

```
?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
```

```
http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:id="@+android:id/background"
android:drawable="@android:drawable/btn_default_small" />
  <item android:id="@+android:id/toggle" android:drawable="@android:drawable/
btn_toggle" />
</layer-list>
```

This LayerDrawable draws two images on top of each other. One is a standard small button background (@android:drawable/btn_default_small). The other is the actual face of the toggle itself — a StateListDrawable that uses different images for checked and unchecked states.

In the <layer-list>, you can have several <item> elements. Each <item> element usually will need an android:drawable attribute, pointing to the drawable that should be drawn. Optionally, you can assign ID values to the items via android:id attributes, much like you would do for widgets in a layout XML resource. Later on, you can call findDrawableByLayerId() on the LayerDrawable to retrieve an individual Drawable representing the layer, given its android:id value.

There are also android:left, android:right, android:top, and android:bottom attributes, which you can use to provide dimension values to offset an image within the layered set. For example, you could use android:left to inset one of the layers by a certain number of pixels (or dp or whatever).

By default, the layers in the LayerDrawable are scaled to fit the size of whatever View is holding them (e.g., the size of the ToggleButton using the LayerDrawable as a background). To prevent this, you can skip the android:drawable attribute, and instead nest a <bitmap> element inside the <item>, where you can provide an android:gravity attribute to control how the image should be handled relative to its containing View. We will get more into nested <bitmap> elements [later in this chapter](#).

TransitionDrawable

A TransitionDrawable is a LayerDrawable with one added feature: for a two-layer drawable, it can smoothly transition from showing one layer to another on top.

For example, you may have noticed that when you tap-and-hold on a row in a ListView that the selector highlight has an animated effect, slowly shifting colors from the color used for a simple click to one signifying that you have long-clicked the row. Android accomplishes this via a TransitionDrawable, set up as a <transition> XML drawable resource:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

    Licensed under the Apache License, Version 2.0 (the "License");
    you may not use this file except in compliance with the License.
    You may obtain a copy of the License at

        http://www.apache.org/licenses/LICENSE-2.0

    Unless required by applicable law or agreed to in writing, software
    distributed under the License is distributed on an "AS IS" BASIS,
    WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    See the License for the specific language governing permissions and
    limitations under the License.
-->

<transition xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:drawable="@android:drawable/list_selector_background_pressed"
/>
    <item android:drawable="@android:drawable/
list_selector_background_longpress" />
</transition>
```

The TransitionDrawable object has a startTransition() method that you can use, that will have Android smoothly switch from the first drawable to the second. You specify the duration of the transition as a number of milliseconds passed to startTransition(). There are also options to reverse the transition, set up more of a cross-fade effect, and the like.

LevelListDrawable

A LevelListDrawable is similar in some respects to a StateListDrawable, insofar as one specific item from the “list drawable” will be displayed based upon certain conditions. In the case of StateListDrawable, the conditions are based upon the

state of the widget using the drawable (e.g., checked, pressed, disabled). In the case of `LevelListDrawable`, it is merely an integer level.

For example, the status or system bar of your average Android device has an icon indicating the battery charge level. That is actually implemented as a `LevelListDrawable`, via an XML resource containing a root `<level-list>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/stat_sys_battery.xml
**
** Copyright 2007, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->

<level-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:maxLevel="4" android:drawable="@android:drawable/
stat_sys_battery_0" />
    <item android:maxLevel="15" android:drawable="@android:drawable/
stat_sys_battery_15" />
    <item android:maxLevel="35" android:drawable="@android:drawable/
stat_sys_battery_28" />
    <item android:maxLevel="49" android:drawable="@android:drawable/
stat_sys_battery_43" />
    <item android:maxLevel="60" android:drawable="@android:drawable/
stat_sys_battery_57" />
    <item android:maxLevel="75" android:drawable="@android:drawable/
stat_sys_battery_71" />
    <item android:maxLevel="90" android:drawable="@android:drawable/
stat_sys_battery_85" />
    <item android:maxLevel="100" android:drawable="@android:drawable/
stat_sys_battery_100" />
</level-list>
```

This `LevelListDrawable` has eight items, whose `android:drawable` attributes point to specific other drawable resources (in this case, standard PNG files with different implementations for different densities). Each `<item>` has an `android:maxLevel` value. When someone calls `setLevel()` on the `Drawable` or `setImageLevel()` on the

`ImageView`, Android will choose the item with the lowest `maxLevel` that meets or exceeds the requested level, and show that. In the case of the battery icon, when the battery level changes, the status bar picks up that change and calls `setImageLevel()` with the battery charge percentage (expressed as an integer from 0–100) — that, in turn, triggers the right PNG file to be displayed.

Another use of `LevelListDrawable` is with a `RemoteViews`, such as for an [app widget](#). The `setImageLevel()` method is “remotable”, despite not being directly part of the `RemoteViews` API. Hence, given that you use a `LevelListDrawable` in your app widget’s layout, you should be able to use `setInt()` with a method name of “`setImageLevel`” to have the app widget update to display the proper image.

ScaleDrawable and ClipDrawable

A `ScaleDrawable` does pretty much what its name suggests: it scales another drawable. A `ClipDrawable` does pretty much what *its* name suggests: it clips another drawable.

How they do this, and how you control it, requires a bit more explanation.

Like `LevelListDrawable`, `ScaleDrawable` and `ClipDrawable` leverage the `setLevel()` method on `Drawable` (or the `setImageLevel()` method on `ImageView`). Whereas `LevelListDrawable` uses this to choose an individual image out of a set of possible images, `ScaleDrawable` and `ClipDrawable` use the level to control how much an image should be scaled or clipped. For this, they support a range of levels from 0 to 10000.

Scaling

For a level of 0, `ScaleDrawable` will not draw anything. For a level from 1 to 10000, `ScaleDrawable` will scale an image from a configurable minimum size to the bounds of the `View` to which the drawable is applied.

The amount of scaling is determined by `android:scaleHeight` and `android:scaleWidth` attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<scale xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@android:drawable/btn_default"
    android:scaleGravity="left|top"
    android:scaleHeight="50%"
    android:scaleWidth="50%" />
```

The above `ScaleDrawable` (denoted by the `<scale>` root element) says that we should scale both height and width of the underlying drawable to 50% of the available space for the drawable, when the level is at its maximum (10000).

Note that you do not have to scale along both dimensions. If, for example, you kept `android:scaleWidth` but deleted `android:scaleHeight`, `setImageLevel()` would control the scaled width of the underlying image (provided via `android:drawable`) but not the height.

The `android:scaleGravity` attribute indicates where the scaled image should reside within the available space (the 10000 level, determined by the bounds of the `View` to which the drawable is applied). The value shown above, `center`, keeps the image centered within the available space, and shrinks or expands it around the center. A value of `left|top` would keep the image in the upper-left corner of the space, having the visual effect of moving the lower-right corner based upon the supplied level.

Clipping

Scaling proportionally reduces the height and/or width of an image. Clipping, on the other hand, chops off part of the height or width of the image.

```
<clip xmlns:android="http://schemas.android.com/apk/res/android"
    android:clipOrientation="horizontal"
    android:drawable="@drawable/btn_default_normal"
    android:gravity="left"/>
```

In this sample `ClipDrawable` (indicated by the `<clip>` root element), we are going to allow the level to chop off part of the image indicated by the `android:drawable` attribute. Our `android:clipOrientation`, set to `horizontal`, means we are going to chop off part of the width (vertical would have us chop off part of the height). The amount that is going to be chopped off is the level you supply (e.g., `setImageLevel()`) divided by 10000. Hence, a level of 5000 will chop off 0.5 (a.k.a., 50%) of the image.

Where in the image the clipping occurs is determined by the `android:gravity` attribute. An `android:clipOrientation` of `horizontal` and an `android:gravity` of `left`, as in the sample drawable above, means that the left side of the image is retained, and the image will be clipped on the right. Specifying `right` instead of `left` would reverse that, clipping the image from the right, while `center` would clip equally from both sides. There are other gravity values as well, such as `top` and `bottom` values to be used with a vertical orientation.

Seeing It In Action

To see these effects, take a look at the [Drawable/ScaleClip](#) sample project. This is derived from [an earlier example](#) showing how to use ViewPager with PagerTabStrip. In that example, we had 10 tabs, each being a large EditText widget. In this example, we have 2 tabs, “Scale” and “Clip”, both using the same layout:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ImageView
        android:id="@+id/image"
        android:layout_width="150dp"
        android:layout_height="150dp"
        android:layout_centerHorizontal="true"
        android:layout_marginTop="20dp"
        android:scaleType="fitXY"/>

    <SeekBar
        android:id="@+id/level"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_alignParentBottom="true"
        android:layout_marginBottom="20dp"
        android:layout_marginLeft="20dp"
        android:layout_marginRight="20dp"
        android:max="10000"
        android:progress="10000"/>

</RelativeLayout>
```

This is simply a 150dp square ImageView towards the top of the screen and a SeekBar towards the bottom of the screen. The SeekBar will be used to control the level applied to a ScaleDrawable and ClipDrawable, which is why we have android:max set to 10000. We also have our “progress” (original SeekBar value) set to 10000, so the bar’s thumb will be fully slid over to the right at the outset.

The fragments that we will use for the tabs both inherit from a common abstract FragmentBase class:

```
package com.commonware.android.scaleclip;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
```

```
import android.widget.SeekBar;

abstract public class FragmentBase extends Fragment implements
    SeekBar.OnSeekBarChangeListener {
    abstract void setBackgroundImage(ImageView image);

    private ImageView image=null;

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        setRetainInstance(true);

        View result=inflater.inflate(R.layout.scaleclip, container, false);
        SeekBar bar=((SeekBar)result.findViewById(R.id.level));

        bar.setOnSeekBarChangeListener(this);
        image=(ImageView)result.findViewById(R.id.image);
        setBackgroundImage(image);
        image.setImageLevel(bar.getProgress());

        return(result);
    }

    @Override
    public void onProgressChanged(SeekBar seekBar, int progress,
                                 boolean fromUser) {
        image.setImageLevel(progress);
    }

    @Override
    public void onStartTrackingTouch(SeekBar seekBar) {
        // no-op
    }

    @Override
    public void onStopTrackingTouch(SeekBar seekBar) {
        // no-op
    }
}
```

In `onCreateView()`, we inflate the above layout file, hook up the fragment itself to be the listener for `SeekBar` change events, call the subclass' `setBackgroundImage()` method to populate the `ImageView` with an image, and set the `ImageView`'s level to be the initial value of the `SeekBar`. When the `SeekBar` value changes, our `onProgressChanged()` method will adjust the level.

The concrete subclasses — `ScaleFragment` and `ClipFragment` — simply populate the `ImageView` with the `ScaleDrawable` and `ClipDrawable` resources shown earlier in this section:

CUSTOM DRAWABLES

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ScaleFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.scale);
    }
}
```

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ClipFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.clip);
    }
}
```

Those two drawables based their scaling and clipping on `res/drawable-xdpi/btn_default_normal.9.png`. This is a slightly-modified copy of the default button background, and is a nine-patch PNG file. We will discuss nine-patch PNG files [later in this chapter](#) — suffice it to say for now that it is a PNG file with rules about how it should be stretched.

Our scale tab starts off showing the full image:

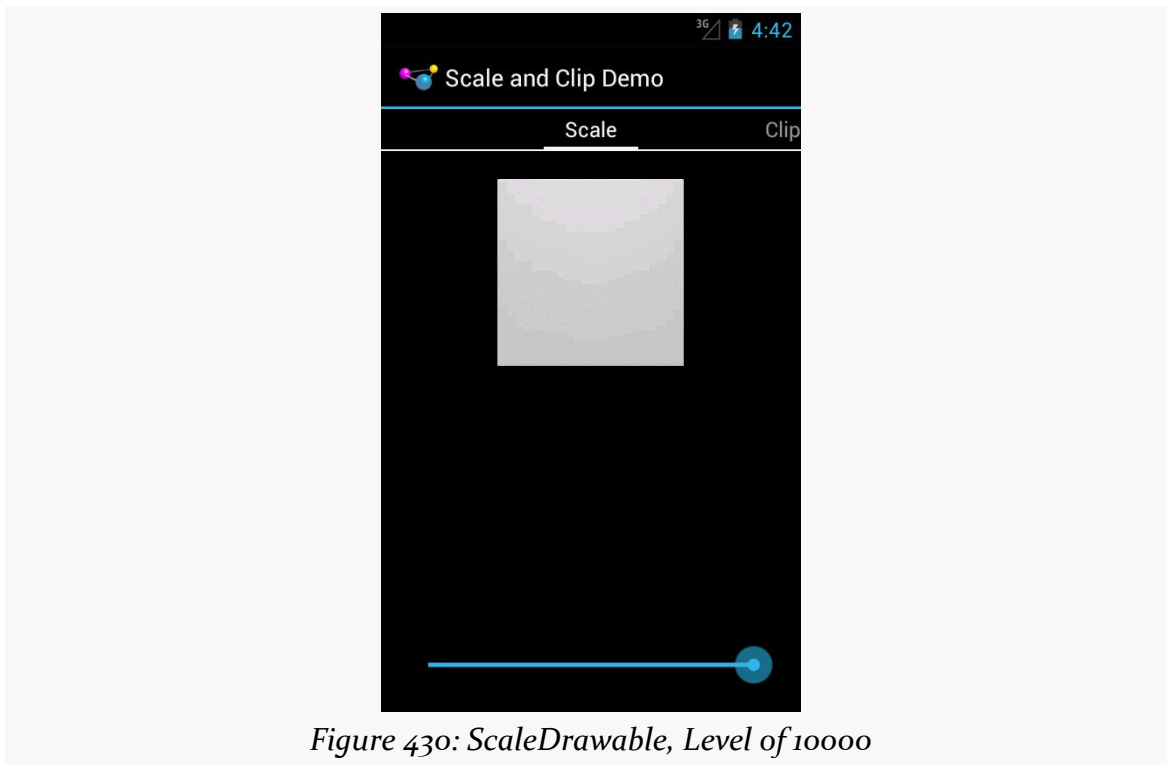

Figure 430: ScaleDrawable, Level of 10000

As we start sliding the SeekBar thumb to the left, the image shrinks progressively:

Figure 431: ScaleDrawable, Level of Approximately 5000

It eventually tends towards the 50% level specified in our `android:scaleHeight` and `android:scaleWidth` values:

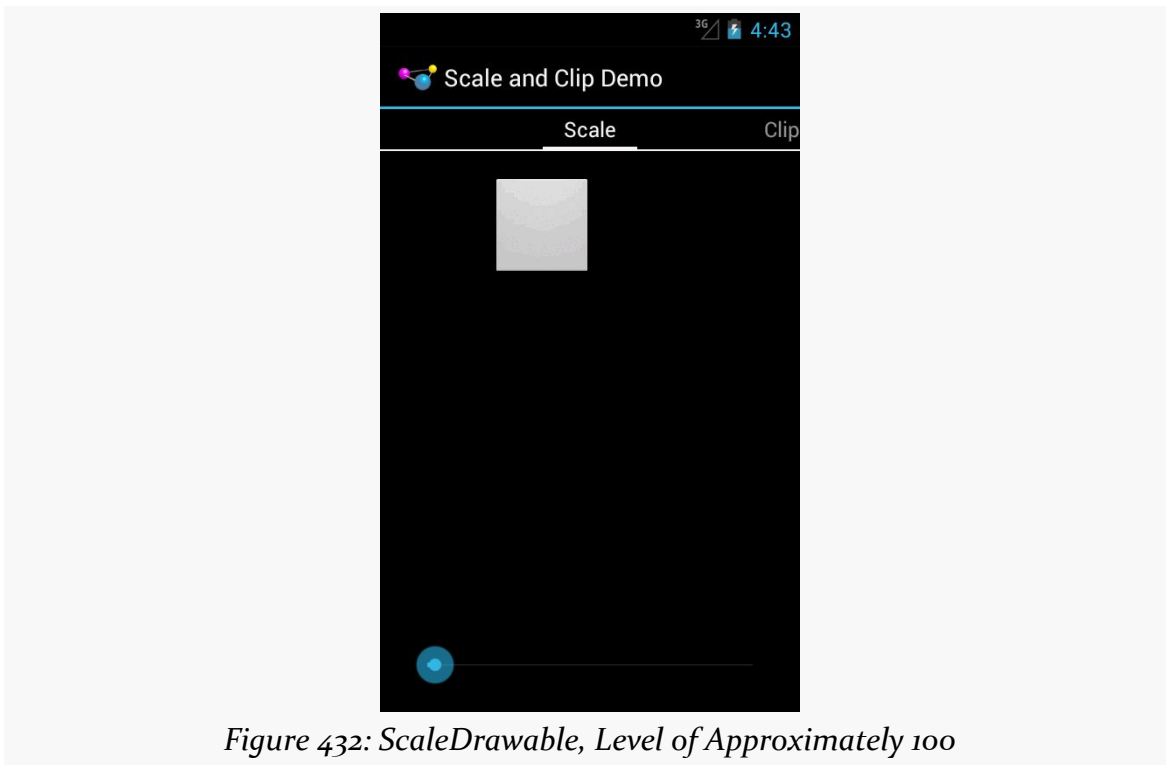

Figure 432: ScaleDrawable, Level of Approximately 100

Sliding it all the way to the left, though, causes the image to vanish.

The ClipDrawable starts off looking much like the ScaleDrawable:

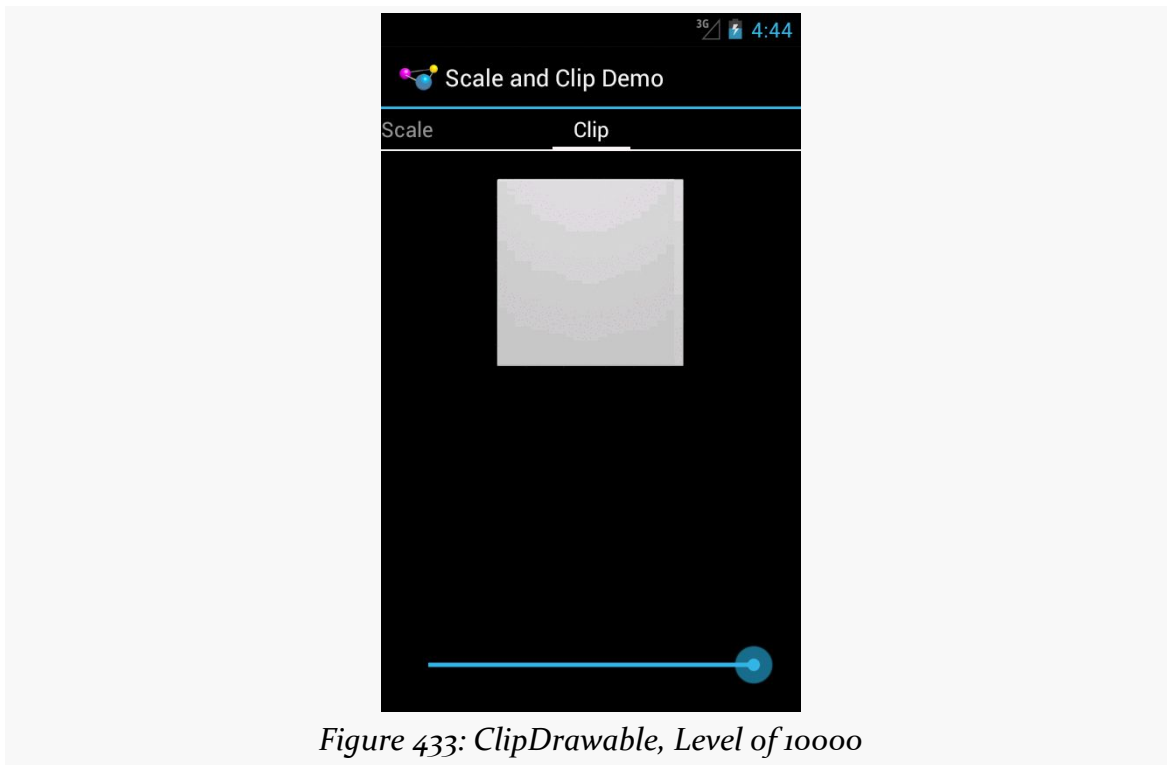

Figure 433: ClipDrawable, Level of 10000

As we slide the SeekBar to the left, the right side of the image gets clipped:

Figure 434: ClipDrawable, Level of Approximately 5000

InsetDrawable

An InsetDrawable allows you to apply insets on any side (or all sides) of some other drawable resource. The use case cited in [the documentation](#) is “This is used when a View needs a background that is smaller than the View’s actual bounds”. However, at the present time, nothing in the Android open source code uses this particular type of resource, or even the Java class.

In principle, though, you could have an XML drawable resource that looked like this:

```
<?xml version="1.0" encoding="utf-8"?>
<inset xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@drawable/something_or_another"
    android:insetLeft="20dp"
    android:insetTop="10dp" />
```

When used as the background for some View, for example, Android would pull in the `something_or_another` resource and effectively add 20dp of left margin and 10dp of top margin on the background when calculating its size and drawing it on the screen.

ShapeDrawable

Far and away the most complex of the XML drawable formats is the ShapeDrawable. It gives you what amounts to a very tiny subset of SVG, for creating simple vector art shapes.

The root element of a ShapeDrawable resource is <shape>, which may have child elements, along with attributes, to configure what gets rendered on the screen when the drawable is applied.

This section will review the elements and attributes available to you, with sample drawables (and screenshots) culled from the [Drawable/Shape](#) sample project.

This is a “sampler” project, designed to depict a number of ShapeDrawables. To accomplish this, we will use action bar tabs. Our activity (MainActivity) has a pair of static int arrays, one pointing at string resources to use for tab captions, the other pointing at corresponding drawable resources:

```
package com.commonware.android.shape;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.widget.ImageView;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string.solid, R.string.gradient,
        R.string.border, R.string.rounded, R.string.ring,
        R.string.layered };
    private static final int DRAWABLES[] = { R.drawable.rectangle,
        R.drawable.gradient, R.drawable.border, R.drawable.rounded,
        R.drawable.ring, R.drawable.layered };
    private ImageView image=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        image=(ImageView)findViewById(R.id.image);

        ActionBar bar=getActionBar();
        bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

        for (int i=0; i < TABS.length; i++) {
```

```
        bar.addTab(bar.newTab().setText(getString(TABS[i]))
                    .setTabListener(this));
    }
}

@Override
public void onTabSelected(Tab tab, FragmentTransaction ft) {
    image.setImageResource(DRAWABLES[tab.getPosition()]);
}

@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
}
}
```

In `onCreate()`, we toggle the `ActionBar` into tab-navigation mode, then iterate over the arrays and add one tab per element.

Our layout is an `ImageView`, named `image`, centered on the screen, taking up 80% of the horizontal space, plus has 20dp of top and bottom margin:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/LinearLayout1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal"
    android:gravity="center"
    android:weightSum="10">

    <ImageView
        android:id="@+id/image"
        android:src="@drawable/rectangle"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_marginTop="20dp"
        android:layout_marginBottom="20dp"
        android:layout_gravity="center"
        android:layout_weight="8"/>

</LinearLayout>
```

In our activity's `onTabSelected()` — implemented because the activity is the `TabListener` for our tabs — we get the position of our tab and fill in the appropriate drawable into the `ImageView`.

Given that, let's take a look at how to construct a ShapeDrawable, along with some sample drawables.

<shape>

Your root element, not surprisingly, is <shape>.

The primary thing that you will define on the <shape> element is the redundantly-named android:shape attribute, to define what sort of shape you want:

- line (a shape with no interior)
- oval (also for ellipses)
- rectangle (including rounded rectangles)
- ring (for partially-filled circles)

There are some other attributes available on <shape> for a ring, which we will examine [later in this chapter](#).

<solid>

Your shape will usually require some sort of fill, to say what color goes in the shape. There are two types of fills: solid and gradient.

For a solid fill, add a <solid> child element to the <shape>, with an android:color attribute indicating what color to use. As with most places in Android, this can either be a literal color or a reference to a color resource.

So, for example, we can specify a solid red rectangle as:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <solid android:color="#FFAA0000"/>
</shape>
```

This gives us the following visual result:

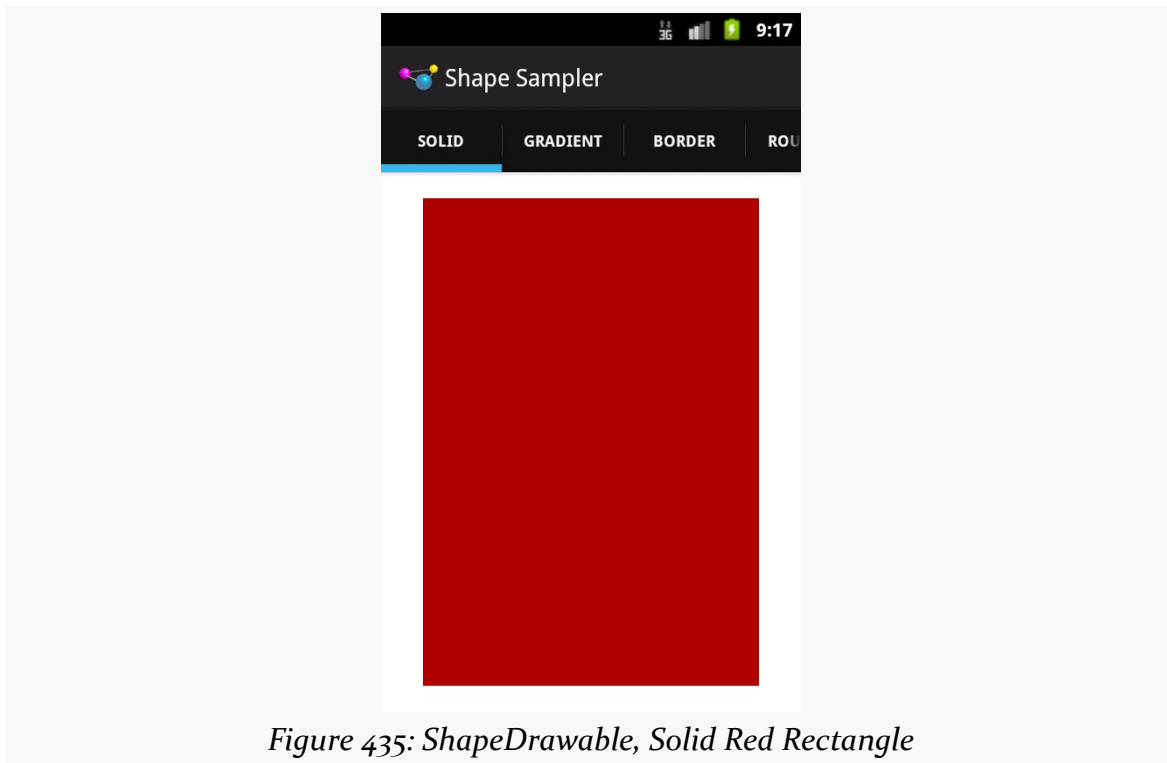

Figure 435: ShapeDrawable, Solid Red Rectangle

<gradient>

Your alternative fill is a gradient. The nice thing about gradients with ShapeDrawable is that they are generated at runtime from the specifications in the ShapeDrawable, and therefore will be smooth. Gradients that appear in PNG files and the like, if stretched, will tend to have a banding effect.

Gradient fills are defined via a <gradient> child element of the <shape> element.

The simplest way to set up a gradient is to use three attributes:

- android:startColor and android:endColor, to specify the starting and ending colors of the gradient, respectively, and
- android:angle, to specify what direction the gradient “flows” in

The angle must be a multiple of 45 degrees. 0 degrees is left-to-right, 90 degrees is bottom-to-top, 180 degrees is right-to-left, and 270 degrees is top-to-bottom.

So, for example, we could change our rectangle to have a gradient fill, from red to blue, with red at the top, via:

CUSTOM DRAWABLES

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>

</shape>
```

That gives us:

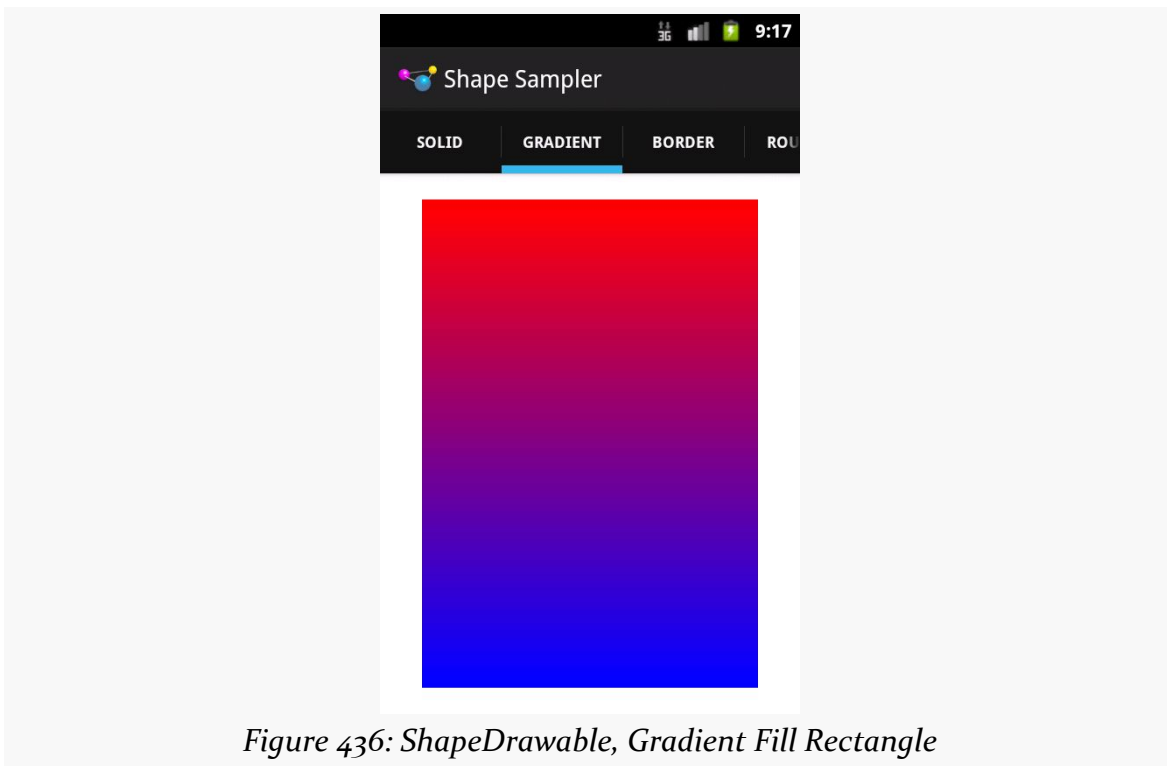

Figure 436: ShapeDrawable, Gradient Fill Rectangle

We will examine some other gradient options in the section on rings, [later in this chapter](#).

<stroke>

If you want a separate color for a border around your shape, you can use the `<stroke>` element, as a child of the `<shape>` element, to configure one.

There are four attributes that you can declare. The two that you will probably always use are `android:color` (to indicate the color of the border) and `android:width` (to indicate the thickness of the border). By default, using just those two will give you a solid line around the edge of your shape.

If you would prefer a dashed border, you can add in `android:dashWidth` (to indicate how long each dash segment should be) and `android:dashGap` (to indicate how long the gaps between dash segments should be).

So, for example, we can add a dashed border to our gradient rectangle via a suitable `<stroke>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>

    <stroke
        android:width="2dp"
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:color="#FF000000"/>

</shape>
```

This gives us:

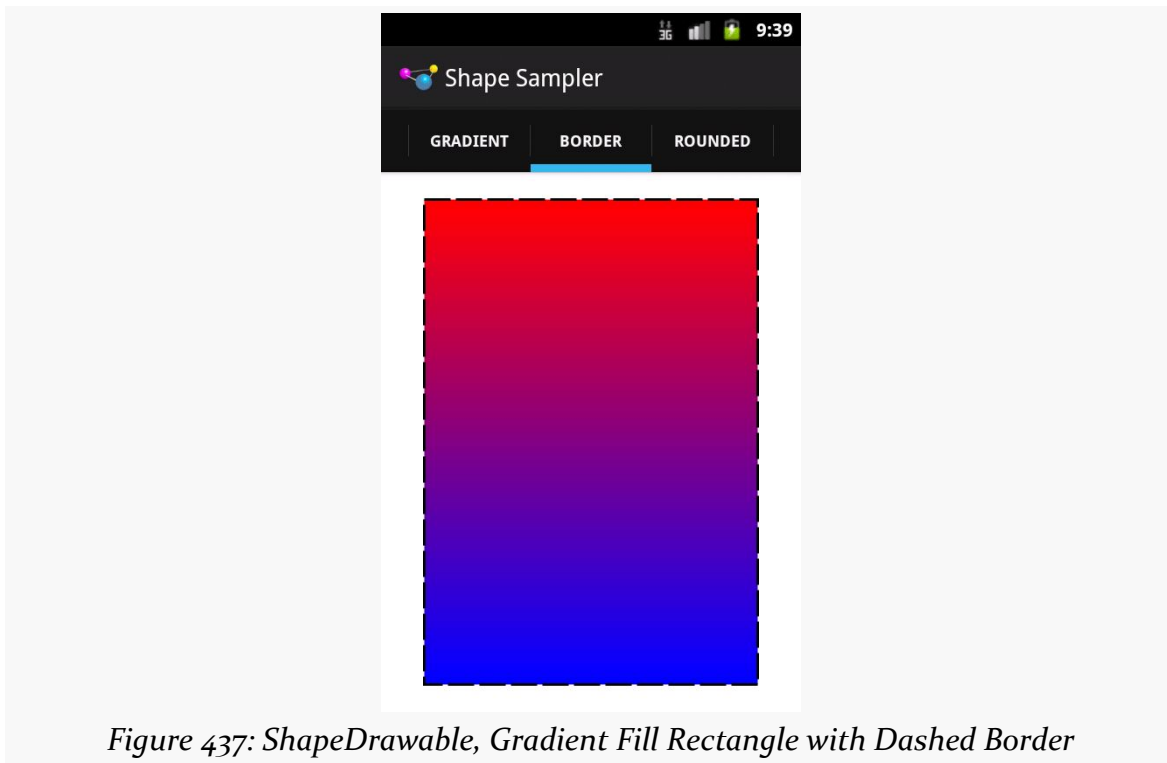

Figure 437: *ShapeDrawable, Gradient Fill Rectangle with Dashed Border*

<corners>

If we are implementing a rectangle shape, but we really want it to be a rounded rectangle, we can add a `<corners>` element as a child of the `<shape>` element. You can specify the radius to apply to the corners, either for all corners (e.g., `android:radius`), or for individual corners (e.g., `android:topLeftRadius`). Here, “radius” basically means the size of the circle that should implement the corner, where a radius of `0dp` would indicate the default square corner.

So, if we wanted to add rounded corners to our gradient-filled, dash-outlined rectangle, we could use this:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>

    <stroke
```

```
    android:dashGap="4dp"
    android:dashWidth="20dp"
    android:width="2dp"
    android:color="#FF000000" />

    <corners android:radius="8dp" />
</shape>
```

This gives us the following:

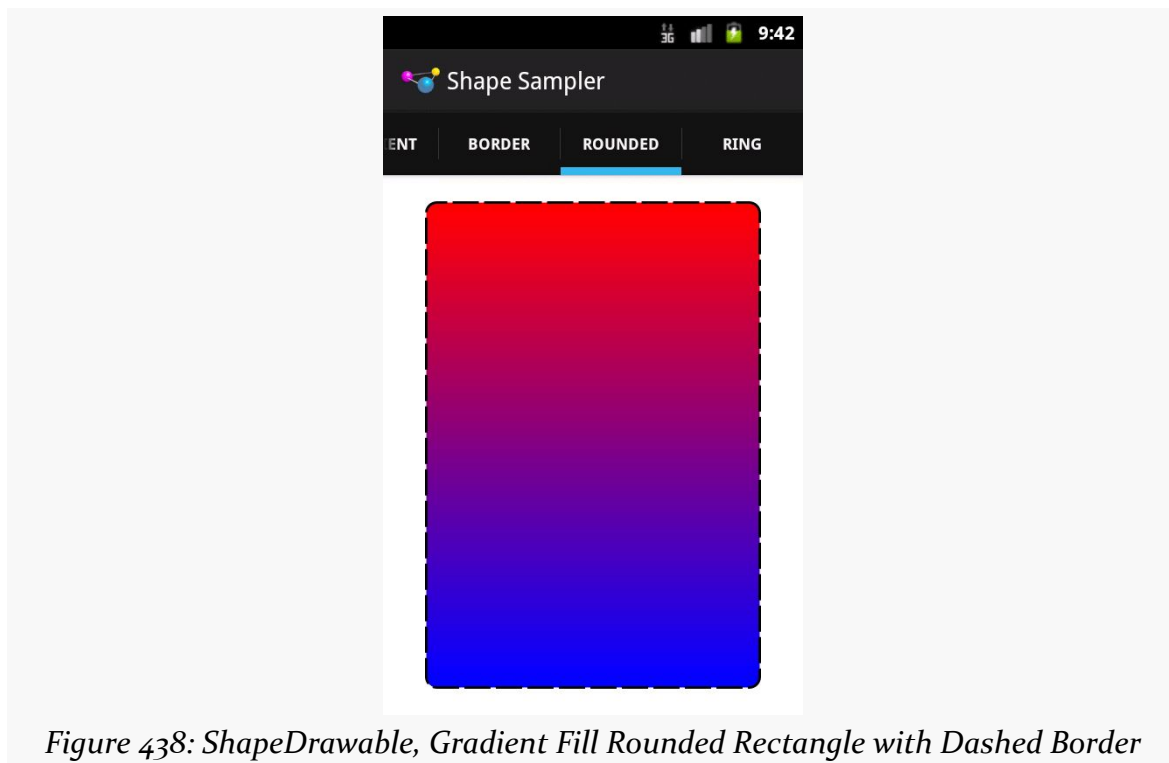

Figure 438: ShapeDrawable, Gradient Fill Rounded Rectangle with Dashed Border

<padding> and <size>

There are also <padding> and <size> elements that you can add, that specify padding to put on the various sides and the overall size of the drawable. More often than not, you would actually handle this on the `ImageView` or other widget that is using your drawable, but if you would prefer to define those things in the drawable itself, you are welcome to do so.

Put a Ring On It

Rings are a bit more complicated, in large part because they are not completely filled. With a ring, the “fill” is filling what goes in the ring itself, not the “hole” in the center of the ring. This means that we need to teach Android more about how that “hole” is supposed to be set up.

To do that, we need to provide two pieces of information:

1. How big the inner radius should be, where by “inner radius” Android means “the radius of the hole”
2. How thick the ring should be

The ring will then be drawn based upon that inner radius and thickness.

You might wonder, “well, where does the size of the actual drawable come into play?” After all, if we specify an inner radius of 20dp and a thickness of 10dp, that would give us an outer radius of 30dp, for a total width of 60dp... regardless of how big the actual drawable is.

And that is completely correct.

However, for both the inner radius and the thickness, you have two choices of how to specify their values:

1. As actual sizes (dimensions or references to dimension resources)
2. As ratios to the overall drawable width (defined by <size> or the widget that is using the drawable)

This gives us four total attributes to choose from, to be placed on the <shape> element for ring drawables:

1. `android:innerRadius`
2. `android:innerRadiusRatio`
3. `android:thickness`
4. `android:thicknessRatio`

Therefore, if you want the ring’s size to be based on the size of the drawable, you would use `innerRadiusRatio`, `thicknessRatio`, or both.

The other thing about rings is that they are round. Hence, a default linear gradient fill — going from one side of the drawable to another — may not be what you really want. You can control the type of gradient fill to use via the `android:type` attribute on the `<gradient>` element. There are three possible values:

1. `linear` (the default behavior)
2. `radial`, where the gradient starts from the center (or another point that you define) and changes color from that center to the edges
3. `sweep`, where the gradient revolves clockwise in a circle, starting from whatever `android:angle` you specify (or 0, meaning “east”, as the default)

So, for example, take a look at the following `ShapeDrawable`:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:innerRadiusRatio="3"
    android:shape="ring"
    android:thickness="15dp"
    android:useLevel="false">

    <gradient
        android:centerColor="#4c737373"
        android:endColor="#ff9933cc"
        android:startColor="#4c737373"
        android:type="sweep" />

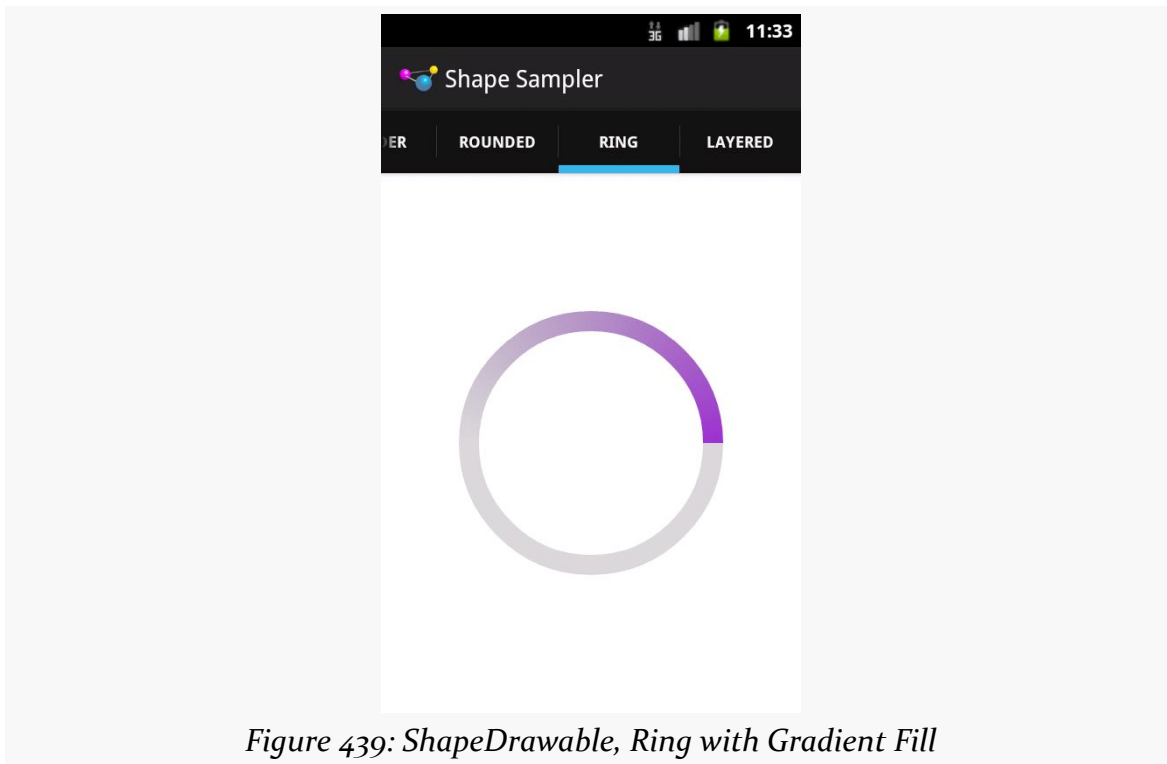

</shape>
```

Here, we:

- Declare that our shape is a ring
- Indicate that the distance between the inner radius and the outer radius of the ring should be 15dp
- Indicate that there is a 3:1 ratio between the width of the image and the radius of the “hole” in the ring
- Indicate that the fill should be a gradient that sweeps clockwise from the default angle of 0
- Indicate that the first half of the gradient (start to center) should remain a constant color
- Indicate that the second half of the gradient (center to end) should change color from gray to purple

We also have `android:useLevel="false"` in the `<shape>` element. For unknown reasons, this is required for rings but not for other types of shapes.

This gives us:

BitmapDrawable

Having an XML drawable format named `BitmapDrawable` may seem like a contradiction in terms. However, `BitmapDrawable` is not an XML representation of a bitmap, but rather an XML representation of operations to perform on an actual bitmap.

The big thing that `BitmapDrawable` offers is `android:tileMode`, which turns a single bitmap into a repeating bitmap. The bitmap is tiled, horizontally and vertically, using a tiling mode that you specify.

This is demonstrated in the [Drawable/TileMode](#) sample project.

Our activity's layout is just a `LinearLayout`, set to fill the screen:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/widget"
```

```
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

</LinearLayout>
```

Our activity populates action bar tabs, where it applies a particular background image to the LinearLayout (known as R.id.widget) based on the selected tab:

```
package com.commonware.android.tilemode;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.view.View;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string._default, R.string.clamp,
        R.string.repeat, R.string.mirror };
    private static final int DRAWABLES[] = { R.drawable._default,
        R.drawable.clamp, R.drawable.repeat, R.drawable.mirror };
    private View widget=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        widget=findViewById(R.id.widget);

        ActionBar bar=getActionBar();
        bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

        for (int i=0; i < TABS.length; i++) {
            bar.addTab(bar.newTab().setText(getString(TABS[i]))
                .setTabListener(this));
        }
    }

    @Override
    public void onTabSelected(Tab tab, FragmentTransaction ft) {
        widget.setBackgroundResource(DRAWABLES[tab.getPosition()]);
    }

    @Override
    public void onTabUnselected(Tab tab, FragmentTransaction ft) {
        // no-op
    }

    @Override
```

CUSTOM DRAWABLES

```
public void onTabReselected(Tab tab, FragmentTransaction ft) {  
    // no-op  
}
```

The `res/drawable/_default.xml` resource, used on the first tab, is an unadorned `BitmapDrawable` resource, where our `<bitmap>` element simply has an `android:src` attribute pointing to a bitmap to be used for this `BitmapDrawable`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"  
    android:src="@drawable/hatch"/>
```

Since we have not specified a tile mode, the image is stretched to fill the size of our `LinearLayout` when serving as its background:

Figure 440: BitmapDrawable, Without android:tileMode

The `res/drawable/clamp.xml` resource, used on the second tab, adds `android:tileMode="clamp"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"  
    android:src="@drawable/hatch"  
    android:tileMode="clamp"/>
```

CUSTOM DRAWABLES

This causes the right-most column of pixels and the bottom-most column of pixels to be repeated to fill the available space:

Figure 441: BitmapDrawable, Clamped

Zooming in on the upper-left portion of our LinearLayout demonstrates this:

Figure 442: Portion of BitmapDrawable, Clamped

The `res/drawable/repeat.xml` resource, used on the third tab, employs `android:tileMode="repeat"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"
    android:tileMode="repeat"/>
```

Here, the image is simply repeated *in toto* to fill the available space, rather than only its lower-right edges:

Figure 443: BitmapDrawable, Repeated

Zooming in on an arbitrary chunk of the LinearLayout shows this effect:

Figure 444: Portion of BitmapDrawable, Repeated

CUSTOM DRAWABLES

The `res/drawable/mirror.xml` resource, used on the fourth tab, uses `android:tileMode="mirror"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"
    android:tileMode="mirror"/>
```

Here, the image is repeated, but alternately mirrored along the repeating axis. So, it is flipped horizontally for each repeat along the horizontal axis, and it is flipped vertically for each repeat along the vertical axis:

Figure 445: BitmapDrawable, Mirrored

Zooming in on an arbitrary chunk of the `LinearLayout` shows this effect:

Figure 446: Portion of BitmapDrawable, Mirrored

Composite Drawables

Let's say that we wanted to have a pair of ShapeDrawable images, one superimposed on another. Since a single ShapeDrawable defines only one shape, we would need something else to assist with stacking the images.

One possibility would be to use a LayerDrawable, creating three total resources:

1. The first ShapeDrawable, in its own resource file
2. The second ShapeDrawable, in its own resource file
3. The LayerDrawable, holding references to the two ShapeDrawable resources

And this will certainly work. But you have an alternative: put all of it into a single drawable resource.

An `android:drawable` attribute in an `<item>` element can be replaced by child elements representing another drawable structure. Hence, rather than having a LayerDrawable with two `<item>` elements pointing to other drawable resources, we could have those same `<item>` elements *contain* the other drawable XML structures, and thereby cut our number of files from 3 to 1.

For example, we could have something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item>
        <shape android:shape="rectangle">
            <gradient
```

```
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>

        <stroke
            android:dashGap="4dp"
            android:dashWidth="20dp"
            android:width="2dp"
            android:color="#FF000000"/>

        <corners android:radius="8dp"/>
    </shape>
</item>
<item>
    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thickness="15dp"
        android:useLevel="false">
        <gradient
            android:endColor="#FFFFFFF"
            android:startColor="#ff000000"
            android:type="sweep"/>
        </shape>
    </item>
</layer-list>
```

This is a LayerDrawable, layering two ShapeDrawable structures. The first ShapeDrawable is our dash-bordered, gradient-filled, rounded rectangle from before. The second ShapeDrawable is a ring with a simple gradient sweep fill, from black to white.

This gives us:

Figure 447: Composite Drawable

Hence, any of the drawable XML structures other than ShapeDrawable can, in their `<item>` elements, hold any drawable XML structure, instead of pointing to another separate resource.

Android uses this trick as well. For example, the stock ProgressBar image is based off of a LayerDrawable wrapped around three ShapeDrawable structures:

```

        </shape>
    </clip>
</item>
</layer-list>
```

We will get into how this works with a ProgressBar in [a separate chapter](#).

A Stitch In Time Saves Nine

Most of the types of non-traditional drawable resources you can create in Android are described in XML... but not all.

As you read through the Android documentation, you no doubt ran into references to “nine-patch” or “9-patch” and wondered what Android had to do with [quilting](#). Rest assured, you will not need to take up needlework to be an effective Android developer.

If, however, you are looking to create backgrounds for resizable widgets, like a Button, you may wish to work with nine-patch images.

As the Android documentation states, a nine-patch is “a PNG image in which you define stretchable sections that Android will resize to fit the object at display time to accommodate variable sized sections, such as text strings”. By using a specially-created PNG file, Android can avoid trying to use vector-based formats (e.g., ShapeDrawable) and their associated overhead when trying to create a background at runtime. Yet, at the same time, Android can still resize the background to handle whatever you want to put inside of it, such as the text of a Button.

In this section, we will cover some of the basics of nine-patch graphics, including how to customize and apply them to your own Android layouts.

The Name and the Border

Nine-patch graphics are PNG files whose names end in `.9.png`. This means they can be edited using normal graphics tools, but Android knows to apply nine-patch rules to their use.

What makes a nine-patch graphic different than an ordinary PNG is a one-pixel-wide border surrounding the image. When drawn, Android will remove that border, showing only the stretched rendition of what lies inside the border. The border is used as a control channel, providing instructions to Android for how to deal with stretching the image to fit its contents.

Padding and the Box

Along the right and bottom sides, you can draw one-pixel-wide black lines to indicate the “padding box”. Android will stretch the image such that the contents of the widget will fit inside that padding box.

For example, suppose we are using a nine-patch as the background of a Button. When you set the text to appear in the button (e.g., “Hello, world!”), Android will compute the size of that text, in terms of width and height in pixels. Then, it will stretch the nine-patch image such that the text will reside inside the padding box. What lies outside the padding box forms the border of the button, typically a rounded rectangle of some form.

Figure 448: The padding box, as shown by a set of control lines to the right and bottom of the stretchable image

Stretch Zones

To tell Android where on the image to actually do the stretching, draw one-pixel-wide black lines on the top and left sides of the image. Android will scale the graphic only in those areas — areas outside the stretch zones are not stretched.

Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.
2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

Tooling

To experiment with nine-patch images, you may wish to use the `draw9patch` program, found in the `tools/` directory of your SDK installation:

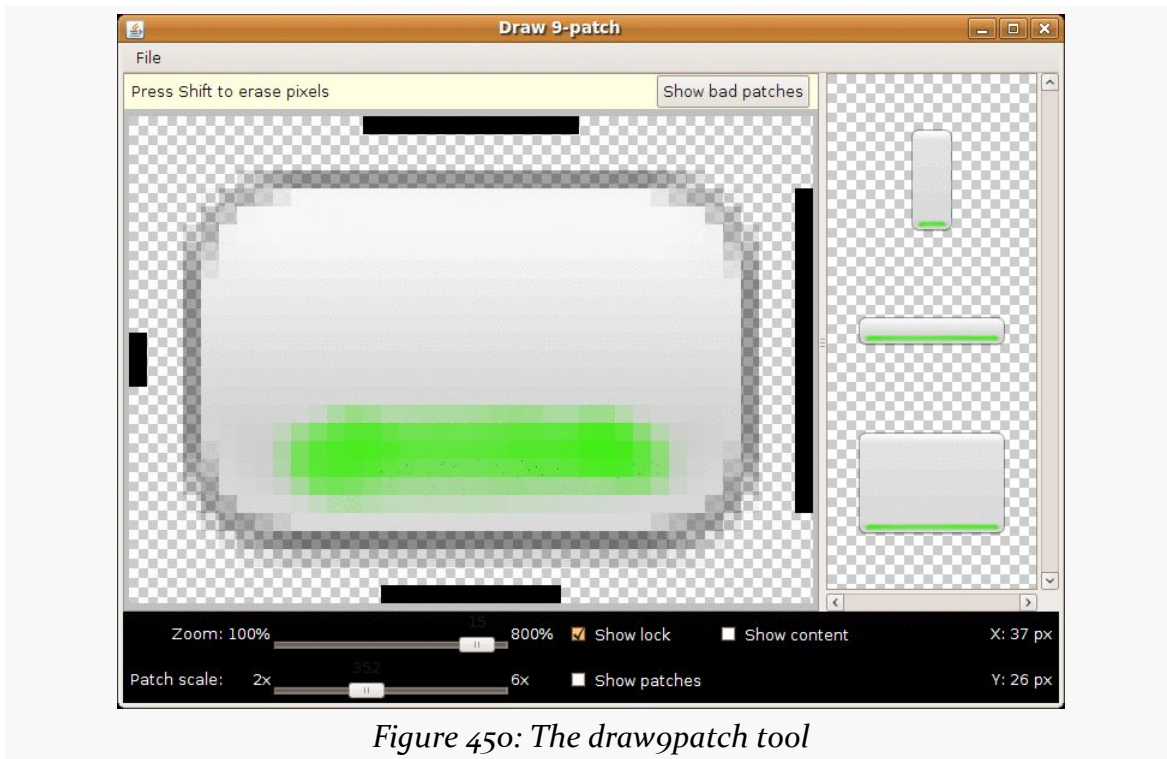

Figure 450: The draw9patch tool

Neither Android Studio nor Eclipse, at the present time, have a built-in version of `draw9patch`, so IDE users will need to run the standalone copy from their SDK installation.

While a regular graphics editor would allow you to draw any color on any pixel, `draw9patch` limits you to drawing or erasing pixels in the control area. If you attempt to draw inside the main image area itself, you will be blocked.

On the right, you will see samples of the image in various stretched sizes, so you can see the impact as you change the stretchable zones and padding box.

While this is convenient for working with the nine-patch nature of the image, you will still need some other graphics editor to create or modify the body of the image itself. For example, the image shown above, from the `Drawable/NinePatch` project, is

a modified version of a nine-patch graphic from the SDK's ApiDemos, where the GIMP was used to add the neon green stripe across the bottom portion of the image.

Using Nine-Patch Images

Nine-patch images are most commonly used as backgrounds, as illustrated by the following layout from the [Drawable/NinePatch](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:stretchColumns="1"
        >
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            >
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Horizontal:"
            />
            <SeekBar android:id="@+id/horizontal"
                android:layout_width="match_parent"
                android:layout_height="wrap_content"
            />
        </TableRow>
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            >
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Vertical:"
            />
            <SeekBar android:id="@+id/vertical"
                android:layout_width="match_parent"
                android:layout_height="wrap_content"
            />
        </TableRow>
    </TableLayout>
</LinearLayout>
```

```
        android:orientation="vertical"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    >
    <Button android:id="@+id/resize"
        android:layout_width="96px"
        android:layout_height="96px"
        android:text="Hi!"
        android:textSize="5pt"
        android:background="@drawable/button"
    />
</LinearLayout>
</LinearLayout>
```

Here, we have two SeekBar widgets, labeled for the horizontal and vertical axes, plus a Button set up with our nine-patch graphic as its background (android:background = "@drawable/button").

The NinePatchDemo activity then uses the two SeekBar widgets to let the user control how large the button should be drawn on-screen, starting from an initial size of 64px square:

```
package com.commonware.android.ninepatch;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.LinearLayout;
import android.widget.SeekBar;

public class NinePatchDemo extends Activity {
    SeekBar horizontal=null;
    SeekBar vertical=null;
    View thingToResize=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        thingToResize=findViewById(R.id.resize);

        horizontal=(SeekBar)findViewById(R.id.horizontal);
        vertical=(SeekBar)findViewById(R.id.vertical);

        horizontal.setMax(144); // 240 less 96 starting size
        vertical.setMax(144); // keep it square @ max

        horizontal.setOnSeekBarChangeListener(h);
        vertical.setOnSeekBarChangeListener(v);
    }
}
```

```
}

SeekBar.OnSeekBarChangeListener h=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
                                   int progress,
                                   boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(64+progress,
                                                                           old.height);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};

SeekBar.OnSeekBarChangeListener v=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
                                   int progress,
                                   boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(old.width,
                                                                           64+progress);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
}
```

The result is an application that can be used much like the right pane of draw9patch, to see how the nine-patch graphic looks on an actual device or emulator in various sizes:

CUSTOM DRAWABLES

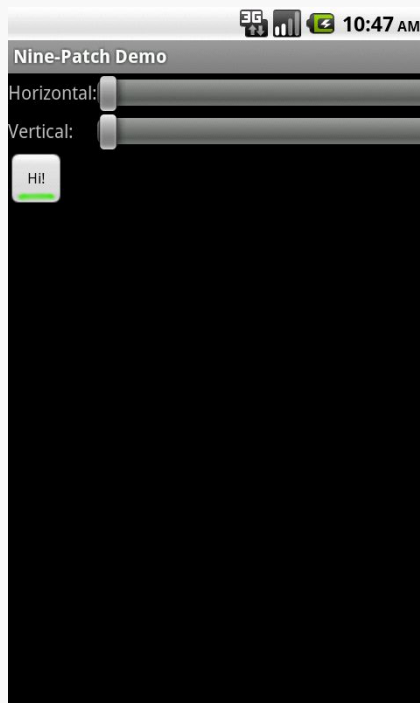

Figure 451: The NinePatch sample project, in its initial state

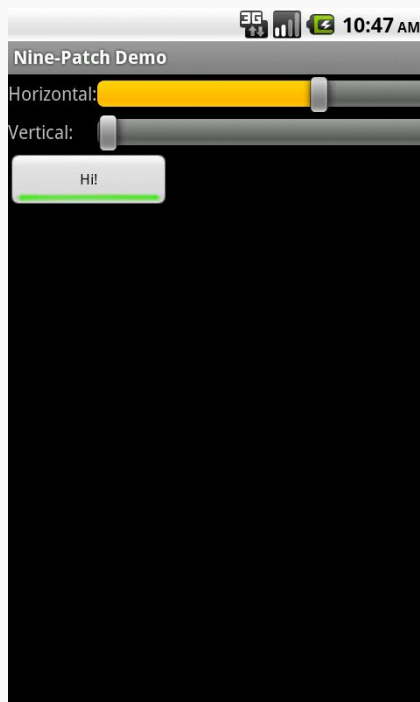

Figure 452: The NinePatch sample project, after making it bigger horizontally

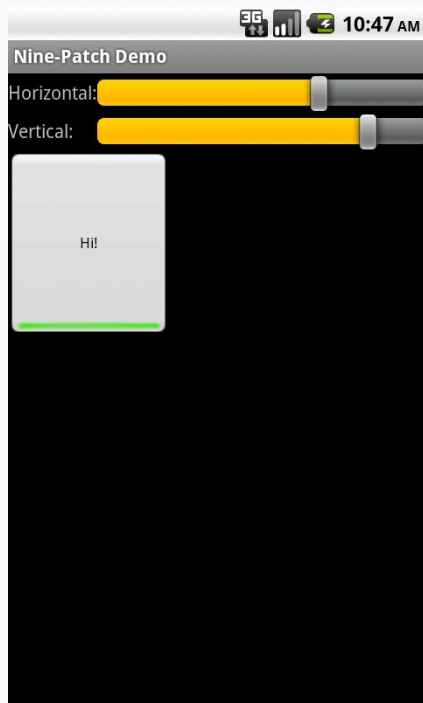

Figure 453: The NinePatch sample application, after making it bigger in both dimensions

Mapping with Maps V2

One of Google's most popular services — after search, of course – is Google Maps, where you can find everything from the nearest pizza parlor to directions from New York City to San Francisco (only 2,905 miles!) to street views and satellite imagery.

Android has had mapping capability from the beginning, with an API available to us as developers to bake maps into our apps. However, as we will [see shortly](#), that original API was getting a bit stale.

In December 2012, Google released a long-awaited update to the mapping capabilities available to Android app developers. The original mapping solution, now known as the Maps V1, worked but had serious limitations. The new mapping solution, known as Maps V2, offers greater power and greater ease of handling common situations, though it too has its rough edges.

Prerequisites

Understanding this chapter requires that you have read the core chapters, along with [the chapter on drawables](#). Many of the samples also employ [list navigation in the action bar](#) — while this is not needed to use Maps V2, knowing that material will help you understand a bit of how the samples work. Also, one of the samples involves [location tracking](#), and another of the samples involves the use of [the animator framework](#).

This chapter also makes the occasional reference back to Maps V1 for comparisons, mostly for the benefit of developers already familiar with Maps V1 and looking to migrate to Maps V2. However, prior experience with Maps V1 is not necessary to understand this chapter.

One section involves the use of Picasso, covered in [the chapter on Internet access](#).

A Brief History of Mapping on Android

Back in the dawn of Android, we were given the Maps SDK add-on. This would allow us to load a firmware-hosted mapping library into our applications, then embed maps into our activities, by means of a MapView widget.

And it worked.

More importantly, from the standpoint of users, the results from our apps were visually indistinguishable from the built-in Maps application available on devices that had the Maps SDK add-on.

This was the case through most of 2009. Eventually, though, the Google Maps team wanted to update the Maps application... but, for whatever reason, the decision was made to *not* update the Maps SDK add-on as well. At this point, the Google Maps team effectively forked the Maps SDK add-on, causing the Maps application to diverge from what other Android app developers could deliver. Over time, this feature gap became quite pronounced.

The release of Android 3.0 in early 2011 compounded the problems. Now, we needed to consider using fragments to help manage our code and deliver solutions to all screen sizes. Alas, while we could add maps to our fragments, we could only do so on API Level 11 or higher — the fragments backport from the Android Support package did not work with the Maps SDK add-on.

The release of Maps V2 helped all of this significantly. Now we have proper map support for native and backported versions of the fragment framework. We also have a look and feel that is closer to what the Maps application itself supports. While we still cannot reach feature parity with the Maps application, our SDK apps can at least look like they belong on the same device as the Maps application.

More importantly, as of the time of this writing, Maps V1 is no longer an option for new developers. Those who already have Maps V1 API keys can use Maps V1, but no new Maps V1 API keys are being offered. That leaves you with either using Maps V2 or [some alternative mapping solution](#).

Where You Can Use Maps V2

Many devices will be able to use Maps V2... but not all. Notably:

- Devices need to support OpenGL ES 2.0+, to handle the new vector-based tiles that Maps V2 uses. [Over 99% of Android devices](#) in use today that support the Play Store (or its “Android Market” predecessor) also support OpenGL ES 2.0+.
- Devices will need an update to the Google Services Framework that accompanies the Play Store. Devices that do not have the Play Store — either because they are forever stuck on the old Android Market or, like the Kindle Fire, never had Play Store support in the first place — will be unable to use Maps V2.

[Later in this chapter](#), we will look at other mapping libraries that you could use instead of either of Google’s mapping solutions.

For many developers, the biggest limitation at the present time is that Maps V2 support does not exist in the Android emulator images. Google has indicated that this will be resolved in the not-too-distant future. While there are recipes online for hacking Maps V2 support into other emulator images, these recipes rely upon pirated versions of various pieces of Google software and therefore are not recommended.

Licensing Terms for Maps V2

As with the original Maps SDK add-on, to use Maps V2, you must agree to [a terms of service agreement](#) to be authorized to embed Google Maps within your application. If you intend to use Maps V2, you should review these terms closely, as they place many restrictions on developers. The most notorious of these is that you cannot use Maps V2 to create an application that offers “real time navigation or route guidance, including but not limited to turn-by-turn route guidance that is synchronized to the position of a user’s sensor-enabled device.”

If you find these terms to be an issue for your application, you may need to consider [alternative mapping solutions](#).

What You Need to Start

If you wish to use Maps V2 in one or more of your Android applications, this section will outline what you need to get started.

Your Signing Key Fingerprint(s)

As with the legacy Maps SDK add-on, you will need fingerprints of your app signing keys, to tie your apps to your Google account and the API keys you will be generating. However, unlike the legacy Maps SDK add-on, the fingerprints you will be using will be created using the SHA-1 hash algorithm, rather than MD5.

First, you will need to know where the keystore is for your signing key. For a production keystore that you created yourself for your production apps, you should know where it is located already. For the debug keystore, used by default during development, the location is dependent upon operating system:

- OS X and Linux: `~/.android/debug.keystore`
- Windows XP: `C:\Documents and Settings\%USER\.android\debug.keystore`
- Windows Vista and Windows 7: `C:\Users\%USER\.android\debug.keystore`

(where `%USER` is your Windows user name)

You will then need to run the `keytool` command, to dump information related to this keystore. The `keytool` command is in your Java SDK, not the Android SDK. You will need to run this from a command line (e.g., Command Prompt in Windows). The specific command to run is:

```
keytool -list -v -keystore ... -alias androiddebugkey -storepass android  
-keypass android
```

where the `...` is replaced by the path to your debug keystore, enclosed in quotation marks if the path contains spaces. For your production keystore, you would supply your own alias and passwords.

This should emit output akin to:

```
Alias name: androiddebugkey  
Creation date: Aug 7, 2011  
Entry type: PrivateKeyEntry  
Certificate chain length: 1
```

```
Certificate[1]:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
  MD5: 98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
  SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
  Signature algorithm name: SHA1withRSA
  Version: 3
```

You will need to make note of the SHA1 entry (see third line from the bottom of the above sample).

Your Google Account

To sign up for an API key, you need a Google account. Ideally, this account would be the same one you intend to use for submitting apps to the Play Store (if, indeed, you intend to do so).

Your API Key

Given that you are logged into the aforementioned Google account, you can visit [the Google Cloud Console](#) to request access to the Maps V2 API. They have a tendency to keep changing this set of pages, but these instructions were good as of late February 2014:

- Create a project via the “Create project” option, if you have not done so already for something else (e.g., [GCM](#))
- Open your project, then select “APIs & auth” from the left navigation bar, and in there select “APIs”
- Sift through the various APIs until you find “Google Maps Android API v2”, then toggle that on
- Agree to the Terms of Service that appears when you try to toggle on Maps V2 access
- Click “Credentials” in the left navigation bar
- Click the “CREATE NEW KEY” button
- In the popup dialog, choose “Android key”
- In the fields that appear once you chose “Android key”, fill in your app’s package name and your SHA1 fingerprint, then click the “Create” button

This will give you an “API key” that you will need for your application.

MAPPING WITH MAPS V2

If you wish to have more than one app use Maps V2, you can click “Edit allowed Android applications” for a key, to return to the dialog where you can paste in another SHA1 fingerprint and package name, separated by a semicolon. Or, if you prefer, you can create new keys for each application.

For apps that are in (or going to) production, you will need to supply both the debug and production SHA1 fingerprints with your package name. By doing this on the same key, you will use the same API key string for both debug and production builds, which simplifies things a fair bit over the separate API keys you would have used with the legacy Maps SDK add-on.

Also note that a single API key seems to only support a few fingerprint/package pairs. If you try adding a new pair, and the form ignores you, you will need to set up a separate API key for additional pairs.

The Play Services Library

You also need to set up the Google Play Services library for use with your app.

First, you will need to download the “Google Play services” package in your SDK Manager (see highlighted line):

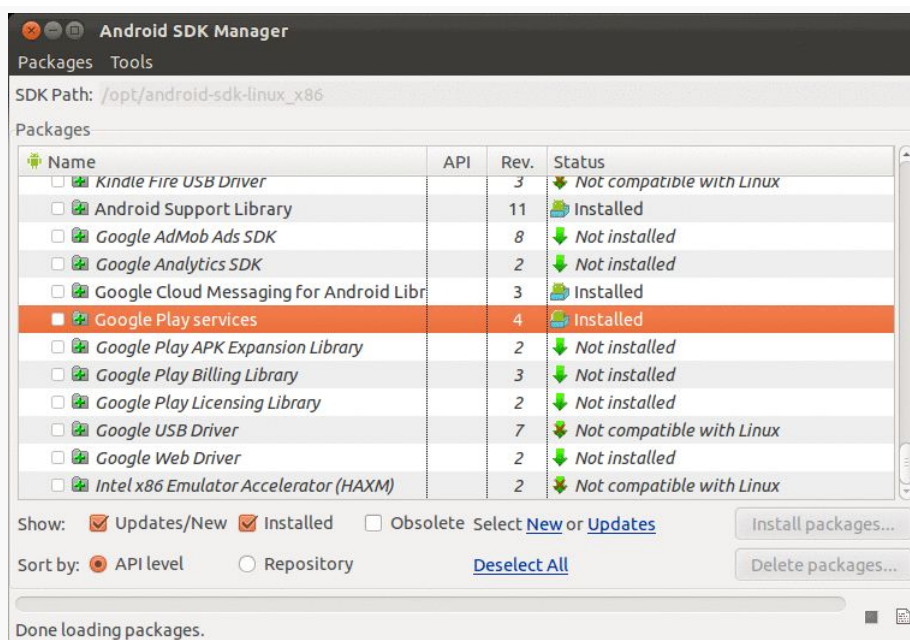

Figure 454: Android SDK Manager, Showing “Google Play services”

Android Studio users will also want to download the “Google Repository”, also in the same “Extras” area of the SDK Manager.

From there, things vary based on IDE.

Android Studio

Given that you have downloaded the above items, all you need to do is add a dependency on `com.google.android.gms:play-services-maps` for some likely version (e.g., `com.google.android.gms:play-services-maps:6.5.87`) to your dependencies closure.

Eclipse

You will need to add the Play Services Android library project to your workspace. You can do this via the “Import Existing Android Code into Workspace” wizard, pointing Eclipse to the `extras/google/google_play_services/libproject/google-play-services_lib/` directory inside of your Android SDK (or to a copy of it that you make elsewhere, if you prefer).

When you create a project that is to use Maps V2, you will need to add a reference to that library project, via the Eclipse project properties dialog.

Play Services and ProGuard

Note that [the Play Services documentation](#) requests that you add the following stanza to your `proguard-project.txt` file for use by your production builds:

```
-keep class * extends java.util.ListResourceBundle {
    protected Object[][] getContents();
}

-keep public class
com.google.android.gms.common.internal.safeparcel.SafeParcelable {
    public static final *** NULL;
}

-keepnames @com.google.android.gms.common.annotation.KeepName class *
-keepclassmembernames class * {
    @com.google.android.gms.common.annotation.KeepName *;
}

-keepnames class * implements android.os.Parcelable {
```

```
    public static final ** CREATOR;  
}
```

The Book Samples... And You!

If you wish to try to run the book samples outlined in this chapter, you will need to make a few fixes to them for your own environment:

- Replace the Maps V2 API key in the manifest with your own
- Replace the reference to the Play Services Android library project with your own
- Change the build target to an Android SDK that you have downloaded (or download the Android SDK used by the project)

Setting Up a Basic Map

With that preparation work completed, now you can start working on projects that use the Maps V2 API. In this section, we will review the [MapsV2/Basic](#) sample project, which simply brings up a Maps V2 map on the world.

The Project Setup and the Manifest

This project uses Maps V2, and so it has a reference to that library project.

Our manifest file is fairly traditional, though there are a number of elements in it that are required by Maps V2:

```
<?xml version="1.0" encoding="utf-8"?>  
<manifest xmlns:android="http://schemas.android.com/apk/res/android"  
    package="com.commonware.android.mapsv2.basic"  
    android:versionCode="1"  
    android:versionName="1.0">  
  
    <uses-sdk  
        android:minSdkVersion="14"  
        android:targetSdkVersion="16"/>  
  
    <uses-permission android:name="android.permission.INTERNET"/>  
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>  
    <uses-permission  
android:name="com.google.android.providers.gsf.permission.READ_GSERVICES"/>  
    <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"/>  
  
    <uses-feature
```

```
    android:glEsVersion="0x00020000"
    android:required="false"/>

<application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
        android:name="MainActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>

    <meta-data
        android:name="com.google.android.maps.v2.API_KEY"
        android:value="AIzaSyC4iyT46cB00IdKGcy5EmAxK5uCOQX20y8"/>

    <meta-data
        android:name="com.google.android.gms.version"
        android:value="@integer/google_play_services_version"/>

    <activity android:name="LegalNoticesActivity">
    </activity>
</application>

</manifest>
```

Specifically:

- We need the INTERNET, ACCESS_NETWORK_STATE, and WRITE_EXTERNAL_STORAGE permissions, plus the com.google.android.providers.gsf.permission.READ_GSERVICES permission, all defined in <uses-permission> elements
- We need a <meta-data> element, with a name of com.google.android.maps.v2.API_KEY, whose value is the API key we got from the Google APIs Console for use with this particular package name
- We need a second <meta-data> element, with a name of com.google.android.gms.version, with a value of the @integer/google_play_services_version (an integer resource supplied by the Play Services SDK library project)

We also should include a <uses-feature> element for OpenGL ES 2.0. If your app absolutely must be able to run Maps V2, have android:required="true" (or drop

the `android:required` attribute entirely, as `true` is the default), which will force devices to have OpenGL ES 2.0 to run your app. If your app will gracefully degrade for devices incapable of running Maps V2, use `android:required="false"`, as is shown in the sample.

Beyond those items, everything else in this project is based on what the app needs, more so than what Maps V2 needs.

Note that we used to need to define and use a custom permission, based upon our app's package name and ending in `MAPS_RECEIVE`. This is not required as of Play Services 3.1.59 and the “rev 8” release of the Play Services SDK.

The Play Services Detection

In the fullness of time, all devices that are capable of using Maps V2 will already have the on-device portion of this logic, known as the “Google Play services” app.

However, it is entirely possible, in the short term, that you will encounter devices that are capable of using Maps V2 (e.g., they have OpenGL ES 2.0 or higher), but do not have the “Google Play services” app from the Play Store, and therefore you cannot actually *use* Maps V2 in your app.

This is a departure from the Maps V1 approach, where either the device shipped with maps capability, or it did not, and nothing (legally) could be done to change that state.

To determine whether or not the Maps V2 API is available to you, the best option is to call the `isGooglePlayServicesAvailable()` static method on the `GooglePlayServicesUtil` utility class supplied by the Play Services library. This will return an `int`, with a value of `ConnectionResult.SUCCESS` if Maps V2 can be used right away.

Actually assisting the user to get Maps V2 set up all the way is conceivable but is also bug-riddled and annoying. The `MapsV2/Basic` sample app has an `AbstractMapActivity` base class that is designed to hide most of this annoyance from you. If you wish to know the details of how this works, we will cover it [later in this chapter](#). The fact that this is bug-riddled also has impacts on whether or not you should be using Maps V2 at all for your app, a point which we will examine [in an upcoming section](#).

The Fragment and Activity

Our main activity — MainActivity — extends from the aforementioned AbstractMapActivity and simply overrides onCreate(), as most activities do:

```
package com.commonware.android.mapsv2.basic;

import android.os.Bundle;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);
        }
    }
}
```

We call setContentView() to load up the activity_main layout resource:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/map"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    class="com.google.android.gms.maps.MapFragment"/>
```

That resource, in turn, has a <fragment> element pointing to a com.google.android.gms.maps.MapFragment class supplied by the Play Services library. This is a fragment that knows how to display a Maps V2 map. There is a corresponding com.google.android.gms.maps.SupportMapFragment class for use with the fragments backport from the Android Support library.

You will notice, though, that we only call setContentView() if a readyToGo() method returns true. The readyToGo() method is supplied by the AbstractMapActivity class and returns true if we are safe to go ahead and use Maps V2, false otherwise. In the false case, AbstractMapActivity will be taking care of trying to get Maps V2 going, and we need do nothing further.

The License

According to the terms of use for Maps V2, you must show Maps V2 license information in your app's UI, in some likely spot. Apps that show their own license

terms, or have an “about” activity (or dialog) could display them there. Otherwise, you will need to have a dedicated spot for the Maps V2 license.

To obtain the license text, you can call `getOpenSourceSoftwareLicenseInfo()` on the `GooglePlayServicesUtil` utility class. This text can then be popped into a `TextView` somewhere in your app. `AbstractMapActivity` adds an action bar overflow item to display the license, which in turn invokes a `LegalNoticesActivity`, which simply displays the license text in a `TextView`. We will examine this in more detail [later in this chapter](#).

The Result

When you run the app, assuming that Maps V2 is ready for use, you will get a basic map showing the west coast of Africa:

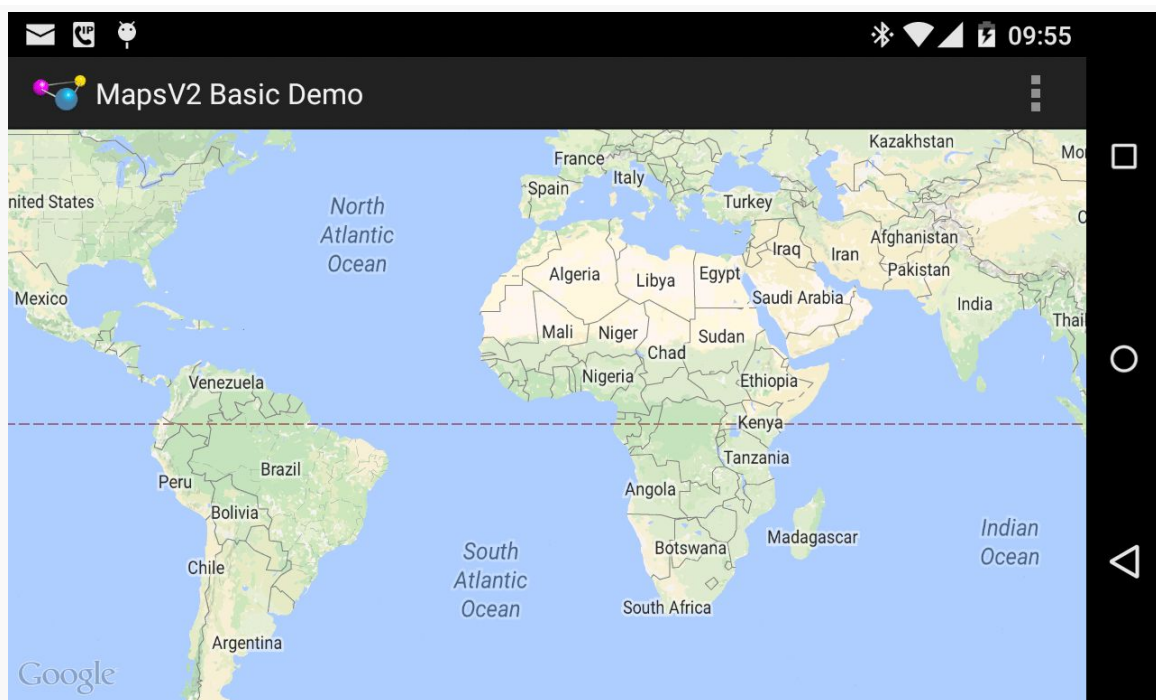

Figure 455: Maps V2 Map, as Initially Viewed

If you choose the “Legal Notices” action bar item, the view shifts to show a bunch of license terms:

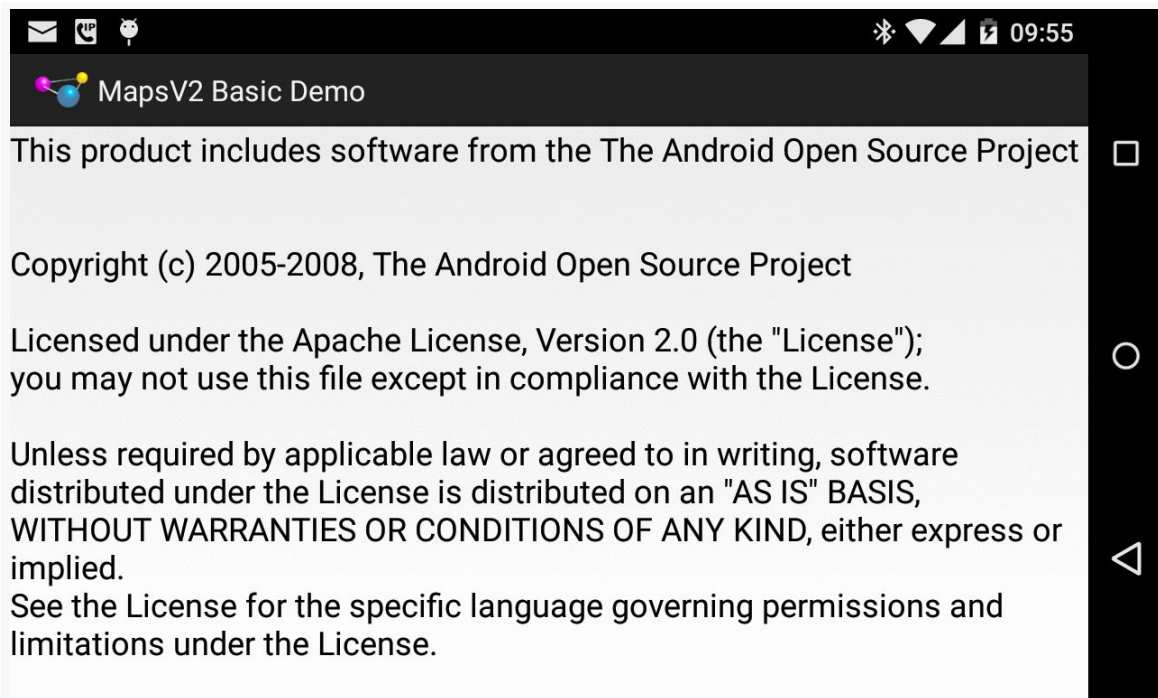

Figure 456: Maps V2 License Terms

If your Maps V2 API key is incorrect, or you do not have this app's package name set up for that key in the Google APIs Console, you will get an "Authorization failure" error message in LogCat, and you will get a blank map, akin to the behavior seen in Maps V1 when you had an invalid `android:apiKey` attribute on the `MapView`.

Playing with the Map

Showing a map of the west coast of Africa is nice, and it is entirely possible that is precisely what you wanted to show the user. If, on the other hand, you wanted to show the user something else — another location, a closer look, etc. — you will need to further configure your map, via a `GoogleMap` object.

To see how this is done, take a look at the [MapsV2/NooYawk](#) sample application. This is a clone of `MapsV2/Basic` that adds in logic to center and zoom the map over a portion of New York City.

The `onCreate()` method of the revised `MapActivity` is now a bit more involved:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);

if (readyToGo()) {
    setContentView(R.layout.activity_main);

    MapFragment mapFrag=
        (MapFragment)getFragmentManager().findFragmentById(R.id.map);

    if (savedInstanceState == null) {
        mapFrag.getMapAsync(this);
    }
}
```

After calling `setContentView()`, we can retrieve our `MapFragment` via `findFragmentById()`, no different than any other static fragment.

Then, if `savedInstanceState` is `null` — meaning that the activity is not being recreated, but instead is being created from scratch — we call `getMapAsync()` on the `MapFragment`. This triggers some asynchronous work to set up a `GoogleMap` object. `getMapAsync()` takes an implementation of `OnMapReadyCallback` as a parameter. In this case, `OnMapReadyCallback` is implemented on the activity itself.

That `GoogleMap` object will then be delivered to us in `onMapReady()`. Most of our work in configuring the map will be accomplished by calling methods on this `GoogleMap` object.

To change where the map is centered, we can create a `CameraUpdate` object from the `CameraUpdateFactory` (“camera” in this case referring to the position of the user’s virtual eyes with respect to the surface of the Earth). The `newLatLng()` factory method on `CameraUpdateFactory` will give us a `CameraUpdate` object that can re-center the map over a supplied latitude and longitude. Those coordinates are encapsulated in a `LatLng` object and are maintained as decimal degrees as Java `float` or `double` values (as opposed to the Maps V1 `GeoPoint`, which used integer microdegrees).

To change the zoom level of the map, we need another `CameraUpdate` object, this time from the `zoomTo()` factory method on `CameraUpdateFactory`. As with Maps V1, the zoom levels start at 1 and zoom in by powers of two. As you will see, a value of 15 gives you a nice block-level view of a city like New York City.

To actually apply these changes to the map, we have two methods on `GoogleMap`:

- In our case, we immediately shift to the proper position, but then zoom in from the default zoom level to 15, giving us a map centered over Columbus Circle, in the southwest corner of Central Park in Manhattan:

Map Tiles

The map, by default, shows the normal tile set. `setMapType()` on the `GoogleMap` allows you to switch to satellite, hybrid (satellite view plus place labels), or terrain tile sets.

Placing Simple Markers

In Maps V1, if we wanted to annotate a map, we used an `Overlay`. For markers — push-pins and the like — typically we would use an `ItemizedOverlay`, which handled a lot of the work of rendering these markers and responding to taps upon markers. However, `ItemizedOverlay` had its issues, particularly with regards to performance with large numbers of markers.

With Maps V2, the entire `Overlay` system is eliminated. Instead, you simply hand markers to the `GoogleMap` for display, as is illustrated in the [MapsV2/Markers](#) sample application. This is a clone of `MapsV2/NooYawk`, with four markers for four landmarks within Manhattan.

Our `onCreate()` method on `MainActivity` now always invokes `getMapAsync()`, not just when the activity is first created. However, we still check `savedInstanceState` and set a new `needsInit` boolean data member to `true` if `savedInstanceState` is `null`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
        setContentView(R.layout.activity_main);

        MapFragment mapFrag=
            (MapFragment)getFragmentManager().findFragmentById(R.id.map);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        mapFrag.getMapAsync(this);
    }
}
```

MAPPING WITH MAPS V2

Our `onMapReady()` method performs the camera adjustments if `needsInit` is true. It also has four additional statements – calls to a private `addMarker()` method to define the four landmarks:

```
@Override
public void onMapReady(GoogleMap map) {
    if (needsInit) {
        CameraUpdate center=
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                                                        -73.98180484771729));

        CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

        map.moveCamera(center);
        map.animateCamera(zoom);
    }

    addMarker(map, 40.748963847316034, -73.96807193756104,
               R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
               R.string.lincoln_center,
               R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
               R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
               R.string.downtown_club, R.string.heisman_trophy);
}
```

The `addMarker()` method on our `MainActivity` adds markers by creating a `MarkerOptions` object and passing it to the `addMarker()` on `GoogleMap`. `MarkerOptions` offers a so-called “fluent” interface, with a series of methods to affect one aspect of the `MarkerOptions`, each of which returns the `MarkerOptions` object itself. That way, configuring a `MarkerOptions` is a chained series of method calls:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                  .title(getString(title))
                  .snippet(getString(snippet)));
}
```

Here, we:

- Set the `position()` of the marker, in the form of another `LatLng` object
- Set the `title()` and `snippet()` of the marker to be a pair of strings loaded from string resources

We will see other methods available on `MarkerOptions` in upcoming sections of this chapter.

MAPPING WITH MAPS V2

`addMarker()` on `GoogleMap` returns an actual `Marker` object, which we could hold onto to change certain aspects of it later on (e.g., its title). In the case of this sample, we ignore this.

Now, you may be wondering why we set up the markers on every `onMapReady()` invocation, not just in the `needsInit` block. That is because while a `MapFragment` retains its camera information (center, zoom, etc.), it does *not* retain its markers on a configuration change. Hence, we need to re-establish the markers in all calls to `onCreate()`, not just the very first one.

With no other changes, we get a version of the map that shows markers at our designated locations:

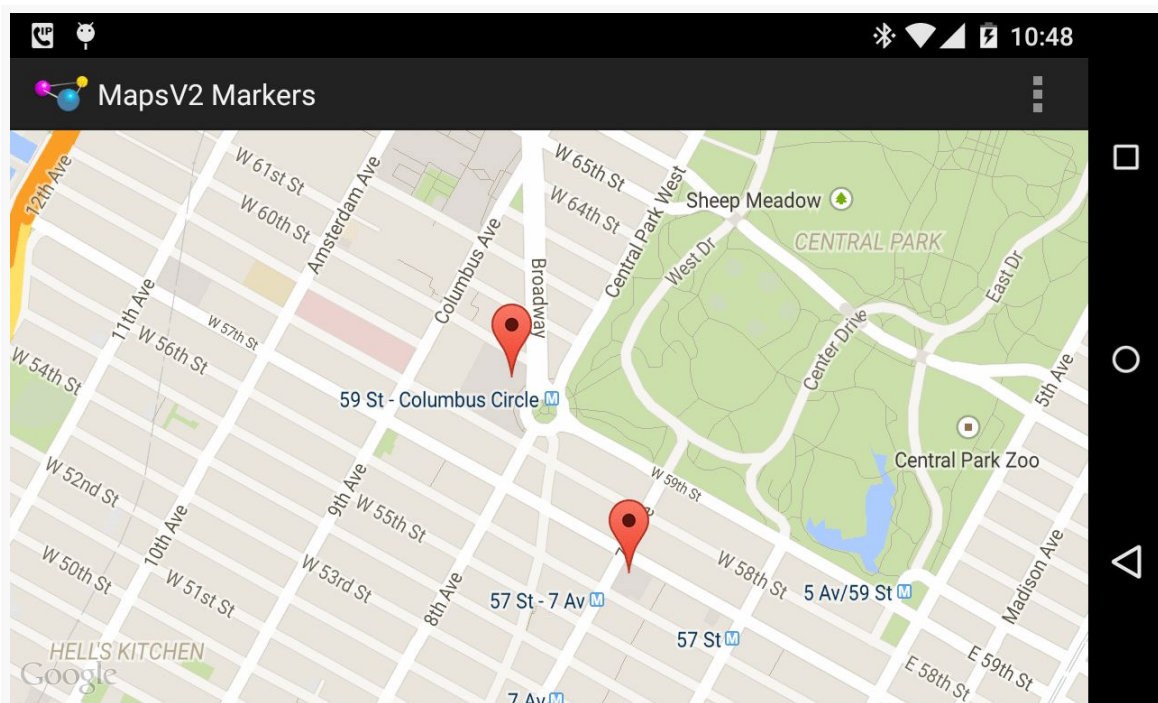

Figure 458: Maps V2 with Two Markers

Initially, we only see two markers, as the other two are outside the current center position and zoom level of the map. If the user changes the center or zoom, markers will come and go as needed:

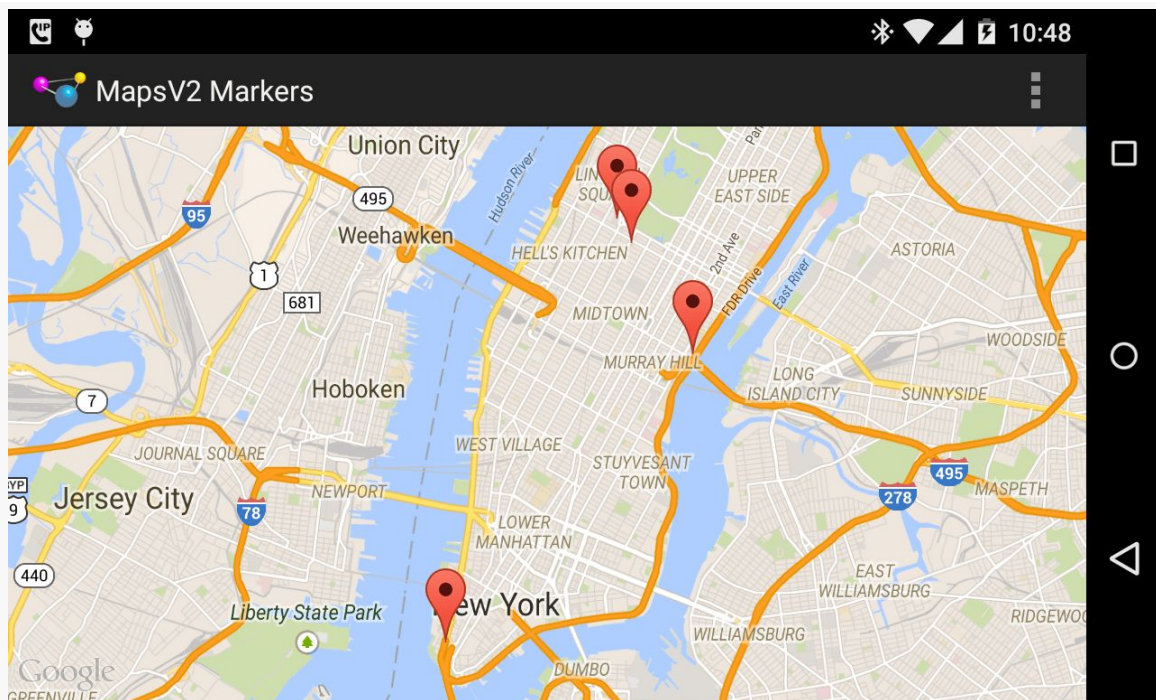

Figure 459: Maps V2 with All Four Markers

We do not need to worry about managing the markers ourselves, so long as the GoogleMap performance is adequate. It is likely that dumping 10,000 markers into a GoogleMap will still result in sluggish responses, though, so you may need to add and remove markers yourself based upon what portion of the world the user happens to be examining in the map at the moment.

Seeing All the Markers

When you add markers to a map, there is no guarantee that the markers will be visible given the map's current center position and zoom level. In fact, it is entirely possible that you add a bunch of markers and *none* are visible, so the user may not realize that the markers were added.

There is a way that you can center and zoom the map to show some set of markers, based on their positions. You get to choose the markers: all of them, the four nearest markers, etc.

MAPPING WITH MAPS V2

We can see how this works in the [MapsV2/Bounds](#) sample application. This is a clone of MapsV2/Markers from the previous section, with reworked code to show all four markers when the map is first displayed.

The key to making this work is a `LatLngBounds` object. This represents a bounding box that contains all `LatLng` locations handed to the `LatLngBounds`. To build up a `LatLngBounds`, you can use the `LatLngBounds.Builder` class. So, our revised `MainActivity` has a `LatLngBounds.Builder` private data member:

```
private LatLngBounds.Builder builder=new LatLngBounds.Builder();
```

Our revised `addMarker()` method adds the `LatLng` values from our markers as they are added to the map:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                      .title(getString(title))
                      .snippet(getString(snippet)));

    builder.include(marker.getPosition());
}
```

Finally, the revised `onMapReady()` moves the `CameraUpdateFactory` work until after all four of the `addMarker()` calls and changes it a bit:

```
@Override
public void onMapReady(final GoogleMap map) {
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy);

    if (needsInit) {
        findViewById(android.R.id.content).post(new Runnable() {
            @Override
            public void run() {
                CameraUpdate allTheThings=
                    CameraUpdateFactory.newLatLngBounds(builder.build(), 32);

                map.moveCamera(allTheThings);
            }
        });
    }
}
```

```
}  
}
```

Specifically, we:

- Ask the `LatLngBounds.Builder` to `build()` the `LatLngBounds`
- Pass that to the `newLatLngBounds()` method on `CameraUpdateFactory`, along with an inset value in pixels (all `LatLng` locations will be that many pixels in from the edges, or more)
- Use `moveCamera()` to center and zoom the map based upon the resulting `CameraUpdate`

All of this is done in a `Runnable` which we `post()` to a `View` (here, the `FrameLayout` of our activity supplied by Android as `android.R.id.content`). `GoogleMap` cannot ensure that all of our markers are visible until it knows how big the map is, and that is not known until the map is rendered to the screen. `post()` will add our work to the end of the main application thread's work queue. The `Runnable` will not be run until after the map is on the screen, at which time the `CameraUpdate` can work.

Flattening and Rotating Markers

Markers, by default, appear to be “push pins” pressed into the surface of the map. This is not necessarily obvious with the default top-down perspective of the map camera. But, if you use a two-finger vertical swiping gesture, you can change the camera tilt, and that will illustrate the “push pin” effect a bit better:

MAPPING WITH MAPS V2

Figure 460: Maps V2 with Markers, Viewed on a Tilt

However, you have options for flat markers and rotated markers.

A flat marker is one that is flat on the map. In other words, rather than theoretically rising out of the Z axis of the map, the marker is kept on the X-Y plane:

MAPPING WITH MAPS V2

Figure 461: Maps V2 with Markers, One Normal, One Flat

It is also possible to rotate a marker. The flat marker in the previous screenshot is rotated 90 degrees from its normal “bulb on the north side” orientation. The following screenshot shows another flat marker, rotated 270 degrees from normal:

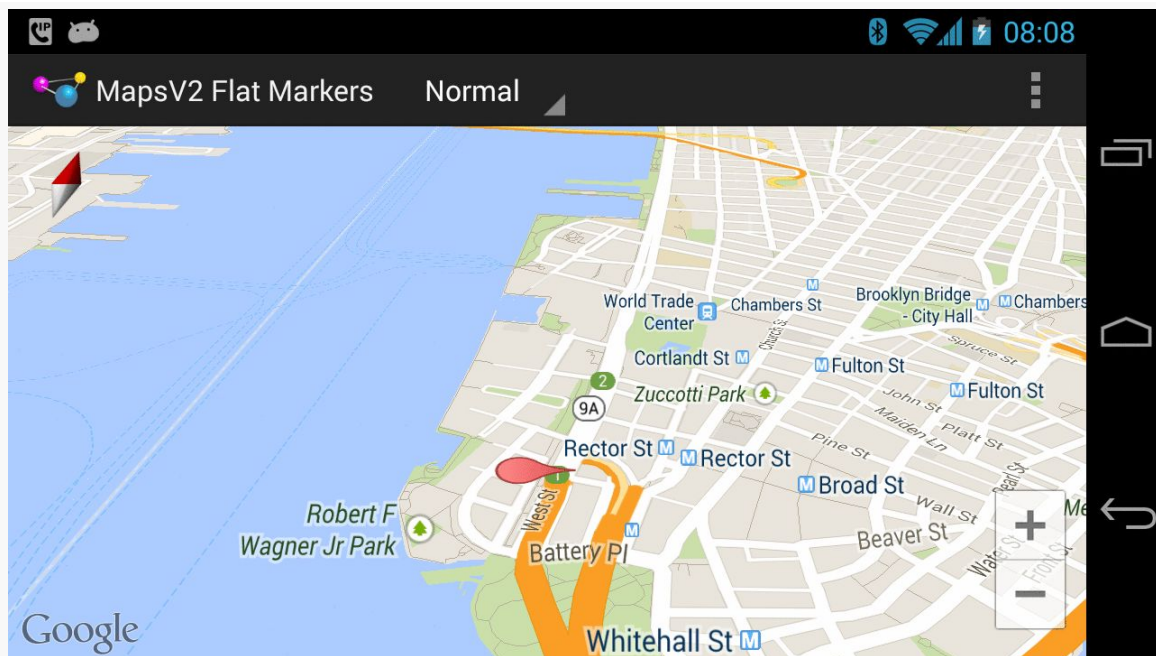

Figure 462: Maps V2 with Markers, Flat and Rotated

These features can be handy for providing pointers in a particular direction, such as indicating not only the location to make a turn, but what direction to turn at that location.

These capabilities are courtesy of new `flat()` and `rotation()` methods on `MarkerOptions`, plus corresponding getters and setters on `Marker` itself. To see how this works, let's examine the [MapsV2/FlatMarkers](#) sample application. This is a clone of `MapsV2/Markers`, with markers applied using different values for `flat()` and `rotation()`.

Specifically, our own `addMarker()` helper method now takes and applies a boolean parameter for `flat` (`true` means it is flat, `false` means normal behavior), as well as a float parameter for `rotation` (a value between 0 and 360 for the rotation off the default in degrees):

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet, boolean flat,
    float rotation) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet))
        .flat(flat).rotation(rotation));
}
```

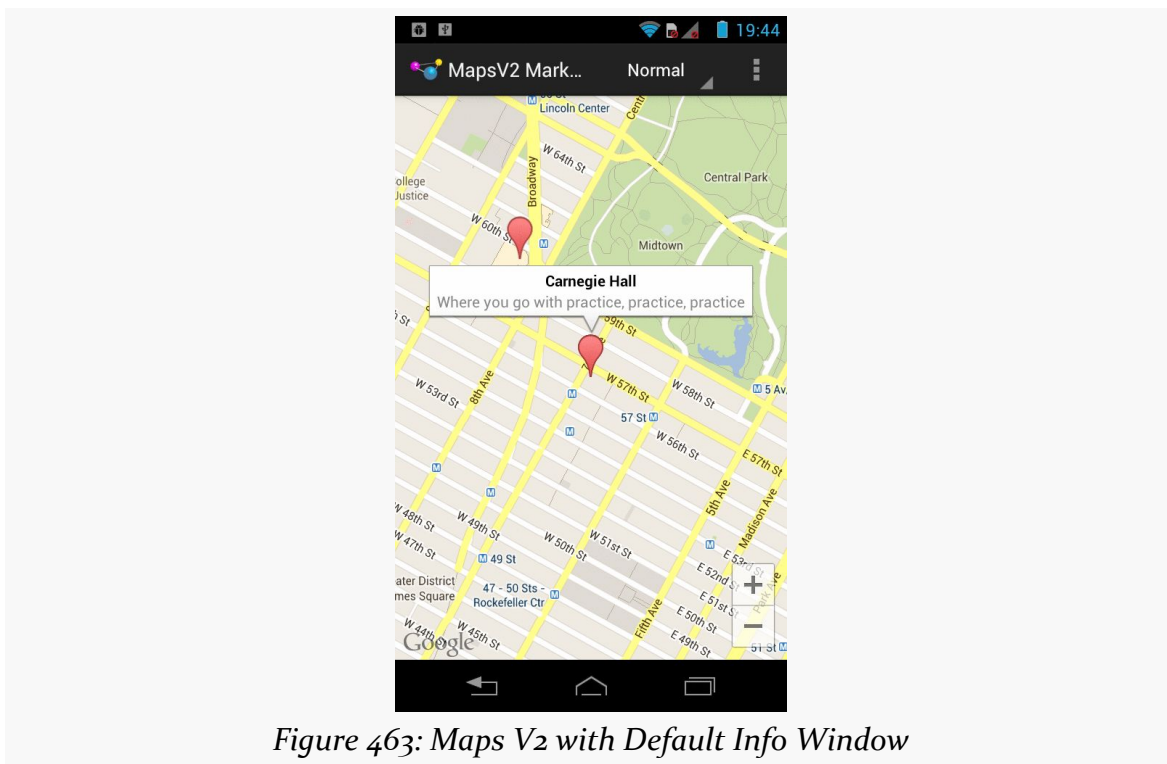

MAPPING WITH MAPS V2

When we call `addMarker()`, we supply corresponding values:

```
addMarker(map, 40.748963847316034, -73.96807193756104,  
          R.string.un, R.string.united_nations, false, 180);  
addMarker(map, 40.76866299974387, -73.98268461227417,  
          R.string.lincoln_center,  
          R.string.lincoln_center_snippet, false, 0);  
addMarker(map, 40.765136435316755, -73.97989511489868,  
          R.string.carnegie_hall, R.string.practice_x3, true, 90);  
addMarker(map, 40.70686417491799, -74.01572942733765,  
          R.string.downtown_club, R.string.heisman_trophy, true,  
          270);
```

Sprucing Up Your “Info Windows”

If the user taps on one of the markers from the preceding sample, Android will automatically display a popup, known as an “info window”:

You can tailor that “info window” if desired, either replacing just the interior portion (leaving the bounding border with its caret intact) or replacing the entire window. However, in the interests of memory conservation, you do not hand new View

widgets to the `MarkerOptions` object. Instead, you can provide an adapter that will be called when info windows (or their contents) are required.

To see how this works, we can examine the [MapsV2/Popups](#) sample application. This is a clone of `MapsV2/Markers`, where we are using our own layout file for the contents of the info windows, from the `popup.xml` layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:padding="2dip"
        android:src="@drawable/ic_launcher"
        android:contentDescription="@string/icon"/>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="vertical">

        <TextView
            android:id="@+id/title"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="25sp"
            android:textStyle="bold"/>

        <TextView
            android:id="@+id/snippet"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="15sp"/>
    </LinearLayout>
</LinearLayout>
```

Here, we will show the title and snippet in our own chosen font size and weight, plus show the launcher icon on the left.

To use this layout, we must create an `InfoWindowAdapter` implementation — in the case of this sample project, that is found in the `PopupAdapter` class:

```
package com.commonware.android.mapsv2.popups;

import android.annotation.SuppressLint;
import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    private View popup=null;
    private LayoutInflater inflater=null;

    PopupAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return(null);
    }

    @SuppressWarnings("InflateParams")
    @Override
    public View getInfoContents(Marker marker) {
        if (popup == null) {
            popup=inflater.inflate(R.layout.popup, null);
        }

        TextView tv=(TextView)popup.findViewById(R.id.title);

        tv.setText(marker.getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
        tv.setText(marker.getSnippet());

        return(popup);
    }
}
```

When an info window is to be displayed, Android will first call `getInfoWindow()` on our `InfoWindowAdapter`, passing in the `Marker` whose info window is needed. If we return a `View` here, that will be used for the entire info window. If, instead, we return `null`, Android will call `getInfoContents()`, passing in the same `Marker` object. If we return a `View` here, Android will use that as the “body” of the info window, with Android supplying the border. If we return `null`, the default info window is displayed. This way, we can conditionally do any of the three possibilities (replace the window, replace the contents, or accept the default).

In our case, `getInfoContents()` will inflate the `popup.xml` layout and populate the two `TextView` widgets with the title and snippet from the `Marker`. However, we cache

MAPPING WITH MAPS V2

the inflated layout and reuse it on the second and subsequent calls to `getInfoContents()`. Despite the “adapter” name conjuring up visions of `ListAdapter` and having multiple outstanding views, `InfoWindowAdapter` will only ever use one `View` at a time. Hence, rather than inflate our layout each time we need to show the info window, we can safely reuse the previously-used `View`.

Then, we just need to tell the `GoogleMap` to use our `InfoWindowAdapter`, via a call to `setInfoWindowAdapter()`, such as this statement from `onMapReady()` of our new edition of `MainActivity`:

```
map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
```

Now, when the user taps on a marker, they will get our customized info window:

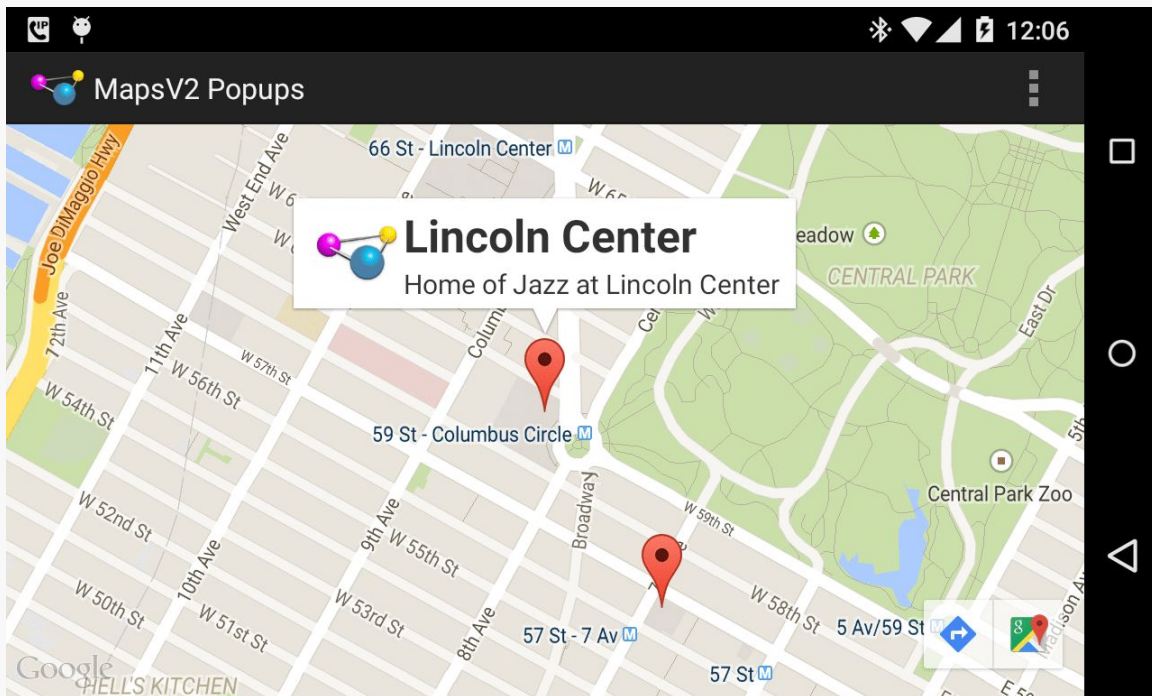

Figure 464: Maps V2 with Customized Info Window

We can also call `setOnInfoWindowClickListener()` on our `GoogleMap`, passing in an implementation of the `OnInfoWindowClickListener` interface, to find out when the user taps on the info window. In the case of `MainActivity`, we set up the activity itself to implement that interface and be the listener:

```
map.setOnInfoWindowClickListener(this);
```

MAPPING WITH MAPS V2

This requires us to implement an `onInfoWindowClick()` method, where we are passed the `Marker` representing the tapped-upon info window:

```
@Override
public void onInfoWindowClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();
}
```

Here, we just display a `Toast` with the title of the `Marker` when the user taps an info window:

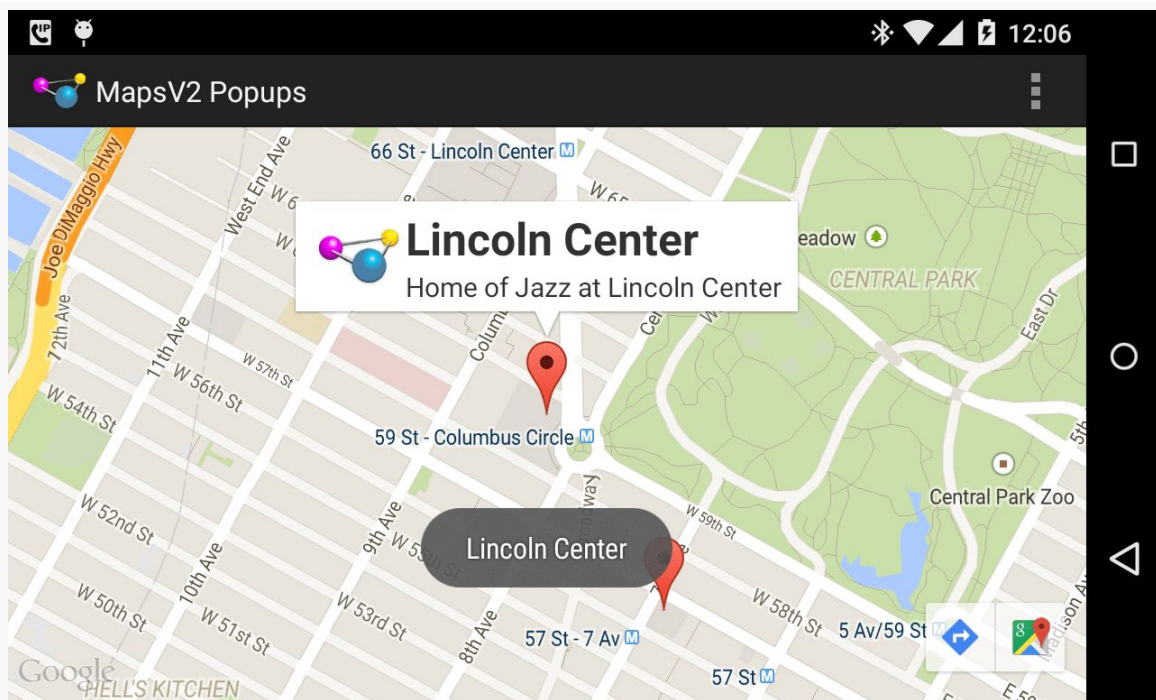

Figure 465: Maps V2 with Toast Triggered by Tap on Info Window

Note that, according to the documentation, you can only find out about taps on the entire info window. Indeed, if you try setting up click listeners on the widgets in your custom layout, you will find that they are not called. This is because the `View` you return for the info window is converted into a `Bitmap`, which is then displayed. Presumably, this is to steer developers in the direction of making larger tap targets, rather than expecting users to tap tiny elements within an info window. On the other hand, if your design calls for a large info window containing several navigation options, you will need to either re-think your design or avoid the info window system. We will see how to find out about taps on markers more directly [later in this chapter](#).

Images and Your Info Window

The `Bitmap` approach that Maps V2 uses for the info window introduces an additional challenge: updating the info window itself. Normally, we would just update the individual widgets in the info window, the way we might update widgets in an already-visible row in a `ListView`. However, that is not an option here, as our widgets are discarded almost immediately.

One particular occurrence of this problem comes when you want to show an image in the info window. If the image is a resource, or is already in memory, showing it is not a big problem, as you can just populate your `ImageView` in your info window with it. However, if the image is a file (or, worse, needs to be downloaded), you want to load the image asynchronously. However, if you kick off some background thread, like an `AsyncTask`, to retrieve the image, you will return from your `InfoWindowAdapter` method long before the task is complete. Your info window will show whatever placeholder image you used; the image you loaded will never be seen, even if you update your original `ImageView`.

There are two solutions to this problem.

The best solution, by far, is to have the images before you need them, wherever possible. For example, if you are showing a map with 25 markers, for which you need 25 thumbnail images, start downloading those images while you are showing the map. With luck, at the point in time when the user taps on a marker to show the info window, you will have your image already.

However, this approach will not work well if:

- You need a ridiculous number of images, or
- You need images, but they need to be downloaded full-sized and turned into thumbnails locally, as that might consume quite a bit of bandwidth, or
- Your last name is Murphy, and therefore the user taps on an info window before you have had a chance to prepare its image

The workaround is to make note of the `Marker` the user tapped upon to open its info window, then call `showInfoWindow()` on that `Marker` to cause the info window to be redisplayed once you have your image, triggering calls to your `InfoWindowAdapter`. There, you can see that your image cache includes the image that you need, and you can apply it to the info window.

The problem *here* is that it is possible that the user tapped on another marker, after the first one, while you were busily fetching and loading the image. Hence, rather than blindly calling `showInfoWindow()` on the Marker, you should call `isInfoWindowShown()` first, and only call `showInfoWindow()` to force the refresh if `isInfoWindowShown()` returns true. Otherwise, some other marker's info window is shown. The user is not expecting this earlier info window to somehow magically reappear.

All of this is a pain. It can be made a bit less of a pain by use of an image fetching-and-caching library like [Picasso](#). We can see how this can be applied by looking at the [MapsV2/ImagePopups](#) sample application. This is a clone of MapsV2/Popups, with some additions to handle lazy-populating an info window based upon a downloaded image.

First, since we are going to be generating some thumbnails based on downloaded imagery, it helps to establish a fixed-size `ImageView` for our icon. So, this project has a pair of dimension resources, for the image height and width:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <dimen name="icon_width">96dp</dimen>
    <dimen name="icon_height">64dp</dimen>
</resources>
```

Those are then used in a revised version of the popup layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="@dimen/icon_width"
        android:layout_height="@dimen/icon_height"
        android:padding="2dip"
        android:src="@drawable/ic_launcher"
        android:contentDescription="@string/icon"/>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:orientation="vertical">

        <TextView
```

```
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

        <TextView
            android:id="@+id/snippet"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="15sp"/>
    </LinearLayout>
</LinearLayout>
```

We need some way of keeping track of what images should be used for each marker. This is somewhat annoying to implement, as we cannot subclass `Marker`, since it is marked as `final` and cannot be extended. However, we can use `getId()` on a `Marker` to obtain a unique ID, and we can use that as the key to additional model data. We will examine variations on this technique [later in this chapter](#). For now, this sample gets away with a simple `HashMap`, mapping the string ID of a `Marker` to a `Uri` representing an image to be shown for that `Marker`'s info window:

```
private HashMap<String, Uri> images=new HashMap<String, Uri>();
```

Our private `addMarker()` method now takes a `String` name of an image, and it adds a `Uri` pointing to that image to the `HashMap`, keyed by the ID of the generated `Marker`:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet, String image) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                      .title(getString(title))
                      .snippet(getString(snippet)));

    if (image != null) {
        images.put(marker.getId(),
                  Uri.parse("http://misc.commonsware.com/mapsv2/"
                           + image));
    }
}
```

For three of our markers, we pass in actual filenames; for a fourth, `null` is used, indicating that there is no suitable image for use:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations, "UN_HQ.jpg");
addMarker(map, 40.76866299974387, -73.98268461227417,
```

```
        R.string.lincoln_center,
        R.string.lincoln_center_snippet,
        "Avery_Fisher_Hall.jpg");
    addMarker(map, 40.765136435316755, -73.97989511489868,
        R.string.carnegie_hall, R.string.practice_x3,
        "Carnegie_Hall.jpg");
    addMarker(map, 40.70686417491799, -74.01572942733765,
        R.string.downtown_club, R.string.heisman_trophy, null);
```

Note that the three images being used in this chapter come from Wikipedia. One is public domain, the others are licensed under the Creative Commons Attribution 1.0 license. Those two are a picture of [Avery Fisher Hall](#), part of the Lincoln Center for the Performing Arts (courtesy of [Geographer](#)) and the other is a picture of [the United Nations building](#) (courtesy of [WorldIslandInfo](#)).

The PopupAdapter needs access to these images. It will also need access to a Context, for use with Picasso. So, PopupAdapter now has data members for these, which are passed into a revised version of its constructor by MainActivity. That constructor not only holds onto the new objects, but it retrieves the values of the dimension resources for our images, converted by Android into pixels for the screen density of the device that we are running on:

```
PopupAdapter(Context ctxt, LayoutInflater inflater,
    HashMap<String, Uri> images) {
    this.ctxt=ctxt;
    this.inflater=inflater;
    this.images=images;

    iconWidth=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_width);
    iconHeight=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_height);
}
```

The revised getInfoContents() method is significantly more complicated than was its predecessor:

```
@SuppressWarnings("InflateParams")
@Override
public View getInfoContents(Marker marker) {
    if (popup == null) {
        popup=inflater.inflate(R.layout.popup, null);
    }

    if (lastMarker == null
        || !lastMarker.getId().equals(marker.getId())) {
        lastMarker=marker;

        TextView tv=(TextView)popup.findViewById(R.id.title);
```

```
tv.setText(marker.getTitle());
tv=(TextView)popup.findViewById(R.id.snippet);
tv.setText(marker.getSnippet());

Uri image=images.get(marker.getId());
ImageView icon=(ImageView)popup.findViewById(R.id.icon);

if (image == null) {
    icon.setVisibility(View.GONE);
}
else {
    Picasso.with(ctxt).load(image).resize(iconWidth, iconHeight)
        .centerCrop().noFade()
        .placeholder(R.drawable.placeholder)
        .into(icon, new MarkerCallback(marker));
}

return(popup);
}
```

We track the last Marker that we have processed in a `lastMarker` data member. Initially, of course, that will be `null`. If it is, or if the Marker passed into `getInfoContents()` is a different one (based on the `getId()` value), then we populate the popup View. This includes fetching the `Uri` from the `HashMap` of `Uri` values (given the Marker ID). If there is no `Uri`, `getInfoContents()` marks the `ImageView` as `GONE`, so it will not take up space in the popup. If, however, there is an image `Uri`, `getInfoContents()` asks Picasso to “do its thing”:

- Load the image from the `Uri`
- Resize the image to be the desired dimensions for the `ImageView`, center-cropping to keep the right aspect ratio
- Skip the fade-in animation that is normally applied when Picasso populates an `ImageView` (as the Maps V2 `Bitmap` is generated before the animation completes, resulting in a washed-out image)
- Use a particular placeholder drawable resource while the image is loading
- Populate the `ImageView` with the results, specifying a `MarkerCallback` to be notified of the results

`MarkerCallback`, as an implementation of Picasso’s `Callback` interface, needs `onError()` and `onSuccess()` methods. `onError()` just dumps a message to `LogCat`, while `onSuccess()` refreshes the info window, via a call to `showInfoWindow()` on the Marker, if that info window is still showing:

```
static class MarkerCallback implements Callback {
    Marker marker=null;
```

```
MarkerCallback(Marker marker) {
    this.marker=marker;
}

@Override
public void onError() {
    Log.e(getClass().getSimpleName(), "Error loading thumbnail!");
}

@Override
public void onSuccess() {
    if (marker != null && marker.isInfoWindowShown()) {
        marker.showInfoWindow();
    }
}
}
```

Setting the Marker Icon

Maps V2 includes a stock marker icon that looks a lot like the standard Google Maps marker. You have three major choices for what to use for your own markers:

1. Stick with the stock icon, which is the default behavior
2. Change the stock icon to a different hue
3. Replace the stock icon with your own from an asset, resource, file, or in-memory `Bitmap`

To indicate that you want a different icon than the stock one, use the `icon()` method on the `MarkerOptions` fluent interface. This takes a `BitmapDescriptor`, which you get from one of a series of static methods on the `BitmapDescriptorFactory` class.

For example, you might have a revised version of the `addMarker()` method of `MainActivity` that took a hue — a value from 0 to 360 representing different colors along a color wheel. 0 represents red, 120 represents green, and 240 represents blue, with different shades in between. There is a series of `HUE_` constants defined on `BitmapDescriptorFactory`, plus a `defaultMarker()` method that takes a hue as a parameter and returns a `BitmapDescriptor` that will use the stock icon, colored to the specified hue:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet, int hue) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                  .title(getString(title))
                  .snippet(getString(snippet))
                  .icon(BitmapDescriptorFactory.defaultMarker(hue)));
}
```

This could then be used to give you different colors per marker, or by category of marker, etc.:

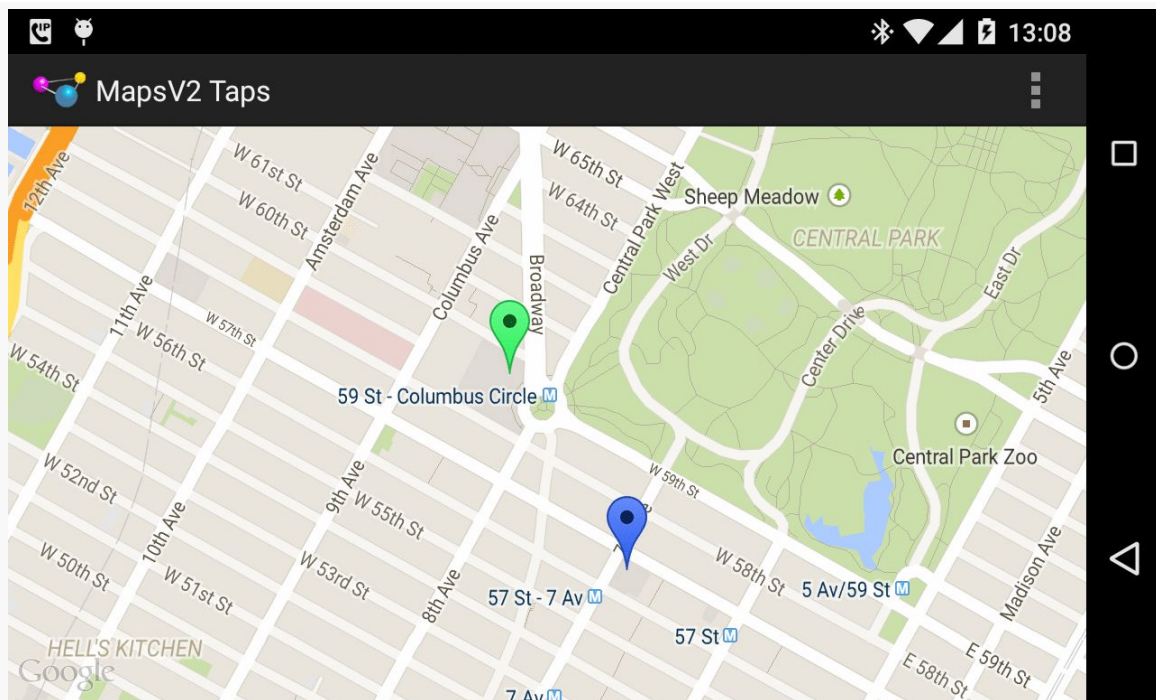

Figure 467: Maps V2 with Alternate Marker Hues

Note that you can modify the icon at runtime via the `setIcon()` method on the Marker returned by `addMarker()` method on `GoogleMap`.

However, you cannot draw the marker directly yourself, the way you might have with Maps V1. What you *can* do is draw to a `Bitmap`-backed `Canvas` object, then use the resulting `Bitmap` with `BitmapFactoryDescriptor` and its `fromBitmap()` factory method.

Responding to Taps

Perhaps we would like to find out when a user taps on one of our markers, instead of displaying an info window. Maybe we want to have some other UI response to that tap in our app.

To do that, simply create an implementation of the `OnMarkerClickListener` interface and attach it to the `GoogleMap` via `setOnMarkerClickListener()`. You will then be called with `onMarkerClick()` when the user taps on a marker, and you are passed the `Marker` object in question. If you return `true`, you are indicating that you

MAPPING WITH MAPS V2

are handling the event; returning false means that default handling (the info window) should be done.

You can see this, plus the multi-colored markers, in the [MapsV2/Taps](#) sample application. This takes MapsV2/Popups and adds a Toast when the user taps a marker, in addition to displaying the info window:

```
@Override
public boolean onMarkerClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();

    return(false);
}
```

Figure 468: Maps V2 with Toast and Info Window

Our call to `setOnMarkerClickListener()` is up in the `onMapReady()` method of `MainActivity`:

```
map.setOnMarkerClickListener(this);
```

Dragging Markers

In Maps V1, if you wanted to drag-and-drop map markers, you had to handle all of that yourself, using low-level touch events.

Conversely, Maps V2 handles marker drag-and-drop for you.

By default, markers are not draggable. But, if you call `draggable(true)` on your `MarkerOptions` when creating the marker — or call `setDraggable(true)` on the `Marker` later on — Android will automatically support drag-and-drop. The user can tap-and-hold on the marker to enable drag mode, then slide the marker around the map.

Note that at the present time, this functionality is a little odd. When you tap-and-hold the marker, with drag mode enabled, the marker initially jumps away from its original position. The user can reposition the marker to any desired location, and the marker will seem to “drop” where the user requests. Why the marker makes the sudden shift at the outset, using the default marker settings, is unclear.

Of course, your code may need to know about drag-and-drop events, such as to update your own data model to reflect the newly-chosen location. You can register an `OnMarkerDragListener` that will be notified of the start of the drag, where the marker slides during the drag, and where the marker is dropped at the end of the drag.

You can see all of this in the [MapsV2/Drag](#) sample application, which is a clone of `MapsV2/Popup` with drag-and-drop enabled.

To enable drag-and-drop, we just chain `draggable(true)` onto the series of calls on our `MarkerOptions` when creating the markers:

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet))
        .draggable(true));
}
```

We also register `MainActivity` as being the drag listener, up in `onMapReady()`:

```
map.setOnMarkerDragListener(this);
```

MAPPING WITH MAPS V2

That requires MainActivity to implement OnMarkerDragListener, which in turn requires three methods to be defined: onMarkerDragStart(), onMarkerDrag(), and onMarkerDragEnd():

```
@Override
public void onMarkerDragStart(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Drag from %f:%f",
                                                    position.latitude,
                                                    position.longitude));
}

@Override
public void onMarkerDrag(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(),
          String.format("Dragging to %f:%f", position.latitude,
                        position.longitude));
}

@Override
public void onMarkerDragEnd(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Dragged to %f:%f",
                                                    position.latitude,
                                                    position.longitude));
}
```

Here, we just dump the information about the new marker position in LogCat.

So, if you run this app and drag-and-drop a marker, you will see output in LogCat akin to:

```
12-19 13:10:36.442: D/MainActivity(22510): Drag from 40.770876:-73.982499
12-19 13:10:36.892: D/MainActivity(22510): Dragging to 40.770876:-73.981593
12-19 13:10:36.912: D/MainActivity(22510): Dragging to 40.770795:-73.981352
12-19 13:10:36.932: D/MainActivity(22510): Dragging to 40.770754:-73.981141
.
.
.
12-19 13:10:38.292: D/MainActivity(22510): Dragging to 40.769596:-73.983615
12-19 13:10:38.372: D/MainActivity(22510): Dragged to 40.769596:-73.983615
```

The actual list of events was much longer, as onMarkerDrag() is called a *lot*, so the ... in the LogCat entries above reflect another 50 or so lines for a drag-and-drop that took a couple of seconds.

Also, up in `onCreate()`, we retain our `MapFragment` across configuration changes via `setRetainInstance(true)`:

```
mapFrag.setRetainInstance(true);
```

Retaining the fragment instance causes the fragment to keep our markers in their moved positions, rather than resetting them to their original positions.

The “Final” Limitations

With Maps V1 and `ItemizedOverlay`, `OverlayItem` was a regular Java class. You could extend this class, to support additional data or behaviors that were unique to your app.

Of course, an even more flexible approach would have been for `OverlayItem` to be an interface, with a stock `SimpleOverlayItem` concrete implementation. That way, you could implement `OverlayItem` on some Java class resident elsewhere in your app’s class hierarchy (e.g., inheriting from some class needed for a persistence framework).

Rather than taking a step forward, Maps V2 took a step backward instead.

In Maps V2, not only do you not create `Marker` objects directly yourself, but `Marker` is marked as `final` and cannot be extended.

However, `Marker` does have `getId()`, an immutable identifier for the `Marker`. We can use that as a key for a `HashMap` that allows us to get at additional model data associated with the `Marker`.

You can see this approach in the [MapsV2/Models](#) sample application, which is a clone of `MapsV2/Popup` where we use the ID in just this fashion.

Our simplified model is merely the data we poured into our `Marker` objects in the original `MapsV2/Popup` project:

```
package com.commonware.android.mapsv2.model;

import android.content.Context;

public class Model {
    String title;
    String snippet;
    double lat;
```

```
double lon;

Model(Context ctxt, double lat, double lon, int title,
      int snippet) {
    this.title=ctxt.getString(title);
    this.snippet=ctxt.getString(snippet);
    this.lat=lat;
    this.lon=lon;
}

String getTitle() {
    return(title);
}

String getSnippet() {
    return(snippet);
}

double getLatitude() {
    return(lat);
}

double getLongitude() {
    return(lon);
}
}
```

Our activity holds onto a HashMap of these Model objects, with the map keyed by the Marker ID (a String):

```
private HashMap<String, Model> models=new HashMap<String, Model>();
```

Of course, a real application would have a much more elaborate setup than this.

We then arrange to populate our map with Marker objects created from our Model objects, moving the add-the-markers-to-the-map logic to an addMarkers() method:

```
private void addMarkers(GoogleMap map) {
    Model model=
        new Model(this, 40.748963847316034, -73.96807193756104,
                  R.string.un, R.string.united_nations);

    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.76866299974387, -73.98268461227417,
                  R.string.lincoln_center,
                  R.string.lincoln_center_snippet);
    models.put(addMarkerForModel(map, model).getId(), model);

    model=
```

MAPPING WITH MAPS V2

```
        new Model(this, 40.765136435316755, -73.97989511489868,
                  R.string.carnegie_hall, R.string.practice_x3);
models.put(addMarkerForModel(map, model).getId(), model);

model=
    new Model(this, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy);
models.put(addMarkerForModel(map, model).getId(), model);
}

private Marker addMarkerForModel(GoogleMap map, Model model) {
    LatLng position=
        new LatLng(model.getLatitude(), model.getLongitude());

    return(map.addMarker(new MarkerOptions().position(position)
                                                .title(model.getTitle())
                                                .snippet(model.getSnippet())));
}
```

Notice that `addMarkerForModel()` returns the `Marker`, and we use `getId()` on that `Marker` as the key when adding a `Model` to the `HashMap`.

Our `PopupAdapter` gets the data for the info window from the `Model` (though, in truth, in this case, it could have gotten the data from the `Marker` itself, since we did not add more information to the info window):

```
package com.commonware.android.mapsv2.model;

import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import java.util.HashMap;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    LayoutInflater inflater=null;
    HashMap<String, Model> models=null;

    PopupAdapter(LayoutInflater inflater, HashMap<String, Model> models) {
        this.inflater=inflater;
        this.models=models;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return(null);
    }

    @Override
    public View getInfoContents(Marker marker) {
```

MAPPING WITH MAPS V2

```
View popup=inflater.inflate(R.layout.popup, null);

TextView tv=(TextView)popup.findViewById(R.id.title);

tv.setText(models.get(marker.getId()).getTitle());
tv=(TextView)popup.findViewById(R.id.snippet);
tv.setText(models.get(marker.getId()).getSnippet());

return(popup);
}
```

Visually, this is indistinguishable from the original MapsV2/Popups project. Of course, a real app would have more complex models, perhaps containing more discrete information for a more complex info window.

A Bit More About IPC

IPC is not only a problem in terms of disappearing Marker objects.

If you run a Maps V2 app under [Traceview](#), to see what methods get called and how much time everything takes, you will see that many, many operations with GoogleMap do little in your process, but instead make synchronous calls to a Play Services process to do the real work:

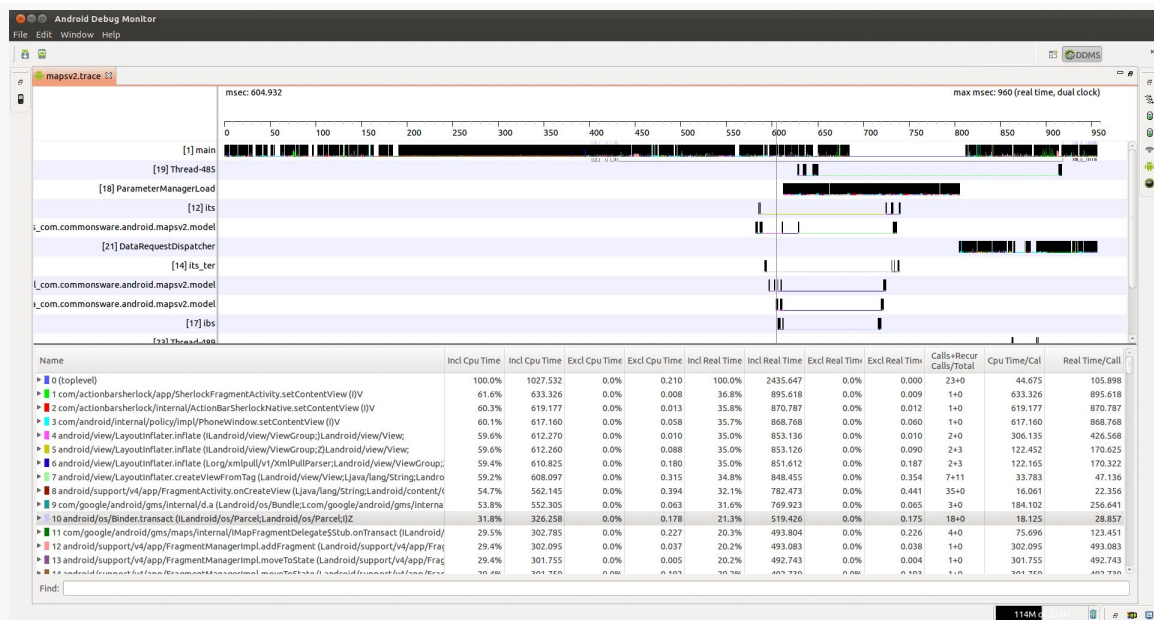

Figure 469: Traceview Results for Maps V2 Map Creation

The preceding trace came from just the `onCreate()` method of the `MapsV2/Models` sample from the preceding section. Over 30% of the time to run `onCreate()` is tied up in IPC calls. And, unfortunately, you are not allowed to do much manipulation of a `GoogleMap` from a background thread (e.g., `moveCamera()`).

The moral of this story is to avoid manipulating your `GoogleMap` in time-sensitive portions of your code.

(the author would once again like to thank Cyril Mottier for pointing out this limitation in Maps V2)

Finding the User

Many times, the user is looking at a map to figure out where they are. Perhaps they are lost. Perhaps their spouse or significant other thinks that they are lost. Perhaps they think that they were teleported somewhere (e.g., a North African desert) after turning a “[frozen wheel](#)” in an icy cavern beneath an island, and therefore are *really* lost. Stranger things have happened.

(well, OK, perhaps not)

Regardless, it is often useful to help point out to the user their current location. That is a matter of adding a suitable location permission (e.g., `ACCESS_FINE_LOCATION`) and calling `setMyLocationEnabled(true)` on your `GoogleMap`. This activates a layer that will highlight their location, with the user having an option of having the “camera” (i.e., their perspective on the map) reposition itself to their location and move as they move. This latter capability is activated by a small icon in the upper right of the map.

You can see this in operation in the [MapsV2/MyLocation](#) sample application, which is a clone of `MapsV2/Popup` with standard location tracking enabled.

All we do is call two additional methods on our `GoogleMap` in `onCreate()`:

- `setMyLocationEnabled()`, indicating that we want the “my location” layer added and automatic tracking to be enabled, and
- `setOnMyLocationChangeListener()`, indicating that we *also* want to be notified about changes in the user position

```
map.setMyLocationEnabled(true);
map.setOnMyLocationChangeListener(this);
```

MAPPING WITH MAPS V2

That latter method also requires our activity to implement the `OnMyLocationChangeListener` interface, which in turn requires us to implement the `onMyLocationChange()` method, which will be called when Maps V2 gets a new location fix:

```
@Override
public void onMyLocationChange(Location lastKnownLocation) {
    Log.d(getClass().getSimpleName(),
        String.format("%f:%f", lastKnownLocation.getLatitude(),
            lastKnownLocation.getLongitude()));
}
```

Here, we simply log the location to LogCat.

This is nice and easy, giving us our my-location overlay and arrow indicating the user's location and orientation:

Figure 470: Maps V2, Showing the User's Location

However, there are two problems here. First, `setOnMyLocationChangeListener()` is now deprecated, as Google would prefer that you directly request the locations through [the `LocationClient` available from Play Services](#).

Second, there does not appear to be a way to *force* camera tracking of the user's position — you are reliant upon the user tapping that icon. You also have no control over the nature of the location provider that is used.

However, there is a workaround for this, proposed in [a Stack Overflow answer](#) – provide your own location data and update the camera yourself, by means of `setLocationSource()`. `setLocationSource()` lets you push locations to the `GoogleMap`, making other adjustments (e.g., camera position) along the way.

To see how this works, take a peek at the [MapsV2/Location](#) sample application, which is a clone of `MapsV2/Popup` with custom location tracking enabled.

Along with adding `ACCESS_FINE_LOCATION` to the manifest, this sample project adds some lines to the `onMapReady()` implementation of `MainActivity` to configure the `GoogleMap`:

```
locMgr=(LocationManager)getSystemService(LOCATION_SERVICE);
crit.setAccuracy(Criteria.ACCURACY_FINE);
locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);

map.setLocationSource(this);
map.setMyLocationEnabled(true);
map.getUiSettings().setMyLocationButtonEnabled(false);
```

The first three lines get access to a `LocationManager`, indicate that a `Criteria` object (initialized as a data member) should require fine accuracy, and request location updates. These come from the [location tracking](#) subsystem in Android.

The next two lines register our activity as being the source of location data and turns on location tracking in the `GoogleMap`, so the user's position will be marked on the map.

The last line disables the user's control over whether the camera position tracks their movement, since we want that to always be on in this case.

In `onResume()` and `onPause()` of `MainActivity`, we enable and disable getting location updates, as is typical of an activity needing location data. However, we also tell the `GoogleMap` that we are going to supply it with location data, rather than it having to obtain location data itself:

```
@Override
public void onResume() {
    super.onResume();
```

```
if (locMgr!=null) {
    locMgr.requestLocationUpdates(OL, 0.0f, crit, this, null);
}

if (map!=null) {
    map.setLocationSource(this);
}
}

@Override
public void onPause() {
    map.setLocationSource(null);
    locMgr.removeUpdates(this);

    super.onPause();
}
```

Note that we are blindly assuming that we will get location data. A production-grade app would put in better smarts to confirm that we will actually learn our location via this Criteria (e.g., the user does not have all location providers disabled).

Also note that because the map initialization is now happening on a background thread, `onResume()` might be called before `onMapReady()`, and so `onResume()` has to check to see if we already have a `LocationManager` and `GoogleMap` before proceeding.

The call to `setLocationSource()` — both in `onMapReady()` and `onResume()` — tells `GoogleMap` that our `MainActivity` itself is to be the source of location data. This requires `MainActivity` to implement the `LocationSource` interface, requiring us to implement `activate()` and `deactivate()` methods:

```
@Override
public void activate(OnLocationChangeListener listener) {
    this.mapLocationListener=listener;
}

@Override
public void deactivate() {
    this.mapLocationListener=null;
}
```

`activate()` provides us with an `OnLocationChangeListener`, from `GoogleMap`, to which we need to pass location data as we get it. `deactivate()` indicates that we should no longer attempt to contact that listener. In addition to holding onto that listener (or removing our reference to it when deactivated), we also take this opportunity to request and remove location updates.

The `onLocationChanged()` method — where we get our location fixes from `LocationManager` via the `LocationListener` interface — must pass the location along to the GoogleMap-supplied `OnLocationChangedListener`, if we have such a listener available:

```
@Override
public void onLocationChanged(Location location) {
    if (mapLocationListener != null) {
        mapLocationListener.onLocationChanged(location);

        LatLng latLng=
            new LatLng(location.getLatitude(), location.getLongitude());
        CameraUpdate cu=CameraUpdateFactory.newLatLng(latLng);

        map.animateCamera(cu);
    }
}
```

Here, we also create a `CameraUpdate` representing the new location and animate that update, to have the map slide over to the new location, centering the camera on the user's updated position.

The net effect of all of this is that the map continuously re-centers itself to show the user's position, which GoogleMap is highlighting on the map for us.

Drawing Lines and Areas

If you wanted to draw on a map in the Maps V1 framework, you created an `Overlay` and drew upon it. This forced you to handle low-level drawing work yourself, as you were handed a `Canvas` object and had to handle all the lines, fills, and so forth yourself.

Maps V2 offers a different approach. Free-form drawing is still conceivable, though it appears to have to be handled in the form of tile overlays instead of map overlays. However, for the simpler cases of drawing lines and areas, Maps V2 has built-in polyline, polygon, and circle support. You tell the GoogleMap what needs to be drawn, and it handles drawing it, both initially and as the map is zoomed or panned. A polyline is a line connecting a series of points; a polygon is a region defined by a series of corners. A circle, from the standpoint of Maps V2, is defined by a center coordinate and a radius.

We can see polylines and polygons on a GoogleMap in the [MapsV2/Polylines](#) sample application, which is a clone of MapsV2/Popup with two additions:

- A polyline connecting the locations of our four markers
- A polygon enclosing the area of Manhattan known as the Garment District (bounded by 34th Street, 42nd Street, Fifth Avenue, and Ninth Avenue)

To draw those, we simply add a few lines to `onMapReady()` of `MainActivity`:

```
PolylineOptions line=
    new PolylineOptions().add(new LatLng(40.70686417491799,
        -74.01572942733765),
        new LatLng(40.76866299974387,
        -73.98268461227417),
        new LatLng(40.765136435316755,
        -73.97989511489868),
        new LatLng(40.748963847316034,
        -73.96807193756104))
        .width(5).color(Color.RED);

map.addPolyline(line);

PolygonOptions area=
    new PolygonOptions().add(new LatLng(40.748429, -73.984573),
        new LatLng(40.753393, -73.996311),
        new LatLng(40.758393, -73.992705),
        new LatLng(40.753484, -73.980882))
        .strokeColor(Color.BLUE);

map.addPolygon(area);
```

The API for adding polylines and polygons is reminiscent of the API for adding markers: define an `...Options` object with the characteristics of the item to be drawn, then call an `add...()` method on `GoogleMap` to add the item.

So, to add a polyline, we create a `PolylineOptions` object. Using its fluent interface, we `add()` a series of `LatLng` objects, representing the points to be connected by the line. We also specify the line width in *pixels* via `width()` and the color of the line via `color()`. If we had several lines that might overlap, we could specify the `zIndex()`, where higher indexes indicate lines to be drawn over the top of lines with lower indexes. We add the polyline to the map by passing our `PolylineOptions` to `addPolyline()` on `GoogleMap`.

This gives us a line connecting the four markers, with `GoogleMap` handling the details of where the line should be drawn on the screen given the current map center and zoom levels:

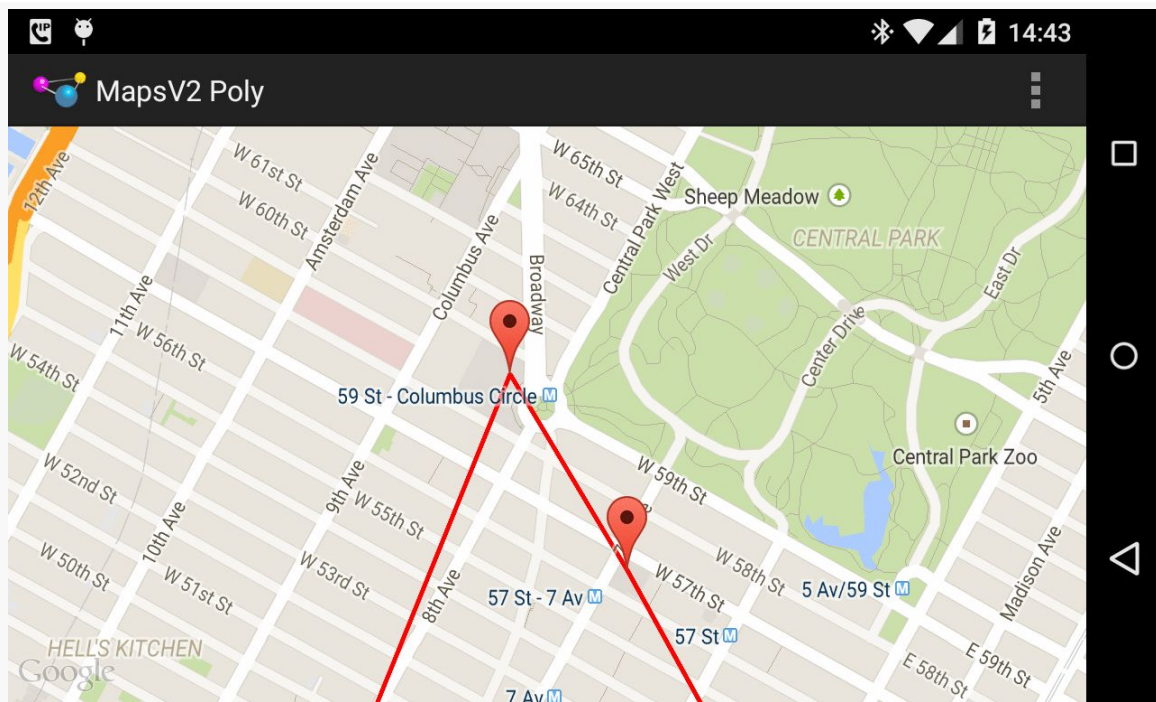

Figure 471: Maps V2 with Polyline

Note that the polyline is drawn using a flat Mercator projection by default. For most maps, that is perfectly fine. If your map will be showing countries and continents, rather than city blocks, you might want to call `geodesic(true)` on the `PolylineOptions`, to have the line drawn on a geodesic curve, reflecting the spherical nature of the Earth ([dissenting opinions on that](#) notwithstanding).

Similarly, we create a `PolygonOptions` object, configure it, and pass it to `addPolygon` for our Garment District box. The `add()` method on `PolygonOptions` will take the corners of our polygon, automatically enclosing that region. We also specify the `strokeColor()`. We could have specified a `fillColor()` (default is transparent), `strokeWidth()` (default is 10 pixels), `zIndex()`, and `geodesic()`.

If we run the app and pan the map down to the south a bit, we see our polygon:

Figure 472: Maps V2 with Polyline and Polygon

As with the polyline, Android automatically handles drawing what is needed based on map center and zoom levels.

Note that, as with markers, we need to re-add the polylines and polygons after a configuration change, as the GoogleMap does not retain that information.

Gestures and Controls

By default, standard gestures and controls are enabled on your map:

- The user can change zoom level either by + and - buttons or via “pinch-to-zoom” gestures
- The user can change the center of the map via simple swipe gestures
- The user can change the camera tilt via two-finger vertical swipes, so instead of a traditional top-down perspective, the user can see things on an angle
- The user can change the orientation of the map via a two-finger rotating swipe, to change the typical “north is to the top of the map” to some other orientation

You can obtain a `UiSettings` object from your `GoogleMap` via `getUiSettings()` to disable these features, if desired:

- `setRotateGesturesEnabled()`
- `setScrollGesturesEnabled()` (for panning the map)
- `setTiltGesturesEnabled()`
- `setZoomControlsEnabled()` (for the + and - buttons)
- `setZoomGesturesEnabled()` (for pinch-to-zoom)

There is also `setAllGesturesEnabled()` to toggle on or off all gesture-based map control. This is roughly analogous to the `android:clickable` attribute on the Maps V1 edition of `MapView`.

There is also `setCompassEnabled()`, to indicate if a compass should be shown if the user changes the map orientation via a rotate gesture.

Tracking Camera Changes

If you have gestures enabled, the user can change the perspective of the map, referred to as changing the camera position. You may need to know about these changes, to perform various operations in your app based upon what is presently visible on the screen. To find out when the camera position changes, you can call `setOnCameraChangeListener()` on the `GoogleMap`, supplying an implementation of `OnCameraChangeListener`, which will be called with `onCameraChange()` as the user pans, zooms, or tilts the map.

To see how this works, we can take a quick peek at the [MapsV2/Camera](#) sample application, which is a clone of `MapsV2/Popup` with camera position tracking enabled.

Late in `onMapReady()` of `MainActivity`, we call `setOnCameraChangeListener()` on our `GoogleMap`, supplying `MainActivity` itself as the listener:

```
map.setOnCameraChangeListener(this);
```

This requires `MainActivity` to implement `OnCameraChangeListener` and supply an implementation of `onCameraChange()`:

```
@Override
public void onCameraChange(CameraPosition position) {
    Log.d(getClass().getSimpleName(),
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
```

MAPPING WITH MAPS V2

```
        position.target.latitude,  
        position.target.longitude, position.zoom,  
        position.tilt));  
    }
```

Here, we just log a message to LogCat on each camera position change, logging:

- the latitude and longitude of the map center, obtained from the target `LatLng` data member of the `CameraPosition` object supplied to `onCameraChange()`,
- the zoom level of the map, from the zoom data member of `CameraPosition`, and
- the tilt of the map, in degrees, from the tilt data member of `CameraPosition`

As a result, if you run this app and play around with the various gestures, you get a series of LogCat messages with the results:

```
12-26 15:36:39.456: D/MainActivity(31419): lat: 40.763727, lon: -73.983163,  
zoom: 15.000000, tilt: 0.000000  
12-26 15:36:39.536: D/MainActivity(31419): lat: 40.763797, lon: -73.983118,  
zoom: 15.000000, tilt: 0.000000  
12-26 15:36:40.796: D/MainActivity(31419): lat: 40.767982, lon: -73.979181,  
zoom: 15.000000, tilt: 0.000000  
12-26 15:36:41.966: D/MainActivity(31419): lat: 40.766275, lon: -73.981911,  
zoom: 15.000000, tilt: 0.000000

12-26 15:36:45.846: D/MainActivity(31419): lat: 40.766083, lon: -73.982028,  
zoom: 15.875862, tilt: 50.859375  
12-26 15:36:45.886: D/MainActivity(31419): lat: 40.766083, lon: -73.982028,  
zoom: 15.875862, tilt: 52.968750
```

```
12-26 15:36:45.926: D/MainActivity(31419): lat: 40.766083, lon: -73.982028,
zoom: 15.875862, tilt: 56.484375
12-26 15:36:45.966: D/MainActivity(31419): lat: 40.766083, lon: -73.982028,
zoom: 15.875862, tilt: 57.890625
12-26 15:36:46.096: D/MainActivity(31419): lat: 40.766083, lon: -73.982028,
zoom: 15.875862, tilt: 59.296875
```

Maps in Fragments and Pagers

One key limitation of Maps V1 was that you could only have one `MapView` instance per *process*. Presumably, the proprietary code at the heart of the Maps SDK add-on used static data members for some state management, ones that would get messed up if there were two or more `MapView` widgets in active use.

Fortunately, Maps V2 gets rid of this restriction. You are welcome to have multiple `MapFragment` objects if that makes sense. Maps are relatively memory-intensive, so you should not be planning on having dozens or hundreds of them in use at a time, but you can have more than one.

To showcase this, the [MapsV2/Pager](#) sample application hosts 10 `MapFragment` instances as pages in a `ViewPager`. The bulk of the application is a clone of one of the `ViewPager` samples from [the chapter on ViewPager](#).

Having maps in a `ViewPager` presents a bit of a problem, in terms of interpreting horizontal swipe events. Normally, `ViewPager` handles those itself. However, that would mean that the user cannot pan the map horizontally, which makes using the map somewhat challenging. In this sample, we will augment the `ViewPager` with logic to allow horizontal swiping on the maps and on the tab strip.

Our activity inflates a layout that contains our `ViewPager` along with a `PagerTabStrip`:

```
<?xml version="1.0" encoding="utf-8"?>
<com.commonware.android.mapsv2.pager.MapAwarePager
xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</com.commonware.android.mapsv2.pager.MapAwarePager>
```

MAPPING WITH MAPS V2

However, you will note that this is not ViewPager, but rather MapAwarePager, a custom subclass of ViewPager that we will examine shortly.

MainActivity then populates the MapAwarePager with an instance of a MapPagerAdapter:

```
package com.commonware.android.mapsv2.pager;

import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);

            ViewPager pager=(ViewPager)findViewById(R.id.pager);

            pager.setAdapter(buildAdapter());
        }
    }

    private PagerAdapter buildAdapter() {
        return new MapPagerAdapter(this, getFragmentManager());
    }
}
```

MapPagerAdapter is a FragmentStatePagerAdapter, not a FragmentPagerAdapter. This means that as the user swipes through our ViewPager, the adapter has the right to discard old fragments when it creates new ones. This helps reduce the overall memory footprint of our activity.

```
package com.commonware.android.mapsv2.pager;

import android.content.Context;
import android.app.Fragment;
import android.app.FragmentManager;
import android.support.v13.app.FragmentStatePagerAdapter;

public class MapPagerAdapter extends FragmentStatePagerAdapter {
    Context ctxt=null;

    public MapPagerAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
```

```
@Override
public int getCount() {
    return(10);
}

@Override
public Fragment getItem(int position) {
    return(new PageMapFragment());
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(R.string.map_page_title) + String.valueOf(position +
1));
}
}
```

MapPageAdapter declares that there should be ten pages (in `getCount()`) and returns an instance of `PageMapFragment` for each page. `PageMapFragment` is a subclass of `MapFragment`, and so is responsible for displaying our map:

```
package com.commonware.android.mapsv2.pager;

import android.os.Bundle;
import com.google.android.gms.maps.CameraUpdate;
import com.google.android.gms.maps.CameraUpdateFactory;
import com.google.android.gms.maps.GoogleMap;
import com.google.android.gms.maps.MapFragment;
import com.google.android.gms.maps.OnMapReadyCallback;
import com.google.android.gms.maps.model.LatLng;
import com.google.android.gms.maps.model.MarkerOptions;

public class PageMapFragment extends MapFragment implements
    OnMapReadyCallback {
    private boolean needsInit=false;

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        getMapAsync(this);
    }

    @Override
    public void onMapReady(final GoogleMap map) {
        if (needsInit) {
            CameraUpdate center=
                CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                    -73.98180484771729));
        }
    }
}
```

MAPPING WITH MAPS V2

```
CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

map.moveCamera(center);
map.animateCamera(zoom);
}

addMarker(map, 40.748963847316034, -73.96807193756104, R.string.un,
          R.string.united_nations);
addMarker(map, 40.76866299974387, -73.98268461227417,
          R.string.lincoln_center, R.string.lincoln_center_snippet);
addMarker(map, 40.765136435316755, -73.97989511489868,
          R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
          R.string.downtown_club, R.string.heisman_trophy);
}

private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                  .title(getString(title))
                  .snippet(getString(snippet)));
}
}
```

If we simply wanted to display an unconfigured map, we could just have `MapPageAdapter` create and return instances of `MapFragment` directly. If we want to configure our map, though, we need to get control when the `GoogleMap` object is ready for use. One way to do that is to extend `MapFragment` and override `onActivityCreated()` and call `getMapAsync()` there to begin the whole get-the-`GoogleMap`-loaded process. In `onMapReady()`, we can then go ahead and configure the map much as we have done in previous examples, just from within the fragment itself rather than from the hosting activity.

`MapAwarePager` overrides one key method of `ViewPager`: `canScroll()`:

```
package com.commonware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.view.PagerTabStrip;
import android.support.v4.view.ViewPager;
import android.util.AttributeSet;
import android.view.SurfaceView;
import android.view.View;

public class MapAwarePager extends ViewPager {
    public MapAwarePager(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    @Override
```

MAPPING WITH MAPS V2

```
protected boolean canScroll(View v, boolean checkV, int dx, int x,
                             int y) {
    if (v instanceof SurfaceView || v instanceof PagerTabStrip) {
        return(true);
    }

    return(super.canScroll(v, checkV, dx, x, y));
}
```

`canScroll()` should return `true` if the `View` (and specifically the supplied X and Y coordinates within that `View`) can be scrolled horizontally, `false` otherwise. In our case, we want to say that the map and the tab strip are each scrollable horizontally. As it turns out, the passed-in `View` for our `MapFragment` will be the map if it is a subclass of `SurfaceView` (determined by trial and error on the author's part, with hopes for a more authoritative solution in a future edition of the Maps V2 API). So, if the passed-in `View` is either a `SurfaceView` or a `PagerTabStrip`, we return `true`, otherwise we default to normal logic.

The result is a series of independent maps, one per page:

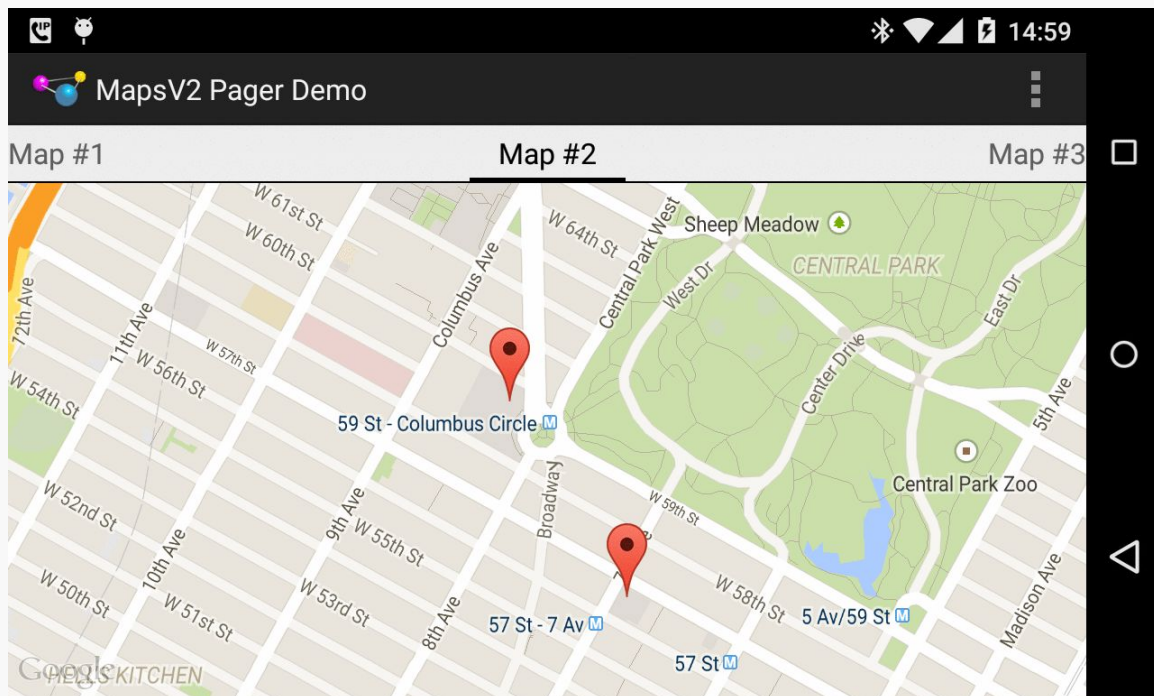

Figure 473: Multiple Maps V2 Maps in a ViewPager

Each map is independent: if the user pans or zooms one map, that has no impact on any of the other pages. Panning the maps horizontally works; to move between pages, use the tab strip.

Animating Marker Movement

Markers, by default, are static, unless you make them be draggable, and then only the user can drag them.

However, you are welcome to update the position of a Marker at any point, by calling `setPosition()` and supplying a new `LatLng`. The Marker then will jump to that position.

But what if you want to animate the movement of a Marker from its current position to a new one? Maps V2 does not offer anything “out of the box” for implementing this, but Google demonstrated approaches for this in [a “DevBytes” video](#) and related [bit of code in a GitHub Gist](#). This section will cover the technique appropriate for API Level 14+, including a full working sample (the Gist shows code but not its usage).

Problem #1: Animating a LatLng

The position of a Marker is a `LatLng`, as we have seen previously. `LatLng` is not a simple number, and so the animator framework needs our assistance to animate them. Specifically, we need a `TypeEvaluator` for `LatLng`, with our `evaluate()` method taking the initial and end positions and computing another `LatLng` representing the fraction position between those other positions. This concept was introduced back in [the chapter on the animator framework](#).

A simple approach to computing the fractional `LatLng` would be to apply the fraction to the latitude and the longitude as Java double values:

```
LatLng interpolate(float fraction, LatLng initial, LatLng end) {  
    double lat = (end.latitude - initial.latitude) * fraction + initial.latitude;  
    double lng = (end.longitude - initial.longitude) * fraction +  
initial.longitude;  
  
    return(new LatLng(lat, lng));  
}
```

That would work reasonably well for fairly close points, such as animating a marker within a city. However, animating markers across longer distances means that we

have to take into account some geographic realities that a simple calculation will miss.

Problem #2: The Earth Is Not Flat (Really!)

One bit of reality is that the Earth is round. The above calculation assumes that the Earth is flat. Calculating “great circle” positions requires a fair bit of spherical trigonometry, known to cause loss of hair in software developers.

Hence, ideally, we will use somebody’s existing debugged algorithm for that.

Problem #3: 180 Equals –180, At Least For Longitude

The other problem is that longitudes wrap around, as 180 degrees longitude is equivalent to –180 degrees longitude, and longitudinal values are considered to be between 180 and –180. In cases where we would not cross 180 degrees longitude, this is not an issue. However, a simple calculation might miss this and wind up having our animation “take the long way” (e.g., animating from –175 degrees longitude to 175 degrees longitude by going 350 degrees around the Earth, rather than just 10 degrees and crossing the International Date Line).

Introducing Some Googly Assistance

Google themselves have released a [utility library for Maps V2](#). It offers polyline and polygon decoding, primarily for interoperability with other location-related Google services like the Google Directions API. The `SphericalUtil` class handles all of the nasty math for computing distances along the surface of the Earth and related calculations. It also offers `BubbleIconFactory`, which makes it easy to create marker icons that look a bit like info windows (complete with border and caret) wrapping around a bit of text or an icon.

In our case, we can use `SphericalUtil` to handle Problem #2 and Problem #3, interpolating the location between two `LatLng` values, taking the curvature of the Earth and longitude idiosyncrasies into account.

Seeing This in Action

The [MapsV2/Animator](#) sample project is a modified version of the `MapsV2/Markers` project, adding in the notion of animating a marker from its original position (Lincoln Center) to a new position (Penn Station) within Manhattan.

MAPPING WITH MAPS V2

Since we want to use the Google map utility library, we need to add it as a dependency.

- Android Studio users can simply add compile 'com.google.maps.android:android-maps-utils:0.3.4' (or a higher version) to the dependencies closure.
- Eclipse users will need to [download](#) and add it to the project by one means or another. Note, though, that this library project depends upon the Play Services SDK. Hence, you will need to update the project's configuration to have it reference your development environment's copy of the Play Services SDK. Then, when you attach the library project to your project, you can remove your own reference to the Play Services SDK, as you will get that through the utility library.

We need to know where our starting and ending position for the animation will be, in terms of LatLng objects. Since those have no dependencies upon a Context or anything, we can simply declare them as static final values:

```
private static final LatLng PENN_STATION=new LatLng(40.749972,
                                                    -73.992319);
private static final LatLng LINCOLN_CENTER=
    new LatLng(40.76866299974387, -73.98268461227417);
```

We will also need the actual Marker object created when we add our starting position (LINCOLN_CENTER) to the map. So far, we have ignored the Marker returned by addMarker() on GoogleMap, but now we need that. So, our own addMarker() method now returns this value:

```
private Marker addMarker(GoogleMap map, double lat, double lon,
                          int title, int snippet) {
    return(map.addMarker(new MarkerOptions().position(new LatLng(lat,
                                                                    lon))
                        .title(getString(title))
                        .snippet(getString(snippet))));
}
```

We also now have a markerToAnimate data member of the activity, for our Marker, which we populate from our modified addMarker() method:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations);
markerToAnimate=
    addMarker(map, LINCOLN_CENTER.latitude,
              LINCOLN_CENTER.longitude, R.string.lincoln_center,
              R.string.lincoln_center_snippet);
```

MAPPING WITH MAPS V2

```
addMarker(map, 40.765136435316755, -73.97989511489868,  
          R.string.carnegie_hall, R.string.practice_x3);  
addMarker(map, 40.70686417491799, -74.01572942733765,  
          R.string.downtown_club, R.string.heisman_trophy);
```

To make the sample work repeatedly, it would be nice to support bi-directional animation, starting with animating from Lincoln Center to Penn Station, then reversing the animation to go back to Lincoln Center. That means that we need to know, for any particular animation, where the end position should be. So, we track a `LatLng` for the next end position, surprisingly named `nextAnimationEnd`, initializing it to be `PENN_STATION` (since we are starting at the outset at `LINCOLN_CENTER`):

```
private LatLng nextAnimationEnd=PENN_STATION;
```

Next, we need to give the user a means of actually requesting the animation to run. To do that, we define a new menu XML resource for an animate menu item (using the directions icon for lack of a better handy icon):

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">  
  
    <item  
        android:id="@+id/animate"  
        android:icon="@android:drawable/ic_menu_directions"  
        android:showAsAction="ifRoom"  
        android:title="@string/animate"/>  
  
</menu>
```

We then load that menu resource in an overridden `onCreateOptionsMenu()` and direct the click event to an `animateMarker()` method in `onOptionsItemSelected()`:

```
@Override  
public boolean onCreateOptionsMenu(Menu menu) {  
    getMenuInflater().inflate(R.menu.animate, menu);  
  
    return(super.onCreateOptionsMenu(menu));  
}  
  
@Override  
public boolean onOptionsItemSelected(MenuItem item) {  
    if (item.getItemId() == R.id.animate) {  
        animateMarker();  
  
        return(true);  
    }  
  
    return(super.onOptionsItemSelected(item));  
}
```

In `animateMarker()`, we need to do two things:

1. Actually run the animation
2. Ensure that the camera position is such that the animation will actually be visible, as it is pointless to animate a marker between two points if the currently-viewed portion of the map does not show those points

To handle the camera position, we need to use `moveCamera()` with a `CameraUpdate` from `CameraUpdateFactory`, as we used to set the initial camera position and zoom level. To handle the case where we want one or more points to be visible, we can use the `newLatLngBounds()` method on `CameraUpdateFactory`. This takes a `LatLngBounds` describing the area that needs to be visible, plus a padding amount in pixels for where that area should be inset within the map.

Of course, this implies that we have a `LatLngBounds`.

Since `LatLngBounds` also does not depend upon a `Context` or much of anything, we can define one of those as a static final data member, using a `LatLngBounds.Builder` instance:

```
private static final LatLngBounds bounds=
    new LatLngBounds.Builder().include(LINCOLN_CENTER)
                              .include(PENN_STATION).build();
```

A `LatLngBounds.Builder` takes one or more `LatLng` objects — passed in via `include()` — then constructs a `LatLngBounds` that encompasses all of those points via `build()`.

Our `animateMarker()` method then starts off by using `moveCamera()` to reset the camera to show that defined region:

```
private void animateMarker() {
    map.moveCamera(CameraUpdateFactory.newLatLngBounds(bounds, 48));

    Property<Marker, LatLng> property=
        Property.of(Marker.class, LatLng.class, "position");
    ObjectAnimator animator=
        ObjectAnimator.ofObject(markerToAnimate, property,
                                new LatLngEvaluator(), nextAnimationEnd);
    animator.setDuration(2000);
    animator.start();

    if (nextAnimationEnd == LINCOLN_CENTER) {
        nextAnimationEnd=PENN_STATION;
    }
    else {
```

```
        nextAnimationEnd=LINCOLN_CENTER;
    }
}
```

Then, we need to set up the animation. To do this, we will use the object animator framework, specifically an `ObjectAnimator`. We know the Marker that we want to animate (`markerToAnimate`) and we know where we want to animate it to (`nextAnimationEnd`). What we need is to indicate the property to animate on this object, plus provide help to actually animate a `LatLng`.

To specify the property, we could just pass in the name of the property ("position"). However, in `animateMarker()`, we set up a `Property` object via the static `of()` factory method. This makes our use of `ofObject()` more type-safe, as `Property` will help enforce that we are animating a Marker using `LatLng` values.

To animate `LatLng` values, we need a `TypeEvaluator` for `LatLng`, here defined as a static inner class named `LatLngEvaluator`:

```
private static class LatLngEvaluator implements TypeEvaluator<LatLng> {
    @Override
    public LatLng evaluate(float fraction, LatLng startValue,
                          LatLng endValue) {
        return(SphericalUtil.interpolate(startValue, endValue, fraction));
    }
}
```

Our `evaluate()` method turns around and calls the static `interpolate()` method on `SphericalUtil`, supplied by Google's map utility library. `interpolate()` handles all the nasty spherical trigonometry and stuff, so we do not have to.

We then set the duration of the animation to be two seconds, and start the animation.

Finally, to reverse the animation for the next request, `animateMarker()` resets the value of `nextAnimationEnd` to be `PENN_STATION` or `LINCOLN_CENTER`, wherever we will animate to next.

This version of the app starts off as do all the others, except for the new action bar item:

MAPPING WITH MAPS V2

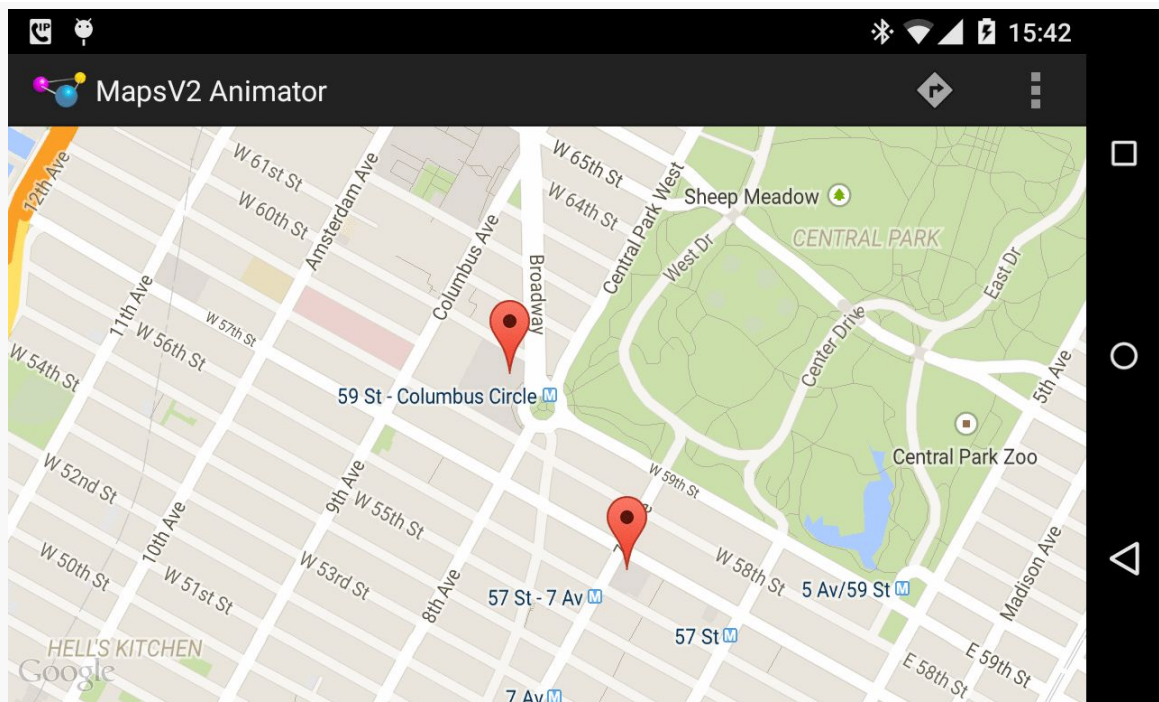

Figure 474: Maps V2 Animator Demo, As Initially Launched

Tapping that action bar item (“directions” icon) will reset the camera position and start animating the marker:

MAPPING WITH MAPS V2

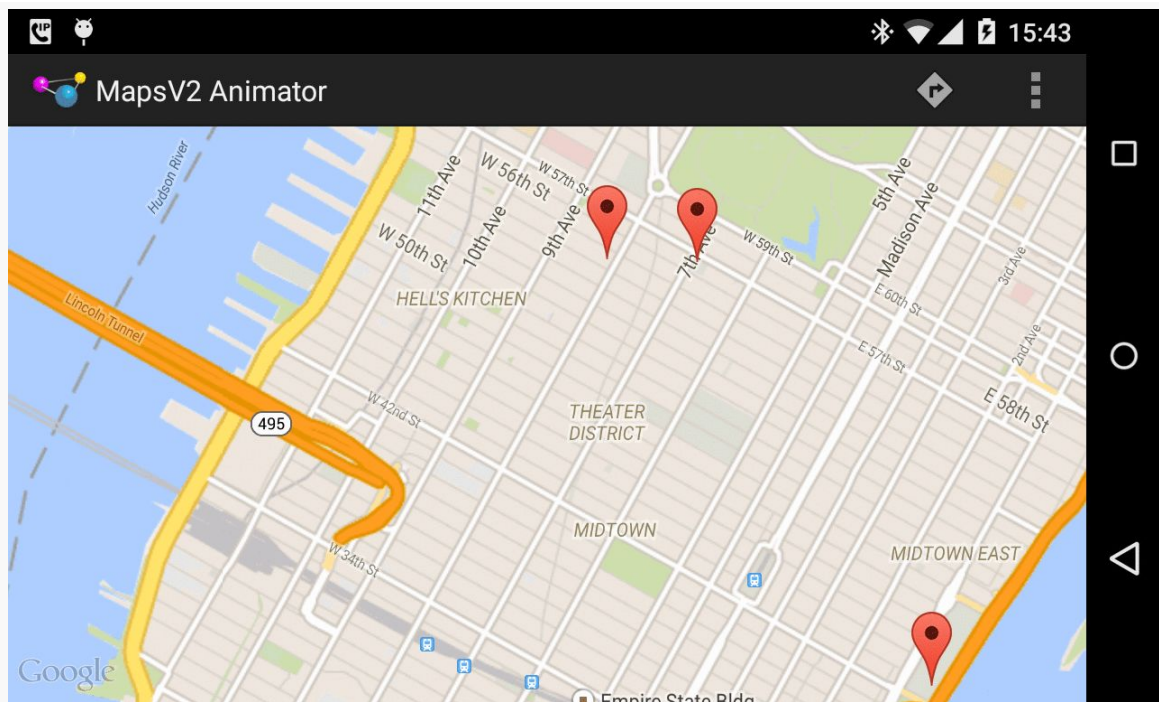

Figure 475: Maps V2 Animator Demo, Partially Through an Animation

Two seconds later, the marker will reach its destination, presumably to board a train:

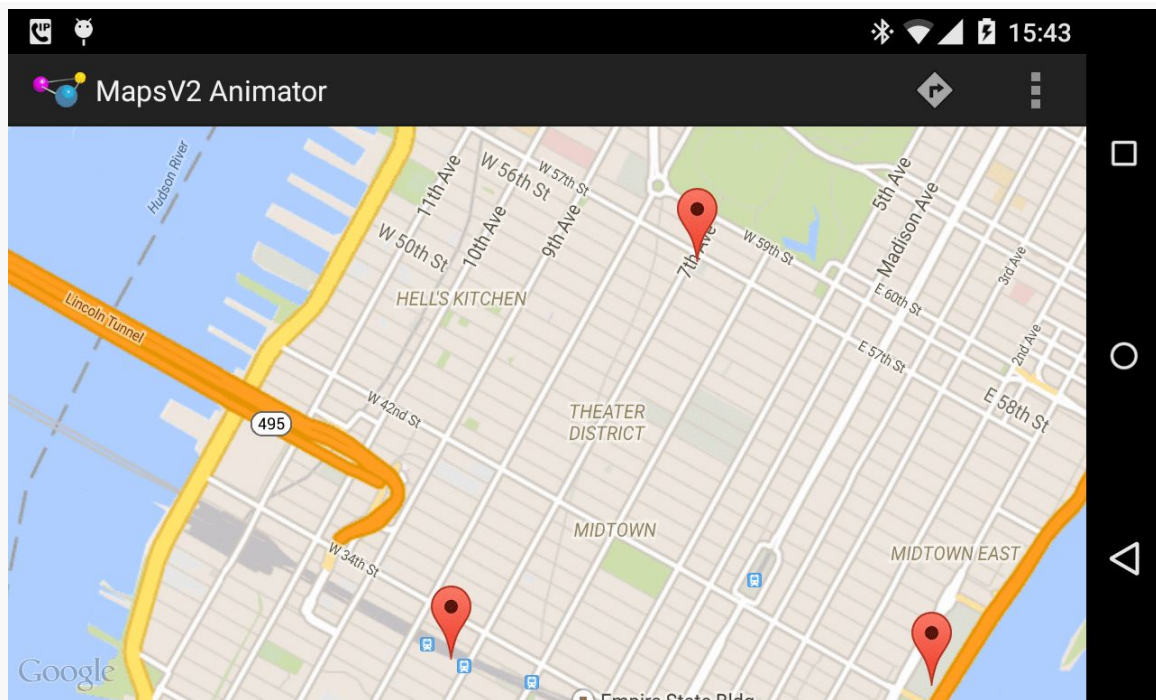

Figure 476: Maps V2 Animator Demo, with Marker Animated to Penn Station

Honoring Traffic Rules, Like “Drive Only On Streets”

You will notice that our animation ignores other aspects of reality, such as buildings that might be in the way. Sometimes, that is appropriate, such as animating the movement of:

- a bird
- a plane
- [a costumed superhero with independent flight capability](#)

Sometimes, though, we need to take into account those obstacles, such as animating the movement of:

- a pedestrian
- a car
- [a costumed superhero “flying” by means of swinging between buildings using dynamically-generated cables of either natural or synthetic origin](#)

However, to do this implies that we know where the obstacles are. Or, more accurately, we would need to animate the marker along known good waypoints, such as streets.

The animation would not be especially difficult, as `ofObject()` can take a series of waypoints. However, we would need to find those waypoints, and there is nothing in Maps V2 itself that supplies this data.

Maps, of the Indoor Variety

The good news is that Maps V2 supports Google's indoor maps, for those venues for which Google has indoor map data.

The bad news is that for some reason, only one map at a time supports indoor maps. The default will be that the first map you create will support indoor maps, and others will not.

To see if a given map offers indoor map capability, you can call `isIndoorEnabled()` on `GoogleMap`. To toggle this capability, call `setIndoorEnabled()`.

Taking a Snapshot of a Map

Once a map is drawn, you can take a snapshot of it, converting the viewed map into a `Bitmap` object. This is designed to take an image of the map and use it in places where a `MapFragment`, or even a `MapView`, cannot go, such as:

- Things tied to a `RemoteViews`, such as a custom `Notification`
- Thumbnails of maps, for an app that allows users to manipulate several maps at once

The `GoogleMap` object has two flavors of a `snapshot()` method. Both take a `SnapshotReadyCallback` object. You will need to supply an instance of something implementing the `SnapshotReadyCallback` interface, overriding `onSnapshotReady()`, where you will receive your `Bitmap`.

One flavor of `snapshot()` takes just the `SnapshotReadyCallback`; the other also takes a `Bitmap` of the proper dimensions, such as a previous snapshot `Bitmap` that you want to recycle. Using the latter `snapshot()` is recommended where possible, so you do not need to allocate new `Bitmap` objects on each `snapshot()` call.

Note that `snapshot()` will only work once the map is actually rendered. So, for example, calling `snapshot()` from `onCreate()` of your activity will fail, because the map has not been rendered yet. `snapshot()` is designed to be called based upon user input, either to manually capture a snapshot or based on navigation (e.g., tapping on a `ListView` item triggers saving a snapshot of the current map as a thumbnail before changing the map contents).

Also, the documentation for `snapshot()` contains the following:

Note: Images of the map must not be transmitted to your servers, or otherwise used outside of the application. If you need to send a map to another application or user, send data that allows them to reconstruct the map for the new user instead of a snapshot.

As this statement may be tied to the terms and conditions of your use of Maps V2, you should talk with qualified legal counsel before:

- Saving a snapshot to external storage
- Sharing a snapshot via `ACTION_SEND`
- Sending a snapshot to your server

or similar operations.

MapFragment vs. MapView

So far, all the examples shown in this chapter use `MapFragment`. In most cases, this is the right thing to use.

However, there may be places where you really want to use a `View`, rather than a `Fragment`, for your maps.

The good news is that Maps V2 does have a `MapView`. `MapFragment` usually handles creating and managing the `MapView` for you, but you can, if you wish, eschew `MapFragment` and manage the `MapView` yourself.

The biggest limitation is that you need to forward the lifecycle methods from your activity or fragment on to the `MapView`, calling `onCreate()`, `onResume()`, `onPause()`, `onDestroy()`, and `onSaveInstanceState()` on the `MapView`. Normally, `MapFragment` would do that for you, saving you the trouble.

Also note that while `MapView` is a `ViewGroup`, you are not allowed to add child widgets to it.

About That `AbstractMapActivity` Class...

Early on, we hand-waved our way past the `AbstractMapActivity` that all of our `MainActivity` classes inherit from, and we skirted past the `readyToGo()` method that we were calling. Also, you may have noticed that our app has an action bar overflow item, that we do not seem to be creating in `MainActivity`.

Now, it is time to dive into what is going on in our `AbstractMapActivity` implementations.

Getting Maps V2 Ready to Go

The `readyToGo()` method in `AbstractMapActivity` is designed to help us determine if Maps V2 is “ready to go” and, if not, to help the user perhaps fix their device such that Maps V2 will work in the future:

```
protected boolean readyToGo() {
    int status=
        GooglePlayServicesUtil.isGooglePlayServicesAvailable(this);

    if (status == ConnectionResult.SUCCESS) {
        if (getVersionFromPackageManager(this) >= 2) {
            return(true);
        }
        else {
            Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
            finish();
        }
    }
    else if (GooglePlayServicesUtil.isUserRecoverableError(status)) {
        AlertDialogFragment.newInstance(status)
            .show(getFragmentManager(),
                TAG_ERROR_DIALOG_FRAGMENT);
    }
    else {
        Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
        finish();
    }

    return(false);
}
```

MAPPING WITH MAPS V2

First, we call the static `isGooglePlayServicesAvailable()` method on `GooglePlayServicesUtil`. This will return an integer indicating whether Maps V2 is available for our use or not.

If the return value is `ConnectionResult.SUCCESS` — meaning Maps V2 is indeed available to us – we check to see if OpenGL ES is version 2.0 or higher, as we did not require that in the manifest. There are a few ways in Android to check the OpenGL ES version. This sample uses some code from the Compatibility Test Suite (CTS), examining `PackageManager` to determine the major level:

```
// following from
// https://android.googlesource.com/platform/cts/+/master/tests/tests/graphics/
src/android/opengl/cts/OpenGLESVersionTest.java

/*

 */

private static int getVersionFromPackageManager(Context context) {
    PackageManager packageManager=context.getPackageManager();
    FeatureInfo[] featureInfos=
        packageManager.getSystemAvailableFeatures();
    if (featureInfos != null && featureInfos.length > 0) {
        for (FeatureInfo featureInfo : featureInfos) {
            // Null feature name means this feature is the open
            // gl es version feature.
            if (featureInfo.name == null) {
                if (featureInfo.reqGlEsVersion != FeatureInfo.GL_ES_VERSION_UNDEFINED)
            {
                return getMajorVersion(featureInfo.reqGlEsVersion);
            }
            else {
                return 1; // Lack of property means OpenGL ES
                           // version 1
            }
        }
    }
}
```

```
    }  
    return 1;  
}  
  
/** @see FeatureInfo#getGLESVersion() */  
private static int getMajorVersion(int glEsVersion) {  
    return((glEsVersion & 0xffff0000) >> 16);  
}
```

If the major version is 2 (or, theoretically, higher), we return true from `readyToGo()`, so `MainActivity` knows to continue on setting up the map. If the major version is 1, we display a `Toast` — a production-grade app would do something else to let the user know of the problem, most likely.

But, what if `isGooglePlayServicesAvailable()` returns something else?

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling the static `isUserRecoverableError()` on `GooglePlayServicesUtil`, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return true if the user might be able to fix the problem, false otherwise.

In the false case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return false, so `MainActivity` skips over the rest of its work.

In the true case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on the `GooglePlayServicesUtil` class. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```
public static class ErrorDialogFragment extends DialogFragment {  
    static final String ARG_STATUS="status";  
  
    static ErrorDialogFragment newInstance(int status) {  
        Bundle args=new Bundle();  
  
        args.putInt(ARG_STATUS, status);  
    }  
}
```

```
ErrorDialogFragment result=new ErrorDialogFragment();

result.setArguments(args);

return(result);
}

@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    Bundle args=getArguments();

    return GooglePlayServicesUtil.getErrorDialog(args.getInt(ARG_STATUS),
                                                getActivity(), 0);
}

@Override
public void onDismiss(DialogInterface dlg) {
    if (getActivity() != null) {
        getActivity().finish();
    }
}
}
```

While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Maps V2 is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Google Play Services.

Testing this code requires an older device, one in which the “Google Play services” app can be uninstalled... if it can be installed at all.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. Notably, if the device [lacks the Play Store](#), `isUserRecoverableError()` returns true, even though the user cannot recover from this situation (except perhaps via a firmware update).

(An earlier problem where `getErrorDialog()` [could return null](#) even for cases where the error is supposedly user-recoverable has been fixed)

Handling the License Terms

`AbstractMapActivity` has implementations of `onCreateOptionsMenu()` and `onOptionsItemSelected()` that will add a “Legal Notices” item to the overflow menu and bring up `LegalNoticesActivity` when that menu item is tapped:

```
package com.commonware.android.mapsv2.basic;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
import com.google.android.gms.common.GooglePlayServicesUtil;

public class LegalNoticesActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.legal);

        TextView legal=(TextView)findViewById(R.id.legal);

        legal.setText(GooglePlayServicesUtil.getOpenSourceSoftwareLicenseInfo(this));
    }
}
```

`LegalNoticesActivity` simply has a `TextView` inside of a `ScrollView` and fills in the `TextView` with the results of calling `getOpenSourceSoftwareLicenseInfo()` on `GooglePlayServicesUtil`. This method returns the legalese that you need to display to the users from somewhere in your app.

Helper Libraries for Maps V2

Many developers have been busy writing libraries that help in the development of Maps V2 applications, beyond Google’s own utility library mentioned in [the section on animating markers](#).

Perhaps the most expansive of these is [the Android Maps Extensions library](#), by Maciej Górski. The big thing that this library offers is marker clustering, where as the user zooms out, individual markers are replaced by a marker representing a cluster, so you avoid flooding a small area with too many individual markers:

MAPPING WITH MAPS V2

Figure 477: Map with Many Markers (from Android Maps Extensions demo app)

MAPPING WITH MAPS V2

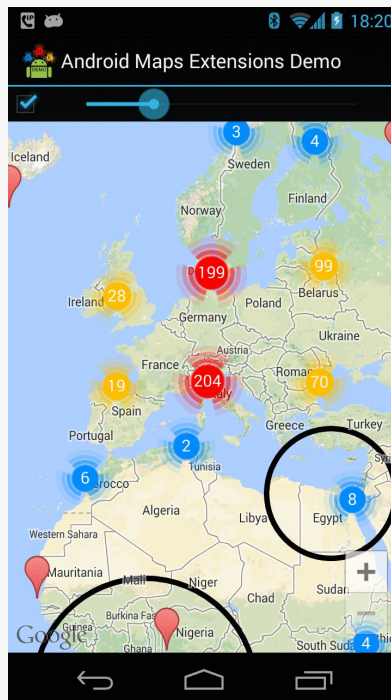

Figure 478: Same Map with Cluster Markers (from Android Maps Extensions demo app)

Figure 479: Same Map with Zoomed In Cluster Markers (from Android Maps Extensions demo app)

This library wraps the Maps V2 classes, allowing the library to offer extensions to the standard Maps V2 API, including:

- Associating your own data with Marker, Polygon, Polyline, and other classes, to tie them back to your models
- Getters to retrieve previously-defined markers, etc.
- Etc.

Another library offering marker clustering is [clusterkraf](#), from Two Toasters.

The clusterkraf library can optionally integrate with [Cyril Mottier's Polaris2 library](#). His original Polaris library aimed to provide more features to Maps V1; Polaris2 fills a similar role for Maps V2. At this time, Polaris2 is a smaller library, simply because Maps V2 handles much of what Polaris provided. Polaris2, like Android Maps Extensions, wraps the Maps V2 API with its own classes, in lieu of subclassing (since most Maps V2 classes are marked `final`). Of note, Polaris2 offers `reset()` methods on many of the `...Options` classes (e.g., `MarkerOptions`), and offers constants for the minimum and maximum valid latitude and longitude.

Problems with Maps V2 at Runtime

Portions of the logic that powers your Maps V2 MapFragment are supplied by the Google Play Services app. As a result, many operations with Maps V2, such as manipulating markers, require IPC calls between your app and Google Play Services. If those IPC calls are synchronous, they will add a bit of overhead to your app — enough that you will want to avoid them in time-critical pieces of code, tight loops, and the like.

Problems with Maps V2 Deployment

Of course, the key question is: should you be using Maps V2 at all?

Google thinks so, as they have [turned off access to new API keys for Maps V1](#). That makes ongoing development of Maps V1 solutions a bit risky, as you cannot create new API keys for new signing keys, such as if you need to replace your debug keystore.

However, Maps V2 has some deployment limitations at this time. While 99.8+% of Android devices that have the Play Store have the requisite OpenGL ES 2.0+, some devices that have a suitable OpenGL ES version may not have the Play Store or otherwise be unable to get Google Play Services, required for using Maps V2. The `isGooglePlayServicesAvailable()` approach advocated by Google can help determine this at runtime, though this approach used to have some bugs, and it still cannot always help you recover from this problem.

What Non-Compliant Devices Show

If your app tries to bring up Maps V2 on a device that cannot possibly have the Play Services Framework — such as a Kindle Fire — the user will see an error dialog:

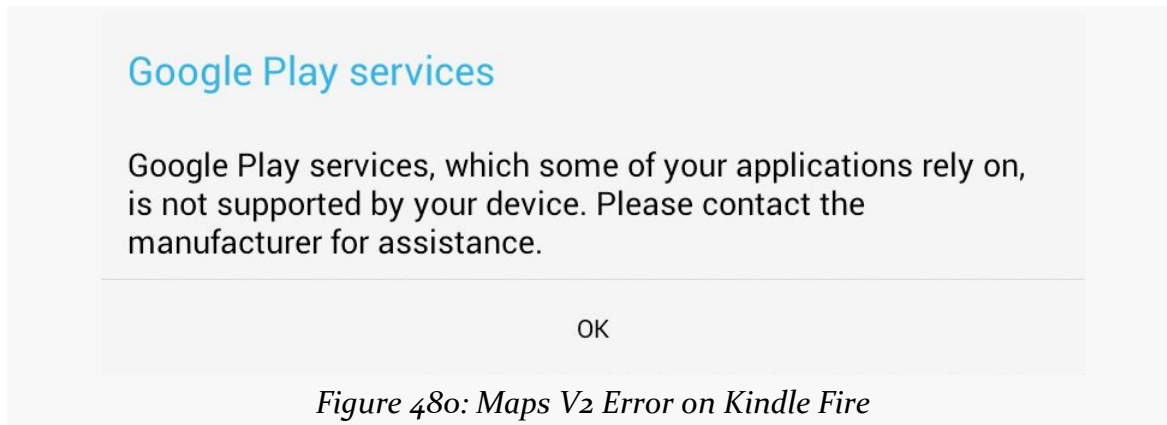

Figure 480: Maps V2 Error on Kindle Fire

Mapping Alternatives

Beyond using Maps V2 or Maps V1, you may need to consider other mapping alternatives. The Google mapping APIs are only available on Android devices that have the Maps SDK add-on (Maps V1) or Google Play Services (Maps V2). Not all devices have those. And, the limitations of Maps V2 deployment and the deprecation of Maps V1 may convince you that relying upon Google for maps is not safe at the present time.

The most common native replacement for Google's mapping is [OpenStreetMap](#), which to some extent is "the Wikipedia of maps". [OSMDroid](#) is a library that provides a Maps V1-ish API for embedding OpenStreetMap-based maps into your application.

Another solution is to integrate Web-based Google maps into your app, the same way that you might embed them into your Web site. An activity hosting a `WebView` can display a Web-based Google Map, for example.

Certain devices may have access to other native mapping solutions. For example, Amazon has published [their own maps API](#) for use with the Kindle Fire.

News and Getting Help

The Maps V2 team maintains [a set of release notes](#) for when they ship updates to the Maps V2 support in the Play Services library project.

MAPPING WITH MAPS V2

The official support point for Maps V2 for Android is Stack Overflow. Questions [tagged with both android and google-maps](#) should show up on Google's radar.

Crafting Your Own Views

One of the classic forms of code reuse is the GUI widget. Since the advent of Microsoft Windows — and, to some extent, even earlier — developers have been creating their own widgets to extend an existing widget set. These range from 16-bit Windows “custom controls” to 32-bit Windows OCX components to the innumerable widgets available for Java Swing and SWT, and beyond. Android lets you craft your own widgets as well, such as extending an existing widget with a new UI or new behaviors.

Note that the material in this chapter is focused on creating custom View classes for use within a single Android project. If your goal is to truly create reusable custom widgets, you will also need to learn how to package them so they can be reused — that is covered in a [later chapter](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Pick Your Poison

You have five major options for creating a custom View class.

First, your “custom View class” might really only be custom Drawable resources. Many widgets can adopt a radically different look and feel just with replacement graphics. For example, you might think that these toggle buttons from the Android 2.1 Google Maps application are some fancy custom widget:

Figure 481: Google Maps navigation toggle buttons

In reality, those are just radio buttons with replacement images.

Second, your custom View class might be a simple subclass of an existing widget, where you override some behaviors or otherwise inject your own logic. Unfortunately, most of the built-in Android widgets are not really designed for this sort of simple subclassing, so you may be disappointed in how well this particular technique works.

Third, your custom View class might be a composite widget — akin to an activity’s contents, complete with layout and such, but encapsulated in its own class. This allows you to create something more elaborate than you will just by tweaking resources. We will see this later in the chapter with ColorMixer.

Fourth, you might want to implement your own layout manager, if your GUI rules do not fit well with RelativeLayout, TableLayout, or other built-in containers. For example, you might want to create a layout manager that more closely mirrors the “box model” approach taken by XUL and Flex, or you might want to create one that mirrors Swing’s FlowLayout (laying widgets out horizontally until there is no more room on the current row, then start a new row).

Finally, you might want to do something totally different, where you need to draw the widget yourself. For example, the ColorMixer widget uses SeekBar widgets to control the mix of red, blue, and green. But, you might create a ColorWheel widget that draws a spectrum gradient, detects touch events, and lets the user pick a color that way.

Some of these techniques are fairly simple; others are fairly complex. All share some common traits, such as widget-defined attributes, that we will see throughout the remainder of this chapter.

Colors, Mixed How You Like Them

The classic way for a user to pick a color in a GUI is to use a color wheel like this one:

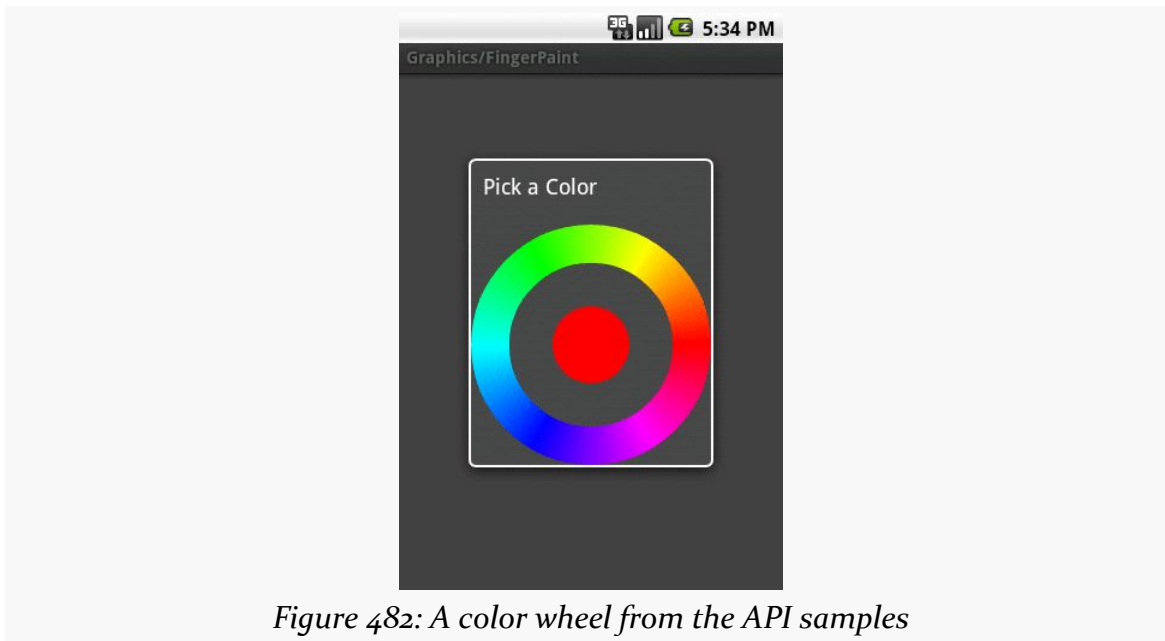

Figure 482: A color wheel from the API samples

There is even code to make one in the [API samples](#).

However, a color wheel like that is difficult to manipulate on a touch screen, particularly a capacitive touchscreen designed for finger input. Fingers are great for gross touch events and lousy for selecting a particular color pixel.

Another approach is to use a mixer, with sliders to control the red, green, and blue values:

That is the custom widget you will see in this section, based on the code in the [Views/ColorMixer](#) sample project.

The Layout

ColorMixer is a composite widget, meaning that its contents are created from other widgets and containers. Hence, we can use a layout file to describe what the widget should look like.

The layout to be used for the widget is not that much: three SeekBar widgets (to control the colors), three TextView widgets (to label the colors), and one plain View (the “swatch” on the left that shows what the currently selected color is). Here is the file, found in `res/layout/mixer.xml` in the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <View android:id="@+id/swatch"
        android:layout_width="40dip"
        android:layout_height="40dip"
        android:layout_alignParentLeft="true"
        android:layout_centerVertical="true"
        android:layout_marginLeft="4dip"
```

```
/>
<TextView android:id="@+id/redLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/swatch"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:text="@string/red"
    android:textSize="10pt"
/>
<SeekBar android:id="@+id/red"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/redLabel"
    android:layout_toRightOf="@id/redLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
/>
<TextView android:id="@+id/greenLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/redLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
    android:text="@string/green"
    android:textSize="10pt"
/>
<SeekBar android:id="@+id/green"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/greenLabel"
    android:layout_toRightOf="@id/greenLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
/>
<TextView android:id="@+id/blueLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/greenLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
    android:text="@string/blue"
    android:textSize="10pt"
/>
<SeekBar android:id="@+id/blue"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/blueLabel"
    android:layout_toRightOf="@id/blueLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
```

```
/>  
</merge>
```

One thing that is a bit interesting about this layout, though, is the root element: `<merge>`. A `<merge>` layout is a bag of widgets that can be poured into some other container. The layout rules on the children of `<merge>` are then used in conjunction with whatever container they are added to. As we will see shortly, `ColorMixer` itself inherits from `RelativeLayout`, and the children of the `<merge>` element will become children of `ColorMixer` in Java. Basically, the `<merge>` element is only there because XML files need a single root — otherwise, the `<merge>` element itself is ignored in the layout.

The Attributes

Widgets usually have attributes that you can set in the XML file, such as the `android:src` attribute you can specify on an `ImageButton` widget. You can create your own custom attributes that can be used in your custom widget, by creating a `res/values/attrs.xml` file containing `declare-styleable` resources to specify them.

For example, here is the attributes file for `ColorMixer`:

```
<resources>  
  <declare-styleable name="ColorMixer">  
    <attr name="initialColor" format="color" />  
  </declare-styleable>  
</resources>
```

The `declare-styleable` element describes what attributes are available on the widget class specified in the `name` attribute — in our case, `ColorMixer`. Inside `declare-styleable` you can have one or more `attr` elements, each indicating the name of an attribute (e.g., `initialColor`) and what data format the attribute has (e.g., `color`). The data type will help with compile-time validation and in getting any supplied values for this attribute parsed into the appropriate type at runtime.

Here, we indicate there is only one attribute: `initialColor`, which will hold the initial color we want the mixer set to when it first appears.

There are many possible values for the `format` attribute in an `attr` element, including:

1. `boolean`
2. `color`

3. dimension
4. float
5. fraction
6. integer
7. reference (which means a reference to another resource, such as a Drawable)
8. string

You can even support multiple formats for an attribute, by separating the values with a pipe (e.g., `reference|color`).

The Class

Our `ColorMixer` class, a subclass of `RelativeLayout`, will take those attributes and provide the actual custom widget implementation, for use in activities.

Constructor Flavors

A `View` has three possible constructors:

1. One takes just a `Context`, which usually will be an `Activity`
2. One takes a `Context` and an `AttributeSet`, the latter of which represents the attributes supplied via layout XML
3. One takes a `Context`, an `AttributeSet`, and the default style to apply to the attributes

If you are expecting to use your custom widget in layout XML files, you will need to implement the second constructor and chain to the superclass. If you want to use styles with your custom widget when declared in layout XML files, you will need to implement the third constructor and chain to the superclass. If you want developers to create instances of your `View` class in Java code directly, you probably should implement the first constructor and, again, chain to the superclass.

In the case of `ColorMixer`, all three constructors are implemented, eventually routing to the three-parameter edition, which initializes our widget. Below, you will see the first two of those constructors, with the third coming up in the next section:

```
public ColorMixer(Context context) {  
    this(context, null);  
}  
  
public ColorMixer(Context context, AttributeSet attrs) {
```

```
    this(context, attrs, 0);  
}
```

Using the Attributes

The ColorMixer has a starting color — after all, the SeekBar widgets and swatch View have to show something. Developers can, if they wish, set that color via a `setColor()` method:

```
public void setColor(int color) {  
    red.setProgress(Color.red(color));  
    green.setProgress(Color.green(color));  
    blue.setProgress(Color.blue(color));  
    swatch.setBackgroundColor(color);  
}
```

If, however, we want developers to be able to use layout XML, we need to get the value of `initialColor` out of the supplied `AttributeSet`. In `ColorMixer`, this is handled in the three-parameter constructor:

```
public ColorMixer(Context context, AttributeSet attrs, int defStyle) {  
    super(context, attrs, defStyle);  
  
    ((Activity)getContext())  
        .getLayoutInflater()  
        .inflate(R.layout.mixer, this, true);  
  
    swatch=findViewById(R.id.swatch);  
  
    red=(SeekBar)findViewById(R.id.red);  
    red.setMax(0xFF);  
    red.setOnSeekBarChangeListener(onMix);  
  
    green=(SeekBar)findViewById(R.id.green);  
    green.setMax(0xFF);  
    green.setOnSeekBarChangeListener(onMix);  
  
    blue=(SeekBar)findViewById(R.id.blue);  
    blue.setMax(0xFF);  
    blue.setOnSeekBarChangeListener(onMix);  
  
    if (attrs!=null) {  
        TypedArray a=getContext()  
            .obtainStyledAttributes(attrs,  
                                   R.styleable.ColorMixer,
